The cached path is followed by the string “ (deleted)” to indicate that the path by which the file was opened has been deleted.

Because intervening changes made to the path – i.e., renames with *mv*(1) or *rename*(2) – are not recorded in the cached path, what *lsOf* reports is only the path by which the file was opened, not its possibly different final path.

-z [z] specifies how Solaris 10 and higher zone information is to be handled.

Without a following argument – e.g., NO *z* – the option specifies that zone names are to be listed in the ZONE output column.

The **-z** option may be followed by a zone name, *z*. That causes *lsOf* to list only open files for processes in that zone. Multiple **-z z** option and argument pairs may be specified to form a list of named zones. Any open file of any process in any of the zones will be listed, subject to other conditions specified by other options and arguments.

-Z [Z] specifies how SELinux security contexts are to be handled. It and 'Z' field output character support are inhibited when SELinux is disabled in the running Linux kernel. See **OUTPUT FOR OTHER PROGRAMS** for more information on the 'Z' field output character.

Without a following argument – e.g., NO *Z* – the option specifies that security contexts are to be listed in the SECURITY-CONTEXT output column.

The **-Z** option may be followed by a wildcard security context name, *Z*. That causes *lsOf* to list only open files for processes in that security context. Multiple **-Z Z** option and argument pairs may be specified to form a list of security contexts. Any open file of any process in any of the security contexts will be listed, subject to other conditions specified by other options and arguments. Note that *Z* can be A:B:C or *:B:C or A:B:* or *:*:C to match against the A:B:C context.

-- The double minus sign option is a marker that signals the end of the keyed options. It may be used, for example, when the first file name begins with a minus sign. It may also be used when the absence of a value for the last keyed option must be signified by the presence of a minus sign in the following option and before the start of the file names.

names These are path names of specific files to list. Symbolic links are resolved before use. The first name may be separated from the preceding options with the “--” option.

If a *name* is the mounted-on directory of a file system or the device of the file system, *lsOf* will list all the files open on the file system. To be considered a file system, the *name* must match a mounted-on directory name in *mount*(8) output, or match the name of a block device associated with a mounted-on directory name. The **+|-f** option may be used to force *lsOf* to consider a *name* a file system identifier (**+f**) or a simple file (**-f**).

If *name* is a path to a directory that is not the mounted-on directory name of a file system, it is treated just as a regular file is treated – i.e., its listing is restricted to processes that have it open as a file or as a process-specific directory, such as the root or current working directory. To request that *lsOf* look for open files inside a directory name, use the **+d s** and **+D D** options.

If a *name* is the base name of a family of multiplexed files – e. g, AIX's */dev/pt[cs]* – *lsOf* will list all the associated multiplexed files on the device that are open – e.g., */dev/pt[cs]/1*, */dev/pt[cs]/2*, etc.

If a *name* is a UNIX domain socket name, *lsOf* will usually search for it by the characters of the name alone – exactly as it is specified and is recorded in the kernel socket structure. (See the

next paragraph for an exception to that rule for Linux.) Specifying a relative path – e.g., *./file* – in place of the file’s absolute path – e.g., */tmp/file* – won’t work because *lsOf* must match the characters you specify with what it finds in the kernel UNIX domain socket structures.

If a *name* is a Linux UNIX domain socket name, in one case *lsOf* is able to search for it by its device and inode number, allowing *name* to be a relative path. The case requires that the absolute path -- i.e., one beginning with a slash ('/') be used by the process that created the socket, and hence be stored in the */proc/net/unix* file; and it requires that *lsOf* be able to obtain the device and node numbers of both the absolute path in */proc/net/unix* and *name* via successful *stat(2)* system calls. When those conditions are met, *lsOf* will be able to search for the UNIX domain socket when some path to it is specified in *name*. Thus, for example, if the path is */dev/log*, and an *lsOf* search is initiated when the working directory is */dev*, then *name* could be *./log*.

If a *name* is none of the above, *lsOf* will list any open files whose device and inode match that of the specified path *name*.

If you have also specified the **-b** option, the only *names* you may safely specify are file systems for which your mount table supplies alternate device numbers. See the **AVOIDING KERNEL BLOCKS** and **ALTERNATE DEVICE NUMBERS** sections for more information.

Multiple file names are joined in a single ORed set before participating in AND option selection.

AFS

lsOf supports the recognition of AFS files for these dialects (and AFS versions):

- AIX 4.1.4 (AFS 3.4a)
- HP-UX 9.0.5 (AFS 3.4a)
- Linux 1.2.13 (AFS 3.3)
- Solaris 2.[56] (AFS 3.4a)

It may recognize AFS files on other versions of these dialects, but has not been tested there. Depending on how AFS is implemented, *lsOf* may recognize AFS files in other dialects, or may have difficulties recognizing AFS files in the supported dialects.

lsOf may have trouble identifying all aspects of AFS files in supported dialects when AFS kernel support is implemented via dynamic modules whose addresses do not appear in the kernel’s variable name list. In that case, *lsOf* may have to guess at the identity of AFS files, and might not be able to obtain volume information from the kernel that is needed for calculating AFS volume node numbers. When *lsOf* can’t compute volume node numbers, it reports blank in the NODE column.

The **-A A** option is available in some dialect implementations of *lsOf* for specifying the name list file where dynamic module kernel addresses may be found. When this option is available, it will be listed in the *lsOf* help output, presented in response to the **-h** or **-?**

See the *lsOf* FAQ (The **FAQ** section gives its location.) for more information about dynamic modules, their symbols, and how they affect *lsOf* options.

Because AFS path lookups don’t seem to participate in the kernel’s name cache operations, *lsOf* can’t identify path name components for AFS files.

SECURITY

lsOf has three features that may cause security concerns. First, its default compilation mode allows anyone to list all open files with it. Second, by default it creates a user-readable and user-writable device cache file in the home directory of the real user ID that executes *lsOf*. (The list-all-open-files and device cache features may be disabled when *lsOf* is compiled.) Third, its **-k** and **-m** options name alternate kernel name list or memory files.

Restricting the listing of all open files is controlled by the compile-time HASSECURITY and HASNOSOCKSECURITY options. When HASSECURITY is defined, *lsOf* will allow only the root user to list all open files. The non-root user may list only open files of processes with the same user IDentification

number as the real user ID number of the *lsof* process (the one that its user logged on with).

However, if `HASSECURITY` and `HASNOSOCKSECURITY` are both defined, anyone may list open socket files, provided they are selected with the `-i` option.

When `HASSECURITY` is not defined, anyone may list all open files.

Help output, presented in response to the `-h` or `-?` option, gives the status of the `HASSECURITY` and `HASNOSOCKSECURITY` definitions.

See the **Security** section of the `00README` file of the *lsof* distribution for information on building *lsof* with the `HASSECURITY` and `HASNOSOCKSECURITY` options enabled.

Creation and use of a user-readable and user-writable device cache file is controlled by the compile-time `HASDCACHE` option. See the **DEVICE CACHE FILE** section and the sections that follow it for details on how its path is formed. For security considerations it is important to note that in the default *lsof* distribution, if the real user ID under which *lsof* is executed is root, the device cache file will be written in root's home directory – e.g., `/` or `/root`. When `HASDCACHE` is not defined, *lsof* does not write or attempt to read a device cache file.

When `HASDCACHE` is defined, the *lsof* help output, presented in response to the `-h`, `-D?`, or `-?` options, will provide device cache file handling information. When `HASDCACHE` is not defined, the `-h` or `-?` output will have no `-D` option description.

Before you decide to disable the device cache file feature – enabling it improves the performance of *lsof* by reducing the startup overhead of examining all the nodes in `/dev` (or `/devices`) – read the discussion of it in the `00DCACHE` file of the *lsof* distribution and the *lsof* FAQ (The **FAQ** section gives its location.)

WHEN IN DOUBT, YOU CAN TEMPORARILY DISABLE THE USE OF THE DEVICE CACHE FILE WITH THE `-Di` OPTION.

When *lsof* user declares alternate kernel name list or memory files with the `-k` and `-m` options, *lsof* checks the user's authority to read them with `access(2)`. This is intended to prevent whatever special power *lsof*'s modes might confer on it from letting it read files not normally accessible via the authority of the real user ID.

OUTPUT

This section describes the information *lsof* lists for each open file. See the **OUTPUT FOR OTHER PROGRAMS** section for additional information on output that can be processed by another program.

Lsof only outputs printable (declared so by `isprint(3)`) 8 bit characters. Non-printable characters are printed in one of three forms: the C “`\bfrnt`” form; the control character “`^`” form (e.g., “`^@`”); or hexadecimal leading “`\x`” form (e.g., “`\xab`”). Space is non-printable in the **COMMAND** column (“`\x20`”) and printable elsewhere.

For some dialects – if `HASSETLOCALE` is defined in the dialect's machine.h header file – *lsof* will print the extended 8 bit characters of a language locale. The *lsof* process must be supplied a language locale environment variable (e.g., `LANG`) whose value represents a known language locale in which the extended characters are considered printable by `isprint(3)`. Otherwise *lsof* considers the extended characters non-printable and prints them according to its rules for non-printable characters, stated above. Consult your dialect's `setlocale(3)` man page for the names of other environment variables that may be used in place of `LANG` – e.g., `LC_ALL`, `LC_CTYPE`, etc.

Lsof's language locale support for a dialect also covers wide characters – e.g., UTF-8 – when `HASSETLOCALE` and `HASWIDECHAR` are defined in the dialect's machine.h header file, and when a suitable language locale has been defined in the appropriate environment variable for the *lsof* process. Wide characters are printable under those conditions if `iswprint(3)` reports them to be. If `HASSETLOCALE`, `HASWIDECHAR` and a suitable language locale aren't defined, or if `iswprint(3)` reports wide characters that aren't printable, *lsof* considers the wide characters non-printable and prints each of their 8 bits according to its rules for non-printable characters, stated above.

Consult the answers to the "Language locale support" questions in the *lsof* FAQ (The **FAQ** section gives its location.) for more information.

Lsof dynamically sizes the output columns each time it runs, guaranteeing that each column is a minimum size. It also guarantees that each column is separated from its predecessor by at least one space.

COMMAND contains the first nine characters of the name of the UNIX command associated with the process. If a non-zero *w* value is specified to the **+c w** option, the column contains the first *w* characters of the name of the UNIX command associated with the process up to the limit of characters supplied to *lsof* by the UNIX dialect. (See the description of the **+c w** command or the *lsof* FAQ for more information. The **FAQ** section gives its location.)

If *w* is less than the length of the column title, “COMMAND”, it will be raised to that length.

If a zero *w* value is specified to the **+c w** option, the column contains all the characters of the name of the UNIX command associated with the process.

All command name characters maintained by the kernel in its structures are displayed in field output when the command name descriptor (‘c’) is specified. See the **OUTPUT FOR OTHER COMMANDS** section for information on selecting field output and the associated command name descriptor.

PID is the Process IDentification number of the process.

TID is the task (thread) IDentification number, if task (thread) reporting is supported by the dialect and a task (thread) is being listed. (If help output – i.e., the output of the **-h** or **-?** options – shows this option, then task (thread) reporting is supported by the dialect.)

A blank TID column in Linux indicates a process – i.e., a non-task.

ZONE is the Solaris 10 and higher zone name. This column must be selected with the **-z** option.

SECURITY-CONTEXT

is the SELinux security context. This column must be selected with the **-Z** option. Note that the **-Z** option is inhibited when SELinux is disabled in the running Linux kernel.

PPID is the Parent Process IDentification number of the process. It is only displayed when the **-R** option has been specified.

PGID is the process group IDentification number associated with the process. It is only displayed when the **-g** option has been specified.

USER is the user ID number or login name of the user to whom the process belongs, usually the same as reported by *ps*(1). However, on Linux **USER** is the user ID number or login that owns the directory in */proc* where *lsof* finds information about the process. Usually that is the same value reported by *ps*(1), but may differ when the process has changed its effective user ID. (See the **-l** option description for information on when a user ID number or login name is displayed.)

FD is the File Descriptor number of the file or:

| | |
|-------------|---|
| cwd | current working directory; |
| Lnn | library references (AIX); |
| err | FD information error (see NAME column); |
| jld | jail directory (FreeBSD); |
| ltx | shared library text (code and data); |
| Mxx | hex memory-mapped type number xx. |
| m86 | DOS Merge mapped file; |
| mem | memory-mapped file; |
| mmap | memory-mapped device; |
| pd | parent directory; |
| rtd | root directory; |
| tr | kernel trace file (OpenBSD); |

txt program text (code and data);
v86 VP/ix mapped file;

FD is followed by one of these characters, describing the mode under which the file is open:

r for read access;
w for write access;
u for read and write access;
 space if mode unknown and no lock character follows;
 ‘-’ if mode unknown and lock character follows.

The mode character is followed by one of these lock characters, describing the type of lock applied to the file:

N for a Solaris NFS lock of unknown type;
r for read lock on part of the file;
R for a read lock on the entire file;
w for a write lock on part of the file;
W for a write lock on the entire file;
u for a read and write lock of any length;
U for a lock of unknown type;
x for an SCO OpenServer Xenix lock on part of the file;
X for an SCO OpenServer Xenix lock on the entire file;
 space if there is no lock.

See the **LOCKS** section for more information on the lock information character.

TYPE The FD column contents constitutes a single field for parsing in post-processing scripts. is the type of the node associated with the file – e.g., GDIR, GREG, VDIR, VREG, etc. or “IPv4” for an IPv4 socket;
 or “IPv6” for an open IPv6 network file – even if its address is IPv4, mapped in an IPv6 address;
 or “ax25” for a Linux AX.25 socket;
 or “inet” for an Internet domain socket;
 or “lla” for a HP-UX link level access file;
 or “rte” for an AF_ROUTE socket;
 or “sock” for a socket of unknown domain;
 or “unix” for a UNIX domain socket;
 or “x.25” for an HP-UX x.25 socket;
 or “BLK” for a block special file;
 or “CHR” for a character special file;
 or “DEL” for a Linux map file that has been deleted;
 or “DIR” for a directory;
 or “DOOR” for a VDOOR file;
 or “FIFO” for a FIFO special file;
 or “KQUEUE” for a BSD style kernel event queue file;
 or “LINK” for a symbolic link file;

or “MPB” for a multiplexed block file;
or “MPC” for a multiplexed character file;
or “NOFD” for a Linux `/proc/<PID>/fd` directory that can’t be opened -- the directory path appears in the NAME column, followed by an error message;
or “PAS” for a `/proc/as` file;
or “PAXV” for a `/proc/auxv` file;
or “PCRE” for a `/proc/cred` file;
or “PCTL” for a `/proc` control file;
or “PCUR” for the current `/proc` process;
or “PCWD” for a `/proc` current working directory;
or “PDIR” for a `/proc` directory;
or “PETY” for a `/proc` executable type (*etype*);
or “PFD” for a `/proc` file descriptor;
or “PFDR” for a `/proc` file descriptor directory;
or “PFIL” for an executable `/proc` file;
or “PFPR” for a `/proc` FP register set;
or “PGD” for a `/proc/pagedata` file;
or “PGID” for a `/proc` group notifier file;
or “PIPE” for pipes;
or “PLC” for a `/proc/lwpctl` file;
or “PLDR” for a `/proc/lpw` directory;
or “PLDT” for a `/proc/ldt` file;
or “PLPI” for a `/proc/lpsinfo` file;
or “PLST” for a `/proc/lstatus` file;
or “PLU” for a `/proc/lusage` file;
or “PLWG” for a `/proc/gwindows` file;
or “PLWI” for a `/proc/lwpsinfo` file;
or “PLWS” for a `/proc/lwpstatus` file;
or “PLWU” for a `/proc/lwpusage` file;
or “PLWX” for a `/proc/xregs` file;
or “PMAP” for a `/proc` map file (*map*);
or “PMEM” for a `/proc` memory image file;
or “PNTF” for a `/proc` process notifier file;
or “POBJ” for a `/proc/object` file;
or “PODR” for a `/proc/object` directory;
or “POLP” for an old format `/proc` light weight process file;
or “POPF” for an old format `/proc` PID file;
or “POPG” for an old format `/proc` page data file;
or “PORT” for a SYSV named pipe;

or “PREG” for a */proc* register file;
 or “PRMP” for a */proc/rmap* file;
 or “PRTD” for a */proc* root directory;
 or “PSGA” for a */proc/sigact* file;
 or “PSIN” for a */proc/psinfo* file;
 or “PSTA” for a */proc* status file;
 or “PSXSEM” for a POSIX semaphore file;
 or “PSXSHM” for a POSIX shared memory file;
 or “PUSG” for a */proc/usage* file;
 or “PW” for a */proc/watch* file;
 or “PXMP” for a */proc/xmap* file;
 or “REG” for a regular file;
 or “SMT” for a shared memory transport file;
 or “STSO” for a stream socket;
 or “UNNM” for an unnamed type file;
 or “XNAM” for an OpenServer Xenix special file of unknown type;
 or “XSEM” for an OpenServer Xenix semaphore file;
 or “XSD” for an OpenServer Xenix shared data file;
 or the four type number octets if the corresponding name isn’t known.

FILE-ADDR contains the kernel file structure address when **f** has been specified to **+f**;
 FCT contains the file reference count from the kernel file structure when **c** has been specified to **+f**;
 FILE-FLAG when **g** or **G** has been specified to **+f**, this field contains the contents of the `f_flag[s]` member of the kernel file structure and the kernel’s per-process open file flags (if available); ‘G’ causes them to be displayed in hexadecimal; ‘g’, as short-hand names; two lists may be displayed with entries separated by commas, the lists separated by a semi-colon (;); the first list may contain short-hand names for `f_flag[s]` values from the following table:

| | |
|------|---------------------------------|
| AIO | asynchronous I/O (e.g., FAIO) |
| AP | append |
| ASYN | asynchronous I/O (e.g., FASYNC) |
| BAS | block, test, and set in use |
| BKIU | block if in use |
| BL | use block offsets |
| BSK | block seek |
| CA | copy avoid |
| CIO | concurrent I/O |
| CLON | clone |
| CLRD | CL read |
| CR | create |
| DF | defer |
| DFI | defer IND |
| DFLU | data flush |
| DIR | direct |
| DLY | delay |
| DOCL | do clone |

| | |
|------|-------------------------------|
| DSYN | data-only integrity |
| DTY | must be a directory |
| EVO | event only |
| EX | open for exec |
| EXCL | exclusive open |
| FSYN | synchronous writes |
| GCDF | defer during unp_gc() (AIX) |
| GCMK | mark during unp_gc() (AIX) |
| GTTY | accessed via /dev/tty |
| HUP | HUP in progress |
| KERN | kernel |
| KIOC | kernel-issued ioctl |
| LCK | has lock |
| LG | large file |
| MBLK | stream message block |
| MK | mark |
| MNT | mount |
| MSYN | multiplex synchronization |
| NATM | don't update atime |
| NB | non-blocking I/O |
| NBDR | no BDRM check |
| NBIO | SYSV non-blocking I/O |
| NBF | n-buffering in effect |
| NC | no cache |
| ND | no delay |
| NDSY | no data synchronization |
| NET | network |
| NFLK | don't follow links |
| NMFS | NM file system |
| NOTO | disable background stop |
| NSH | no share |
| NTTY | no controlling TTY |
| OLRM | OLR mirror |
| PAIO | POSIX asynchronous I/O |
| PP | POSIX pipe |
| R | read |
| RC | file and record locking cache |
| REV | revoked |
| RSH | shared read |
| RSYN | read synchronization |
| RW | read and write access |
| SL | shared lock |
| SNAP | cooked snapshot |
| SOCK | socket |
| SQSH | Sequent shared set on open |
| SQSV | Sequent SVM set on open |
| SQR | Sequent set repair on open |
| SQS1 | Sequent full shared open |
| SQS2 | Sequent partial shared open |
| STPI | stop I/O |
| SWR | synchronous read |
| SYN | file integrity while writing |
| TCPM | avoid TCP collision |
| TR | truncate |

| | |
|------|------------------------------|
| W | write |
| WKUP | parallel I/O synchronization |
| WTG | parallel I/O synchronization |
| VH | vhangup pending |
| VTXT | virtual text |
| XL | exclusive lock |

this list of names was derived from F* #define's in dialect header files <fcntl.h>, <linux/fs.h>, <sys/fcntl.c>, <sys/fcntlcom.h>, and <sys/file.h>; see the lsof.h header file for a list showing the correspondence between the above short-hand names and the header file definitions;

the second list (after the semicolon) may contain short-hand names for kernel per-process open file flags from this table:

| | |
|------|------------------------------------|
| ALLC | allocated |
| BR | the file has been read |
| BHUP | activity stopped by SIGHUP |
| BW | the file has been written |
| CLSG | closing |
| CX | close-on-exec (see fcntl(F_SETFD)) |
| LCK | lock was applied |
| MP | memory-mapped |
| OPIP | open pending – in progress |
| RSVW | reserved wait |
| SHMT | UF_FSHMAT set (AIX) |
| USE | in use (multi-threaded) |

NODE-ID (or INODE-ADDR for some dialects) contains a unique identifier for the file node (usually the kernel vnode or inode address, but also occasionally a concatenation of device and node number) when **n** has been specified to **+f**;

DEVICE contains the device numbers, separated by commas, for a character special, block special, regular, directory or NFS file;

or “memory” for a memory file system node under Tru64 UNIX;

or the address of the private data area of a Solaris socket stream;

or a kernel reference address that identifies the file (The kernel reference address may be used for FIFO's, for example.);

or the base address or device name of a Linux AX.25 socket device.

Usually only the lower thirty two bits of Tru64 UNIX kernel addresses are displayed.

SIZE, SIZE/OFF, or OFFSET

is the size of the file or the file offset in bytes. A value is displayed in this column only if it is available. *Lsof* displays whatever value – size or offset – is appropriate for the type of the file and the version of *Lsof*.

On some UNIX dialects *Lsof* can't obtain accurate or consistent file offset information from its kernel data sources, sometimes just for particular kinds of files (e.g., socket files.) In other cases, files don't have true sizes – e.g., sockets, FIFOs, pipes – so *Lsof* displays for their sizes the content amounts it finds in their kernel buffer descriptors (e.g., socket buffer size counts or TCP/IP window sizes.) Consult the *Lsof* FAQ (The **FAQ** section gives its location.) for more information.

The file size is displayed in decimal; the offset is normally displayed in decimal with a leading “0t” if it contains 8 digits or less; in hexadecimal with a leading “0x” if it is longer than 8 digits. (Consult the **-o o** option description for information on when 8 might default to some other value.)

Thus the leading “0t” and “0x” identify an offset when the column may contain both a size and an offset (i.e., its title is SIZE/OFF).

If the **-o** option is specified, *lsOf* always displays the file offset (or nothing if no offset is available) and labels the column OFFSET. The offset always begins with “0t” or “0x” as described above.

The *lsOf* user can control the switch from “0t” to “0x” with the **-o o** option. Consult its description for more information.

If the **-s** option is specified, *lsOf* always displays the file size (or nothing if no size is available) and labels the column SIZE. The **-o** and **-s** options are mutually exclusive; they can’t both be specified.

For files that don’t have a fixed size – e.g., don’t reside on a disk device – *lsOf* will display appropriate information about the current size or position of the file if it is available in the kernel structures that define the file.

| | |
|-------|--|
| NLINK | contains the file link count when +L has been specified; |
| NODE | is the node number of a local file; or the inode number of an NFS file in the server host; or the Internet protocol type – e. g, “TCP”; or “STR” for a stream; or “CCITT” for an HP-UX x.25 socket; or the IRQ or inode number of a Linux AX.25 socket device. |
| NAME | is the name of the mount point and file system on which the file resides; or the name of a file specified in the <i>names</i> option (after any symbolic links have been resolved); or the name of a character special or block special device; or the local and remote Internet addresses of a network file; the local host name or IP number is followed by a colon (‘:’), the port, “->”, and the two-part remote address; IP addresses may be reported as numbers or names, depending on the + -M , -n , and -P options; colon-separated IPv6 numbers are enclosed in square brackets; IPv4 INADDR_ANY and IPv6 IN6_IS_ADDR_UNSPECIFIED addresses, and zero port numbers are represented by an asterisk (‘*’); a UDP destination address may be followed by the amount of time elapsed since the last packet was sent to the destination; TCP, UDP and UDPLITE remote addresses may be followed by TCP/TPI information in parentheses – state (e.g., “(ESTABLISHED)”, “(Unbound)”), queue sizes, and window sizes (not all dialects) – in a fashion similar to what <i>netstat</i> (1) reports; see the -T option description or the description of the TCP/TPI field in OUTPUT FOR OTHER PROGRAMS for more information on state, queue size, and window size; or the address or name of a UNIX domain socket, possibly including a stream clone device name, a file system object’s path name, local and foreign kernel addresses, socket pair information, and a bound vnode address; or the local and remote mount point names of an NFS file; or “STR”, followed by the stream name; or a stream character device name, followed by “->” and the stream name or a list of stream module names, separated by “->”; or “STR:” followed by the SCO OpenServer stream device and module names, separated by “->”; |

or system directory name, “--”, and as many components of the path name as *lsOf* can find in the kernel’s name cache for selected dialects (See the **KERNEL NAME CACHE** section for more information.);

or “PIPE->”, followed by a Solaris kernel pipe destination address;

or “COMMON:”, followed by the vnode device information structure’s device name, for a Solaris common vnode;

or the address family, followed by a slash (/), followed by fourteen comma-separated bytes of a non-Internet raw socket address;

or the HP-UX x.25 local address, followed by the virtual connection number (if any), followed by the remote address (if any);

or “(dead)” for disassociated Tru64 UNIX files – typically terminal files that have been flagged with the TIOCNOTTY ioctl and closed by daemons;

or “rd=<offset>” and “wr=<offset>” for the values of the read and write offsets of a FIFO;

or “clone *n*:/dev/event” for SCO OpenServer file clones of the /dev/event device, where *n* is the minor device number of the file;

or “(socketpair: *n*)” for a Solaris 2.6, 8, 9 or 10 UNIX domain socket, created by the *socketpair*(3N) network function;

or “no PCB” for socket files that do not have a protocol block associated with them, optionally followed by “, CANTSENDMORE” if sending on the socket has been disabled, or “, CANTRCVMORE” if receiving on the socket has been disabled (e.g., by the *shutdown*(2) function);

or the local and remote addresses of a Linux IPX socket file in the form <net>:[<node>:]<port>, followed in parentheses by the transmit and receive queue sizes, and the connection state;

or “dgram” or “stream” for the type UnixWare 7.1.1 and above in-kernel UNIX domain sockets, followed by a colon (:) and the local path name when available, followed by “->” and the remote path name or kernel socket address in hexadecimal when available;

or the association value, association index, endpoint value, local address, local port, remote address and remote port for Linux SCTP sockets;

or “protocol: ” followed by the Linux socket’s protocol attribute.

For dialects that support a “namefs” file system, allowing one file to be attached to another with *fattach*(3C), *lsOf* will add “(FA:<address1><direction><address2>)” to the NAME column. <address1> and <address2> are hexadecimal vnode addresses. <direction> will be “<-” if <address2> has been *fattach*’ed to this vnode whose address is <address1>; and “->” if <address1>, the vnode address of this vnode, has been *fattach*’ed to <address2>. <address1> may be omitted if it already appears in the DEVICE column.

lsOf may add two parenthetical notes to the NAME column for open Solaris 10 files: “(?)” if *lsOf* considers the path name of questionable accuracy; and “(deleted)” if the -X option has been specified and *lsOf* detects the open file’s path name has been deleted. Consult the *lsOf* FAQ (The **FAQ** section gives its location.) for more information on these NAME column additions.

LOCKS

lsOf can’t adequately report the wide variety of UNIX dialect file locks in a single character. What it reports in a single character is a compromise between the information it finds in the kernel and the limitations of the reporting format.

Moreover, when a process holds several byte level locks on a file, *lsOf* only reports the status of the first lock it encounters. If it is a byte level lock, then the lock character will be reported in lower case – i.e., ‘r’, ‘w’, or ‘x’ – rather than the upper case equivalent reported for a full file lock.

Generally *lsOf* can only report on locks held by local processes on local files. When a local process sets a lock on a remotely mounted (e.g., NFS) file, the remote server host usually records the lock state. One exception is Solaris – at some patch levels of 2.3, and in all versions above 2.4, the Solaris kernel records information on remote locks in local structures.

Lsof has trouble reporting locks for some UNIX dialects. Consult the **BUGS** section of this manual page or the *lsOf* FAQ (The **FAQ** section gives its location.) for more information.

OUTPUT FOR OTHER PROGRAMS

When the **-F** option is specified, *lsOf* produces output that is suitable for processing by another program – e.g, an *awk* or *Perl* script, or a C program.

Each unit of information is output in a field that is identified with a leading character and terminated by a NL (012) (or a NUL (000) if the 0 (zero) field identifier character is specified.) The data of the field follows immediately after the field identification character and extends to the field terminator.

It is possible to think of field output as process and file sets. A process set begins with a field whose identifier is ‘p’ (for process IDentifier (PID)). It extends to the beginning of the next PID field or the beginning of the first file set of the process, whichever comes first. Included in the process set are fields that identify the command, the process group IDentification (PGID) number, the task (thread) ID (TID), and the user ID (UID) number or login name.

A file set begins with a field whose identifier is ‘f’ (for file descriptor). It is followed by lines that describe the file’s access mode, lock state, type, device, size, offset, inode, protocol, name and stream module names. It extends to the beginning of the next file or process set, whichever comes first.

When the NUL (000) field terminator has been selected with the 0 (zero) field identifier character, *lsOf* ends each process and file set with a NL (012) character.

Lsof always produces one field, the PID (‘p’) field. All other fields may be declared optionally in the field identifier character list that follows the **-F** option. When a field selection character identifies an item *lsOf* does not normally list – e.g., PPID, selected with **-R** – specification of the field character – e.g., “**-FR**” – also selects the listing of the item.

It is entirely possible to select a set of fields that cannot easily be parsed – e.g., if the field descriptor field is not selected, it may be difficult to identify file sets. To help you avoid this difficulty, *lsOf* supports the **-F** option; it selects the output of all fields with NL terminators (the **-F0** option pair selects the output of all fields with NUL terminators). For compatibility reasons neither **-F** nor **-F0** select the raw device field.

These are the fields that *lsOf* will produce. The single character listed first is the field identifier.

| | |
|---|---|
| a | file access mode |
| c | process command name (all characters from proc or user structure) |
| C | file structure share count |
| d | file’s device character code |
| D | file’s major/minor device number (0x<hexadecimal>) |
| f | file descriptor (always selected) |
| F | file structure address (0x<hexadecimal>) |
| G | file flaGs (0x<hexadecimal>; names if +fg follows) |
| g | process group ID |
| i | file’s inode number |
| K | task ID |
| k | link count |
| l | file’s lock status |
| L | process login name |
| m | marker between repeated output |
| n | file name, comment, Internet address |
| N | node identifier (0x<hexadecimal>) |
| o | file’s offset (decimal) |

| | |
|-----|--|
| p | process ID (always selected) |
| P | protocol name |
| r | raw device number (0x<hexadecimal>) |
| R | parent process ID |
| s | file's size (decimal) |
| S | file's stream identification |
| t | file's type |
| T | TCP/TPI information, identified by prefixes (the '=' is part of the prefix): QR=<read queue size> QS=<send queue size> SO=<socket options and values> (not all dialects) SS=<socket states> (not all dialects) ST=<connection state> TF=<TCP flags and values> (not all dialects) WR=<window read size> (not all dialects) WW=<window write size> (not all dialects) (TCP/TPI information isn't reported for all supported UNIX dialects. The -h or -? help output for the -T option will show what TCP/TPI reporting can be requested.) |
| u | process user ID |
| z | Solaris 10 and higher zone name |
| Z | SELinux security context (inhibited when SELinux is disabled) |
| 0 | use NUL field terminator character in place of NL |
| 1-9 | dialect-specific field identifiers (The output of -F? identifies the information to be found in dialect-specific fields.) |

You can get on-line help information on these characters and their descriptions by specifying the **-F?** option pair. (Escape the '?' character as your shell requires.) Additional information on field content can be found in the **OUTPUT** section.

As an example, "**-F pcfm**" will select the process ID ('p'), command name ('c'), file descriptor ('f') and file name ('n') fields with an NL field terminator character; "**-F pcfm0**" selects the same output with a NUL (000) field terminator character.

Lsof doesn't produce all fields for every process or file set, only those that are available. Some fields are mutually exclusive: file device characters and file major/minor device numbers; file inode number and protocol name; file name and stream identification; file size and offset. One or the other member of these mutually exclusive sets will appear in field output, but not both.

Normally *lsof* ends each field with a NL (012) character. The 0 (zero) field identifier character may be specified to change the field terminator character to a NUL (000). A NUL terminator may be easier to process with *xargs* (1), for example, or with programs whose quoting mechanisms may not easily cope with the range of characters in the field output. When the NUL field terminator is in use, *lsof* ends each process and file set with a NL (012).

Three aids to producing programs that can process *lsof* field output are included in the *lsof* distribution. The first is a C header file, *lsof_fields.h*, that contains symbols for the field identification characters, indexes for storing them in a table, and explanation strings that may be compiled into programs. *Lsof* uses this header file.

The second aid is a set of sample scripts that process field output, written in *awk*, *Perl* 4, and *Perl* 5. They're located in the *scripts* subdirectory of the *lsof* distribution.

The third aid is the C library used for the *lsof* test suite. The test suite is written in C and uses field output to validate the correct operation of *lsof*. The library can be found in the *tests/LTlib.c* file of the *lsof* distribution. The library uses the first aid, the *lsof_fields.h* header file.

BLOCKS AND TIMEOUTS

Lsof can be blocked by some kernel functions that it uses – *lstat(2)*, *readlink(2)*, and *stat(2)*. These functions are stalled in the kernel, for example, when the hosts where mounted NFS file systems reside become inaccessible.

Lsof attempts to break these blocks with timers and child processes, but the techniques are not wholly reliable. When *Lsof* does manage to break a block, it will report the break with an error message. The messages may be suppressed with the **-t** and **-w** options.

The default timeout value may be displayed with the **-h** or **-?** option, and it may be changed with the **-S [t]** option. The minimum for *t* is two seconds, but you should avoid small values, since slow system responsiveness can cause short timeouts to expire unexpectedly and perhaps stop *Lsof* before it can produce any output.

When *Lsof* has to break a block during its access of mounted file system information, it normally continues, although with less information available to display about open files.

Lsof can also be directed to avoid the protection of timers and child processes when using the kernel functions that might block by specifying the **-O** option. While this will allow *Lsof* to start up with less overhead, it exposes *Lsof* completely to the kernel situations that might block it. Use this option cautiously.

AVOIDING KERNEL BLOCKS

You can use the **-b** option to tell *Lsof* to avoid using kernel functions that would block. Some cautions apply.

First, using this option usually requires that your system supply alternate device numbers in place of the device numbers that *Lsof* would normally obtain with the *lstat(2)* and *stat(2)* kernel functions. See the **ALTERNATE DEVICE NUMBERS** section for more information on alternate device numbers.

Second, you can't specify *names* for *Lsof* to locate unless they're file system names. This is because *Lsof* needs to know the device and inode numbers of files listed with *names* in the *Lsof* options, and the **-b** option prevents *Lsof* from obtaining them. Moreover, since *Lsof* only has device numbers for the file systems that have alternates, its ability to locate files on file systems depends completely on the availability and accuracy of the alternates. If no alternates are available, or if they're incorrect, *Lsof* won't be able to locate files on the named file systems.

Third, if the names of your file system directories that *Lsof* obtains from your system's mount table are symbolic links, *Lsof* won't be able to resolve the links. This is because the **-b** option causes *Lsof* to avoid the kernel *readlink(2)* function it uses to resolve symbolic links.

Finally, using the **-b** option causes *Lsof* to issue warning messages when it needs to use the kernel functions that the **-b** option directs it to avoid. You can suppress these messages by specifying the **-w** option, but if you do, you won't see the alternate device numbers reported in the warning messages.

ALTERNATE DEVICE NUMBERS

On some dialects, when *Lsof* has to break a block because it can't get information about a mounted file system via the *lstat(2)* and *stat(2)* kernel functions, or because you specified the **-b** option, *Lsof* can obtain some of the information it needs – the device number and possibly the file system type – from the system mount table. When that is possible, *Lsof* will report the device number it obtained. (You can suppress the report by specifying the **-w** option.)

You can assist this process if your mount table is supported with an */etc/mstab* or */etc/mnttab* file that contains an options field by adding a "dev=xxxx" field for mount points that do not have one in their options strings. Note: you must be able to edit the file – i.e., some mount tables like recent Solaris */etc/mnttab* or Linux */proc/mounts* are read-only and can't be modified.

You may also be able to supply device numbers using the **+m** and **+m m** options, provided they are supported by your dialect. Check the output of *Lsof*'s **-h** or **-?** options to see if the **+m** and **+m m** options are available.

The "xxxx" portion of the field is the hexadecimal value of the file system's device number. (Consult the *st_dev* field of the output of the *lstat(2)* and *stat(2)* functions for the appropriate values for your file

systems.) Here's an example from a Sun Solaris 2.6 */etc/mnttab* for a file system remotely mounted via NFS:

```
nfs ignore,noquota,dev=2a40001
```

There's an advantage to having "dev=xxxx" entries in your mount table file, especially for file systems that are mounted from remote NFS servers. When a remote server crashes and you want to identify its users by running *lsdf* on one of its clients, *lsdf* probably won't be able to get output from the *lstat(2)* and *stat(2)* functions for the file system. If it can obtain the file system's device number from the mount table, it will be able to display the files open on the crashed NFS server.

Some dialects that do not use an ASCII */etc/mntab* or */etc/mnttab* file for the mount table may still provide an alternative device number in their internal mount tables. This includes AIX, Apple Darwin, FreeBSD, NetBSD, OpenBSD, and Tru64 UNIX. *lsdf* knows how to obtain the alternative device number for these dialects and uses it when its attempt to *lstat(2)* or *stat(2)* the file system is blocked.

If you're not sure your dialect supplies alternate device numbers for file systems from its mount table, use this *lsdf* incantation to see if it reports any alternate device numbers:

```
lsdf -b
```

Look for standard error file warning messages that begin "assuming "dev=xxxx" from ...".

KERNEL NAME CACHE

lsdf is able to examine the kernel's name cache or use other kernel facilities (e.g., the ADVFS 4.x *tag_to_path()* function under Tru64 UNIX) on some dialects for most file system types, excluding AFS, and extract recently used path name components from it. (AFS file system path lookups don't use the kernel's name cache; some Solaris VxFS file system operations apparently don't use it, either.)

lsdf reports the complete paths it finds in the NAME column. If *lsdf* can't report all components in a path, it reports in the NAME column the file system name, followed by a space, two '-' characters, another space, and the name components it has located, separated by the '/' character.

When *lsdf* is run in repeat mode – i.e., with the *-r* option specified – the extent to which it can report path name components for the same file may vary from cycle to cycle. That's because other running processes can cause the kernel to remove entries from its name cache and replace them with others.

lsdf's use of the kernel name cache to identify the paths of files can lead it to report incorrect components under some circumstances. This can happen when the kernel name cache uses device and node number as a key (e.g., SCO OpenServer) and a key on a rapidly changing file system is reused. If the UNIX dialect's kernel doesn't purge the name cache entry for a file when it is unlinked, *lsdf* may find a reference to the wrong entry in the cache. The *lsdf* FAQ (The **FAQ** section gives its location.) has more information on this situation.

lsdf can report path name components for these dialects:

```
FreeBSD
HP-UX
Linux
NetBSD
NEXTSTEP
OpenBSD
OPENSTEP
SCO OpenServer
SCO|Caldera UnixWare
Solaris
Tru64 UNIX
```

lsdf can't report path name components for these dialects:

```
AIX
```

If you want to know why *lsdf* can't report path name components for some dialects, see the *lsdf* FAQ (The

FAQ section gives its location.)

DEVICE CACHE FILE

Examining all members of the */dev* (or */devices*) node tree with *stat(2)* functions can be time consuming. What's more, the information that *lsOf* needs – device number, inode number, and path – rarely changes.

Consequently, *lsOf* normally maintains an ASCII text file of cached */dev* (or */devices*) information (exception: the */proc*-based Linux *lsOf* where it's not needed.) The local system administrator who builds *lsOf* can control the way the device cache file path is formed, selecting from these options:

- Path from the **-D** option;
- Path from an environment variable;
- System-wide path;
- Personal path (the default);
- Personal path, modified by an environment variable.

Consult the output of the **-h**, **-D?**, or **-?** help options for the current state of device cache support. The help output lists the default read-mode device cache file path that is in effect for the current invocation of *lsOf*. The **-D?** option output lists the read-only and write device cache file paths, the names of any applicable environment variables, and the personal device cache path format.

lsOf can detect that the current device cache file has been accidentally or maliciously modified by integrity checks, including the computation and verification of a sixteen bit Cyclic Redundancy Check (CRC) sum on the file's contents. When *lsOf* senses something wrong with the file, it issues a warning and attempts to remove the current cache file and create a new copy, but only to a path that the process can legitimately write.

The path from which a *lsOf* process may attempt to read a device cache file may not be the same as the path to which it can legitimately write. Thus when *lsOf* senses that it needs to update the device cache file, it may choose a different path for writing it from the path from which it read an incorrect or outdated version.

If available, the **-Dr** option will inhibit the writing of a new device cache file. (It's always available when specified without a path name argument.)

When a new device is added to the system, the device cache file may need to be recreated. Since *lsOf* compares the mtime of the device cache file with the mtime and ctime of the */dev* (or */devices*) directory, it usually detects that a new device has been added; in that case *lsOf* issues a warning message and attempts to rebuild the device cache file.

Whenever *lsOf* writes a device cache file, it sets its ownership to the real UID of the executing process, and its permission modes to 0600, this restricting its reading and writing to the file's owner.

LSOF PERMISSIONS THAT AFFECT DEVICE CACHE FILE ACCESS

Two permissions of the *lsOf* executable affect its ability to access device cache files. The permissions are set by the local system administrator when *lsOf* is installed.

The first and rarer permission is *setuid-root*. It comes into effect when *lsOf* is executed; its effective UID is then root, while its real (i.e., that of the logged-on user) UID is not. The *lsOf* distribution recommends that versions for these dialects run *setuid-root*.

HP-UX 11.11 and 11.23
Linux

The second and more common permission is *setgid*. It comes into effect when the effective group IDentification number (GID) of the *lsOf* process is set to one that can access kernel memory devices – e.g., “*knmem*”, “*sys*”, or “*system*”.

An *lsOf* process that has *setgid* permission usually surrenders the permission after it has accessed the kernel memory devices. When it does that, *lsOf* can allow more liberal device cache path formations. The *lsOf* distribution recommends that versions for these dialects run *setgid* and be allowed to surrender *setgid* permission.

AIX 5.[12] and 5.3-ML1

Apple Darwin 7.x Power Macintosh systems
 FreeBSD 4.x, 4.1x, 5.x and [6789].x for x86-based systems
 FreeBSD 5.x and [6789].x for Alpha, AMD64 and Sparc64-based systems
 HP-UX 11.00
 NetBSD 1.[456], 2.x and 3.x for Alpha, x86, and SPARC-based systems
 NEXTSTEP 3.[13] for NEXTSTEP architectures
 OpenBSD 2.[89] and 3.[0–9] for x86-based systems
 OPENSTEP 4.x
 SCO OpenServer Release 5.0.6 for x86-based systems
 SCO|Caldera UnixWare 7.1.4 for x86-based systems
 Solaris 2.6, 8, 9 and 10
 Tru64 UNIX 5.1

(Note: *lsOf* for AIX 5L and above needs `setuid=`root permission if its `-X` option is used.)

Lsof for these dialects does not support a device cache, so the permissions given to the executable don't apply to the device cache file.

Linux

DEVICE CACHE FILE PATH FROM THE `-D` OPTION

The `-D` option provides limited means for specifying the device cache file path. Its `?` function will report the read-only and write device cache file paths that *lsOf* will use.

When the `-D b`, `r`, and `u` functions are available, you can use them to request that the cache file be built in a specific location (`b[path]`); read but not rebuilt (`r[path]`); or read and rebuilt (`u[path]`). The `b`, `r`, and `u` functions are restricted under some conditions. They are restricted when the *lsOf* process is `setuid=`root. The path specified with the `r` function is always read-only, even when it is available.

The `b`, `r`, and `u` functions are also restricted when the *lsOf* process runs `setgid` and *lsOf* doesn't surrender the `setgid` permission. (See the **LSOF PERMISSIONS THAT AFFECT DEVICE CACHE FILE ACCESS** section for a list of implementations that normally don't surrender their `setgid` permission.)

A further `-D` function, `i` (for ignore), is always available.

When available, the `b` function tells *lsOf* to read device information from the kernel with the `stat(2)` function and build a device cache file at the indicated path.

When available, the `r` function tells *lsOf* to read the device cache file, but not update it. When a path argument accompanies `-Dr`, it names the device cache file path. The `r` function is always available when it is specified without a path name argument. If *lsOf* is not running `setuid=`root and surrenders its `setgid` permission, a path name argument may accompany the `r` function.

When available, the `u` function tells *lsOf* to attempt to read and use the device cache file. If it can't read the file, or if it finds the contents of the file incorrect or outdated, it will read information from the kernel, and attempt to write an updated version of the device cache file, but only to a path it considers legitimate for the *lsOf* process effective and real UIDs.

DEVICE CACHE PATH FROM AN ENVIRONMENT VARIABLE

Lsof's second choice for the device cache file is the contents of the `LSOFDEVCACHE` environment variable. It avoids this choice if the *lsOf* process is `setuid=`root, or the real UID of the process is root.

A further restriction applies to a device cache file path taken from the `LSOFDEVCACHE` environment variable: *lsOf* will not write a device cache file to the path if the *lsOf* process doesn't surrender its `setgid` permission. (See the **LSOF PERMISSIONS THAT AFFECT DEVICE CACHE FILE ACCESS** section for information on implementations that don't surrender their `setgid` permission.)

The local system administrator can disable the use of the `LSOFDEVCACHE` environment variable or change its name when building *lsOf*. Consult the output of `-D?` for the environment variable's name.

SYSTEM-WIDE DEVICE CACHE PATH

The local system administrator may choose to have a system-wide device cache file when building *lsOf*. That file will generally be constructed by a special system administration procedure when the system is booted or when the contents of */dev* or */devices* changes. If defined, it is *lsOf*'s third device cache file path choice.

You can tell that a system-wide device cache file is in effect for your local installation by examining the *lsOf* help option output – i.e., the output from the **-h** or **-?** option.

lsOf will never write to the system-wide device cache file path by default. It must be explicitly named with a **-D** function in a root-owned procedure. Once the file has been written, the procedure must change its permission modes to 0644 (owner-read and owner-write, group-read, and other-read).

PERSONAL DEVICE CACHE PATH (DEFAULT)

The default device cache file path of the *lsOf* distribution is one recorded in the home directory of the real UID that executes *lsOf*. Added to the home directory is a second path component of the form *.lsOf_hostname*.

This is *lsOf*'s fourth device cache file path choice, and is usually the default. If a system-wide device cache file path was defined when *lsOf* was built, this fourth choice will be applied when *lsOf* can't find the system-wide device cache file. This is the **only** time *lsOf* uses two paths when reading the device cache file.

The *hostname* part of the second component is the base name of the executing host, as returned by *gethostname(2)*. The base name is defined to be the characters preceding the first '.' in the *gethostname(2)* output, or all the *gethostname(2)* output if it contains no '.'.

The device cache file belongs to the user ID and is readable and writable by the user ID alone – i.e., its modes are 0600. Each distinct real user ID on a given host that executes *lsOf* has a distinct device cache file. The *hostname* part of the path distinguishes device cache files in an NFS-mounted home directory into which device cache files are written from several different hosts.

The personal device cache file path formed by this method represents a device cache file that *lsOf* will attempt to read, and will attempt to write should it not exist or should its contents be incorrect or outdated.

The **-Dr** option without a path name argument will inhibit the writing of a new device cache file.

The **-D?** option will list the format specification for constructing the personal device cache file. The conversions used in the format specification are described in the *00DCACHE* file of the *lsOf* distribution.

MODIFIED PERSONAL DEVICE CACHE PATH

If this option is defined by the local system administrator when *lsOf* is built, the LSOFPERSDCPATH environment variable contents may be used to add a component of the personal device cache file path.

The LSOFPERSDCPATH variable contents are inserted in the path at the place marked by the local system administrator with the "%p" conversion in the HASPERSDC format specification of the dialect's *machine.h* header file. (It's placed right after the home directory in the default *lsOf* distribution.)

Thus, for example, if LSOFPERSDCPATH contains "LSOF", the home directory is "/Homes/abe", the host name is "lsOf.itap.purdue.edu", and the HASPERSDC format is the default ("%h/%p.lsOf_%L"), the modified personal device cache file path is:

/Homes/abe/LSOF/.lsOf_vic

The LSOFPERSDCPATH environment variable is ignored when the *lsOf* process is setuid-root or when the real UID of the process is root.

lsOf will not write to a modified personal device cache file path if the *lsOf* process doesn't surrender setgid permission. (See the **LSOF PERMISSIONS THAT AFFECT DEVICE CACHE FILE ACCESS** section for a list of implementations that normally don't surrender their setgid permission.)

If, for example, you want to create a sub-directory of personal device cache file paths by using the LSOFPERSDCPATH environment variable to name it, and *lsOf* doesn't surrender its setgid permission, you will have to allow *lsOf* to create device cache files at the standard personal path and move them to your subdirectory with shell commands.

The local system administrator may: disable this option when *lsyf* is built; change the name of the environment variable from `LSOFPERSDCPATH` to something else; change the `HASPERSDC` format to include the personal path component in another place; or exclude the personal path component entirely. Consult the output of the `-D?` option for the environment variable's name and the `HASPERSDC` format specification.

DIAGNOSTICS

Errors are identified with messages on the standard error file.

Lsof returns a one (1) if any error was detected, including the failure to locate command names, file names, Internet addresses or files, login names, NFS files, PIDs, PGIDs, or UIDs it was asked to list. If the `-V` option is specified, *lsyf* will indicate the search items it failed to list.

It returns a zero (0) if no errors were detected and if it was able to list some information about all the specified search arguments.

When *lsyf* cannot open access to `/dev` (or `/devices`) or one of its subdirectories, or get information on a file in them with `stat(2)`, it issues a warning message and continues. That *lsyf* will issue warning messages about inaccessible files in `/dev` (or `/devices`) is indicated in its help output – requested with the `-h` or `>B -?` options – with the message:

Inaccessible /dev warnings are enabled.

The warning message may be suppressed with the `-w` option. It may also have been suppressed by the system administrator when *lsyf* was compiled by the setting of the `WARNDEVACCESS` definition. In this case, the output from the help options will include the message:

Inaccessible /dev warnings are disabled.

Inaccessible device warning messages usually disappear after *lsyf* has created a working device cache file.

EXAMPLES

For a more extensive set of examples, documented more fully, see the `00QUICKSTART` file of the *lsyf* distribution.

To list all open files, use:

`lsyf`

To list all open Internet, x.25 (HP-UX), and UNIX domain files, use:

`lsyf -i -U`

To list all open IPv4 network files in use by the process whose PID is 1234, use:

`lsyf -i 4 -a -p 1234`

Presuming the UNIX dialect supports IPv6, to list only open IPv6 network files, use:

`lsyf -i 6`

To list all files using any protocol on ports 513, 514, or 515 of host `wonderland.cc.purdue.edu`, use:

`lsyf -i @wonderland.cc.purdue.edu:513-515`

To list all files using any protocol on any port of `mace.cc.purdue.edu` (`cc.purdue.edu` is the default domain), use:

`lsyf -i @mace`

To list all open files for login name “abe”, or user ID 1234, or process 456, or process 123, or process 789, use:

`lsyf -p 456,123,789 -u 1234,abe`

To list all open files on device `/dev/hd4`, use:

`lsyf /dev/hd4`

To find the process that has `/u/abe/foo` open, use:

```
lsof /u/abe/foo
```

To send a SIGHUP to the processes that have /u/abe/bar open, use:

```
kill -HUP `lsof -t /u/abe/bar`
```

To find any open file, including an open UNIX domain socket file, with the name /dev/log, use:

```
lsof /dev/log
```

To find processes with open files on the NFS file system named /nfs/mount/point whose server is inaccessible, and presuming your mount table supplies the device number for /nfs/mount/point, use:

```
lsof -b /nfs/mount/point
```

To do the preceding search with warning messages suppressed, use:

```
lsof -bw /nfs/mount/point
```

To ignore the device cache file, use:

```
lsof -Di
```

To obtain PID and command name field output for each process, file descriptor, file device number, and file inode number for each file of each process, use:

```
lsof -FpcfDi
```

To list the files at descriptors 1 and 3 of every process running the *lsof* command for login ID “abe” every 10 seconds, use:

```
lsof -c lsof -a -d 1 -d 3 -u abe -r10
```

To list the current working directory of processes running a command that is exactly four characters long and has an ‘o’ or ‘O’ in character three, use this regular expression form of the *-c c* option:

```
lsof -c /^..o.$/i -a -d cwd
```

To find an IP version 4 socket file by its associated numeric dot-form address, use:

```
lsof -i@128.210.15.17
```

To find an IP version 6 socket file (when the UNIX dialect supports IPv6) by its associated numeric colon-form address, use:

```
lsof -i@[0:1:2:3:4:5:6:7]
```

To find an IP version 6 socket file (when the UNIX dialect supports IPv6) by an associated numeric colon-form address that has a run of zeroes in it – e.g., the loop-back address – use:

```
lsof -i@[::1]
```

To obtain a repeat mode marker line that contains the current time, use:

```
lsof -rm====%T====
```

To add spaces to the previous marker line, use:

```
lsof -r "m==== %T===="
```

BUGS

Since *lsof* reads kernel memory in its search for open files, rapid changes in kernel memory may produce unpredictable results.

When a file has multiple record locks, the lock status character (following the file descriptor) is derived from a test of the first lock structure, not from any combination of the individual record locks that might be described by multiple lock structures.

Lsof can’t search for files with restrictive access permissions by *name* unless it is installed with root set-UID permission. Otherwise it is limited to searching for files to which its user or its set-GID group (if any) has access permission.

The display of the destination address of a raw socket (e.g., for *ping*) depends on the UNIX operating system. Some dialects store the destination address in the raw socket's protocol control block, some do not.

Lsof can't always represent Solaris device numbers in the same way that *ls*(1) does. For example, the major and minor device numbers that the *lstat*(2) and *stat*(2) functions report for the directory on which CD-ROM files are mounted (typically */cdrom*) are not the same as the ones that it reports for the device on which CD-ROM files are mounted (typically */dev/sr0*). (*Lsof* reports the directory numbers.)

The support for */proc* file systems is available only for BSD and Tru64 UNIX dialects, Linux, and dialects derived from SYSV R4 – e.g., FreeBSD, NetBSD, OpenBSD, Solaris, UnixWare.

Some */proc* file items – device number, inode number, and file size – are unavailable in some dialects. Searching for files in a */proc* file system may require that the full path name be specified.

No text (**txt**) file descriptors are displayed for Linux processes. All entries for files other than the current working directory, the root directory, and numerical file descriptors are labeled **mem** descriptors.

Lsof can't search for Tru64 UNIX named pipes by name, because their kernel implementation of *lstat*(2) returns an improper device number for a named pipe.

Lsof can't report fully or correctly on HP-UX 9.01, 10.20, and 11.00 locks because of insufficient access to kernel data or errors in the kernel data. See the *lsof* FAQ (The **FAQ** section gives its location.) for details.

The AIX SMT file type is a fabrication. It's made up for file structures whose type (15) isn't defined in the AIX */usr/include/sys/file.h* header file. One way to create such file structures is to run X clients with the *DISPLAY* variable set to ":0.0".

The **+|-f[*cfgGn*]** option is not supported under */proc*-based Linux *lsof*, because it doesn't read kernel structures from kernel memory.

ENVIRONMENT

Lsof may access these environment variables.

| | |
|----------------|--|
| LANG | defines a language locale. See <i>setlocale</i> (3) for the names of other variables that can be used in place of LANG – e.g., LC_ALL, LC_TYPE, etc. |
| LSOFDEVCACHE | defines the path to a device cache file. See the DEVICE CACHE PATH FROM AN ENVIRONMENT VARIABLE section for more information. |
| LSOFPERSDCPATH | defines the middle component of a modified personal device cache file path. See the MODIFIED PERSONAL DEVICE CACHE PATH section for more information. |

FAQ

Frequently-asked questions and their answers (an FAQ) are available in the *00FAQ* file of the *lsof* distribution.

That file is also available via anonymous ftp from *lsof.itap.purdue.edu* at *pub/tools/unix/lsof/FAQ*. The URL is:

<ftp://lsof.itap.purdue.edu/pub/tools/unix/lsof/FAQ>

FILES

| | |
|-----------------------|--|
| <i>/dev/kmem</i> | kernel virtual memory device |
| <i>/dev/mem</i> | physical memory device |
| <i>/dev/swap</i> | system paging device |
| <i>.lsof_hostname</i> | <i>lsof</i> 's device cache file (The suffix, <i>hostname</i> , is the first component of the host's name returned by <i>gethostname</i> (2).) |

AUTHORS

Lsof was written by Victor A. Abell <abe@purdue.edu> of Purdue University. Many others have contributed to *lsof*. They're listed in the *00CREDITS* file of the *lsof* distribution.

DISTRIBUTION

The latest distribution of *lsof* is available via anonymous ftp from the host *lsof.itap.purdue.edu*. You'll find the *lsof* distribution in the *pub/tools/unix/lsof* directory.

You can also use this URL:

`ftp://lsof.itap.purdue.edu/pub/tools/unix/lsof`

Lsof is also mirrored elsewhere. When you access *lsof.itap.purdue.edu* and change to its *pub/tools/unix/lsof* directory, you'll be given a list of some mirror sites. The *pub/tools/unix/lsof* directory also contains a more complete list in its *mirrors* file. Use mirrors with caution – not all mirrors always have the latest *lsof* revision.

Some pre-compiled *Lsof* executables are available on *lsof.itap.purdue.edu*, but their use is discouraged – it's better that you build your own from the sources. If you feel you must use a pre-compiled executable, please read the cautions that appear in the README files of the *pub/tools/unix/lsof/binaries* subdirectories and in the 00* files of the distribution.

More information on the *lsof* distribution can be found in its *README.lsof_<version>* file. If you intend to get the *lsof* distribution and build it, please read *README.lsof_<version>* and the other 00* files of the distribution before sending questions to the author.

SEE ALSO

Not all the following manual pages may exist in every UNIX dialect to which *lsof* has been ported.

`access(2)`, `awk(1)`, `crash(1)`, `fattach(3C)`, `ff(1)`, `fstat(8)`, `fuser(1)`, `gethostname(2)`, `isprint(3)`, `kill(1)`, `local-time(3)`, `lstat(2)`, `modload(8)`, `mount(8)`, `netstat(1)`, `ofiles(8L)`, `perl(1)`, `ps(1)`, `readlink(2)`, `setlocale(3)`, `stat(2)`, `strftime(3)`, `time(2)`, `uname(1)`.

NAME

lspm – list names and descriptions of Perl modules in a directory

SYNOPSIS

```
lspm -h
```

```
lspm [-p] [-a] [-c [num]] [-l len] [dir [dir dir ...]]
```

DESCRIPTION

Lists all or a subset of installed Perl modules, with version numbers and descriptions.

It will look in Perl's default search path for modules, @INC, if you don't explicitly list any directories to walk. Note that this default search excludes the current directory.

OPTIONS

-h, --help

See a synopsis.

--man

Browse the manpage.

-p, --show-path

Include path of found modules in output.

-a, --align

Vertically align descriptions.

-c, --align-local, --align-cont

Align descriptions in blocks where the module names don't differ too much in length, to avoid pushing all descriptions way over to the right just because a few names are long. The output looks more ragged than with full alignment, but is still lined up locally and only requires the eye to cross small gaps between columns, so is usually more readable.

You can pass an optional positive integer argument to specify the length threshold; the default is 7.

-l, --max-length, --limit

Cut off descriptions at specified length.

NAME

lua – Lua interpreter

SYNOPSIS

lua [*options*] [*script* [*args*]]

DESCRIPTION

lua is the standalone Lua interpreter. It loads and executes Lua programs, either in textual source form or in precompiled binary form. (Precompiled binaries are output by **luac**, the Lua compiler.) **lua** can be used as a batch interpreter and also interactively.

After handling the *options*, the Lua program in file *script* is loaded and executed. The *args* are available to *script* as strings in a global table named **arg** and also as arguments to its main function. When called without arguments, **lua** behaves as **lua -v -i** if the standard input is a terminal, and as **lua -** otherwise.

In interactive mode, **lua** prompts the user, reads lines from the standard input, and executes them as they are read. If the line contains an expression, then the line is evaluated and the result is printed. If a line does not contain a complete statement, then a secondary prompt is displayed and lines are read until a complete statement is formed or a syntax error is found.

Before handling command line options and scripts, **lua** checks the contents of the environment variables **LUA_INIT_5_4** and **LUA_INIT**, in that order. If the contents are of the form '@*filename*', then *filename* is executed. Otherwise, the contents are assumed to be a Lua statement and is executed. When **LUA_INIT_5_4** is defined, **LUA_INIT** is ignored.

OPTIONS

- e** *stat* execute statement *stat*.
- i** enter interactive mode after executing *script*.
- l** *name* require library *name* into global *name*.
- v** show version information.
- E** ignore environment variables.
- W** turn warnings on.
- stop handling options.
- stop handling options and execute the standard input as a file.

ENVIRONMENT VARIABLES

The following environment variables affect the execution of **lua**. When defined, the version-specific variants take priority and the version-neutral variants are ignored.

LUA_INIT, LUA_INIT_5_4

Code to be executed before command line options and scripts.

LUA_PATH, LUA_PATH_5_4

Initial value of package.cpath, the path used by require to search for Lua loaders.

LUA_CPATH, LUA_CPATH_5_4

Initial value of package.cpath, the path used by require to search for C loaders.

EXIT STATUS

If a script calls `os.exit`, then **lua** exits with the given exit status. Otherwise, **lua** exits with `EXIT_SUCCESS` (0 on POSIX systems) if there were no errors and with `EXIT_FAILURE` (1 on POSIX systems) if there were errors. Errors raised in interactive mode do not cause exits.

DIAGNOSTICS

Error messages should be self explanatory.

NAME

luac – Lua compiler

SYNOPSIS

luac [*options*] [*filenames*]

DESCRIPTION

luac is the Lua compiler. It translates programs written in the Lua programming language into binary files containing precompiled chunks that can be later loaded and executed.

The main advantages of precompiling chunks are: faster loading, protecting source code from accidental user changes, and off-line syntax checking. Precompiling does not imply faster execution because in Lua chunks are always compiled into bytecodes before being executed. **luac** simply allows those bytecodes to be saved in a file for later execution. Precompiled chunks are not necessarily smaller than the corresponding source. The main goal in precompiling is faster loading.

In the command line, you can mix text files containing Lua source and binary files containing precompiled chunks. **luac** produces a single output file containing the combined bytecodes for all files given. Executing the combined file is equivalent to executing the given files. By default, the output file is named **luac.out**, but you can change this with the **-o** option.

Precompiled chunks are *not* portable across different architectures. Moreover, the internal format of precompiled chunks is likely to change when a new version of Lua is released. Make sure you save the source files of all Lua programs that you precompile.

OPTIONS

- l** produce a listing of the compiled bytecode for Lua's virtual machine. Listing bytecodes is useful to learn about Lua's virtual machine. If no files are given, then **luac** loads **luac.out** and lists its contents. Use **-l -l** for a full listing.
- o file** output to *file*, instead of the default **luac.out**. (You can use '-' for standard output, but not on platforms that open standard output in text mode.) The output file may be one of the given files because all files are loaded before the output file is written. Be careful not to overwrite precious files.
- p** load files but do not generate any output file. Used mainly for syntax checking and for testing precompiled chunks: corrupted files will probably generate errors when loaded. If no files are given, then **luac** loads **luac.out** and tests its contents. No messages are displayed if the file loads without errors.
- s** strip debug information before writing the output file. This saves some space in very large chunks, but if errors occur when running a stripped chunk, then the error messages may not contain the full information they usually do. In particular, line numbers and names of local variables are lost.
- v** show version information.
- stop handling options.
- stop handling options and process standard input.

NAME

luaenv – print environment needed to start Lua scripts

SYNOPSIS

edrc/lib/luaenv [**-n**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

print the environment used by **luaenv** to access the Lua packages/modules bundled with WA2L/edrc.

To set the environment prior to the execution of **lua**, invoke:

```
eval `luaenv`
```

This command is *only* to be used to prepare the environment to execute Lua scripts when calling the **lua** interpreter not thru **edrc/bin/lua**.

When writing Lua scripts for WA2L/edrc, do *not* use **luaenv**, start the script thru the **.lua_wrapper**. See **lua_wrapper(1)** for information about integrating a Lua script into WA2L/edrc.

When writing recovery scripts in Lua, use the:

```
#!/usr/bin/env lua
```

setting in the script magic key and the environment is set correctly.

OPTIONS

-n no **export** *VARIABLE* ... output.

ENVIRONMENT**\$LUA_PATH**

this variable holds Lua package/module locations additional to the standard applying to an installation. This variable will be expanded with the bundled Lua module locations (**lib/lua/lum/<OSID>/<major>.<minor>/share/lua/<major>.<minor>/?.lua;;**) when executing the **luaenv** command.

\$LUA_CPATH

path of the Lua package/module libs for the related operating system id and Lua version (**lib/lua/lum/<OSID>/<major>.<minor>/lib/lua/<major>.<minor>/[<GLIBC>/]?.so;;**) bundled with WA2L/edrc.

The GLIBC version *<GLIBC>* can be resolved using the **glibc.version(3)**, the **ldd --version** or the **getconf GNU_LIBC_VERSION** command.

\$PATH command search path. This variable will be expanded with the path where the **lua** interpreter was found on the system when executing the **luaenv** command. See also **lua_wrapper(1)** for more information.

EXIT STATUS

0 always

FILES

The *<major>* is the major version number (e.g. 5) and *<minor>* is the minor Lua version (e.g. 4).

etc/lua_wrapper.cfg

configuration file for **.lua_wrapper** and **luaenv**.

lib/lua/lum/<OSID>/<major>.<minor>/

location of all bundled Lua packages/modules.

lib/lua/lum/<OSID>/<major>.<minor>/share/lua/<major>.<minor>/

Pure Lua modules (**.lua** files).

The directory is pre-pended to **\$LUA_PATH**.

lib/lua/lum/<OSID>/<major>.<minor>/lib/lua/<major>.<minor>/[<GLIBC>/]

Compiled Lua modules (**.so** files).

The directory is pre-pended to the **\$LUA_CPATH**.

The logic of the libraries is identical to the **os_wrapper(1)** to support operating systems having different versions of the **glibc** library.

The GLIBC version *<GLIBC>* can be resolved using the **glibc.version(3)**, the **ldd --version** or the **getconf GNU_LIBC_VERSION** command.

lib/lua/lum/<OSID>/<major>.<minor>/bin/

Scripts provided by some Lua modules.

EXAMPLES

1) Start a Lua script from a recovery script

To start a Lua script that uses a bundled Lua module from a recovery script, just call the **lua** interpreter.

Recovery script:

```
#!/bin/ksh
#
# 1:ascript - A Recovery Script calling a Lua script
#
# [00] 08.02.2009 CWa Initial Version
#
#
test "$DEBUG" = True && set -x
:
:
lua ./luascript
:
```

Lua script:

```
--
-- luascript - Lua script using bundled lcomplex module
--
-- [00] 18.03.2009 CWa      Initial Version
--
:
:
local complex = require "complex"
:
```

2) Write a recovery script in Lua

Write the recovery script in Lua.

Lua recovery script:

```
#!/usr/bin/env lua
--
-- 1:ascript - A Recovery Script in Lua
--
-- [00] 08.02.2009 CWa      Initial Version
--
:
:
local complex = require "complex"
:
```

Note the use of `'#!/usr/bin/env lua'` in the magic key to start the Lua script. This ensures that the **lua** interpreter is found independent of the installation base directory of WA2L/edrc.

3) Write a Lua script outside of WA2L/edrc and profit from bundled Lua modules

The startup method uses the **lua** interpreter start thru `~edrc/bin/lua` that automatically enables to use all Lua packages/modules bundled with WA2L/edrc.

This method is similar to the use of the **.lua_wrapper**, but the Lua script can be placed somewhere of your liking outside of WA2L/edrc.

Set the permissions of the script to executable:

```
chmod +x luascript
```

Lua script:

```
#!/bin/ksh
#
# luascript - Lua script using bundled modules
#
# [00] 18.03.2009 CWa Initial Version
#

sed '1,/^exit \$\$/d' $0 | ~edrc/bin/lua - "$0" "$@"
exit $?

-- Lua
--
:
:
local complex = require "complex"
:
```

4) Write a Lua script outside of WA2L/edrc and profit from bundled Lua modules

The startup method method below allows to start the **lua** interpreter from a specific installation directory on the system and also enables to use all Lua packages/modules bundled with WA2L/edrc using the **luaenv** command to dynamically initialize the environment.

This method is similar to the use of the **.lua_wrapper**, but the Lua script can be placed somewhere of your liking outside of WA2L/edrc.

Set the permissions of the script to executable:

```
chmod +x luascript
```

Lua script:

```
#!/bin/ksh
#
# luascript - Lua script using bundled modules
#
# [00] 18.03.2009 CWa Initial Version
#

eval `~edrc/lib/luaenv`

sed '1,/^exit \$\$/d' $0 | /usr/bin/lua - "$0" "$@"
exit $?
```

```
-- Lua
--
:
:
local complex = require "complex"
:
```

5) Test the availability of a specific Lua package/module

Try to access the Lua module:

```
[ / ]
[ root@acme007 ][*edrc*/bash]: ~edrc/bin/lua -e 'require "complex"'
```

If an error message like

```
/opt/edrc/bin/Linux-64/2.27/lua: (command line):1: module 'complex' not
no field package.preload['complex']
no file '/opt/edrc/lib/lua/lum/Linux-64/5.4/share/lua/5.4/complex.l
no file '/usr/local/share/lua/5.4/complex.lua'
no file '/usr/local/share/lua/5.4/complex/init.lua'
no file '/usr/local/lib/lua/5.4/complex.lua'
no file '/usr/local/lib/lua/5.4/complex/init.lua'
no file './complex.lua'
no file './complex/init.lua'
no file '/opt/edrc/lib/lua/lum/Linux-64/5.4/lib/complex.so'
no file '/usr/local/lib/lua/5.4/complex.so'
no file '/usr/local/lib/lua/5.4/loadall.so'
no file './complex.so'
stack traceback:
[C]: in function 'require'
(command line):1: in main chunk
[C]: in ?
```

appears, the package/module cannot be found, if the package/module can be found there is no output.

SEE ALSO

edrcintro(1), **glibc.version(3)**, **ldd(1)**, **lua(1)**, **luarocks(1)**, **luaversion(3)**, **lua_wrapper(1)**, **osid(3)**, **pkgdir(1m)**, <https://luarocks.org/>, <https://github.com/luarocks/luarocks/blob/main/docs/index.md>

NOTES

because the **lua** executable is bundled with WA2L/edrc the use of **luaenv** is not so extensively needed as **perlenv(3)** for Perl scripts or **pythonenv(3)** for Python scripts.

NAME

luarocks - module deployment system for Lua

SYNOPSIS

luarocks [*options*] *command*

DESCRIPTION

LuaRocks is a module deployment system for Lua

Variables from the "variables" table of the configuration file can be overridden with VAR=VALUE assignments.

Options:

--from=<server>

Fetch rocks/rockspecs from this server (takes priority over config file)

--only-from=<server>

Fetch rocks/rockspecs from this server only (overrides any entries in the config file)

--to=<tree>

Which tree to operate on.

Commands:

build Build/compile a rock.

download

Download a specific rock file from a rocks server.

help Help on commands.

install Install a rock.

list Lists currently installed rocks.

make Compile package in current directory using a rockspec.

pack Create a rock, packing sources or binaries.

remove

Uninstall a rock.

search Query the LuaRocks servers.

unpack

Unpack the contents of a rock.

config Query configuration

etc/luarocks.cfg

AUTHOR

Enrico Tassi <gareuselesinge@debian.org>

NAME

luarocks.cfg – configuration file for luarocks

SYNOPSIS

edrc/etc/luarocks.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **luarocks** command.

FILEFORMAT

In general the **luarocks.cfg** file is a **lua** file. However, not all language features and commands are available.

For a detail description of the configuration file syntax, see: <https://github.com/luarocks/luarocks/blob/main/docs/index.md>

The description given in this manual page reflects the settings needed to integrate Lua and **luarocks** properly into WA2L/edrc.

OPTIONS**ENVIRONMENT VARIABLES**

The following environment variables holding WA2L/edrc settings are available within the configuration file.

```
local APPROOT    = os_getenv("APPROOT")
local OSID       = os_getenv("OSID")
local LIBC       = os_getenv("LIBC")
local LUAVERSION = os_getenv("LUAVERSION")
```

Whereas **APPROOT** contains the output of **approot**, **OSID** the output of **osid**, **LIBC** the output of **glibc.version** and **LUAVERSION** contains the output of **luaversion**.

rocks_trees

Base directory of the Lua modules distributed with WA2L/edrc and handled by the **luarocks** command within WA2L/edrc.

```
rocks_trees = {
  { name = "system", root = APPROOT .. "/lib/lua/lum/" .. OSID .. "/"
```

```
}
```

lib_modules_path

Sub-directory in the **rocks_tree** with the name **system**. This directory holds compiled Lua package libraries (**.so** files).

```
lib_modules_path = "lib/lua/" .. LUAVERSION .. "/" .. LIBC
```

After installing a package/module that provides compiled libraries into the **lib_modules_path** directory **edrc/lib/lua/lum/<OSID>/<major>.<minor>/lib/lua/<major>.<minor>/<GLIBC>/** ensure to manually create the related symbolic links in **edrc/lib/lua/lum/<OSID>/<major>.<minor>/lib/lua/<major>.<minor>/** and **edrc/lib/lua/lum/<OSID>/<major>.<minor>/lib/lua/<major>.<minor>/<GLIBC>/** to provide maximal portability.

variables The **variables** section contain settings that point to several Lua components needed to build and install a Lua package.

```
variables = {
    LUA_DIR      = APPROOT .. "/bin/" .. OSID;
    LUA_INCDIR   = APPROOT .. "/lib/" .. OSID .. "/includes";
    LUA_BINDIR   = APPROOT .. "/bin/" .. OSID .. "/" .. LIBC;
    LUA_LIBDIR   = APPROOT .. "/lib/" .. OSID .. "/" .. LIBC .. "libs";
    LUA_VERSION  = LUAVERSION;
    LUA          = APPROOT .. "/bin/" .. OSID .. "/" .. LIBC .. "lua";
}
```

NAME

lua_wrapper – wrap Lua scripts to ensure lua startup

SYNOPSIS

edrc/bin/luaprogram -> .lua_wrapper

edrc/lib/luaprogram -> .lua_wrapper

AVAILABILITY

WA2L/edrc

DESCRIPTION

Wrap Lua scripts/programs to avoid using `#!/usr/bin/lua` or similar path names in the magic key. This enhances the portability of WA2L/edrc commands written in Lua to systems where **lua** is not installed in the default install locations or to use **lua** distributed with WA2L/edrc.

lua has to be installed in **edrc/bin/**, **/usr/bin/**, **/bin/**, **/sbin/**, **/usr/local/bin/** or **/usr/contrib/bin/**.

Further **lua** locations can be configured in the optional config file **lua_wrapper.cfg**.

The Lua packages/modules bundled with WA2L/edrc that are installed in **lib/lua/lum/<OSID>/<major>.<minor>/** are included in the Lua path (**LUA_PATH**, **LUA_CPATH**).

To start a new command thru the **.lua_wrapper**, follow the following steps:

- 1.) create a symlink to the new command in the **edrc/bin/** or **edrc/lib/** directory depending on your needs:

```
[ /opt/edrc/bin ]
[ root@acme001 ][*edrc*/bash]: ln -s .lua_wrapper new_cmd
```

- 2.) install the Lua script/program in the **edrc/lib/lua/** directory:

```
[ /opt/edrc/lib/lua ]
[ root@acme001 ][*edrc*/bash]: vi new_cmd

[ /opt/edrc/lib/lua ]
[ root@acme001 ][*edrc*/bash]: chmod 644 new_cmd
```

OPTIONS

-

ENVIRONMENT

-

EXIT STATUS

- 101** shell (**lua**) not found. If **lua** is installed on the system and you get this error, add the **lua** location in the configuration file **lua_wrapper.cfg**.
- 102** the Lua script to be started that should be located in **lib/lua/** does not exist.
- 103** user calling the command has no permission to access/execute the called *lua* program.
- 107** the **.lua_wrapper** was called directly.

FILES

For a detailed description of the **FILES**, see: **luaenv(3)**.

etc/lua_wrapper.cfg

configuration file for the **.lua_wrapper** command.

lib/lua/

location of the wrapped Lua scripts/programs. This files should have the file permissions *644* to show, that those scripts should not be started directly.

lib/lua/lum/<OSID>/<major>.<minor>/

location of the Lua packages/modules bundled with WA2L/edrc.

NAME

lua_wrapper.cfg – configuration file for `.lua_wrapper`

SYNOPSIS

`edrc/etc/lua_wrapper.cfg`

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the `.lua_wrapper` command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**SEARCH_PATH**

Colon separated search path where to search for the **lua** interpreter.

Example: `SEARCH_PATH="/usr/bin:/bin:/sbin:/usr/local/bin:/usr/contrib/bin"`

Default: `SEARCH_PATH="`approot`/bin:/usr/bin:/bin:/sbin:/usr/local/bin:/usr/contrib/bin"`

SEE ALSO

`edrcintro(1)`, `lua_wrapper(1)`

NAME

lynx – a general purpose distributed information browser for the World Wide Web

SYNOPSIS

lynx [*options*] [*optional paths or URLs*]

lynx [*options*] [*path or URL*] **-get_data**
data

lynx [*options*] [*path or URL*] **-post_data**
data

Use “lynx -help” to display a complete list of current options.

DESCRIPTION

Lynx is a fully-featured World Wide Web (WWW) client for users running cursor-addressable, character-cell display devices (e.g., vt100 terminals, vt100 emulators running on Windows 95/NT/XP/7/8 or any POSIX platform, or any other “curses-oriented” display). It will display hypertext markup language (HTML) documents containing links to files residing on the local system, as well as files residing on remote systems running Gopher, HTTP, FTP, WAIS, and NNTP servers. Current versions of *Lynx* run on Unix, VMS, Windows 95/NT/XP/7/8, DOS DJGPP and OS/2.

Lynx can be used to access information on the World Wide Web, or to build information systems intended primarily for local access. For example, *Lynx* has been used to build several Campus Wide Information Systems (CWIS). In addition, *Lynx* can be used to build systems isolated within a single LAN.

OPTIONS

At start up, *Lynx* will load any local file or remote URL specified at the command line. For help with URLs, press “?” or “H” while running *Lynx*. Then follow the link titled, “Help on URLs.”

If more than one local file or remote URL is listed on the command line, *Lynx* will open only the last interactively. All of the names (local files and remote URLs) are added to the **G)oto** history.

Lynx uses only long option names. Option names can begin with double dash “--” as well, underscores and dashes can be intermixed in option names (in the reference below, options are shown with one dash “-” before them, and with underscores “_”).

Lynx provides many command-line options. Some options require a value (string, number or keyword). These are noted in the reference below. The other options set boolean values in the program. There are three types of boolean options: set, unset and toggle. If no option value is given, these have the obvious meaning: set (to true), unset (to false), or toggle (between true/false). For any of these, an explicit value can be given in different forms to allow for operating system constraints, e.g.,

```
-center:off
-center=off
-center-
```

Lynx recognizes “1”, “+”, “on” and “true” for true values, and “0”, “-”, “off” and “false” for false values. Other option-values are ignored.

The default boolean, number and string option values that are compiled into *Lynx* are displayed in the help-message provided by **lynx -help**. Some of those may differ according to how *Lynx* was built; see the help message itself for these values. The **-help** option is processed in the third pass of options-processing, so any option which sets a value, as well as runtime configuration values are reflected in the help-message.

- If the argument is only “-”, then *Lynx* expects to receive the arguments from the standard input. This is to allow for the potentially very long command line that can be associated with the **-get_data** or **-post_data** arguments (see below). It can also be used to avoid having sensitive information in the invoking command line (which would be visible to other processes on most systems), especially when the **-auth** or **-pauth** options are used.

- accept_all_cookies**
accept all cookies.
- anonymous**
apply restrictions for anonymous account, see also **-restrictions**.
- assume_charset=MIMEname**
charset for documents that do not specify it.
- assume_local_charset=MIMEname**
charset assumed for local files, i.e., files which *Lynx* creates such as internal pages for the options menu.
- assume_unrec_charset=MIMEname**
use this instead of unrecognized charsets.
- auth=ID:PASSWORD**
set authorization ID and password for protected documents at startup. Be sure to protect any script files which use this switch.
- base** prepend a request URL comment and BASE tag to text/html outputs for **-source** dumps.
- bibhost=URL**
specify a local bibp server (default `http://bibhost/`).
- blink** forces high intensity background colors for color mode, if available and supported by the terminal. This applies to the **slang** library (for a few terminal emulators), or to OS/2 EMX with **ncurses**.
- book** use the bookmark page as the startfile. The default or command line startfile is still set for the Main screen command, and will be used if the bookmark page is unavailable or blank.
- buried_news**
toggles scanning of news articles for buried references, and converts them to news links. Not recommended because email addresses enclosed in angle brackets will be converted to false news links, and uuencoded messages can be trashed.
- cache=NUMBER**
set the NUMBER of documents cached in memory. The default is 10.
- case** enable case-sensitive string searching.
- center**
Toggle center alignment in HTML TABLE.
- cfg=FILENAME**
specifies a *Lynx* configuration file other than the default `lynx.cfg`.
- child** exit on left-arrow in startfile, and disable save to disk and associated print/mail options.
- child_relaxed**
exit on left-arrow in startfile, but allow save to disk and associated print/mail options.
- cmd_log=FILENAME**
write keystroke commands and related information to the specified file.
- cmd_script=FILENAME**
read keystroke commands from the specified file. You can use the data written using the **-cmd_log** option. *Lynx* will ignore other information which the command-logging may have written to the logfile. Each line of the command script contains either a comment beginning with "#", or a keyword:
exit
causes the script to stop, and forces *Lynx* to exit immediately.

key

the character value, in printable form. Cursor and other special keys are given as names, e.g., “Down Arrow”. Printable 7-bit ASCII codes are given as-is, and hexadecimal values represent other 8-bit codes.

set

followed by a “name=value” allows one to override values set in the lynx.cfg or .lynxrc files. *Lynx* tries the cfg-file setting first.

-collapse_br_tags

toggles collapsing of BR tags.

-color forces color mode on, if available. Default color control sequences which work for many terminal types are assumed if the terminal capability description does not specify how to handle color. *Lynx* needs to be compiled with the **slang** library for this flag, it is equivalent to setting the **COLORTERM** environment variable. (If color support is instead provided by a color-capable curses library like **ncurses**, *Lynx* relies completely on the terminal description to determine whether color mode is possible, and this flag is not needed and thus unavailable.) A saved show_color=always setting found in a .lynxrc file at startup has the same effect. A saved show_color=never found in .lynxrc on startup is overridden by this flag.

-connect_timeout=N

Sets the connection timeout, where N is given in seconds.

-cookie_file=FILENAME

specifies a file to use to read cookies. If none is specified, the default value is ~/.lynx_cookies for most systems, but ~/cookies for MS-DOS.

-cookie_save_file=FILENAME

specifies a file to use to store cookies. If none is specified, the value given by **-cookie_file** is used.

-cookies

toggles handling of Set-Cookie headers.

-core toggles forced core dumps on fatal errors. Turn this option off to ask *Lynx* to force a core dump if a fatal error occurs.

-crawl with **-traversal**, output each page to a file. with **-dump**, format output as with **-traversal**, but to the standard output.

-curses_pads

toggles the use of curses “pad” feature which supports left/right scrolling of the display. The feature is normally available for curses configurations, but inactive. To activate it, use the “[” character or the LINEWRAP_TOGGLE command. Toggling this option makes the feature altogether unavailable.

-debug_partial

separate incremental display stages with MessageSecs delay

-default_colors

toggles the default-colors feature which is normally set in the lynx.cfg file.

-delay add DebugSecs delay after each progress-message

-display=DISPLAY

set the display variable for X rexec-ed programs.

-display_charset=MIMEname

set the charset for the terminal output.

-dont_wrap_pre

inhibit wrapping of text when **-dump**’ing and **-crawl**’ing, mark wrapped lines of <pre> in interactive session.

-dump

dumps the formatted output of the default document or those specified on the command line to standard output. Unlike interactive mode, all documents are processed. This can be used in the following way:

```
lynx -dump http://www.subir.com/lynx.html
```

Files specified on the command line are formatted as HTML if their names end with one of the standard web suffixes such as “.htm” or “.html”. Use the **-force_html** option to format files whose names do not follow this convention.

-editor=EDITOR

enable external editing, using the specified EDITOR. (vi, ed, emacs, etc.)

-emacskeys

enable emacs-like key movement.

-enable_scrollback

toggles compatibility with communication programs’ scrollback keys (may be incompatible with some curses packages).

-error_file=FILE

define a file where *Lynx* will report HTTP access codes.

-exec enable local program execution (normally not configured).**-fileversions**

include all versions of files in local VMS directory listings.

-find_leaks

toggle memory leak-checking. Normally this is not compiled-into your executable, but when it is, it can be disabled for a session.

-force_empty_hrefless_a

force HREF-less “A” elements to be empty (close them as soon as they are seen).

-force_html

forces the first document to be interpreted as HTML.

This is most useful when processing files specified on the command line which have an unrecognized suffix (or the suffix is associated with a non-HTML type, such as “.txt” for plain text files).

Lynx recognizes these file suffixes as HTML:

```
".ht3",
".htm",
".html3",
".html",
".htmlx",
".php3",
".php",
".phtml",
".sht", and
".shtml".
```

-force_secure

toggles forcing of the secure flag for SSL cookies.

-forms_options

toggles whether the Options Menu is key-based or form-based.

-from toggles transmissions of From headers.

- ftp** disable ftp access.
- get_data**
 properly formatted data for a *get* form are read in from the standard input and passed to the form.
 Input is terminated by a line that starts with “----”.
- Lynx* issues an HTTP **GET**, sending the form to the path or URL given on the command-line and
 prints the response of the server. If no path or URL is given, *Lynx* sends the form to the start-page.
- head** send a HEAD request for the mime headers.
- help** print the *Lynx* command syntax usage message, and exit.
- hiddenlinks=[option]**
 control the display of hidden links.
- merge**
 hidden links show up as bracketed numbers and are numbered together with other links in the
 sequence of their occurrence in the document.
- listonly**
 hidden links are shown only on **L**ist screens and listings generated by **-dump** or from the
 Print menu, but appear separately at the end of those lists. This is the default behavior.
- ignore**
 hidden links do not appear even in listings.
- historical**
 toggles use of “>” or “-->” as a terminator for comments.
- homepage=URL**
 set homepage separate from start page.
- image_links**
 toggles inclusion of links for all images.
- index=URL**
 set the default index file to the specified URL.
- ismap**
 toggles inclusion of ISMAP links when client-side MAPs are present.
- justify**
 do justification of text.
- link=NUMBER**
 starting count for lnk#.dat files produced by **-crawl**.
- list_inline**
 for **-dump**, show the links inline with the text.
- listonly**
 for **-dump**, show only the list of links.
- localhost**
 disable URLs that point to remote hosts.
- locexec**
 enable local program execution from local files only (if *Lynx* was compiled with local execution
 enabled).
- lss=FILENAME**
 specify filename containing color-style information. The default is lynx.lss. If you give an empty
 filename, *Lynx* uses a built-in monochrome scheme which imitates the non-color-style
 configuration.

- mime_header**
prints the MIME header of a fetched document along with its source.
- minimal**
toggles minimal versus valid comment parsing.
- nested_tables**
toggles nested-tables logic (for debugging).
- newschunksize=NUMBER**
number of articles in chunked news listings.
- newsmaxchunk=NUMBER**
maximum news articles in listings before chunking.
- nobold**
disable bold video-attribute.
- nobrowse**
disable directory browsing.
- nocc** disable Cc: prompts for self copies of mailings. Note that this does not disable any CCs which are incorporated within a mailto URL or form ACTION.
- nocolor**
force color mode off, overriding terminal capabilities and any **-color** flags, COLORTERM variable, and saved .lynxrc settings.
- noexec**
disable local program execution. (DEFAULT)
- nofilereferer**
disable transmissions of Referer headers for file URLs.
- nolist** disable the link list feature in dumps.
- nolog** disable mailing of error messages to document owners.
- nomargins**
disable left/right margins in the default style sheet.
- nomore**
disable **-more-** string in statusline messages.
- nonrestarting_sigwinch**
This flag is not available on all systems, *Lynx* needs to be compiled with HAVE_SIGACTION defined. If available, this flag *may* cause *Lynx* to react more immediately to window changes when run within an **xterm**.
- nonumbers**
disable link- and field-numbering. This overrides **-number_fields** and **-number_links**.
- nopause**
disable forced pauses for statusline messages.
- noprint**
disable most print functions.
- noredir**
prevents automatic redirection and prints a message with a link to the new URL.
- noreferer**
disable transmissions of Referer headers.
- noreverse**
disable reverse video-attribute.

- nosocks**
disable SOCKS proxy usage by a SOCKSified *Lynx*.
- nostatus**
disable the retrieval status messages.
- notitle**
disable title and blank line from top of page.
- nounderline**
disable underline video-attribute.
- number_fields**
force numbering of links as well as form input fields
- number_links**
force numbering of links.
- partial**
toggles display partial pages while loading.
- partial_thres=NUMBER**
number of lines to render before repainting display with partial-display logic
- passive_ftp**
toggles passive ftp connections.
- pauth=ID:PASSWORD**
set authorization ID and password for a protected proxy server at startup. Be sure to protect any script files which use this switch.
- popup**
toggles handling of single-choice SELECT options via popup windows or as lists of radio buttons.
- post_data**
properly formatted data for a *post* form are read in from the standard input and passed to the form. Input is terminated by a line that starts with "——".

Lynx issues an HTTP **POST**, sending the form to the path or URL given on the command-line and prints the response of the server. If no path or URL is given, *Lynx* sends the form to the start-page.
- preparsed**
show HTML source preparsed and reformatted when used with **-source** or in source view.
- prettysrc**
show HTML source view with lexical elements and tags in color.
- print** enable print functions. (default)
- pseudo_inlines**
toggles pseudo-ALTs for inline images with no ALT string.
- raw** toggles default setting of 8-bit character translations or CJK mode for the startup character set.
- realm**
restricts access to URLs in the starting realm.
- read_timeout=N**
Sets the read-timeout, where N is given in seconds.
- reload**
flushes the cache on a proxy server (only the first document given on the command-line is affected).
- restrictions=[option][,option][,option]...**
allows a list of services to be disabled selectively. Dashes and underscores in option names can be intermixed. The following list is printed if no options are specified.

all

restricts all options listed below.

bookmark

disallow changing the location of the bookmark file.

bookmark_exec

disallow execution links via the bookmark file.

change_exec_perms

disallow changing the eXecute permission on files (but still allow it for directories) when local file management is enabled.

default

same as command line option **-anonymous**. Disables default services for anonymous users. Set to all restricted, except for: `inside_telnet`, `outside_telnet`, `inside_ftp`, `outside_ftp`, `inside_rlogin`, `outside_rlogin`, `inside_news`, `outside_news`, `telnet_port`, `jump`, `mail`, `print`, `exec`, and `goto`. The settings for these, as well as additional goto restrictions for specific URL schemes that are also applied, are derived from definitions within `userdefs.h`.

dired_support

disallow local file management.

disk_save

disallow saving to disk in the download and print menus.

dotfiles

disallow access to, or creation of, hidden (dot) files.

download

disallow some downloaders in the download menu (does not imply `disk_save` restriction).

editor

disallow external editing.

exec

disable execution scripts.

exec_frozen

disallow the user from changing the local execution option.

externals

disallow some "EXTERNAL" configuration lines if support for passing URLs to external applications (with the `EXTERN` command) is compiled in.

file_url

disallow using **G**oto, served links or bookmarks for file: URLs.

goto

disable the "g" (goto) command.

inside_ftp

disallow ftps for people coming from inside your domain (utmp required for selectivity).

inside_news

disallow USENET news posting for people coming from inside your domain (utmp required for selectivity).

inside_rlogin

disallow rlogins for people coming from inside your domain (utmp required for selectivity).

inside_telnet

disallow telnets for people coming from inside your domain (utmp required for selectivity).

- jump**
disable the “j” (jump) command.
- multibook**
disallow multiple bookmarks.
- mail**
disallow mail.
- news_post**
disallow USENET News posting.
- options_save**
disallow saving options in .lynxrc.
- outside_ftp**
disallow ftps for people coming from outside your domain (utmp required for selectivity).
- outside_news**
disallow USENET news reading and posting for people coming from outside your domain (utmp required for selectivity). This restriction applies to “news”, “nntp”, “newspost”, and “newsreply” URLs, but not to “snews”, “snewspost”, or “snewsreply” in case they are supported.
- outside_rlogin**
disallow rlogins for people coming from outside your domain (utmp required for selectivity).
- outside_telnet**
disallow telnets for people coming from outside your domain (utmp required for selectivity).
- print**
disallow most print options.
- shell**
disallow shell escapes and lynxexec or lynxprog **G)oto**’s.
- suspend**
disallow Unix Control-Z suspends with escape to shell.
- telnet_port**
disallow specifying a port in telnet **G)oto**’s.
- useragent**
disallow modifications of the User-Agent header.
- resubmit_posts**
toggles forced resubmissions (no-cache) of forms with method POST when the documents they returned are sought with the PREV_DOC command or from the History List.
- rlogin**
disable recognition of rlogin commands.
- scrollbar**
toggles showing scrollbar.
- scrollbar_arrow**
toggles showing arrows at ends of the scrollbar.
- selective**
require .www_browsable files to browse directories.
- session=FILENAME**
resumes from specified file on startup and saves session to that file on exit.

- sessionin=FILENAME**
resumes session from specified file.
- sessionout=FILENAME**
saves session to specified file.
- short_url**
show very long URLs in the status line with “...” to represent the portion which cannot be displayed. The beginning and end of the URL are displayed, rather than suppressing the end.
- show_cfg**
Print the configuration settings, e.g., as read from “lynx.cfg”, and exit.
- show_cursor**
If enabled the cursor will not be hidden in the right hand corner but will instead be positioned at the start of the currently selected link. Show cursor is the default for systems without FANCY_CURSES capabilities. The default configuration can be changed in userdefs.h or lynx.cfg. The command line switch toggles the default.
- show_rate**
If enabled the transfer rate is shown in bytes/second. If disabled, no transfer rate is shown. Use lynx.cfg or the options menu to select KB/second and/or ETA.
- soft_dquotes**
toggles emulation of the old Netscape and Mosaic bug which treated “>” as a co-terminator for double-quotes and tags.
- source**
works the same as dump but outputs HTML source instead of formatted text. For example

```
lynx -source . >foo.html
```

generates HTML source listing the files in the current directory. Each file is marked by an HREF relative to the parent directory. Add a trailing slash to make the HREF's relative to the current directory:

```
lynx -source ./ >foo.html
```
- stack_dump**
disable SIGINT cleanup handler
- startfile_ok**
allow non-http startfile and homepage with **-validate**.
- stderr**
When dumping a document using **-dump** or **-source**, *Lynx* normally does not display alert (error) messages that you see on the screen in the status line. Use the **-stderr** option to tell *Lynx* to write these messages to the standard error.
- stdin** read the startfile from standard input (UNIX only).
- syslog=text**
information for syslog call.
- syslog_urls**
log requested URLs with syslog.
- tagsoup**
initialize parser, using Tag Soup DTD rather than SortaSGML.
- telnet** disable recognition of telnet commands.
- term=TERM**
tell *Lynx* what terminal type to assume it is talking to. (This may be useful for remote execution, when, for example, *Lynx* connects to a remote TCP/IP port that starts a script that, in turn, starts another *Lynx* process.)

- timeout=*N***
For win32, sets the network read-timeout, where *N* is given in seconds.
- tlog** toggles between using a *Lynx* Trace Log and stderr for trace output from the session.
- tna** turns on "Textfields Need Activation" mode.
- trace** turns on *Lynx* trace mode. Destination of trace output depends on **-tlog**.
- trace_mask=*value***
turn on optional traces, which may result in very large trace files. Logically OR the values to combine options:
 - 1** SGML character parsing states
 - 2** color-style
 - 4** TRST (table layout)
 - 8** configuration (lynx.cfg, .lynxrc, .lynx-keymaps, mime.types and mailcap contents)
 - 16** binary string copy/append, used in form data construction.
 - 32** cookies
 - 64** character sets
 - 128** GridText parsing
 - 256** timing
- traversal**
traverse all http links derived from startfile. When used with **-crawl**, each link that begins with the same string as startfile is output to a file, intended for indexing.
See CRAWL.announce for more information.
- trim_blank_lines**
toggles trimming of trailing blank lines as well as the related trimming of blank lines while collapsing BR tags.
- trim_input_fields**
trim input text/textarea fields in forms.
- underline_links**
toggles use of underline/bold attribute for links.
- underscore**
toggles use of `_underline_` format in dumps.
- unique_urls**
check for duplicate link numbers in each page and corresponding lists, and reuse the original link number.
- use_mouse**
turn on mouse support, if available. Clicking the left mouse button on a link traverses it. Clicking the right mouse button pops back. Click on the top line to scroll up. Click on the bottom line to scroll down. The first few positions in the top and bottom line may invoke additional functions. *Lynx* must be compiled with **ncurses** or **slang** to support this feature. If **ncurses** is used, clicking the middle mouse button pops up a simple menu. Mouse clicks may only work reliably while *Lynx* is idle waiting for input.
- useragent=*Name***
set alternate *Lynx* User-Agent header.

- validate**
accept only http URLs (for validation). Complete security restrictions also are implemented.
- verbose**
toggle [LINK], [IMAGE] and [INLINE] comments with filenames of these images.
- version**
print version information, and exit.
- vikeys**
enable vi-like key movement.
- wdebug**
enable Waterloo tcp/ip packet debug (print to watt debugfile). This applies only to DOS versions compiled with WATTCP or WATT-32.
- width=NUMBER**
number of columns for formatting of dumps, default is 80. This is limited by the number of columns that *Lynx* could display, typically 1024 (the *MAX_LINE* symbol).
- with_backspaces**
emit backspaces in output if **-dump**'ing or **-crawl**'ing (like **man** does)
- xhtml_parsing**
tells *Lynx* that it can ignore certain tags which have no content in an XHTML 1.0 document. For example "<p/>" will be discarded.

COMMANDS

More than one key can be mapped to a given command. Here are some of the most useful:

- Use **Up arrow** and **Down arrow** to scroll through hypertext links.
- **Right arrow** or **Return** will follow a highlighted hypertext link.
- **Left Arrow** or **"u"** will retreat from a link.
- Type **"H"**, **"?"**, or **F1** for online help and descriptions of key-stroke commands.
- Type **"k"** or **"K"** for a list of the current key-stroke command mappings.

If the same command is mapped to the same letter differing only by upper/lowercase only the lowercase mapping is shown.

- Type **Delete** to view history list.

ENVIRONMENT

In addition to various "standard" environment variables such as **HOME**, **PATH**, **USER**, **DISPLAY**, **TMPDIR**, etc, *Lynx* utilizes several *Lynx*-specific environment variables, if they exist.

Others may be created or modified by *Lynx* to pass data to an external program, or for other reasons. These are listed separately below.

See also the sections on **SIMULATED CGI SUPPORT** and **NATIVE LANGUAGE SUPPORT**, below.

Note: Not all environment variables apply to all types of platforms supported by *Lynx*, though most do. Feedback on platform dependencies is solicited.

Environment Variables Used By *Lynx*:

- | | |
|------------------|--|
| COLORTERM | If set, color capability for the terminal is forced on at startup time. The actual value assigned to the variable is ignored. This variable is only meaningful if <i>Lynx</i> was built using the slang screen-handling library. |
| LYNX_CFG | This variable, if set, will override the default location and name of the global configuration file (normally, lynx.cfg) that was defined by the LYNX_CFG_FILE constant in the userdefs.h file, during installation. |

See the `userdefs.h` file for more information.

| | |
|--------------------------|--|
| LYNX_CFG_PATH | If set, this variable overrides the compiled-in search-list of directories used to find the configuration files, e.g., lynx.cfg and lynx.lss . The list is delimited with ":" (or ";" for Windows) like the PATH environment variable. |
| LYNX_HELPFILE | If set, this variable overrides the compiled-in URL and configuration file URL for the <i>Lynx</i> help file. |
| LYNX_LOCALEDIR | If set, this variable overrides the compiled-in location of the locale directory which contains native language (NLS) message text. |
| LYNX_LSS | This variable, if set, specifies the location of the default <i>Lynx</i> character style sheet file. [Currently only meaningful if <i>Lynx</i> was built using curses color style support.] |
| LYNX_SAVE_SPACE | This variable, if set, will override the default path prefix for files saved to disk that is defined in the lynx.cfg SAVE_SPACE: statement. See the lynx.cfg file for more information. |
| LYNX_TEMP_SPACE | This variable, if set, will override the default path prefix for temporary files that was defined during installation, as well as any value that may be assigned to the TMPDIR variable. |
| MAIL | This variable specifies the default inbox <i>Lynx</i> will check for new mail, if such checking is enabled in the lynx.cfg file. |
| NEWS_ORGANIZATION | This variable, if set, provides the string used in the Organization: header of USENET news postings. It will override the setting of the ORGANIZATION environment variable, if it is also set (and, on UNIX , the contents of an <code>/etc/organization</code> file, if present). |
| NNTPSERVER | If set, this variable specifies the default NNTP server that will be used for USENET news reading and posting with <i>Lynx</i> , via news: URL's. |
| ORGANIZATION | This variable, if set, provides the string used in the Organization: header of USENET news postings. On UNIX , it will override the contents of an <code>/etc/organization</code> file, if present. |
| PROTOCOL_proxy | <i>Lynx</i> supports the use of proxy servers that can act as firewall gateways and caching servers. They are preferable to the older gateway servers (see WWW_access_GATEWAY , below). |

Each protocol used by *Lynx*, (http, ftp, gopher, etc), can be mapped separately by setting environment variables of the form **PROTOCOL_proxy**. Protocols are indicated in a URI by the name before ":", e.g., "http" in "http://some.server.dom:port/" for HTML.

Depending on your system configuration and supported protocols, the environment variables recognized by *lynx* may include

```
cso_proxy
finger_proxy
ftp_proxy
gopher_proxy
https_proxy
http_proxy
newspost_proxy
newsreply_proxy
news_proxy
```

```

nntp_proxy
no_proxy
snewsproxy_proxy
snewsreply_proxy
snews_proxy
wais_proxy

```

See **Lynx Users Guide** for additional details and examples.

SSL_CERT_DIR Set to the directory containing trusted certificates.

SSL_CERT_FILE Set to the full path and filename for your file of trusted certificates.

WWW_access_GATEWAY

Lynx still supports use of gateway servers, with the servers specified via “WWW_access_GATEWAY” variables (where “access” is lower case and can be “http”, “ftp”, “gopher” or “wais”). However most gateway servers have been discontinued. Note that you do not include a terminal “/” for gateways, but do for proxies specified by *PROTOCOL_proxy* environment variables.

See **Lynx Users Guide** for details.

WWW_HOME This variable, if set, will override the default startup URL specified in any of the *Lynx* configuration files.

Environment Variables **Set** or **Modified** By *Lynx*:

LYNX_PRINT_DATE This variable is set by the *Lynx* p(rint) function, to the **Date:** string seen in the document’s “**Information about**” page (= cmd), if any. It is created for use by an external program, as defined in a **lynx.cfg PRINTER:** definition statement. If the field does not exist for the document, the variable is set to a null string under **UNIX**, or “No Date” under **VMS**.

LYNX_PRINT_LASTMOD

This variable is set by the *Lynx* p(rint) function, to the **Last Mod:** string seen in the document’s “**Information about**” page (= cmd), if any. It is created for use by an external program, as defined in a **lynx.cfg PRINTER:** definition statement. If the field does not exist for the document, the variable is set to a null string under **UNIX**, or “No LastMod” under **VMS**.

LYNX_PRINT_TITLE

This variable is set by the *Lynx* p(rint) function, to the **Linkname:** string seen in the document’s “**Information about**” page (= cmd), if any. It is created for use by an external program, as defined in a **lynx.cfg PRINTER:** definition statement. If the field does not exist for the document, the variable is set to a null string under **UNIX**, or “No Title” under **VMS**.

LYNX_PRINT_URL This variable is set by the *Lynx* p(rint) function, to the **URL:** string seen in the document’s “**Information about**” page (= cmd), if any. It is created for use by an external program, as defined in a **lynx.cfg PRINTER:** definition statement. If the field does not exist for the document, the variable is set to a null string under **UNIX**, or “No URL” under **VMS**.

LYNX_TRACE If set, causes *Lynx* to write a trace file as if the **-trace** option were supplied.

LYNX_TRACE_FILE

If set, overrides the compiled-in name of the trace file, which is either **Lynx.trace** or **LY-TRACE.LOG** (the latter on the DOS/Windows platforms). The trace file is in either case relative to the home directory.

LYNX_VERSION This variable is always set by *Lynx*, and may be used by an external program to determine if it was invoked by *Lynx*.

See also the comments in the distribution's sample **mailcap** file, for notes on usage in such a file.

TERM

Normally, this variable is used by *Lynx* to determine the terminal type being used to invoke *Lynx*. If, however, it is unset at startup time (or has the value "unknown"), or if the **-term** command-line option is used (see **OPTIONS** section above), *Lynx* will set or modify its value to the user specified terminal type (for the *Lynx* execution environment). Note: If set/modified by *Lynx*, the values of the **LINES** and/or **COLUMNS** environment variables may also be changed.

SIMULATED CGI SUPPORT

If built with the **cgi-links** option enabled, *Lynx* allows access to a cgi script directly without the need for an http daemon.

When executing such "lynxcgi scripts" (if enabled), the following variables may be set for simulating a CGI environment:

CONTENT_LENGTH**CONTENT_TYPE****DOCUMENT_ROOT****HTTP_ACCEPT_CHARSET****HTTP_ACCEPT_LANGUAGE****HTTP_USER_AGENT****PATH_INFO****PATH_TRANSLATED****QUERY_STRING****REMOTE_ADDR****REMOTE_HOST****REQUEST_METHOD****SERVER_SOFTWARE**

Other environment variables are not inherited by the script, unless they are provided via a **LYNXCGI_ENVIRONMENT** statement in the configuration file. See the **lynx.cfg** file, and the (draft) CGI 1.1 Specification <<http://Web.Golux.Com/coar/cgi/draft-coar-cgi-v11-00.txt>> for the definition and usage of these variables.

The CGI Specification, and other associated documentation, should be consulted for general information on CGI script programming.

NATIVE LANGUAGE SUPPORT

If configured and installed with **Native Language Support**, *Lynx* will display status and other messages in your local language. See the file **ABOUT-NLS** in the source distribution, or at your local **GNU** site, for more information about internationalization.

The following environment variables may be used to alter default settings:

LANG This variable, if set, will override the default message language. It is an **ISO 639** two-letter code identifying the language. Language codes are **NOT** the same as the country codes given in **ISO 3166**.

LANGUAGE This variable, if set, will override the default message language. This is a **GNU** extension that has higher priority for setting the message catalog than **LANG** or **LC_ALL**.

LC_ALL and

| | |
|--------------------|--|
| LC_MESSAGES | These variables, if set, specify the notion of native language formatting style. They are POSIXly correct. |
| LINGUAS | This variable, if set prior to configuration, limits the installed languages to specific values. It is a space-separated list of two-letter codes. Currently, it is hard-coded to a wish list. |
| NLSPATH | This variable, if set, is used as the path prefix for message catalogs. |

NOTES

This is the *Lynx* v2.8.9 Release; development is in progress for 2.9.0.

If you wish to contribute to the further development of *Lynx*, subscribe to our mailing list. Send email to <lynx-dev-request@nongnu.org> with “subscribe lynx-dev” as the only line in the body of your message.

Send bug reports, comments, suggestions to <lynx-dev@nongnu.org> after subscribing.

Unsubscribe by sending email to <lynx-dev-request@nongnu.org> with “unsubscribe lynx-dev” as the only line in the body of your message. Do not send the unsubscribe message to the lynx-dev list, itself.

SEE ALSO

catgets(3), **curses(3)**, **environ(7)**, **execve(2)**, **ftp(1)**, **gettext(GNU)**, **localeconv(3)**, **ncurses(3)**, **setlocale(3)**, **slang(?)**, **termcap(5)**, **terminfo(5)**, **wget(GNU)**

Note that man page availability and section numbering is somewhat platform dependent, and may vary from the above references.

A section shown as (GNU), is intended to denote that the topic may be available via an info page, instead of a man page (i.e., try “info subject”, rather than “man subject”).

A section shown as (?) denotes that documentation on the topic exists, but is not part of an established documentation retrieval system (see the distribution files associated with the topic, or contact your System Administrator for further information).

ACKNOWLEDGMENTS

Lynx has incorporated code from a variety of sources along the way. The earliest versions of *Lynx* included code from Earl Fogel of Computing Services at the University of Saskatchewan, who implemented HYPERREZ in the Unix environment. HYPERREZ was developed by Niel Larson of Think.com and served as the model for the early versions of *Lynx*. Those versions also incorporated libraries from the Unix Gopher clients developed at the University of Minnesota, and the later versions of *Lynx* rely on the WWW client library code developed by Tim Berners-Lee and the WWW community. Also a special thanks to Foteos Macrides who ported much of *Lynx* to VMS and did or organized most of its development since the departures of Lou Montulli and Garrett Blythe from the University of Kansas in the summer of 1994 through the release of v2.7.2, and to everyone on the net who has contributed to *Lynx*’s development either directly (through patches, comments or bug reports) or indirectly (through inspiration and development of other systems).

NAME

mail_file – mail file(s) as attachments

SYNOPSIS

edrc/bin/mail_file [**-h**]

echo *message* | **mail_file** **-s** "*subject*" **-t** *to* [**-c** *carbon_copy*] [**-b** *blind_carbon_copy*] [[**-d**] **-a** *attachments*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

with **mail_file** a mail with a message content and file attachments can be sent with a single command.

The message content is received from **stdin** what enables easy script integration of the command.

In the configuration file **mail_file.cfg** can be configured if the mail should be sent locally, or if the mail should be sent from a remote (hub) system. It is possible to define a list of hosts that can be used as a hub. If the local host name is part of the list, the mail is sent locally; else the mail is sent from the first host in the hub list that is up.

OPTIONS

-h usage message.

"subject" subject of the mail to be sent.

-t to comma separated list of mail recipients.

-c cc comma separated list of carbon copy mail recipients.

-b bcc comma separated list of blind carbon copy mail recipients.

-d convert attachment file(s) to DOS.

-f from sender address of the mail. The default sender address can be configured in the **mail_file.cfg** configuration file in the **DEFAULT_SENDER** setting.

-a attachments
space separated list of files to be attached to the mail.

ENVIRONMENT

-

EXIT STATUS

| | |
|-----------|--|
| 0 | no error. |
| 2 | operating system is not supported yet. See osid(3) if you get this error. |
| 3 | specified attachment file does not exist. |
| 4 | usage printed. |
| 5 | command aborted pressing Ctrl+C. |
| 6 | configfile mail_file.cfg does not exist. |
| 7 | cannot connect to mail hub with remote_shell . |
| 11 | temporary directory could not be claimed or created in /tmp . Check the system temporary directory /tmp if you get this error, it is an indicator of system intrusion. |

FILES

etc/mail_file.cfg
configuration file of **mail_file**, see **mail_file.cfg(4)** for more information.

EXAMPLES**1) send a file with a single line message:**

```
echo "See logfile in attachment" | mail_file \
-s "myApplication Logfile" \
-t "fred.flintstone@acme.com" \
-a quarry_moves.log
```

2) send a file with a multiple line message:

```
cat <<EOM | mail_file ...
Hi Fred

Please open the quarry move log in the attachment

Regards
Barney Boulder
EOM
```

SEE ALSO

edrcintro(1), **mail_file.cfg**(4), **remote_shell**(3), **sendmail**(8)

NOTES

mail_file uses the **sendmail** command internally to send the mail.

BUGS

-

AUTHOR

mail_file was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

mail_file.cfg – configuration file for mail_file

SYNOPSIS

edrc/etc/mail_file.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **mail_file** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**DEFAULT_SENDER**

Default mail sender if the **-f from** option is not specified on the command line.

Example: **DEFAULT_SENDER=fred.flintstone@acme.ch**

Default: **DEFAULT_SENDER=smc.base.services@eds.com**

MAIL_HUB

Space separated list of hosts to relay the mail sending. The relay is done using a named pipe and not using mail server functionality.

If the local host name is part of the **MAIL_HUB** list, the mail will be sent locally; else the mail is sent from the first host in the list that is up.

Example: **MAIL_HUB="acme001 acme002 acme003"**

Default: **MAIL_HUB=""**

MAIL_HUB_USER

User to connect to the mail hub as root. Other user use the own unix user id and must ensure that no password is prompted on the remote system.

Example: MAIL_HUB_USER=edrc

Default: MAIL_HUB_USER=edrc

MAIL_CLIENT

Mail client to be used. Currently supported clients are *sendmail* and *msmtp*.

Example: MAIL_CLIENT=msmtp

Default: MAIL_CLIENT=sendmail

MAIL_CLIENT_OPTS

Additional options for the chosen mail client.

Example: MAIL_CLIENT_OPTS=""

Default: MAIL_CLIENT_OPTS=""

MAIL_SERVER_NAME

Mail server. This setting is relevant only, if **MAIL_CLIENT** is set to *msmtp*.

Example: MAIL_SERVER_NAME=exchange.int.acme.ch

Default: MAIL_SERVER_NAME=mail

MAIL_SERVER_PORT

Mailserver port to connect to. This setting is relevant only, if **MAIL_CLIENT** is set to *msmtp*.

Example: MAIL_SERVER_PORT=25

Default: MAIL_SERVER_PORT=25

SEE ALSO

NAME

maketemp – create unique secure temporary dir

SYNOPSIS

edrc/lib/maketemp [**-h**]

maketemp [**-s** *scriptname*] [**-q**] **-d** *dir_basename*

AVAILABILITY

WA2L/edrc

DESCRIPTION

create a unique non existing temporary directory with secure permissions and return the created directory path via **stdout**.

Use **removetemp**(3) to remove a temporary directory created with **maketemp**.

Some operating systems know the **mktemp**(1) command with a very similar functionality. However, if there is a need to write cross-operating system compatible scripts, **maketemp**(3) should be used, due to the fact that the options and the behaviour of this command does not differ between the supported operating systems, as the **mktemp** command does.

OPTIONS

-h usage message.

-s *scriptname*
scriptname in message output of **maketemp**.

-q quiet, no message output.

-d *dir_basename*
directory basename.

If a temporary directory for the command **my_command** in the directory **/tmp** has to be created, **maketemp** ... **-d /tmp.my_command** has to be specified.

See section **EXAMPLES** for additional information.

ENVIRONMENT

-

EXIT STATUS

| | |
|----------|---|
| 0 | no error. |
| 1 | temporary directory could not be created. |
| 4 | usage message listed. |

FILES

<dir_basename>.<PID>.<RANDOM_STRING>/
created temporary directory.

<dir_basename>.<PID>.<RANDOM_STRING>/.maketemp.flagfile
flagfile containing the state information about the command that created the temporary directory. This file is read by the **removetemp(3)** and **listtemp(3)**.

EXAMPLES**1) create a tempdir in '/tmp':**

```
[ /root ]
[ root@acme001 ] [-sh]: maketemp -d /tmp/.example
/tmp/.example.3430.2Hpt0D/
```

2) create/use/remove a tempdir in '/tmp' in a script:

```
#!/bin/sh

Scriptname=`basename $0`
Tmp=`maketemp -s $Scriptname -d /tmp/.$Scriptname` || exit 11

:
:

cat /etc/passwd | sort > ${Tmp}sorted_passwd

:
:

removetemp -q -d ${Tmp}
```

SEE ALSO

edrcintro(1), listtemp(3), purgetemp(3), removetemp(3), mktemp(1)

NOTES

-

BUGS

-

AUTHOR

maketemp was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

makeuser – user friendly interface to mkuser

SYNOPSIS

edrc/bin/makeuser [-h]

makeuser [-u *username*] [-U *uid*] [-G *groupname* | -g *gid*] [-d *home_dir*] [-c *userclass*] [-f]

AVAILABILITY

WA2L/edrc

DESCRIPTION

makeuser is a user friendly interface to the **mkuser**(3) command.

With this command a user **\$HOME** directory can be created interactively. It is not imperative that the user account is already created when creating the user **\$HOME** directory. When the user account does already exist, the defaults for all fields to be specified depend from the user name.

When entering a ? in the fields to be specified a list of available values on the system is printed. If the system is a LDAP or NIS client, the information list printed is a merge between the related name service and the information in the local files (NIS+FILES or LDAP+FILES).

All interactively queried fields can also be specified on the command line; such fields will then not be queried.

The user **\$HOME** directory is created using the **mkuser**(3) command internally.

OPTIONS

-h usage message.

-u *username*
 username of the user to create a **\$HOME** directory for.

-U *uid* User-ID of the user.

-G *groupname*
 name of the primary group the user is member of.

-g Group-ID of the primary group of the user.

-d *home_directory*
 \$HOME directory path of the user.

-c *user_class*

userclass of the user. The userclass is the template of the **\$HOME** directory. The userclass can be queried by the user using the **userclass(1)** command. To enable the **userclass(1)** command to return the userclass, a file with the name **.userclass** containing a single line with the name of the applied userclass has to be created. **makeuser(1)** also reads the **.userclass** file of the related **\$HOME** directory when re-applying the template to an already existing **\$HOME** directory.

ENVIRONMENT

-

EXIT STATUS

- 0** no error.
- 1** classes dir as set in the **CLASSES_DIR** setting in the **makeuser.cfg** does not exist.
- 2** **makeuser** was started with the wrong user. The start user has to be set in the **START_USER** setting in the **makeuser.cfg** file.
- 4** usage printed.
- 5** command aborted pressing Ctrl+C.
- 6** configfile **makeuser.cfg** does not exist.
- 11** temporary directory could not be claimed or created in **/tmp**. Check the system temporary directory **/tmp** if you get this error, it is an indicator of system intrusion.

FILES**etc/makeuser.cfg**

configuration file of **makeuser**, see **makeuser.cfg(4)** for more information.

\$CLASSES_DIR/index

index file for all userclasses. This file is read when displaying the available userclasses when entering ? in the "User-Class : " dialog. See **userclass.index(4)** for more information.

\$CLASSES_DIR/<userclass>/

files of a userclass.

/etc/passwd

local user account definition (NS: FILES).

/etc/group local group definition (NS: FILES).

/etc/auto.home

default local automounter map for \$HOME server location (NS: FILES). See also **makeuser.cfg(4)**.

NS: NIS nis map (**passwd**, **group**, **auto.home**).

NS: LDAP

LDAP map (**passwd** (ou=People), **group** (ou=Group), **auto.home**).

EXAMPLES

1) create a \$HOME directory for an existing user account:

```
[ / ]
[ root@host001.acme.ch ][/bin/bash]: ~edrc/bin/makeuser
makeuser - a user friendly interface to mkuser, by Chr. Walther

SPECIFY SETTINGS:

Username   : jdoe

NAME

makeuser.cfg – configuration file for makeuser

SYNOPSIS

edrc/etc/makeuser.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **makeuser** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**CLASSES_DIR**

Classes directory where the templates are.

Example: CLASSES_DIR='homedir tools-cust'/classes

Default: CLASSES_DIR='approot'/var/makeuser/classes

START_USER

This is the user makeuser has to be started with.

Example: START_USER=root

Default: START_USER=root

LOG

Log output dir of makeuser. If you specify a relative path name the path is relative to the root of the EDRC installation.

Example: LOG='homedir ACME'/log

Default: LOG=var/log

AUTO_HOME

auto home file in **/etc/** or auto home NIS map name

Example: AUTO_HOME=auto_home

Default: AUTO_HOME=auto.home

SEE ALSO

makeuser(1), **edrcintro(1)**

NAME

man2html – format a manual page in html

SYNOPSIS

man2html [options] [file]

DESCRIPTION

man2html converts a manual page as found in *file* (or stdin, in case no file argument, or the argument "-", is given) from man-style nroff into html, and prints the result on stdout. It does support tbl but does not know about eqn. The exit status is 0. If something goes wrong, an error page is printed on stdout.

This can be used as a stand-alone utility, but is mainly intended as an auxiliary, to enable users to browse their man pages using a html browser like **lynx**(1), **xmosaic**(1) or **netscape**(1).

The main part of **man2html** is the troff-to-html engine written by Richard Verhoeven (rcb5@win.tue.nl). It adds hyperlinks for the following constructs:

| | |
|-----------------|--|
| foo(3x) | "http://localhost/cgi-bin/man/man2html?3x+foo" |
| method://string | "method://string" |
| www.host.name | "http://www.host.name" |
| ftp.host.name | "ftp://ftp.host.name" |
| name@host | "mailto:name@host" |
| <string.h> | "file:/usr/include/string.h" |

(The first of these can be tuned by options - see below.) No lookup is done - the links generated need not exist. Also an index with internal hyperlinks to the various sections is generated, so that it is easier to find one's way in large man pages like **bash**(1).

OPTIONS

When reading from stdin, it is not always clear how to do .so expansion. The **-D** option allows a script to define the working directory.

-D pathname

Strip the last two parts from the pathname, and do a *chdir(dir)* before starting the conversion.

The **-E** option allows the easy generation of error messages from a cgi script.

-E string

Output an error page containing the given error message.

The general form of a hyperlink generated for a man page reference is

<method:cgi><man2htmlpath><separator><manpage>

with a default as shown above. The parts of this hyperlink are set using the various options.

-h Set method:cgi to http://localhost. This is the default.

-H *host[.domain][:port]*

Set method:cgi to http://*host.domain:port*.

-l Set method:cgi to lynxcgi:/home/httpd.

-L *dir* Set method:cgi to lynxcgi:*dir*.

-M *man2htmlpath*

Set the man2htmlpath to use. The default is /cgi-bin/man/man2html.

-p Set separator to '/'.

-q Set separator to '?'. This is the default.

-r Use relative html paths, instead of cgi-bin paths.

On a machine without running **httpd**, one can use **lynx** to browse the man pages, using the lynxcgi method.

When some http daemon is running, lynx, or any other browser, can be used to browse the man pages, using the http method. The option `-l` (for 'lynxcgi') selects the former behaviour. With it, the default cgi path is */home/httpd*.

In general, a cgi script can be called by

`<path_to_script>/<more_path>?<query>`

and the environment variables `PATH_INFO` and `QUERY_STRING` will be set to `<more_path>` and `<query>`, respectively. Since lynxcgi does not handle the `PATH_INFO` part, we generate hyperlinks with '?' as a separator by default. The option `-p` (for 'path') selects '/' as a separator, while the option `-q` (for 'query') selects '?' as a separator.

The option `-H host` will specify the host to use (instead of *localhost*). A cgi script could use

`man2html -H $SERVER_NAME`

if the variable `SERVER_NAME` is set. This would allow your machine to act as a server and export man pages.

BUGS

There are many heuristics. The output will not always be perfect. The lynxcgi method will not work if lynx was compiled without selecting support for it. There may be problems with security.

AUTHOR

Richard Verhoeven was the original author of **man2html**. Michael Hamilton and Andries Brouwer subsequently improved on it. Federico Lucifredi <flucifredi@acm.org> is the current maintainer.

NAME

manpages – writing manual pages for WA2L/edrc

SYNOPSIS

-

AVAILABILITY

WA2L/edrc

DESCRIPTION

This man page gives an overview of used **man** macros, the general structure and some conventions of the manual pages for WA2L/edrc.

MANPAGE ORGANIZATION

Due to the fact that WA2L/edrc runs on multiple operating systems some man pages differ for some different operating systems. This is especially the case for compiled commands distributed with WA2L/edrc. Those operating system dependent man pages are marked with a plus (+) in the **EDRC(1)** man page. Place operating system dependent manual pages to the correct directory related to the osid in the **man/** basedir. See **edrcman(1)** for the description of the placement of the man pages.

MANPAGE SECTIONS

Unfortunately the man page sections are organized differently in different operating systems.

The man pages in WA2L/edrc are organized in the following sections which is very similar to the SunOS operating system:

- | | |
|--------------|--|
| man1 | General Commands |
| man1m | Maintenance (administrative) Commands |
| man3 | Library Functions and Library Commands |
| man4 | File Formats and Configuration Files |

MANPAGE STRUCTURE

All listed sections below should be used when writing a man page for the WA2L/edrc package. If there are no information for a certain section, do not remove the section title, simply add a dash (–) instead of the text. This shows to the reader that the author of the man page did not forget the section, but there is

currently no information needed there.

MANPAGES FOR COMMANDS

NAME name and short description of command.

SYNOPSIS

usage of the command.

AVAILABILITY

where the command is available (WA2L/edrc).

DESCRIPTION

detail command description.

OPTIONS

command line options.

ENVIRONMENT

environment variables that influence the command.

EXIT STATUS

all exit states of the command.

FILES

used files by the command.

EXAMPLES

examples of command usage.

SEE ALSO

reference to other man pages or documents.

NOTES

additional command notes that add additional information not given in the DESCRIPTION section.

BUGS

known bugs or limitations of the command.

AUTHOR

author(s) of the command and hint where to send bug reports and suggestions.

COPYRIGHT

copyright notice.

MANPAGES FOR CONFIGURATION FILES

NAME name and short description of the file.

SYNOPSIS

file name and location.

AVAILABILITY

where the command is available (WA2L/edrc).

DESCRIPTION

detail file description.

FILEFORMAT

file format description.

OPTIONS

detail description of all configuration file settings (option,value pairs).

EXAMPLES

examples of the config file.

SEE ALSO

reference to other man pages or documents.

NOTES

additional command notes that add additional information not given in the DESCRIPTION section.

BUGS

known bugs or limitations of the command.

AUTHOR

author(s) of the command and hint where to send bug reports and suggestions.

COPYRIGHT

copyright notice.

CONVENTIONS FOLLOWED IN WA2L/edrc MAN PAGES

The following conventions were followed while writing the man pages for the WA2L/edrc package:

files

are set in bold face (.B).

directories

are set in bold face (.B).

indentation steps

the indentation for all sections, where labels are used is 10.

command line options

are set in bold face (.B).

configuration file options

are set in bold face (.B).

command line settings

are set in italic (.I).

configuration settings (=values)

are set in italic (.I).

using of foreign inventions

if parts of code, documentation or concepts from other individuals as the principal author of the command, config file or manual page is used those individuals should be mentioned in the NOTES and/or AUTHOR section of the man page.

references in SEE ALSO

each manual page should at least reference the **edrcintro**(1) man page.

edrcintro man page

each command that is distributed with WA2L/edrc must have a short description in the **edrcintro**(1) man page.

EDRC man page

each command and related config file that is distributed with WA2L/edrc must have an entry in the **EDRC**(1) man page, this is the main index to all commands and config files.

PostScript, PDF, HTML and eBook man pages

the man pages are formatted to PostScript, PDF, HTML and eBooks using the Makefiles located in **doc/.man/**. To generate the PostScript, PDF and HTML man pages invoke: **cd ~edrc/doc/.man ; make**. If a new man page is written or included to the WA2L/edrc package the **doc/.man/Makefile** has to be edited.

USED MANUAL PAGE MACROS WITH EXAMPLES

The list of macros available for man page exceeds the one given below by many more possibilities. The macros here are those used in the WA2L/edrc package and the explained usage is related to this special usage case. Therefore the option description is given for this particular usage. See **groff_man**(7) for a more complete description.

.TH Set the title of the man page.

Format:

```
.TH manpage section "day month year" "PACKAGE" "SECTION"
```

Example:

```
.TH watchdog 1 "28 November 2005" "EDRC" "General Commands"
```

Result:

```
watchdog(1)          General Commands          watchdog(1)
:
:
```

EDRC

28 November 2005

watchdog(1)

.SH Sets up an unnumbered section heading sticking out to the left.

Format:

`.SH TEXT`

Example:

`.SH AVAILABILITY`

Result:

AVAILABILITY

.SS Sets up a secondary, unnumbered section heading.

Format:

`.SS TEXT`

Example:

`.SS GLOBAL OPTIONS`

Result:

GLOBAL OPTIONS

.TP Sets up an indented paragraph list with label. The indentation is set to `nnn` if that argument is supplied (the default unit is 'n' if omitted), otherwise it is set to the default indentation value.

The first line of text following this macro is interpreted as a string to be printed flush-left, as it is appropriate for a label. It is not interpreted as part of a paragraph, so there is no attempt to fill the first line with text from the following input lines.

Nevertheless, if the label is not as wide as the indentation, then the paragraph starts at the same line (but indented), continuing on the following lines. If the label is wider than the indentation, then the descriptive part of the paragraph begins on the line following the label, entirely indented.

Format:

`.TP indent
.B label_1
description text`

`.TP
.B label_2
description text`

Example:

`.TP 10
.B \-h
usage message.`

```
.TP
.BI "\-n " name
name of the watchdog.
```

Result:

```
-h          usage message.

-n name     name of the watchdog.
```

.IP Sets up a indented list with a marker.

Format:

```
.IP marker [ width ]
description text

.IP marker
description text
```

Example:

available colors are:

```
.IP - 2
red
```

```
.IP -
green
```

```
.IP -
yellow
```

Result:

available colors are:

```
- red

- green

- yellow
```

.PP End an indented paragraph list.

This is only needed, when additional text has to be set in the same section after the indented list.

Format:

```
.TP indent
.B label_1
description text

.TP
```

```
.B label_2
description text
.PP

non indented text
```

Example:

```
.TP 10
.B Mauna Kea
Shield volcano in Hawaii.

.TP
.B Parinacota
Strato volcano in Chile near the border to Bolivia.
.PP

For a list of all volcanos, see:
.B https://www.volcanodiscovery.com/de/volcanoes/alphabetical-list/a-z.
```

Result:

```
Mauna Kea
    Shield volcano in Hawaii.

Parinacota
    Strato volcano in Chile.
```

For a list of all volcanos, see: **<https://www.volcanodiscovery.com/de/volcanoes/alphabetical-list/a-z.html>**

.RS This macro moves the left margin to the right by the value *nnn* if specified (default unit is 'n'; otherwise the default indentation value is used. Calls to the RS macro can be nested.

Format:

```
.RS +number
```

Example:

```
.RS +10
This text is moved by 10 characters to the right.
.RE
```

Result:

```
    This text is moved by 10 characters to the right.
```

.RE This macro moves the left margin back to level *nnn*; if no argument is given, it moves one level back. The first level (i.e., no call to RS yet) has number 1, and each call to RS increases the level by 1.

Format:

```
.RE
```

Examples:

```
.RS +10
This text is moved by 10 characters to the right.
.RS +5
This text is moved 5 more characters to the right.
.RE
.RE
```

Result:

```
    This text is moved by 10 characters to the right.
        This text is moved 5 more characters to the right.
```

- .B** Causes text to appear in bold face. If no text is present on the line where the macro is called, then the text of the next line appears in bold face.

Format:

```
.B text
```

Example:

```
.B abort
```

Result:

```
abort
```

- .I** Causes text to appear in italic. If no text is present on the line where the macro is called, then the text of the next line appears in italic.

Format:

```
.I italic text
```

Example:

```
.I check_script
```

Result:

```
check_script
```

- .BI** Causes text on the same line to appear alternately in bold face and italic. The text must be on the same line as the macro call.

Format:

```
.BI bold italic
```

Example:

```
.BI "-c " check_script
```

Result:

```
-c check_script
```

.IB Causes text on the same line to appear alternately in italic and bold face. The text must be on the same line as the macro call.

Format:

`.IB italic bold`

Example:

`.IB filename ".txt"`

Result:

*filename***.txt**

.BR Causes text on the same line to appear alternately in bold face and roman. The text must be on the same line as the macro call.

Format:

`.BR bold roman`

Example:

`.BR edrcintro (1)`

Result:

edrcintro(1)

.RB Causes text on the same line to appear alternately in roman and bold face. The text must be on the same line as the macro call.

Format:

`.RB roman bold`

Example:

`.BR (/etc/hosts)`

Result:

(etc/hosts)

USED TROFF COMMANDS WITH EXAMPLES

This are commands and escape sequences that were used in the WA2L/edrc manual pages and have been proofed to be compatible over various platforms and understood by **troff**(1) and the GNU variant **groff**(1). There are many more troff/groff commands available on the various Unix and Linux dialects as the ones explained here. For more information see **troff**(1), **groff**(1) and **groff_char**(7).

\(space)

Set a space. This is useful if after a .SS an empty line should be printed.

Format:

`\`

Example:

```
.SS "Step 5: Configure logcheckd"
\

The daemon is configured editing ...
```

\&. Set a dot (.). This is useful if you have to set a dot at the beginning of a line.

Format:

```
\&.
```

Example:

```
the check specified in option
.B -c
\&. If the
```

Result:

```
the check specified in option -c. If the
```

.ds Define a shortcut that can be used in the whole manpage.

Format:

```
.ds name content
```

Example:

```
.ds PK WA2L/edrc
```

```
This is the install directory of the \*(PK package.
```

Result:

```
This is the install directory of the WA2L/edrc package.
```

.\" Comment in a man page.

Format:

```
.\" comment text
```

Example:

```
.\"
.\" manpages.4 - man page for writing manual pages
.\"
.\" [00] 17.06.2006 CWa      Initial Version
.\"
```

.nf The following lines are not formatted and the output is made verbatim as typed. However, short-cuts are resolved.

Format:

```
.nf
```

```
verbatim text
.fi
```

Example:

```
.nf
#
# /etc/hosts - internet hosts list
#
# [00] 01.01.2000 CWa   Initial Version
#
127.0.0.1      localhost
192.168.75.1   w2mzv7t001
192.168.75.129 fc4mzv7t001
.fi
```

.fi End of verbatim output.

Format:

```
.nf
verbatim text
.fi
```

Example:

```
.nf
#
# /etc/hosts - internet hosts list
#
# [00] 01.01.2000 CWa   Initial Version
#
127.0.0.1      localhost
192.168.75.1   w2mzv7t001
192.168.75.129 fc4mzv7t001
.fi
```

.br Insert a line break.

Format:

```
.br
```

Example:

```
This is the first,
.br
that the second and
.br
this is the third line.
```

Result:

```
This is the first,
that the second and
this is the third line.
```

.bp Insert a page break in PostScript/PDF output.

Format:

.bp

Example:

This is on one page,
.bp
And this is on the next page.

' Insert a single quote (').

Format:

'

Example:

.BI MESSAGE=' Text '

Result:

MESSAGE='Text'

" Insert a formatted double quote (").

Format:

.BI "bold=\[dq]" underlined "\[dq]"

Example:

.BI "MESSAGE=\[dq]" Text "\[dq]"

Result:

MESSAGE="Text"

**** Insert a backslash (\).

Format:

\e

Example:

find /data -depth -print \e
cpio -dtvum /save

Result:

find /data -depth -print \
cpio -dtvum /save

\(co Insert the copyright symbol (©).

Format:

\(co

Example:

```
Copyright \ (co 2009 by ACME Switzerland
```

Result:

```
Copyright © 2009 by ACME Switzerland
```

\[tm] Insert the trade mark symbol (™).

Format:

```
\[tm]
```

Example:

```
Trade Mark \[tm] 2009 by ACME Switzerland
```

Result:

```
Trade Mark ™ 2009 by ACME Switzerland
```

.ft CW Switch font to Courier from current line forward. This is seen in a PostScript, PDF or HTML output only.

Format:

```
.ft CW
Text in Courier
.ft R
Text in Times Roman
```

Example:

```
.ft CW
ls -lisa *.txt
.ft R
```

.ft R Switch font to Times Roman from current line forward. This is seen in a PostScript, PDF or HTML output only.

Format:

```
.ft CW
Text in Courier
.ft R
Text in Times Roman
```

Example:

```
.ft CW
ls -lisa *.txt
.ft R
```

\fB Switch font to bold from within a line forward.

- \fI** Switch font to italic from within a line forward.
- \fC** Switch font to Courier from within a line forward.
- \f(CW** Switch font to Courier from within a line forward.
- \fR** Switch font to Times Roman from within a line forward.
- \fP** Switch font to previous font setting from within a line forward.

Format:

`\fB`

Example:

`\fBcp \fR[\fIoption\fR] \fIsource dest`

Result:

cp [*option*] *source dest*

USEFUL OWN DEFINED MACROS

- *(GO** print an "=>" arrow on the terminal and a typographic "->" arrow in a PostScript file.

Definition:

```
.\" print => on terminal, -> on PostScript
.if n .ds GO =>
.if t .ds GO \(->
..
```

Format:

`*(GO text`

Example:

`*(GO goto step 1.`

Result:

→ goto step 1.

- *(co** print an "(c)" copyright on the terminal and a typographic "(c)" copyright symbol, a c in a circle, in a PostScript file.

Definition:

```
.\" print (c) on terminal, c in circle on PostScript
.if n .ds co (c)
.if t .ds co \(\co
..
```

Format:

Copyright `*(co` by ACME Switzerland

Example:

```
Copyright \*(co by ACME Switzerland
```

Result:

```
Copyright © by ACME Switzerland
```

.VB .VE Verbatim Begin, Verbatim End. Set the text between **.VB** and **.VE** verbatim and in Courier font.

Definition:

```
.de VB \" verbatim begin
.ft CW
.nf
..
```

```
.de VE \" verbatim end
.ft R
.fi
..
```

Format:

```
.VB
verbatim text set in courier
.VE
```

Example:

```
.VB
#
# /etc/hosts - internet hosts list
#
# [00] 01.01.2000 CWa    Initial Version
#
127.0.0.1      localhost
192.168.75.1   w2mzv7t001
192.168.75.129 fc4mzv7t001
.VE
```

Result:

```
#
# /etc/hosts - internet hosts list
#
# [00] 01.01.2000 CWa    Initial Version
#
127.0.0.1      localhost
192.168.75.1   w2mzv7t001
192.168.75.129 fc4mzv7t001
```

.LS .LI .LE

List Start, List Item, List End. Create a unnumbered indented list with list items preceded by a dash (-).

Definition:

```
.de LS \" List Start
.PD 0
.RS 10
..

.de LI \" List Item
.IP - 2
..

.de LE \" List End
.RE
.PP
..
```

Format:

```
.LS
.LI
first list item
.LI
another list item
.LI
one more list item
.LE
```

Example:

```
.LS
.LI
Bern is the capital of Switzerland.
.LI
Berlin is the capital of Germany.
.LI
Paris is the capital of France.
.LI
Rome is the capital of Italy.
.LE
```

Result:

- Bern is the capital of Switzerland.
- Berlin is the capital of Germany.
- Paris is the capital of France.
- Rome is the capital of Italy.

NAME

manvi – edit manual pages in vi

SYNOPSIS

edrc/bin/manvi *manpage*

AVAILABILITY

WA2L/edrc

DESCRIPTION

with **manvi** manual pages located in the **man/*/*/** directories and additional locations as defined in the **etc/manvi.cfg** configuration file can be conveniently edited in the **vi(1)** editor without the need to browse to the file location.

Prior to the editing the manual page file is saved automatically using the **vsav(1)** command internally.

See **man(1)** for additional information.

OPTIONS

manpage manual page to be edited.

ENVIRONMENT

-

EXIT STATUS

0 always.

FILES

man/*/*/ directories of WA2L/edrc manual pages.

etc/manvi.cfg
configuration file for **manvi(1)** containing additional manual page locations.

EXAMPLES

-

SEE ALSO

NAME

manvi.cfg – configuration file for manvi

SYNOPSIS

edrc/etc/manvi.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **.manvi** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**EDITMAN_PATH**

Additional path to search for man page files to be edited.

Example: EDITMAN_PATH="homedir fred/var/Dropbox/bin/WA2L*/man"

Default: EDITMAN_PATH=

SEE ALSO

edrcintro(1), edrcman.cfg(1), manvi(1)

NAME

mc – Visual shell for Unix-like systems.

SYNOPSIS

mc [-abcCdFhPstuUVx] [-l log] [dir1 [dir2]] [-e [file] ...] [-v file]

DESCRIPTION

GNU Midnight Commander is a directory browser/file manager for Unix-like operating systems.

OPTIONS

-a, --stickchars

Disable usage of graphic characters for line drawing.

-b, --nocolor

Force black and white display.

-c, --color

Force color mode, please check the section Colors for more information.

-C arg, --colors=arg

Specify a different color set in the command line. The format of arg is documented in the Colors section.

--configure-options

Display configure options.

-d, --nomouse

Disable mouse support.

-D N, --debuglevel=N

Save the debug level for SMB VFS. N is in 0–10 range.

-e [file], --edit[=file]

Start the internal editor. If the file is specified, open it on startup. See also **mcedit (1)**.

-f, --datadir

Display the compiled-in search paths for Midnight Commander files.

-F, --datadir-info

Display extended info about compiled-in paths for Midnight Commander.

-g, --oldmouse

Force a "normal tracking" mouse mode. Used when running on xterm-capable terminals (tmux/screen).

-k, --resetsoft

Reset softkeys to their default from the termcap/terminfo database. Only useful on HP terminals when the function keys don't work.

-K file, --keymap=file

Specify a name of keymap file in the command line.

-l file, --ftplog=file

Save the ftpfs dialog with the server in file.

--nokeymap

Don't load key bindings from any file, use default hardcoded keys.

-P file, --printwd=file

Print the last working directory to the specified file. This option is not meant to be used directly. Instead, it's used from a special shell script that automatically changes the current directory of the shell to the last directory Midnight Commander was in. Source the file **/usr/local/libexec/mc/mc.sh** (bash and zsh users) or **/usr/local/libexec/mc.csh** (tcsh users) respectively to define **mc** as an alias to the appropriate shell script.

- `-s, --slow`
Turn on the slow terminal mode, in this mode the program will not draw expensive line drawing characters and will toggle verbose mode off.
- `-S arg, --skin=arg`
Specify a name of skin in the command line. Technology of skins is documented in the Skins section.
- `-t, --termcap`
Used only if the code was compiled with S-Lang and terminfo: it makes Midnight Commander use the value of the **TERMCAP** variable for the terminal information instead of the information on the system wide terminal database
- `-u, --nosubshell`
Disable use of the concurrent shell (only makes sense if Midnight Commander has been built with concurrent shell support).
- `-U, --subshell`
Enable use of the concurrent shell support (only makes sense if the Midnight Commander was built with the subshell support set as an optional feature).
- `-v file, --view=file`
Start the internal viewer to view the specified file. See also **mcview (1)**.
- `-V, --version`
Display the version of the program.
- `-x, --xterm`
Force xterm mode. Used when running on xterm-capable terminals (two screen modes, and able to send mouse escape sequences).
- `-X, --no-x11`
Do not use X11 to get the state of modifiers Alt, Ctrl, Shift

If both paths are specified, the first path name is the directory to show in the active panel; the second path name is the directory to be shown in the other panel.

If one path is specified, the path name is the directory to show in the active panel; value of "other_dir" from panels.ini is the directory to be shown in the passive panel.

If no paths are specified, current directory is shown in the active panel; value of "other_dir" from panels.ini is the directory to be shown in the passive panel.

Overview

The screen of Midnight Commander is divided into four parts. Almost all of the screen space is taken up by two directory panels. By default, the second line from the bottom of the screen is the shell command line, and the bottom line shows the function key labels. The topmost line is the menu bar line. The menu bar line may not be visible, but appears if you click the topmost line with the mouse or press the F9 key.

Midnight Commander provides a view of two directories at the same time. One of the panels is the current panel (a selection bar is in the current panel). Almost all operations take place on the current panel. Some file operations like Rename and Copy by default use the directory of the unselected panel as a destination (don't worry, they always ask you for confirmation first). For more information, see the sections on the Directory Panels, the Left and Right Menus and the File Menu.

You can execute system commands from Midnight Commander by simply typing them. Everything you type will appear on the shell command line, and when you press Enter, Midnight Commander will execute the command line you typed; read the Shell Command Line and Input Line Keys sections to learn more about the command line.

Mouse Support

Midnight Commander comes with mouse support. It is activated whenever you are running on an **xterm(1)** terminal (it even works if you take a telnet, ssh or rlogin connection to another machine from the xterm) or

if you are running on a Linux console and have the **gpm** mouse server running.

When you left click on a file in the directory panels, that file is selected; if you click with the right button, the file is marked (or unmarked, depending on the previous state).

Double-clicking on a file will try to execute the command if it is an executable program; and if the extension file has a program specified for the file's extension, the specified program is executed.

Also, it is possible to execute the commands assigned to the function key labels by clicking on them.

The default auto repeat rate for the mouse buttons is 400 milliseconds. This may be changed to other values by editing the `~/config/mc/ini` file and changing the `mouse_repeat_rate` parameter.

If you are running Midnight Commander with the mouse support, you can get the default mouse behavior (cutting and pasting text) by holding down the Shift key.

Keys

Some commands in Midnight Commander involve the use of the *Control* (sometimes labeled CTRL or CTL) and the *Meta* (sometimes labeled ALT or even Compose) keys. In this manual we will use the following abbreviations:

C-**<chr>**

means hold the Control key while typing the character **<chr>**. Thus C-f would be: hold the Control key and type f.

Alt-**<chr>**

means hold the Meta or Alt key down while typing **<chr>**. If there is no Meta or Alt key, type *Esc*, release it, then type the character **<chr>**.

S-**<chr>**

means hold the Shift key down while typing **<chr>**.

All input lines in Midnight Commander use an approximation to the GNU Emacs editor's key bindings (default).

You may redefine key bindings. See *redefine hotkey bindings*

for more info. All other key bindings (described in this manual) are relative to default behavior.

There are many sections which tell about the keys. The following are the most important.

The File Menu section documents the keyboard shortcuts for the commands appearing in the File menu. This section includes the function keys. Most of these commands perform some action, usually on the selected file or the tagged files.

The Directory Panels section documents the keys which select a file or tag files as a target for a later action (the action is usually one from the file menu).

The Shell Command Line section list the keys which are used for entering and editing command lines. Most of these copy file names and such from the directory panels to the command line (to avoid excessive typing) or access the command line history.

Input Line Keys are used for editing input lines. This means both the command line and the input lines in the query dialogs.

Redefine hotkey bindings

Hotkey bindings may be read from external file (keymap-file). Initially, Midnight Commander creates key bindings using keymap defined in the source code. Then, two files `/usr/local/share/mc/mc.keymap` and `/usr/local/etc/mc/mc.keymap` are loaded always, sequentially reassigned key bindings defined earlier. User-defined keymap-file is searched on the following algorithm (to the first one found):

- 1) command line option **-K <keymap>** or **--keymap=<keymap>**
- 2) Environment variable **MC_KEYMAP**

- 3) Parameter **keymap** in section **[Midnight-Commander]** of config file.
- 4) File **~/.config/mc/mc.keymap**

Command line option, environment variable and parameter in config file may contain the absolute path to the keymap-file (with the extension .keymap or without it). Search of keymap-file will occur in (to the first one found):

- 1) **~/.config/mc**
- 2) **/usr/local/etc/mc/**
- 3) **/usr/local/share/mc/**

Miscellaneous Keys

Here are some keys which don't fall into any of the other categories:

- Enter** if there is some text in the command line (the one at the bottom of the panels), then that command is executed. If there is no text in the command line then if the selection bar is over a directory the Midnight Commander does a **chdir(2)** to the selected directory and reloads the information on the panel; if the selection is an executable file then it is executed. Finally, if the extension of the selected file name matches one of the extensions in the extensions file then the corresponding command is executed.
- C-l** repaint all the information in Midnight Commander.
- C-x c** run the Chmod command on a file or on the tagged files.
- C-x o** run the Chown command on the current file or on the tagged files.
- C-x l** run the hard link command.
- C-x s** run the absolute symbolic link command.
- C-x v** run the relative symbolic link command. See the File Menu section for more information about symbolic links.
- C-x i** set the other panel display mode to information.
- C-x q** set the other panel display mode to quick view.
- C-x !** execute the External panelize command.
- C-x h** run the add directory to hotlist command.
- Alt-!** executes the Filtered view command, described in the view command.
- Alt-?** executes the Find file command.
- Alt-c** pops up the quick cd dialog.
- C-o** when the program is being run in the Linux or FreeBSD console or under an xterm, it will show you the output of the previous command. When ran on the Linux console, Midnight Commander uses an external program (cons.saver) to handle saving and restoring of information on the screen.

When the subshell support is compiled in, you can type C-o at any time and you will be taken back to Midnight Commander's main screen, to return to your application just type C-o. If you have an application suspended by using this trick, you won't be able to execute other programs from Midnight Commander until you terminate the suspended application.

Directory Panels

This section lists the keys which operate on the directory panels. If you want to know how to change the appearance of the panels take a look at the section on Left and Right Menus.

Tab, C-i

change the current panel. The old other panel becomes the new current panel and the old current panel becomes the new other panel. The selection bar moves from the old current panel to the new current panel.

Insert, C-t

to tag files you may use the Insert key (the `kich1` terminfo sequence). To untag files, just retag a tagged file.

Alt-e to change charset of panel you may use Alt-e (M-e). Recoding is made from selected codepage into system codepage. To cancel the recoding, select "No translation" in the dialog of encodings.

Alt-g, Alt-r, Alt-j

used to select the top file in a panel, the middle file and the bottom one, respectively.

Alt-t toggle the current display listing to show the next display listing format. With this it is possible to quickly switch to brief listing, long listing, user defined listing format, and back to the default.

C-\ (control-backslash)

show the directory hotlist and change to the selected directory.

+ (plus)

this is used to select (tag) a group of files. Midnight Commander will prompt for a selection options. When *Files only* checkbox is on, only files will be selected. If *Files only* is off, as files as directories will be selected. When *Shell Patterns* checkbox is on, the regular expression is much like the filename globbing in the shell (* standing for zero or more characters and ? standing for one character). If *Shell Patterns* is off, then the tagging of files is done with normal regular expressions (see `ed (1)`). When *Case sensitive* checkbox is on, the selection will be case sensitive characters. If *Case sensitive* is off, the case will be ignored.

\ (backslash)

use the "\ " key to unselect a group of files. This is the opposite of the Plus key.

up-key, C-p

move the selection bar to the previous entry in the panel.

down-key, C-n

move the selection bar to the next entry in the panel.

home, a1, Alt-<

move the selection bar to the first entry in the panel.

end, c1, Alt->

move the selection bar to the last entry in the panel.

next-page, C-v

move the selection bar one page down.

prev-page, Alt-v

move the selection bar one page up.

Alt-o If the currently selected file is a directory, load that directory on the other panel and moves the selection to the next file. If the currently selected file is not a directory, load the parent directory on the other panel and moves the selection to the next file.

Alt-i make the current directory of the current panel also the current directory of the other panel. Put the other panel to the listing mode if needed. If the current panel is panelized, the other panel doesn't become panelized.

C-PageUp, C-PageDown

only when supported by the terminal: change to ".." and to the currently selected directory respectively.

Alt-y moves to the previous directory in the history, equivalent to clicking the < with the mouse.

Alt-u moves to the next directory in the history, equivalent to clicking the > with the mouse.

Alt-S-h, Alt-H

displays the directory history, equivalent to depressing the 'v' with the mouse.

Quick search

The Quick search mode allows you to perform fast file search in file panel. Press *C-s* or *Alt-s* to start a filename search in the directory listing.

When the search is active, the user input will be added to the search string instead of the command line. If the *Show mini-status* option is enabled the search string is shown on the mini-status line. When typing, the selection bar will move to the next file starting with the typed letters. The *Backspace* or *DEL* keys can be used to correct typing mistakes. If *C-s* is pressed again, the next match is searched for.

If quick search is started with double pressing of *C-s*, the previous quick search pattern will be used for current search.

Besides the filename characters, you can also use wildcard characters '*' and '?'.

Shell Command Line

This section lists keys which are useful to avoid excessive typing when entering shell commands.

Alt-Enter

copy the currently selected file name to the command line.

C-Enter

same as Alt-Enter. May not work on remote systems and some terminals.

C-S-Enter

copy the full path name of the currently selected file to the command line. May not work on remote systems and some terminals.

Alt-Tab

does the filename, command, variable, username and hostname completion for you.

C-x t, C-x C-t

copy the tagged files (or if there are no tagged files, the selected file) of the current panel (*C-x t*) or of the other panel (*C-x C-t*) to the command line.

C-x p, C-x C-p

the first key sequence copies the current path name to the command line, and the second one copies the unselected panel's path name to the command line.

C-q

the quote command can be used to insert characters that are otherwise interpreted by Midnight Commander (like the '+' symbol)

Alt-p, Alt-n

use these keys to browse through the command history. Alt-p takes you to the last entry, Alt-n takes you to the next one.

Alt-h displays the history for the current input line.

General Movement Keys

The help viewer, the file viewer and the directory tree use common code to handle moving. Therefore they accept exactly the same keys. Each of them also accepts some keys of its own.

Other parts of Midnight Commander use some of the same movement keys, so this section may be of use for those parts too.

Up, C-p

moves one line backward.

Down, C-n

moves one line forward.

Prev Page, Page Up, Alt-v

moves one page up.

Next Page, Page Down, C-v

moves one page down.

Home, A1

moves to the beginning.

End, C1

move to the end.

The help viewer and the file viewer accept the following keys in addition the to ones mentioned above:

b, C-b, C-h, Backspace, Delete

moves one page up.

Space bar

moves one page down.

u, d moves one half of a page up or down.

g, G moves to the beginning or to the end.

Input Line Keys

The input lines (they are used for the command line and for the query dialogs in the program) accept these keys:

C-a puts the cursor at the beginning of line.

C-e puts the cursor at the end of the line.

C-b, move-left

move the cursor one position left.

C-f, move-right

move the cursor one position right.

Alt-f moves one word forward.

Alt-b moves one word backward.

C-h, Backspace

delete the previous character.

C-d, Delete

delete the character in the point (over the cursor).

C-@ sets the mark for cutting.

C-w copies the text between the cursor and the mark to a kill buffer and removes the text from the input line.

Alt-w copies the text between the cursor and the mark to a kill buffer.

C-y yanks back the contents of the kill buffer.

C-k kills the text from the cursor to the end of the line.

Alt-p, Alt-n

Use these keys to browse through the command history. Alt-p takes you to the last entry, Alt-n takes you to the next one.

Alt-C-h, Alt-Backspace

delete one word backward.

Alt-Tab

does the filename, command, variable, username and hostname completion for you.

Menu Bar

The menu bar pops up when you press F9 or click the mouse on the top row of the screen. The menu bar has five menus: "Left", "File", "Command", "Options" and "Right".

The Left and Right Menus allow you to modify the appearance of the left and right directory panels.

The File Menu lists the actions you can perform on the currently selected file or the tagged files.

The Command Menu lists the actions which are more general and bear no relation to the currently selected file or the tagged files.

The Options Menu lists the actions which allow you to customize Midnight Commander.

Left and Right (Above and Below) Menus

The outlook of the directory panels can be changed from the **Left** and **Right** menus (they are named **Above** and **Below** when the horizontal panel split is chosen from the Layout options dialog).

Listing Format...

The listing mode view is used to display a listing of files, there are four different listing formats available: **Full**, **Brief**, **Long** and **User**. The full directory view shows the file name, the size of the file and the modification time.

The brief view shows only the file name and it has from 1 up to 9 columns (therefore showing more files unlike other views). The long view is similar to the output of **ls -l** command. The long view takes the whole screen width.

If you choose the "User" display format, then you have to specify the display format.

The user display format must start with a panel size specifier. This may be "half" or "full", and they specify a half screen panel and a full screen panel respectively.

After the panel size, you may specify how many listings to fit in the panel, side-by-side (in other words: how many times to repeat the fields horizontally). This defaults to 1. You may change this by adding a number from 1 to 9 to the format string.

After this you add the name of the fields with an optional size specifier. This are the available fields you may display:

- name** displays the file name.
- size** displays the file size.
- bsize** is an alternative form of the **size** format. It displays the size of the files and for directories it just shows SUB-DIR or UP--DIR.
- type** displays a one character wide type field. This character is similar to what is displayed by **ls** with the **-F** flag - * for executable files, / for directories, @ for links, = for sockets, - for character devices, + for block devices, | for pipes, ~ for symbolic links to directories and ! for stale symlinks (links that point nowhere).
- mark** an asterisk if the file is tagged, a space if it's not.
- mtime** file's last modification time.
- atime** file's last access time.
- ctime** file's status change time.
- perm** a string representing the current permission bits of the file.
- mode** an octal value with the current permission bits of the file.
- nlink** the number of links to the file.
- ngid** the GID (numeric).
- nuid** the UID (numeric).
- owner** the owner of the file.
- group** the group of the file.
- inode** the inode of the file.

Also you can use following keywords to define the panel layout:

space a space in the display format.

| add a vertical line to the display format.

To force one field to a fixed size (a size specifier), you just add **:** followed by the number of characters you want the field to have. If the number is followed by the symbol **+**, then the size specifies the minimal field size – if the program finds out that there is more space on the screen, it will then expand that field.

For example, the **Full** display corresponds to this format:

```
half type name | size | mtime
```

And the **Long** display corresponds to this format:

```
full perm space nlink space owner space group space size space mtime space name
```

This is a nice user display format:

```
half name | size:7 | type mode:3
```

Panels may also be set to the following modes:

Info The info view display information related to the currently selected file and if possible information about the current file system.

Tree The tree view is quite similar to the directory tree feature. See the section about it for more information.

Quick View

In this mode, the panel will switch to a reduced viewer that displays the contents of the currently selected file, if you select the panel (with the tab key or the mouse), you will have access to the usual viewer commands.

Sort Order...

The eight sort orders are by name, by extension, by modification time, by access time, and by inode information modification time, by size, by inode and unsorted. In the Sort order dialog box you can choose the sort order and you may also specify if you want to sort in reverse order by checking the reverse box.

By default directories are sorted before files but this can be changed from the Panel options menu (option **Mix all files**).

Filter...

The filter command allows you to specify a shell pattern (for example ***.tar.gz**) which the files must match to be shown. Regardless of the filter pattern, the directories and the links to directories are always shown in the directory panel.

Reread

The reread command reload the list of files in the directory. It is useful if other processes have created or removed files.

File Menu

Midnight Commander uses the F1 – F10 keys as keyboard shortcuts for commands appearing in the file menu. The escape sequences for the function keys are terminfo capabilities **kf1** through **kf10**. On terminals without function key support, you can achieve the same functionality by pressing the Esc key and then a number in the range 1 through 9 and 0 (corresponding to F1 to F9 and F10 respectively).

The File menu has the following commands (keyboard shortcuts in parentheses):

Help (F1)

Invokes the built-in hypertext help viewer. Inside the help viewer, you can use the Tab key to select the next link and the Enter key to follow that link. The keys Space and Backspace are used to move forward and backward in a help page. Press F1 again to get the full list of accepted keys.

Menu (F2)

Invoke the user menu. The user menu provides an easy way to provide users with a menu and add extra features to Midnight Commander.

View (F3, F13)

View the currently selected file. By default this invokes the Internal File Viewer but if the option "Use internal view" is off, it invokes an external file viewer specified by the **VIEWER** environment variable. If **VIEWER** is undefined, the **PAGER** environment variable is tried. If **PAGER** is also undefined, the "view" command is invoked. If you use F13 instead, the viewer will be invoked without doing any formatting or preprocessing to the file.

See parameters for external viewer for explain how you may specify an extended command line options for external viewers.

Filtered View (Alt-!)

This command prompts for a command and its arguments (the argument defaults to the currently selected file name), the output from such command is shown in the internal file viewer.

Edit (F4, F14)

Press F4 to edit the highlighted file. Press F14 (usually F14) to start the editor with a new, empty file. Currently they invoke the **vi** editor, or the editor specified in the **EDITOR** environment variable, or the Internal File Editor if the `use_internal_edit` option is on.

See parameters for external editor for explain how you may specify an extended command line options for external editors.

Copy (F5, F15)

Press F5 to pop up an input dialog to copy the currently selected file (or the tagged files, if there is at least one file tagged) to the directory/filename you specify in the input dialog. The destination defaults to the directory in the non-selected panel. Space for destination file may be preallocated relative to `preallocate_space` configure option. During this process, you can press C-c or Esc to abort the operation. For details about source mask (which will be usually either * or `^(.*)$` depending on setting of Use shell patterns) and possible wildcards in the destination see `Mask copy/rename`.

F15 (usually F15) is similar, but defaults to the directory in the selected panel. It always operates on the selected file, regardless of any tagged files.

On some systems, it is possible to do the copy in the background by clicking on the background button (or pressing Alt-b in the dialog box). The Background Jobs is used to control the background process.

Link (C-x l)

Create a hard link to the current file.

Absolute symlink (C-x s)

Create a absolute symbolic link to the current file.

Relative symLink (C-x v)

Create a relative symbolic link to the current file.

To those of you who don't know what links are: creating a link to a file is a bit like copying the file, but both the source filename and the destination filename represent the same file image. For example, if you edit one of these files, all changes you make will appear in both files. Some people call links aliases or shortcuts.

A hard link appears as a real file. After making it, there is no way of telling which one is the original and which is the link. If you delete either one of them the other one is still intact. It is very difficult to notice that the files represent the same image. Use hard links when you don't even want to know.

A symbolic link is a reference to the name of the original file. If the original file is deleted the symbolic link is useless. It is quite easy to notice that the files represent the same image. Midnight Commander shows an "@"-sign in front of the file name if it is a symbolic link to somewhere (except to directory, where it shows a tilde (~)). The original file which the link points to is shown on mini-status line if the `Show mini-status` option is enabled. Use symbolic links when you want to avoid the confusion that can be caused by hard

links.

When you press "C-x s" Midnight Commander will automatically fill in the complete path+filename of the original file and suggest a name for the link. You can change either one.

Sometimes you may want to change the absolute path of the original into a relative path. An absolute path starts from the root directory:

```
/home/frodo/mc/mc -> /home/frodo/new/mc
```

A relative link describes the original file's location starting from the location of the link itself:

```
/home/frodo/mc/mc -> ../new/mc
```

You can force Midnight Commander to suggest a relative path by pressing "C-x v" instead of "C-x s".

Rename/Move (F6, F16)

Press F6 to pop up an input dialog to copy the currently selected file (or the tagged files, if there is at least one file tagged) to the directory/filename you specify in the input dialog. The destination defaults to the directory in the non-selected panel. For more details look at Copy (F5) operation above, most of the things are quite similar.

F16 (usually F16) is similar, but defaults to the directory in the selected panel. It always operates on the selected file, regardless of any tagged files.

On some systems, it is possible to do the copy in the background by clicking on the background button (or pressing Alt-b in the dialog box). The Background Jobs is used to control the background process.

Mkdir (F7)

Pop up an input dialog and creates the directory specified.

Delete (F8)

Delete the currently selected file or the tagged files in the currently selected panel. During the process, you can press C-c or Esc to abort the operation.

Quick cd (Alt-c) Use the quick cd command if you have full command line and want to cd somewhere.

Select group (+)

This is used to select (tag) a group of files. Midnight Commander will prompt for a selection options. When *Files only* checkbox is on, only files will be selected. If *Files only* is off, as files as directories will be selected. When *Shell Patterns* checkbox is on, the regular expression is much like the filename globbing in the shell (* standing for zero or more characters and ? standing for one character). If *Shell Patterns* is off, then the tagging of files is done with normal regular expressions (see ed (1)). When *Case sensitive* checkbox is on, the selection will be case sensitive characters. If *Case sensitive* is off, the case will be ignored.

Unselect group (\)

Used to unselect a group of files. This is the opposite of the *Select group* command.

Quit (F10, S-F10)

Terminate Midnight Commander. S-F10 is used when you want to quit and you are using the shell wrapper. S-F10 will not take you to the last directory you visited with Midnight Commander, instead it will stay at the directory where you started Midnight Commander.

Quick cd

This command is useful if you have a full command line and want to cd somewhere without having to yank and paste the command line. This command pops up a small dialog, where you enter everything you would enter after **cd** on the command line and then you press enter. This features all the things that are already in the internal cd command.

Command Menu

The Directory tree command shows a tree figure of the directories.

The "Find file" command allows you to search for a specific file.

The "Swap panels" command swaps the contents of the two directory panels.

The "Switch panels on/off" command shows the output of the last shell command. This works only on xterm and on Linux and FreeBSD console.

The "Compare directories" command compares the directory panels with each other. You can then use the Copy (F5) command to make the panels identical. There are three compare methods. The quick method compares only file size and file date. The thorough method makes a full byte-by-byte compare. The thorough method is not available if the machine does not support the mmap(2) system call. The size-only compare method just compares the file sizes and does not check the contents or the date times, it just checks the file size.

The "External panelize" allows you to execute an external program, and make the output of that program the contents of the current panel.

The "Command history" command shows a list of typed commands. The selected command is copied to the command line. The command history can also be accessed by typing Alt-p or Alt-n.

The "Directory hotlist" command makes changing of the current directory to often used directories faster.

The "Screen list" command shows a dialog window with the list of currently running internal editors, viewers and other MC modules that support this mode.

The "Edit extension file" command allows you to specify programs to executed when you try to execute, view, edit and do a bunch of other thing on files with certain extensions (filename endings).

The "Edit Menu File" command may be used for editing the user menu (which appears by pressing F2).

Directory Tree

The Directory Tree command shows a tree figure of the directories. You can select a directory from the figure and Midnight Commander will change to that directory.

There are two ways to invoke the tree. The real directory tree command is available from Commands menu. The other way is to select tree view from the Left or Right menu.

To get rid of long delays, Midnight Commander creates the tree figure by scanning only a small subset of all the directories. If the directory which you want to see is missing, move to its parent directory and press C-r (or F2).

You can use the following keys:

General movement keys
are accepted.

Enter. In the directory tree, exits the directory tree and changes to this directory in the current panel. In the tree view, changes to this directory in the other panel and stays in tree view mode in the current panel.

C-r, F2 (Rescan).

Rescan this directory. Use this when the tree figure is out of date: it is missing subdirectories or shows some subdirectories which don't exist any more.

F3 (Forget).

Delete this directory from the tree figure. Use this to remove clutter from the figure. If you want the directory back to the tree figure press F2 in its parent directory.

F4 (Static/Dynamic).

Toggle between the dynamic navigation mode (default) and the static navigation mode.

In the static navigation mode you can use the Up and Down keys to select a directory. All known directories are shown.

In the dynamic navigation mode you can use the Up and Down keys to select a sibling directory, the Left key to move to the parent directory, and the Right key to move to a child directory. Only the parent, sibling and children directories are shown, others are left out. The tree figure changes dynamically as you traverse.

F5 (Copy).

Copy the directory.

F6 (RenMov).

Move the directory.

F7 (Mkdir).

Make a new directory below this directory.

F8 (Delete).

Delete this directory from the file system.

C-s, Alt-s.

Search the next directory matching the search string. If there is no such directory these keys will move one line down.

C-h, Backspace.

Delete the last character of the search string.

Any other character.

Add the character to the search string and move to the next directory which starts with these characters. In the tree view you must first activate the search mode by pressing C-s. The search string is shown in the mini status line.

The following actions are available only in the directory tree. They aren't supported in the tree view.

F1 (Help).

Invoke the help viewer and show this section.

Esc, F10.

Exit the directory tree. Do not change the directory.

The mouse is supported. A double-click behaves like Enter. See also the section on mouse support.

Find File

The Find File feature first asks for the start directory for the search and the filename to be searched for. By pressing the Tree button you can select the start directory from the directory tree figure.

The "File name" input field contains a filename pattern to be searched for. It is interpreted as a shell pattern or as a regular expression depending on the state of the "Using shell patterns" checkbox. An empty value is valid and matches any file name.

The "Content" input field contains a string to search for within the files. Leave this field empty to disable searching file contents.

Option "Whole words" allows select only those files containing matches that form whole words. Like `grep -w`.

You can start the search by pressing the OK button. During the search you can stop from the Stop button and continue from the Start button.

You can browse the filelist with the up and down arrow keys. The Chdir button will change to the directory of the currently selected file. The Again button will ask for the parameters for a new search. The Quit button quits the search operation. The Panelize button will place the found files to the current directory panel so that you can do additional operations on them (view, copy, move, delete and so on). To return to the normal file listing, change directory to "..".

The 'Enable ignore directories' checkbox and input field below it allow one to set up the list of directories that should be skip during the search files (for example, you may want to avoid searches on a CD-ROM or on a NFS directory that is mounted across a slow link). List components must be separated with a colon, here is an example:

```
/cdrom:/nfs/wuarchive:/afs
```

Relative paths are supported also. The following example shows how to skip special directories of version control systems:

```
/cdrom:/nfs/wuarchive:/afs:.svn:.git:CVS
```

Attention: input field can contain a dot (.), this means the current absolute path.

You may consider using the External panelize command for some operations. Find file command is for simple queries only, while using External panelize you can do as mysterious searches as you would like.

External panelize

The External panelize allows you to execute an external program, and make the output of that program the contents of the current panel.

For example, if you want to manipulate in one of the panels all the symbolic links in the current directory, you can use external panelization to run the following command:

```
find . -type l -print
```

Upon command completion, the directory contents of the panel will no longer be the directory listing of the current directory, but all the files that are symbolic links.

If you want to panelize all of the files that have been downloaded from your FTP server, you can use this awk command to extract the file name from the transfer log files:

```
awk '$9 ~!/incoming/ { print $9 }' < /var/log/xferlog
```

You may want to save often used panelize commands under a descriptive name, so that you can recall them quickly. You do this by typing the command on the input line and pressing Add new button. Then you enter a name under which you want the command to be saved. Next time, you just choose that command from the list and do not have to type it again.

Hotlist

The Directory hotlist command shows the labels of the directories in the directory hotlist. Midnight Commander will change to the directory corresponding to the selected label. From the hotlist dialog, you can remove already created label/directory pairs and add new ones. To add new directories quickly, you can use the Add to hotlist command (C-x h), which adds the current directory into the directory hotlist, asking just for the label for the directory.

This makes cd to often used directories faster. You may consider using the CDPATH variable as described in internal cd command description.

Edit Extension File

This will invoke your editor on the file `~/config/mc/mc.ext`. The format of this file following:

All lines starting with # or empty lines are thrown away.

Lines starting in the first column should have following format:

keyword/expr, i.e. everything after the slash until new line is *expr*.

keyword can be:

shell – *expr* is an extension (no wildcards). File matches if its name ends with *expr*. Example: *shell/tar* matches **.tar*.

regex – *expr* is a regular expression. File matches if its name matches the regular expression.

directory

– *expr* is a regular expression. File matches if it is a directory and its name matches the regular expression.

type – *expr* is a regular expression. File matches if the output of *file %f* without the initial "filename:" part matches regular expression *expr*.

default – matches any file. *expr* is ignored.

include – denotes a common section. *expr* is the name of the section.

Other lines should start with a space or tab and should be of the format: *keyword=command* (with no spaces around =), where *keyword* should be: *Open* (invoked on Enter or double click), *View* (F3), *Edit* (F4) or

Include (to add rules from the common section). *command* is any one-line shell command, with the simple macro substitution.

Rules are matched from top to bottom, thus the order is important. If the appropriate action is missing, search continues as if this rule didn't match (i.e. if a file matches the first and second entry and View action is missing in the first one, then on pressing F3 the View action from the second entry will be used). *default* should match all the actions.

Background Jobs

This lets you control the state of any background Midnight Commander process (only copy and move files operations can be done in the background). You can stop, restart and kill a background job from here.

Edit Menu File

The user menu is a menu of useful actions that can be customized by the user. When you access the user menu, the file `.mc.menu` from the current directory is used if it exists, but only if it is owned by user or root and is not world-writable. If no such file found, `~/config/mc/menu` is tried in the same way, and otherwise mc uses the default system-wide menu `/usr/local/share/mc/mc.menu`.

The format of the menu file is very simple. Lines that start with anything but space or tab are considered entries for the menu (in order to be able to use it like a hot key, the first character should be a letter). All the lines that start with a space or a tab are the commands that will be executed when the entry is selected.

When an option is selected all the command lines of the option are copied to a temporary file in the temporary directory (usually `/usr/tmp`) and then that file is executed. This allows the user to put normal shell constructs in the menus. Also simple macro substitution takes place before executing the menu code. For more information, see macro substitution.

Here is a sample `mc.menu` file:

```
A      Dump the currently selected file
        od -c %f

B      Edit a bug report and send it to root
        I='mktemp ${MC_TMPDIR:-/tmp}/mail.XXXXXX' || exit 1
        vi $I
        mail -s "Midnight Commander bug" root < $I
        rm -f $I

M      Read mail
        emacs -f rmail

N      Read Usenet news
        emacs -f gnus

H      Call the info hypertext browser
        info

J      Copy current directory to other panel recursively
        tar cf - . | (cd %D && tar xvpf -)

K      Make a release of the current subdirectory
        echo -n "Name of distribution file: "
        read tar
        ln -s %d 'dirname %d'/$tar
        cd ..
        tar cvhf ${tar}.tar $tar

= f *.tar.gz | f *.tgz & t n
X      Extract the contents of a compressed tar file
```

```
tar xzvf %f
```

Default Conditions

Each menu entry may be preceded by a condition. The condition must start from the first column with a '=' character. If the condition is true, the menu entry will be the default entry.

Condition syntax: = <sub-cond>
 or: = <sub-cond> | <sub-cond> ...
 or: = <sub-cond> & <sub-cond> ...

Sub-condition is one of following:

| | |
|--------------|--|
| y <pattern> | syntax of current file matching pattern? (for edit menu only) |
| f <pattern> | current file matching pattern? |
| F <pattern> | other file matching pattern? |
| d <pattern> | current directory matching pattern? |
| D <pattern> | other directory matching pattern? |
| t <type> | current file of type? |
| T <type> | other file of type? |
| x <filename> | is it executable filename? |
| ! <sub-cond> | negate the result of sub-condition |

Pattern is a normal shell pattern or a regular expression, according to the shell patterns option. You can override the global value of the shell patterns option by writing "shell_patterns=x" on the first line of the menu file (where "x" is either 0 or 1).

Type is one or more of the following characters:

| | |
|---|------------------|
| n | not a directory |
| r | regular file |
| d | directory |
| l | link |
| c | character device |
| b | block device |
| f | FIFO (pipe) |
| s | socket |
| x | executable file |
| t | tagged |

For example 'rlf' means either regular file, link or fifo. The 't' type is a little special because it acts on the panel instead of the file. The condition '=t t' is true if there are tagged files in the current panel and false if not.

If the condition starts with '=?' instead of '=' a debug trace will be shown whenever the value of the condition is calculated.

The conditions are calculated from left to right. This means

```
= f *.tar.gz | f *.tgz & t n
```

is calculated as

```
( (f *.tar.gz) | (f *.tgz) ) & (t n)
```

Here is a sample of the use of conditions:

```
= f *.tar.gz | f *.tgz & t n
```

```
L      List the contents of a compressed tar-archive
      gzip -cd %f | tar xvf -
```

Addition Conditions

If the condition begins with '+' (or '+?') instead of '=' (or '=?') it is an addition condition. If the condition

is true the menu entry will be included in the menu. If the condition is false the menu entry will not be included in the menu.

You can combine default and addition conditions by starting condition with '+=' or '=+' (or '+=?' or '=+?' if you want debug trace). If you want to use two different conditions, one for adding and another for defaulting, you can precede a menu entry with two condition lines, one starting with '+' and another starting with '='.

Comments are started with '#'. The additional comment lines must start with '#', space or tab.

Options Menu

Midnight Commander has some options that may be toggled on and off in several dialogs which are accessible from this menu. Options are enabled if they have an asterisk or "x" in front of them.

The Configuration command pops up a dialog from which you can change most of settings of Midnight Commander.

The Layout command pops up a dialog from which you specify a bunch of options how mc looks like on the screen.

The Panel options command pops up a dialog from which you specify options of file manager panels.

The Confirmation command pops up a dialog from which you specify which actions you want to confirm.

The Appearance command pops up a dialog from which you specify the skin.

The Display bits command pops up a dialog from which you may select which characters is your terminal able to display.

The Learn keys command pops up a dialog from which you test some keys which are not working on some terminals and you may fix them.

The Virtual FS command pops up a dialog from which you specify some VFS related options.

The Save setup command saves the current settings of the Left, Right and Options menus. A small number of other settings is saved, too.

Configuration

The options in this dialog are divided into several groups: "File operation options", "Esc key mode", "Pause after run" and "Other options".

File operation options

Verbose operation. This toggles whether the file Copy, Rename and Delete operations are verbose (i.e., display a dialog box for each operation). If you have a slow terminal, you may wish to disable the verbose operation. It is automatically turned off if the speed of your terminal is less than 9600 bps.

Compute totals. If this option is enabled, Midnight Commander computes total byte sizes and total number of files prior to any Copy, Rename and Delete operations. This will provide you with a more accurate progress bar at the expense of some speed. This option has no effect, if *Verbose operation* is disabled.

Classic progressbar. If this option is enabled, the progressbar of Copy/Move/Delete operations is always grown from left to right. If disabled, the growing direction of progressbar follows to direction of Copy/Move/Delete operation: from left panel to right one and vice versa. Enabled by default.

Mkdir autoname. When you press F7 to create a new directory, the input line in popup dialog will be filled by name of current file or directory in active panel. Disabled by default.

Preallocate space. Preallocate space for whole target file, if possible, before copy operation. Disabled by default.

Esc key mode.

By default, Midnight Commander treats the Esc key as a key prefix. Therefore, you should press Esc code twice to exit a dialog. But there is a possibility to use a single press of Esc key for that action.

Single press. By default this option is disabled. If you'll enable it, the Esc key will act as a prefix key for set up time interval (see *Timeout* option below), and if no extra keys have arrived, then the Esc key is

interpreted as a cancel key (Esc Esc).

Timeout. This options is used to setup the time interval (in microseconds) for single press of Esc key. By default, this interval is one second (1000000 microseconds). Also the timeout can be set via **KEYBOARD_KEY_TIMEOUT_US** environment variable (also in microseconds), which has higher priority than Timeout option value.

Pause after run

After executing your commands, Midnight Commander can pause, so that you can examine the output of the command. There are three possible settings for this variable:

Never. Means that you do not want to see the output of your command. If you are using the Linux or FreeBSD console or an xterm, you will be able to see the output of the command by typing C-o.

On dumb terminals. You will get the pause message on terminals that are not capable of showing the output of the last command executed (any terminal that is not an xterm or the Linux console).

Always. The program will pause after executing all of your commands.

Other options

Use internal editor. If this option is enabled, the built-in file editor is used to edit files. If the option is disabled, the editor specified in the **EDITOR** environment variable is used. If no editor is specified, **vi** is used. See the section on the internal file editor.

Use internal viewer. If this option is enabled, the built-in file viewer is used to view files. If the option is disabled, the pager specified in the **PAGER** environment variable is used. If no pager is specified, the **view** command is used. See the section on the internal file viewer.

Ask new file name. If this option is enabled, file name is asked before open new file in editor.

Auto menus. If this option is enabled, the user menu will be invoked at startup. Useful for building menus for non-unixers.

Drop down menus. When this option is enabled, the pull down menus will be activated as soon as you press the F9 key. Otherwise, you will only get the menu title, and you will have to activate the menu either with the arrow keys or with the hotkeys. It is recommended if you are using hotkeys.

Shell Patterns. By default the Select, Unselect and Filter commands will use shell-like regular expressions. The following conversions are performed to achieve this: the '*' is replaced by '.*' (zero or more characters); the '?' is replaced by '.' (exactly one character) and '.' by the literal dot. If the option is disabled, then the regular expressions are the ones described in `ed(1)`.

Complete: show all. By default, Midnight Commander pops up all possible completions if the completion is ambiguous only when you press **Alt-Tab** for the second time. For the first time, it just completes as much as possible and beeps in the case of ambiguity. Enable this option if you want to see all possible completions even after pressing **Alt-Tab** the first time.

Rotating dash. If this option is enabled, the Midnight Commander shows a rotating dash in the upper right corner as a work in progress indicator.

Cd follows links. This option, if set, causes Midnight Commander to follow the logical chain of directories when changing current directory either in the panels, or using the `cd` command. This is the default behavior of `bash`. When unset, Midnight Commander follows the real directory structure, so `cd ..` if you've entered that directory through a link will move you to the current directory's real parent and not to the directory where the link was present.

Safe delete. If this option is enabled, deleting files and directory hotlist entries unintentionally becomes more difficult. The default selection in the confirmation dialogs for deletion changes from **Yes** to **No**. This option is disabled by default.

Safe overwrite. If this option is enabled, overwriting files unintentionally becomes more difficult. The default selection in the overwrite confirmation dialog changes from **Yes** to **No**. This option is disabled by default.

Auto save setup. If this option is enabled, when you exit Midnight Commander, the configurable options of Midnight Commander are saved in the `~/config/mc/ini` file.

Layout

The layout dialog gives you a possibility to change the general layout of screen. The options in this dialog are divided into several groups: "Panel split", "Console output" and "Other options".

Panel split

The rest of the screen area is used for the two directory panels. You can specify whether the area is split to the panels in *Vertical* or *Horizontal* direction. Panel layout can be changed using `Alt-`, (`Alt-comma`) short-cut.

Equal split. By default, panels have equal sizes. Using this option you can specify an unequal split.

Console output

On the Linux or FreeBSD console you can specify how many lines are shown in the output window. This option is available if Midnight Commander runs on native console only.

Other options

Menu bar visible. If enabled, main menu of Midnight Commander is always visible on the top row of screen above panels. Enabled by default.

Command prompt. If enabled, command line is available. Enabled by default.

Keybar visible. If enabled, 10 labels associated with F1–F10 keys are located at the bottom row of screen. Enabled by default.

Hintbar visible. If enabled, the one-line hints are visible below panels. Enabled by default.

XTerm window title. When run in a terminal emulator for X11, Midnight Commander sets the terminal window title to the current working directory and updates it when necessary. If your terminal emulator is broken and you see some incorrect output on startup and directory change, turn off this option. Enabled by default.

Show free space. If enabled, free space and total space of current file system is shown at the bottom frame of panel. Enabled by default.

Panel options

Main panel options

Show mini-status. If enabled, one line of status information about the currently selected item is shown at the bottom of the panels. Enabled by default.

Use SI size units. If this option is enabled, Midnight Commander will use SI prefixes (base 10) when displaying any byte sizes. If disabled (default), Midnight Commander will use IEC prefixes (base 2).

Mix all files. If this option is enabled, all files and directories are shown mixed together. If the option is disabled (default), directories (and links to directories) are shown at the beginning of the listing, and other files below.

Show backup files. If enabled, Midnight Commander will show files ending with a tilde. Otherwise, they won't be shown (like GNU's `ls` option `-B`). Enabled by default.

Show hidden files. If enabled, Midnight Commander will show all files that start with a dot (like `ls -a`). Disabled by default.

Fast directory reload. If this option is enabled, Midnight Commander will use a trick to determine if the directory contents have changed. The trick is to reload the directory only if the `i`-node of the directory has changed; this means that reloads only happen when files are created or deleted. If what changes is the `i`-node for a file in the directory (file size changes, mode or owner changes, etc) the display is not updated. In these cases, if you have the option on, you have to rescan the directory manually (with `C-r`). Disabled by default.

Mark moves down. If enabled, the selection bar will move down when you mark a file (with `Insert` key).

Enabled by default.

Reverse files only. Allow revert selection of files only. Enabled by default. If enabled, the reverse selection is applied to files only, not to directories. The selection of directories is untouched. If off, the reverse selection is applied to files as well to directories: all unselected items become selected, and vice versa.

Simple swap. If both panels contain file listing, simple swap means that panels exchange its screen positions: left panel become right one, and vice versa. If this option is unchecked, file listing panels exchange its content keeping listing format and sort options. Unchecked by default.

Auto save panels setup. If this option is enabled, when you exit Midnight Commander, the current settings of panels are saved in the `~/.config/mc/panels.ini` file. Disabled by default.

Navigation

Lynx-like motion. If this option is enabled, you may use the arrows keys to automatically `chdir` if the current selection is a subdirectory and the shell command line is empty. By default, this setting is off.

Page scrolling. If set (the default), panel will scroll by half the display when the cursor reaches the end or the beginning of the panel, otherwise it will just scroll a file at a time.

Center scrolling. If set, panel will scroll when the cursor reaches the middle of the panel column, only hitting the top or bottom of the panel when actually on the first or last file. This behavior applies when scrolling one file at a time, and does not apply to the page up/down keys.

Mouse page scrolling. Controls whenever scrolling with the mouse wheel is done by pages or line by line on the panels.

File highlight

You can specify whether *permissions* and *file types* should be highlighted with distinctive Colors. If the permission highlighting is enabled, the parts of the *perm* and *mode* display fields which apply to the user running Midnight Commander are highlighted with the color defined by the *selected* keyword. If the file type highlighting is enabled, file names are colored according to rules described in `/usr/local/etc/mc/file-highlight.ini` file. See `Filenames Highlight` for more info.

Quick search

You can specify how the Quick search mode should work: case insensitively, case sensitively or be matched to the panel sort order: case sensitive or not.

Confirmation

In this dialog you configure the confirmation options for file deletion, overwriting files, execution by pressing enter, quitting the program, directory hotlist entries deletion and history cleanup.

Appearance

In this dialog you can select the skin to be used and enable shadow for dialogs and drop down menus.

See the `Skins` section for technical details about the skin definition files.

Shadows. If this option is enabled, all dialogs and drop down menus will have a shadow.

Display bits

This is used to configure the range of visible characters on the screen. This setting may be 7-bits if your terminal/curses supports only seven output bits, ISO-8859-1 displays all the characters in the ISO-8859-1 map and full 8 bits is for those terminals that can display full 8 bit characters.

Learn keys

This dialog allows you to test and redefine functional keys, cursor arrows and some other keys to make them work properly on your terminal. They often don't, since many terminal databases are incomplete or broken.

You can move around with the Tab key and with the vi moving keys ('h' left, 'j' down, 'k' up and 'l' right). Once you press any cursor movement key and it is recognized, you can use that key as well.

You can test keys just by pressing each of them. When you press a key and it is recognized properly, OK

should appear next to the name of that key. Once a key is marked OK it starts working as usually, e.g. F1 pressed the first time will just check that the F1 key works, but after that it will show help. The same applies to the arrow keys. The Tab key should be working always.

If some keys do not work properly then you won't see OK appear after pressing one of these. Then you may want to redefine it. Do it by pressing the button with the name of that key (either by the mouse or by Enter or Space after selecting the button with Tab or arrows). Then a message box will appear asking you to press that key. Do it and wait until the message box disappears. If you want to abort, just press Escape once and wait.

When you finish with all the keys, you can Save them. The definitions for the keys you have redefined will be written into the [terminal:TERM] section of your `~/.config/mc/ini` file (where TERM is the name of your current terminal). The definitions of the keys that were already working properly are not saved.

Virtual FS

This option gives you control over the settings of the Virtual File System.

Midnight Commander keeps in memory the information related to some of the virtual file systems to speed up the access to the files in the file system (for example, directory listings fetched from FTP servers).

Also, in order to access the contents of compressed files (for example, compressed tar files), Midnight Commander needs to create temporary uncompressed files on your disk.

Since both the information in memory and the temporary files on disk take up resources, you may want to tune the parameters of the cached information to decrease your resource usage or to maximize the speed of access to frequently used file systems.

Because of the format of the tar archives, the *Tar filesystem* needs to read the whole file just to load the file entries. Since most tar files are usually kept compressed (plain tar files are species in extinction), the tar file system has to uncompress the file on the disk in a temporary location and then access the uncompressed file as a regular tar file.

Now, since we all love to browse files and tar files all over the disk, it's common that you will leave a tar file and then re-enter it later. Since decompression is slow, Midnight Commander will cache the information in memory for a limited time. When the timeout expires, all the resources associated with the file system are released. The default timeout is set to one minute.

The FTP File System (ftpfs) allows you to browse directories on remote FTP servers. It has several options.

ftp anonymous password is the password used when you login as "anonymous". Some sites require a valid e-mail address. On the other hand, you probably don't want to give your real e-mail address to untrusted sites, especially if you are not using spam filtering.

ftpfs keeps the directory listing it fetches from a FTP server in a cache. The cache expire time is configurable with the *ftpfs directory cache timeout* option. A low value for this option may slow down every operation on the ftpfs because every operation would require sending a request to the FTP server.

You can define an FTP proxy host for doing FTP. Note that most modern firewalls are fully transparent at least for passive FTP (see below), so FTP proxies are considered obsolete.

If *Always use ftp proxy* is not set, you can use the exclamation sign to enable proxy for certain hosts. See FTP File System for examples.

If this option is set, the program will do two things: consult the `/usr/local/lib/mc/mc.no_proxy` file for lines containing host names that are local (if the host name starts with a dot, it is assumed to be a domain) and to assume that any hostnames without dots in their names are directly accessible. All other hosts will be accessed through the specified FTP proxy.

You can enable using `~/.netrc` file, which keeps login names and passwords for ftp servers. See netrc (5) for the description of the `.netrc` format.

Use passive mode enables using FTP passive mode, when the connection for data transfer is initiated by the client, not by the server. This option is recommended and enabled by default. If this option is turned off,

the data connection is initiated by the server. This may not work with some firewalls.

Save Setup

At startup, Midnight Commander tries to load initialization information from the `~/.config/mc/ini` file. If this file doesn't exist, the system-wide file `/usr/local/etc/mc/mc.ini` is used. If this file doesn't exist, the system-wide file `/usr/local/share/mc/mc.ini` is used. If this file doesn't exist, MC uses the default settings.

The *Save Setup* command creates the `~/.config/mc/ini` file by saving the current settings of the Left, Right and Options menus.

If you activate the *auto save setup* option, MC will always save the current settings when exiting.

There also exist settings which can't be changed from the menus. To change these settings you have to edit the setup file with your favorite editor. See the section on Special Settings for more information.

Executing operating system commands

You may execute commands by typing them directly in Midnight Commander's input line, or by selecting the program you want to execute with the selection bar in one of the panels and hitting Enter.

If you press Enter over a file that is not executable, Midnight Commander checks the extension of the selected file against the extensions in the Extensions File. If a match is found then the code associated with that extension is executed. A very simple macro expansion takes place before executing the command.

The `cd` internal command

The `cd` command is interpreted by Midnight Commander, it is not passed to the command shell for execution. Thus it may not handle all of the nice macro expansion and substitution that your shell does, although it does some of them:

Tilde substitution. The (`~`) will be substituted with your home directory, if you append a username after the tilde, then it will be substituted with the login directory of the specified user.

For example, `~guest` is the home directory for the user `guest`, while `~/guest` is the directory `guest` in your home directory.

Previous directory. You can jump to the directory you were previously by using the special directory name `'-'` like this: `cd -`

CDPATH directories. If the directory specified to the `cd` command is not in the current directory, then Midnight Commander uses the value in the environment variable **CDPATH** to search for the directory in any of the named directories.

For example you could set your **CDPATH** variable to `~/src:/usr/src`, allowing you to change your directory to any of the directories inside the `~/src` and `/usr/src` directories, from any place in the file system by using its relative name (for example `cd linux` could take you to `/usr/src/linux`).

Macro Substitution

When accessing a user menu, or executing an extension dependent command, or running a command from the command line input, a simple macro substitution takes place.

The macros are:

`%i` The indent of blank space, equal the cursor column position. For edit menu only.

`%y` The syntax type of current file. For edit menu only.

`%k` The block file name.

`%e` The error file name.

`%m` The current menu name.

`%f` and `%p`

In file manager user menu: the current file name in selected panel. In `mcedit` user menu: the name of opened file.

| | |
|-------------------------------------|--|
| <code>%x</code> | The extension of current file name. |
| <code>%b</code> | The current file name without extension. |
| <code>%d</code> | The current directory name. |
| <code>%F</code> | The current file in the unselected panel. |
| <code>%D</code> | The directory name of the unselected panel. |
| <code>%t</code> | The currently tagged files. |
| <code>%T</code> | The tagged files in the unselected panel. |
| <code>%u</code> and <code>%U</code> | Similar to the <code>%t</code> and <code>%T</code> macros, but in addition the files are untagged. You can use this macro only once per menu file entry or extension file entry, because next time there will be no tagged files. |
| <code>%s</code> and <code>%S</code> | The selected files: The tagged files if there are any. Otherwise the current file. |
| <code>%cd</code> | This is a special macro that is used to change the current directory to the directory specified in front of it. This is used primarily as an interface to the Virtual File System. |
| <code>%view</code> | This macro is used to invoke the internal viewer. This macro can be used alone, or with arguments. If you pass any arguments to this macro, they should be enclosed in brackets. The arguments are: <i>ascii</i> to force the viewer into ascii mode; <i>hex</i> to force the viewer into hex mode; <i>nroff</i> to tell the viewer that it should interpret the bold and underline sequences of nroff; <i>unformatted</i> to tell the viewer to not interpret nroff commands for making the text bold or underlined. |
| <code>%%</code> | The <code>%</code> character |
| <code>%{some text}</code> | Prompt for the substitution. An input box is shown and the text inside the braces is used as a prompt. The macro is substituted by the text typed by the user. The user can press Esc or F10 to cancel. This macro doesn't work on the command line yet. |
| <code>%var{ENV:default}</code> | If environment variable <i>ENV</i> is unset, the <i>default</i> is substituted. Otherwise, the value of <i>ENV</i> is substituted. |

The subshell support

The subshell support is a compile time option, that works with the shells: bash, ash (BusyBox and Debian), tcsh, zsh and fish.

When the subshell support is active, Midnight Commander will spawn a concurrent copy of your shell (the one defined in the **SHELL** variable and if it is not defined, then the one in the `/etc/passwd` file) and run it in a pseudo terminal, instead of invoking a new shell each time you execute a command, the command will be passed to the subshell as if you had typed it. This also allows you to change the environment variables, use shell functions and define aliases that are valid until you quit Midnight Commander.

bash users may specify startup commands in `~/.local/share/mc/bashrc` (fallback `~/.bashrc`) and special keyboard maps in `~/.local/share/mc/inputrc` (fallback `~/.inputrc`).

ash/dash users (BusyBox or Debian) may specify startup commands in `~/.local/share/mc/ashrc` (fallback `~/.profile`).

tcsh, zsh, fish users cannot specify mc-specific startup commands at present. They have to rely on shell-specific startup files.

The following paragraphs are relevant only when the subshell support is active:

You can suspend applications at any time with the sequence `C-o` and jump back to Midnight Commander, if you interrupt an application, you will not be able to run other external commands until you quit the

application you interrupted.

The basic prompt displayed by Midnight Commander is of the form "user@host:current_path\$ ". When using a capable shell, like Bash, the prompt displayed by Midnight Commander will be the same prompt that you are currently using in your shell.

(There's a known problem when using fish: the prompt is displayed only in full screen mode (Ctrl-o), not when the panels are visible.)

The OPTIONS section has more information on how you can control subshell usage (-U/-u). Furthermore, to set a specific subshell different from your current SHELL variable or login shell defined in /etc/passwd, you may call MC like this: **SHELL=/bin/myshell mc**

Chmod

The Chmod window is used to change the attribute bits in a group of files and directories. It can be invoked with the C-x c key combination.

The Chmod window has two parts – *Permissions* and *File*.

In the File section are displayed the name of the file or directory and its permissions in octal form, as well as its owner and group.

In the Permissions section there is a set of check buttons which correspond to the file attribute bits. As you change the attribute bits, you can see the octal value change in the File section.

To move between the widgets (buttons and check buttons) use the *arrow keys* or the *Tab* key. To change the state of the check buttons or to select a button use *Space*. You can also use the hotkeys on the buttons to quickly activate them. Hotkeys are shown as highlighted letters on the buttons.

To set the attribute bits, use the Enter key.

When working with a group of files or directories, you just click on the bits you want to set or clear. Once you have selected the bits you want to change, you select one of the action buttons (Set marked or Clear marked).

Finally, to set the attributes exactly to those specified, you can use the **[Set all]** button, which will act on all the tagged files.

[Marked all] set only marked attributes to all selected files

[Set marked] set marked bits in attributes of all selected files

[Clean marked] clear marked bits in attributes of all selected files

[Set] set the attributes of one file

[Cancel] cancel the Chmod command

Chown

The Chown command is used to change the owner/group of a file. The hot key for this command is C-x o.

Advanced Chown

The Advanced Chown command is the Chmod and Chown command combined into one window. You can change the permissions and owner/group of files at once.

Chattr

The Chattr window is used to change the attributes of a group of files and directories on a Linux file system. It can be invoked with the C-x e key combination.

Not all attributes are supported or utilized by all filesystems. List of available attribute flags is represented as a set of check buttons which correspond to the attribute flags (see **chattr(1)** for details). As you change the attribute flags, you can see the symbolic value change below file name.

To move between the widgets (buttons and check buttons) use the *arrow keys* or the *Tab* key. To change the state of the check buttons or to select a button use **Space**.

To set the attributes, use the Enter key.

When working with a group of files or directories, you just click on the flags you want to set or clear. Once you have selected the flags you want to change, you select one of the action buttons (Set marked or Clear marked).

Finally, to set the attributes exactly to those specified, you can use the **[Set all]** button, which will act on all the tagged files.

[Marked all] set only marked attributes to all selected files.

[Set marked] set marked flags in attributes of all selected files.

[Clean marked] clear marked flags in attributes of all selected files.

[Set] set the attributes of one file.

[Cancel] cancel the Chattr command.

File Operations

When you copy, move or delete files, Midnight Commander shows the file operations dialog. It shows the files currently being processed and uses up to three progress bars. The file bar indicates the percentage of the current file that has been processed so far. The count bar shows how many of the tagged files have been handled. The bytes bar indicates the percentage of the total size of the tagged files that has been handled. If the verbose option is off, the file and bytes bars are not shown.

There are two buttons at the bottom of the dialog. Pressing the Skip button will skip the rest of the current file. Pressing the Abort button will abort the whole operation, the rest of the files are skipped.

There are three other dialogs which you can run into during the file operations.

The error dialog informs about error conditions and has three choices. Normally you select either the Skip button to skip the file or the Abort button to abort the operation altogether. You can also select the Retry button if you fixed the problem from another terminal.

The replace dialog is shown when you attempt to copy or move a file on the top of an existing file. The dialog shows the dates and sizes of the both files. Press the Yes button to overwrite the file, the No button to skip the file, the All button to overwrite all the files, the None button to never overwrite and the Update button to overwrite if the source file is newer than the target file. You can abort the whole operation by pressing the Abort button.

The recursive delete dialog is shown when you try to delete a directory which is not empty. Press the Yes button to delete the directory recursively, the No button to skip the directory, the All button to delete all the directories and the None button to skip all the non-empty directories. You can abort the whole operation by pressing the Abort button. If you selected the Yes or All button you will be asked for a confirmation. Type "yes" only if you are really sure you want to do the recursive delete.

If you have tagged files and perform an operation on them only the files on which the operation succeeded are untagged. Failed and skipped files are left tagged.

Mask Copy/Rename

The copy/move operations let you translate the names of files in an easy way. To do it, you have to specify the correct source mask and usually in the trailing part of the destination specify some wildcards. All the files matching the source mask are copied/renamed according to the target mask. If there are tagged files, only the tagged files matching the source mask are renamed.

There are other options which you can set:

Follow links

determines whether make the symlinks and hardlinks in the source directory (recursively in subdirectories) new links in the target directory or whether would you like to copy their content.

Dive into subdirs

determines the behavior when the source directory is about to be copied, but the target directory already exists. The default action is to copy the contents of the source directory into the target directory. Enabling this option causes copying the source directory itself into the target directory.

For example, you want to copy directory */foo* containing file *bar* to */bla/foo*, which is an already existing directory. Normally (when **Dive into subdirs** is not set), mc would copy file */foo/bar* into the file */bla/foo/bar*. By enabling this option the */bla/foo/foo* directory will be created, and */foo/bar* will be copied into */bla/foo/foo/bar*.

Preserve attributes

determines whether to preserve the permissions, timestamps and (if you are root) the ownership of the original files. If this option is not set, the current value of the umask will be respected.

Use shell patterns

When this option is on you can use the '*' and '?' wildcards in the source mask. They work like they do in the shell. In the target mask only the '*' and '<digit>' wildcards are allowed. The first '*' wildcard in the target mask corresponds to the first wildcard group in the source mask, the second '*' corresponds to the second group and so on. The '\1' wildcard corresponds to the first wildcard group in the source mask, the '\2' wildcard corresponds to the second group and so on all the way up to '\9'. The '\0' wildcard is the whole filename of the source file.

Two examples:

If the source mask is "*.tar.gz", the destination is "/bla/*.tgz" and the file to be copied is "foo.tar.gz", the copy will be "foo.tgz" in "bla".

Suppose you want to swap basename and extension so that "file.c" would become "c.file" and so on. The source mask for this is "/*.*" and the destination is "\2.\1".

Use shell patterns off

When the shell patterns option is off the MC doesn't do automatic grouping anymore. You must use '\(...\)' expressions in the source mask to specify meaning for the wildcards in the target mask. This is more flexible but also requires more typing. Otherwise target masks are similar to the situation when the shell patterns option is on.

Two examples:

If the source mask is "\(.*)\tar\gz\$", the destination is "/bla/*.tgz" and the file to be copied is "foo.tar.gz", the copy will be "bla/foo.tgz".

Let's suppose you want to swap basename and extension so that "file.c" will become "c.file" and so on. The source mask for this is "\(.*)\(.*)\$" and the destination is "\2.\1".

Case Conversions

You can also change the case of the filenames. If you use 'u' or 'l' in the target mask, the next character will be converted to uppercase or lowercase correspondingly.

If you use 'U' or 'L' in the target mask, the next characters will be converted to uppercase or lowercase correspondingly up to the next 'E' or next 'U', 'L' or the end of the file name.

The 'u' and 'l' are stronger than 'U' and 'L'.

For example, if the source mask is '*' (*Use shell patterns* on) or '\(.*)\$' (*Use shell patterns* off) and the target mask is '\Lu*' the file names will be converted to have initial upper case and otherwise lower case.

You can also use '\' as a quote character. For example, '\\' is a backslash and '*' is an asterisk.

Stable symlinks

commands Midnight Commander, that it should change symlinks in the target, so that they'll point to the same location as it did before. With absolute symbolic links this does nothing, but if you have a relative one, it will recompute its value, adding necessary ../ and other directory parts and making the value as short as possible (most modern filesystems keep short symlinks inside inodes and thus don't waste much disk space).

Select/Unselect Files

The dialog of group of files and directories selection or unselection. The input line allow enter the regular expression of filenames that will be selected/unselected.

When *Files only* checkbox is on, only files will be selected. If *Files only* is off, as files as directories will be selected. When *Shell Patterns* checkbox is on, the regular expression is much like the filename globbing in the shell (* standing for zero or more characters and ? standing for one character). If *Shell Patterns* is off, then the tagging of files is done with normal regular expressions (see `ed (1)`). When *Case sensitive* checkbox is on, the selection will be case sensitive characters. If *Case sensitive* is off, the case will be ignored.

Internal Diff Viewer

The `mcdiff` is a visual diff tool. You can compare two files and edit them in-place (diffs are updated dynamically). You can browse and view a working copy from popular version control systems (GIT, Subversion, etc).

Following shortcuts are available in internal diff viewer of Midnight Commander.

- F1** Invoke the built-in hypertext help viewer.
- F2** Save modified files.
- F4** Edit file of the left panel in the internal editor.
- F14** Edit file of the right panel in the internal editor.
- F5** Merge the current hunk. Only the current hunk will be merged.
- F7** Start search.
- F17** Continue search.
- F10, Esc, q**
Exit from diff viewer.
- Alt-s, s**
Toggle show of hunk status.
- Alt-n, l**
Toggle show of line numbers.
- f** Maximize left panel.
- =** Make panels equal in width.
- >** Reduce the size of the right panel.
- <** Reduce the size of the left panel.
- c** Toggle show of trailing carriage return (CR) symbol as ^M.
- 2, 3, 4, 8**
Set tabulation size
- C-u** Swap contents of diff panels.
- C-r** Refresh the screen.
- C-o** Switch to the subshell and show the command screen.
- Enter, Space, n**
Find next diff hunk.
- Backspace, p**
Find previous diff hunk.
- g** Go to line.
- Down** Scroll one line forward.

Up Scroll one line backward.

PageUp
Move one page up.

PageDown
Moves one page down.

Home, A1
Moves to the line beginning.

End Moves to the line end.

C-Home
Move to the file beginning.

C-End, C1
Move to the file end.

Internal File Viewer

The internal file viewer provides two display modes: ASCII and hex. To toggle between modes, use the F4 key.

The viewer will try to use the best method provided by your system or the file type to display the information. Some character sequences, which appear most often in preformatted manual pages, are displayed bold and underlined, thus making a pretty display of your files.

When in hex mode, the search function accepts text in quotes and constant numbers. Text in quotes is matched exactly after removing the quotes. Each number matches one byte. You can mix quoted text with constants like this:

"String" 34 0xBB 012 "more text"

Numbers are always interpreted in hex. In the example above, "34" is interpreted as 0x34. The prefix "0x" isn't really needed: we could type "BB" instead of "0xBB". And "012" is interpreted as 0x12, not as an octal number.

Here is a listing of the actions associated with each key that the Midnight Commander handles in the internal file viewer.

F1 Invoke the built-in hypertext help viewer.

F2 Toggle the wrap mode.

F4 Toggle the hex mode.

F5 Goto. You can specify a line number, offset or percentage of file size of position that you want to view.

F7,/,? Start search. These keys call the dialog window that allows you to set up the search options. If key is ? the "Backwards" option is on.

C-s Continue forward search.

C-r Continue reverse search.

F17, n Continue search in the chosen direction.

N Temporary change the search direction: backwards if forward search is chosen, and vice versa.

F8 Toggle Raw/Parsed mode: This will show the file as found on disk or if a processing filter has been specified in the mc.ext file, then the output from the filter. Current mode is always the other than written on the button label, since on the button is the mode which you enter by that key.

F9 Toggle the format/unformat mode: when format mode is on the viewer will interpret some string sequences to show bold and underline with different colors. Also, on button label is the other mode than current.

F10, Esc.

Exit the internal file viewer.

PageDown, space, C-v.

Scroll one page forward.

PageUp, Alt-v, C-b, Backspace.

Scroll one page backward.

Down

Scroll one line forward.

Up

Scroll one line backward.

C-l

Refresh the screen.

C-o

Switch to the subshell and show the command screen.

[n] m

Set the mark n.

[n] r

Jump to the mark n.

C-f

Jump to the next file.

C-b

Jump to the previous file.

Alt-r

Toggle the ruler.

Alt-e

to change charset of displayed text may use Alt-e (M-e). Recoding is made from selected codepage into system codepage. To cancel the recoding you may select "<No translation>" in charset selection dialog.

It's possible to instruct the file viewer how to display a file, look at the Edit Extension File section

Internal File Editor

The internal file editor is a full-featured full screen editor. It can edit files up to 64 megabytes. It is possible to edit binary files. The internal file editor is invoked using **F4** if the `use_internal_edit` option is set in the initialization file.

The features it presently supports are: block copy, move, delete, cut, paste; key for key undo; pull-down menus; file insertion; macro commands; regular expression search and replace; S-arrow text highlighting (if supported by the terminal); insert-overwrite toggle; word wrap; autoindent; tunable tab size; syntax highlighting for various file types; and an option to pipe text blocks through shell commands like indent and ispell.

Sections:

Options of editor in ini-file

The editor is very easy to use and requires no tutoring. To see what keys do what, just consult the appropriate pull-down menu. Other keys are: Shift movement keys do text highlighting. **C-Ins** copies to the file **mcedit.clip** and **S-Ins** pastes from **mcedit.clip**. **S-Del** cuts to **mcedit.clip**, and **C-Del** deletes highlighted text. Mouse highlighting also works, and you can override the mouse as usual by holding down the shift key while dragging the mouse to let normal terminal mouse highlighting work.

To define a macro, press **C-R** and then type out the key strokes you want to be executed. Press **C-R** again when finished. You can then assign the macro to any key you like by pressing that key. The macro is executed when you press **C-A** and then the assigned key. The macro is also executed if you press Meta, Ctrl, or Esc and the assigned key, provided that the key is not used for any other function. Once defined, the macro commands go into the file `~/local/share/mc/mcedit/mcedit.macros`. You can delete a macro by deleting the appropriate line in this file.

To change charset of displayed text may use Alt-e (M-e). Recoding is made from selected codepage into system codepage. To cancel the recoding you may select "<No translation>" in charset selection dialog.

F19 will format the currently highlighted block (plain text or C or C++ code or another). This is controlled by the file `/usr/local/share/mc/edit.indent.rc` which is copied to `~/local/share/mc/mcedit/edit.indent.rc`

in your home directory the first time you use it.

The editor also displays non-us characters (160+). When editing binary files, you should set **display bits** to 7 bits in the options menu to keep the spacing clean.

Options of editor in ini-file

Some editor options of ini-file are described in this section. Options are placed in [Midnight-Commander] section

editor_wordcompletion_collect_entire_file

Search autocomplete candidates in entire of file or just from begin of file to cursor position (0)

Screen selector

Midnight Commander supports running many internal modules (such as editor, viewer and diff viewer) simultaneously and switching between them without closing open files. Using several file managers at a time, however, is not currently supported.

Let's call each of these modules a screen. There are three ways to switch between screens, using one of these global shortcuts:

Alt-} switch to the next screen;

Alt-{ switch to the previous screen;

Alt-' open a dialog window with the list of currently open screens (or use the "Screen list" menu item).

Completion

Let Midnight Commander type for you.

Attempt to perform completion on the text before current position. MC attempts completion treating the text as variable (if the text begins with \$), username (if the text begins with ~), hostname (if the text begins with @) or command (if you are on the command line in the position where you might type a command, possible completions then include shell reserved words and shell built-in commands as well) in turn. If none of these matches, filename completion is attempted.

Filename, username, variable and hostname completion works on all input lines, command completion is command line specific. If the completion is ambiguous (there are more different possibilities), MC beeps and the following action depends on the setting of the Complete: show all option in the Configuration dialog. If it is enabled, a list of all possibilities pops up next to the current position and you can select with the arrow keys and **Enter** the correct entry. You can also type the first letters in which the possibilities differ to move to a subset of all possibilities and complete as much as possible. If you press **Alt-Tab** again, only the subset will be shown in the listbox, otherwise the first item which matches all the previous characters will be highlighted. As soon as there is no ambiguity, dialog disappears, but you can hide it by canceling keys **Esc**, **F10** and left and right arrow keys. If Complete: show all is disabled, the dialog pops up only if you press **Alt-Tab** for the second time, for the first time MC just beeps.

Apply escaping of **?**, *****, and **&** symbols (as **\?**, *****, and **\&**) in filenames to disallow use them as metasymbols in regular expressions when substitution is performed in the input line.

Virtual File System

Midnight Commander is provided with a code layer to access the file system; this code layer is known as the virtual file system switch. The virtual file system switch allows Midnight Commander to manipulate files not located on the Unix file system.

Currently, Midnight Commander is packaged with some Virtual File Systems (VFS): the *local* file system, used for accessing the regular Unix file system; the *ftpfs*, used to manipulate files on remote systems with the FTP protocol; the *tarfs*, used to manipulate tar and compressed tar files; the *undelfs*, used to recover deleted files on ext2 file systems (the default file system for Linux systems), *fish* (for manipulating files over shell connections such as rsh and ssh). If the code was compiled with *sftpfs* (for manipulating files over SFTP connections). If the code was compiled with *smbfs* support, you can manipulate files on remote

systems with the SMB (CIFS) protocol.

A generic *extfs* (EXternal virtual File System) is provided in order to easily expand VFS capabilities using scripts and external software.

The VFS switch code will interpret all of the path names used and will forward them to the correct file system, the formats used for each one of the file systems is described later in their own section.

FTP File System

The FTP File System (ftpfs) allows you to manipulate files on remote machines. To actually use it, you can use the *FTP link* item in the menu or directly change your current directory using the *cd* command to a path name that looks like this:

```
ftp://[!][user[:pass]]@[machine[:port]][remote-dir]
```

The *user*, *port* and *remote-dir* elements are optional. If you specify the *user* element, Midnight Commander will login to the remote machine as that user, otherwise it will use anonymous login or the login name from the *~/.netrc* file. The optional *pass* element is the password used for the connection. Using the password in the VFS directory name is not recommended, because it can appear on the screen in clear text and can be saved to the directory history.

To enable using FTP proxy, prepend ! (an exclamation sign) to the hostname.

Examples:

```
ftp://ftp.nuclecu.unam.mx/linux/local
ftp://tsx-11.mit.edu/pub/linux/packages
ftp://!behind.firewall.edu/pub
ftp://guest@remote-host.com:40/pub
ftp://miguel:xxx@server/pub
```

Please check the Virtual File System dialog box for ftpfs options.

Tar File System

The tar file system provides you with read-only access to your tar files and compressed tar files by using the *chdir* command. To change your directory to a tar file, you change your current directory to the tar file by using the following syntax:

```
/filename.tar/utar://[dir-inside-tar]
```

The *mc.ext* file already provides a shortcut for tar files, this means that usually you just point to a tar file and press return to enter into the tar file, see the Edit Extension File section for details on how this is done.

Examples:

```
mc-3.0.tar.gz/utar://mc-3.0/vfs
/ftp/GCC/gcc-2.7.0.tar/utar://
```

The latter specifies the full path of the tar archive.

File transfer over SHell filesystem

The fish file system is a network based file system that allows you to manipulate the files in a remote machine as if they were local. To use this, the other side has to either run fish server, or has to have bash-compatible shell.

To connect to a remote machine, you just need to *chdir* into a special directory which name is in the following format:

```
sh://[user@]machine[:options]/[remote-dir]
```

The *user*, *options* and *remote-dir* elements are optional. If you specify the *user* element, Midnight Commander will try to login on the remote machine as that user, otherwise it will use your login name.

The available *options* are:

- 'C' – use compression;
- 'r' – use rsh instead of ssh;

`port` – specify the port used by remote server.
 If the `remote-dir` element is present, your current directory on the remote machine will be set to this one.

Examples:

```
sh://onlyrsh.mx:r/linux/local
sh://joe@want.compression.edu:C/private
sh://joe@noncompressed.ssh.edu/private
sh://joe@somehost.ssh.edu:2222/private
```

SFTP (SSH File Transfer Protocol) filesystem

The SFTP file system is a network based file system that allows you to manipulate the files in a remote machine as if they were local.

To connect to a remote machine, you just need to `chdir` into a special directory which name is in the following format:

```
sftp://[user@]machine:[port]/[remote-dir]
```

The `user`, `port` and `remote-dir` elements are optional. If you specify the `user` element, Midnight Commander will try to login on the remote machine as that user, otherwise it will use your login name. `port` – specify the port used by remote server (22 by default). If the `remote-dir` element is present, your current directory on the remote machine will be set to this one.

Examples:

```
sftp://onlyrsh.mx/linux/local
sftp://joe:password@want.compression.edu/private
sftp://joe@noncompressed.ssh.edu/private
sftp://joe@somehost.ssh.edu:2222/private
```

Undelete File System

On Linux systems, if you asked configure to use the ext2fs undelete facilities, you will have the undelete file system available. Recovery of deleted files is only available on ext2 file systems. The undelete file system is just an interface to the ext2fs library to retrieve all of the deleted files names on an ext2fs and provides and to extract the selected files into a regular partition.

To use this file system, you have to `chdir` into the special file name formed by the "undel://" prefix and the file name where the actual file system resides.

For example, to recover deleted files on the second partition of the first SCSI disk on Linux, you would use the following path name:

```
undel://sda2
```

It may take a while for the `undelfs` to load the required information before you start browsing files there.

SMB File System

The `smbfs` allows you to manipulate files on remote machines with SMB (or CIFS) protocol. These include Windows for Workgroups, Windows 9x/ME/XP, Windows NT, Windows 2000 and Samba. To actually use it, you may try to use the panel command "SMB link..." (accessible from the menubar) or you may directly change your current directory to it using the `cd` command to a path name that looks like this:

```
smb://[user@]machine[/service]/[remote-dir]
```

The `user`, `service` and `remote-dir` elements are optional. The `user`, `domain` and `password` can be specified in an input dialog.

Examples:

```
smb://machine/Share
smb://other_machine
smb://guest@machine/Public/Irlex
```

EXtErnal File System

extfs allows you to integrate numerous features and file types into GNU Midnight Commander in an easy way, by writing scripts.

Extfs filesystems can be divided into two categories:

1. Stand-alone filesystems, which are not associated with any existing file. They represent certain system-wide data as a directory tree. You can invoke them by typing `cd fsname://` where `fsname` is an extfs short name (see below). Examples of such filesystems include `audio` (list audio tracks on the CD) or `apt` (list of all Debian packages in the system).

For example, to list CD–Audio tracks on your CD–ROM drive, type

```
cd audio://
```

2. 'Archive' filesystems (like `rpm`, `patchfs` and more), which represent contents of a file as a directory tree. It can consist of 'real' files compressed in an archive (`urar`, `rpm`) or virtual files, like messages in a mailbox (`mailfs`) or parts of a patch (`patchfs`). To access such filesystems `fsname://` should be appended to the archive name. Note that the archive itself can be on another vfs.

For example, to list contents of a zip archive `documents.zip` type

```
cd documents.zip/uzip://
```

In many aspects, you could treat extfs like any other directory. For instance, you can add it to the hotlist or change to it from directory history. An important limitation is that you cannot invoke shell commands inside extfs, just like any other non-local VFS.

Common extfs scripts included with Midnight Commander are:

- a** access 'A:' DOS/Windows diskette (`cd a://`).
- apt** front end to Debian's APT package management system (`cd apt://`).
- audio** audio CD ripping and playing (`cd audio://` or `cd device/audio://`).
- bpp** package of Bad Penguin GNU/Linux distribution (`cd file.bpp/bpp://`).
- deb** package of Debian GNU/Linux distribution (`cd file.deb/deb://`).
- dpkg** Debian GNU/Linux installed packages (`cd deb://`).
- hp48** view and copy files to/from a HP48 calculator (`cd hp48://`).
- lsIR** browsing of lsIR listings as found on many FTPs (`cd filename/lsIR://`).
- mailfs** mbox-style mailbox files support (`cd mailbox/mailfs://`).
- patchfs**
extfs to handle unified and context diffs (`cd filename/patchfs://`).
- rpm** RPM package (`cd filename/rpm://`).
- rpms** RPM database management (`cd rpms://`).
- ulha, urar, uzip, uzoo, uar, uha**
archivers (`cd archive/xxxx://` where `xxxx` is one of: `ulha`, `urar`, `uzip`, `uzoo`, `uar`, `uha`).

You could bind file type/extension to specified extfs as described in the Edit Extension File section. Here is an example entry for Debian packages:

```
regex/.deb$
Open=%cd %p/deb://
```

Colors

Midnight Commander will try to detect if your terminal supports color using the terminal database and your terminal name. Sometimes it gets confused, so you may force color mode or disable color mode using the `-c` and `-b` flag respectively.

If the program is compiled with the S-Lang screen manager instead of ncurses, it will also check the

variable **COLORTERM**, if it is set, it has the same effect as the `-c` flag.

You may specify terminals that always force color mode by adding the *color_terminals* variable to the Colors section of the initialization file. This will prevent Midnight Commander from trying to detect if your terminal supports color. Example:

```
[Colors]
color_terminals=linux,xterm
color_terminals=terminal-name1,terminal-name2...
```

The program can be compiled with both ncurses and S-Lang, ncurses does not provide a way to force color mode: ncurses uses just the information in the terminal database.

Midnight Commander provides a way to change the default colors. Currently the colors are configured using the environment variable **MC_COLOR_TABLE** or the Colors section in the initialization file.

In the Colors section, the default color map is loaded from the *base_color* variable. You can specify an alternate color map for a terminal by using the terminal name as the key in this section. Example:

```
[Colors]
base_color=
xterm=menu=magenta:marked=,magenta:markselect=,red
```

The format for the color definition is:

```
<keyword>=<fgcolor>,<bgcolor>,<attributes>:<keyword>=...
```

The colors are optional, and the keywords are: normal, selected, disabled, marked, markselect, errors, input, inputmark, inputunchanged, commandlinemark, reverse, gauge, header, inputhistory, commandhistory. Button bar colors are: bbarhotkey, bbarbutton. Status bar color: statusbar. Menu colors are: menunormal, menusel, menuhot, menuhotsel, menuinactive. Dialog colors are: dnormal, dfocus, dhotnormal, dhotfocus, dttitle. Error dialog colors are: errdfocus, errdhotnormal, errdhotfocus, errdttitle. Help colors are: helpnormal, helpitalic, helpbold, helplink, helpslink, helptitle. Viewer colors are: viewnormal, viewbold, viewunderline, viewselected. Editor colors are: editnormal, editbold, editmarked, editwhitespace, editlinestate. Popup menu colors are: pmenunormal, pmenusel, pmenutitle.

header determines the color of panel header, the line that contains column titles and sort mode indicator.

input determines the color of input lines used in query dialogs.

gauge determines the color of the filled part of the progress bar (gauge), which is used to show the user the progress of file operations, such as copying.

disabled determines the color of the widget that cannot be selected.

The dialog boxes use the following colors: *dnormal* is used for the normal text, *dfocus* is the color used for the currently selected component, *dhotnormal* is the color used to differentiate the hotkey color in normal components, whereas the *dhotfocus* color is used for the highlighted color in the currently selected component.

Menus use the same scheme but uses the menunormal, menusel, menuhot, menuhotsel and menuinactive tags instead.

Help uses the following colors: *helpnormal* is used for normal text, *helpitalic* is used for text which is emphasized in italic in the manual page, *helpbold* is used for text which is emphasized in bold in the manual page, *helplink* is used for not selected hyperlinks and *helpslink* is used for selected hyperlink.

Popup menu uses following colors: *pmenunormal* is used for non-selected menu items and as a main color of popup menu window, *pmenusel* is used for selected menu item, *pmenutitle* is used for popup menu title.

The possible colors are: black, gray, red, brightred, green, brightgreen, brown, yellow, blue, brightblue, magenta, brightmagenta, cyan, brightcyan, lightgray and white. And there is a special keyword for transparent background. It is 'default'. The 'default' can only be used for background color. Another special keyword "base" means mc's main colors. When 256 colors are available, they can be specified either as color16 to color255, or as rgb000 to rgb555 and gray0 to gray23. Example:

[Colors]

base_color=normal=white,default:marked=magenta,default

Attributes can be any of bold, italic, underline, reverse and blink, appended by a plus sign if more than one are desired. The special word "none" means no attributes, without attempting to fall back to base_color.

Example:

menuhotsel=yellow:black:bold+underline

Skins

You can change the appearance of Midnight Commander. To do this, you must specify a file that contain descriptions of colors and lines to draw boxes. Redefining of the colors is entirely compatible with the assignment of colors, as described in Section Colors.

If your skin contains any true-color definitions, you should define the 'truecolors' key set to TRUE value in [skin] section. If true-color is not used but 256-color is, you should define '256colors' instead.

A skin-file is searched on the following algorithm (to the first one found):

- 1) command line option **-S <skin>** or **--skin=<skin>**
- 2) Environment variable **MC_SKIN**
- 3) Parameter **skin** in section **[Midnight-Commander]** in config file.
- 4) File **/usr/local/etc/mc/skins/default.ini**
- 5) File **/usr/local/share/mc/skins/default.ini**

Command line option, environment variable and parameter in config file may contain the absolute path to the skin-file (with the extension .ini or without it). Search of skin-file will occur in (to the first one found):

- 1) **~/local/share/mc/skins/**
- 2) **/usr/local/etc/mc/skins/**
- 3) **/usr/local/share/mc/skins/**

For getting extended info, refer to:

Description of section and parameters
Color pair definitions
Color and attribute aliases
Draw lines
Compatibility

Description of section and parameters

Section **[skin]** contain metainfo for skin-file. Parameter *description* contain short text about skin.

Section **[filehighlight]** contain descriptions of color pairs for filenames highlighting. Name of parameters must be equal to names of sections into filehighlight.ini file. See Filenames Highlight for getting more info.

Section **[core]** describes the elements that are used everywhere.

default

Default color pair. Used in all other sections if they not contain color definitions

selected

cursor

marked

selected data

markselect
 cursor on selected data

gauge color of the filled part of the progress bar

input color of input lines used in query dialogs

inputmark
 color of input selected text

inputunchanged
 color of input text before first modification or cursor movement

commandlinemark
 color of selected text in command line

reverse reverse color

Section **[dialog]** describes the elements that are placed on dialog windows (except error dialogs).

default
 Default color for this section. Used [core]._default_ if not specified

dfocus Color of active element (in focus)

dhotnormal
 Color of hotkeys

dhotfocus
 Color of hotkeys in focused element

Section **[error]** describes the elements that are placed on error dialog windows

default
 Default color for this section. Used [core]._default_ if not specified

errdhotnormal
 Color of hotkeys

errdhotfocus
 Color of hotkeys in focused element

Section **[menu]** describes the elements that are placed in menu. This section describes system menu (called by F9) and user-defined menus (called by F2 in panels and by F11 in editor).

default
 Default color for this section. Used [core]._default_ if not specified

entry Color of menu items

menuhot
 Color of menu hotkeys

menusel
 Color of active menu item (in focus)

menuhotsel
 Color of menu hotkeys in focused menu item

menuinactive
 Color of inactive menu

Section **[help]** describes the elements that are placed on help window.

default
Default color for this section. Used [core]._default_ if not specified

helpitalic
Color pair for element with **italic** attribute

helpbold
Color pair for element with **bold** attribute

helplink
Color of links

helpslink
Color of active link (on focus)

Section [**editor**] describes the colors of elements placed in editor.

default
Default color for this section. Used [core]._default_ if not specified

editbold
Color pair for element with **bold** attribute

editmarked
Color of selected text

editwhitespace
Color of tabs and trailing spaces highlighting

editlinestate
Color for line state area

Section [**viewer**] describes the colors of elements placed in viewer.

viewunderline
Color pair for element with **underline** attribute

Color pair definitions

Any parameter in skin-file contain definition of color pair.

Color pairs described as two colors and the optional attributes separated by ';'. First field sets the foreground color, second field sets background color, third field sets the attributes. Any of the fields may be omitted, in this case value will be taken from default color pair (global color pair or from default color pair of this section).

Example:

```
[core]
# green on black
_default_=green:black
# green (default) on blue
selected=;blue
# yellow on black (default)
# underlined yellow on black (default)
marked=yellow;;underline
```

Possible colors (names) and attributes are described in Colors. section.

Color and attribute aliases

This optional section might define aliases for single colors (not color pairs) as well as combination of attributes; in other words, for semicolon-separated fragments of parameters. Aliases can refer to other

aliases as long as they don't form a loop.

Example:

```
[aliases]
  myfavfg=green
  myfavbg=black
  myfavattr=bold+italic
[core]
  _default_=myfavfg;myfavbg;myfavattr
```

Draw lines

Lines sets in section **[Lines]** into skin-file. By default single lines are used, but you may redefine to usage of any utf-8 symbols (like to lines, for example).

WARNING!!! When you build Midnight Commander with the ncurses screen library usage of drawing lines is limited! Possible only drawing a single lines. For all questions and comments please contact the developers of ncurses.

Descriptions of parameters **[Lines]**:

lefttop left-top line fragment.

righttop right-top line fragment.

centertop down branch of horizontal line

centerbottom up branch of horizontal line

leftbottom left-bottom line fragment

rightbottom right-bottom line fragment

leftmiddle right branch of vertical line

rightmiddle left branch of vertical line

centermiddle cross of lines

horiz horizontal line

vert vertical line

thinhoriz thin horizontal line

thinvert thin vertical line

Compatibility

Appointment of color by skin-files fully compatible with the appointment of the colors described in Colors. section.

In this case, reassignment of colors has priority over the skin file and is complementary.

Filenames Highlight

Section [filehighlight] in current skin-file contains key names as highlight groups and values as color pairs. Color pairs is documented in Skins section.

Rules of filenames highlight are placed in /usr/local/share/mc/filehighlight.ini file (~/.config/mc/filehighlight.ini). Name of section in this file must be equal to parameters names in [filehighlight] section (in current skin-file).

Keys in these groups are:

type file type. If present, all other options are ignored.

regexp regular expression. If present, 'extensions' option is ignored.

extensions

list of extensions of files. Separated by ';' sign.

extensions_case

(make sense only with 'extensions' parameter) make 'extensions' rule case sensitive (true) or not (false).

'type' key may have values:

- FILE (all files)
- FILE_EXE
- DIR (all directories)
- LINK_DIR
- LINK (all links except stale link)
- HARDLINK
- SYMLINK
- STALE_LINK
- DEVICE (all device files)
- DEVICE_BLOCK
- DEVICE_CHAR
- SPECIAL (all special files)
- SPECIAL_SOCKET
- SPECIAL_FIFO
- SPECIAL_DOOR

Special Settings

Most of Midnight Commander settings can be changed from the menus. However, there are a small number of settings which can only be changed by editing the setup file.

These variables may be set in your ~/.config/mc/ini file:

clear_before_exec

By default, Midnight Commander clears the screen before executing a command. If you would prefer to see the output of the command at the bottom of the screen, edit your ~/.config/mc/ini file and change the value of the field clear_before_exec to 0.

confirm_view_dir

If you press F3 on a directory, normally MC enters that directory. If this flag is set to 1, then MC will ask for confirmation before changing the directory if you have files tagged.

ftpfs_retry_seconds

This value is the number of seconds Midnight Commander will wait before attempting to reconnect to an FTP server that has denied the login. If the value is zero, the login will no be retried.

max_dirt_limit

Specifies how many screen updates can be skipped at most in the internal file viewer. Normally this value is not significant, because the code automatically adjusts the number of updates to skip according to the rate of incoming keystrokes. However, on very slow machines or terminals with a fast keyboard auto repeat, a big value can make screen updates too jumpy.

It seems that setting `max_dirt_limit` to 10 causes the best behavior, and that is the default value.

mouse_move_pages_viewer

Controls if scrolling with the mouse is done by pages or line by line on the internal file viewer.

only_leading_plus_minus

Allow special treatment for '+', '-', '*' in the command line (select, unselect, reverse selection) only if the command line is empty. You don't need to quote those characters in the middle of the command line. On the other hand, you cannot use them to change selection when the command line is not empty.

alternate_plus_minus

If true, use '+', '-', '\` and '*' keys normally. For select/unselect, use 'Alt++', 'Alt--' and 'Alt-*'.

show_output_starts_shell

This variable only works if you are not using the subshell support. When you use the C-o key-stroke to go back to the user screen, if this one is set, you will get a fresh shell. Otherwise, pressing any key will bring you back to Midnight Commander.

timeformat_recent

Change the time format used to display dates less than 6 months from now. See `strftime` or `date` man page for the format specification. If this option is absent, default `timeformat` is used.

timeformat_old

Change the time format used to display dates older than 6 months from now or for dates in the future. See `strftime` or `date` man page for the format specification. If this option is absent, default `timeformat` is used.

torben_fj_mode

If this flag is set, then the home and end keys will work slightly different on the panels, instead of moving the selection to the first and last files in the panels, they will act as follows:

The home key will: Go up to the middle line, if below it; else go to the top line unless it is already on the top line, in this case it will go to the first file in the panel.

The end key has a similar behavior: Go down to the middle line, if over it; else go to the bottom line unless you already are at the bottom line, in such case it will move the selection to the last file name in the panel.

use_file_to_guess_type

If this variable is on (the default) it will spawn the `file` command to match the file types listed on the `mc.ext` file.

xtree_mode

If this variable is on (default is off) when you browse the file system on a Tree panel, it will automatically reload the other panel with the contents of the selected directory.

fish_directory_timeout

This variable holds the lifetime of a directory cache entry in seconds. The default value is 900 seconds.

clipboard_store

This variable contains path (with options) to the external clipboard utility like `xclip` to read text into X selection from file. For example:

```
clipboard_store=xclip -i
```

clipboard_paste

This variable contains path (with options) to the external clipboard utility like `xclip` to print the selection to standard out. For example:

```
clipboard_paste=xclip -o
```

autodetect_codeset

This option allows use the 'enca' command to autodetect codeset of text files in internal viewer and editor. List of valid values can be obtain by the 'enca --list languages | cut -d : -f1' command. Option must be located in the [Misc] section.

For example:

```
autodetect_codeset=russian
```

Parameters for external editor or viewer

Midnight Commander provides a way for specify an options for external editors and viewers. Midnight Commander tries to search the "[External editor or viewer parameters]" section in the system initialization file (the mc.lib file located in Midnight Commander's library directory) and then in the ~/.config/mc/ini file. The option name should be equal to the name (full pathname) of external editor or viewer. The option value can contain following variables:

%filename

The filename to edit/view.

%lineno

The start line in the opening file.

For example:

```
[External editor or viewer parameters]
```

```
vi=%filename +%lineno
```

```
joe=%filename +%lineno
```

```
more=%filename +%lineno
```

Start line is passed to the external editor/viewer only if it is called from the Find file results window.

If external editor/viewer is launched via F4/F3 keys, MC hopes that program (at least "joe", but probably others too) has an own feature that by default opens the file where it was last open. MC doesn't prevent external editor/viewer to save and restore position in opened files.

Terminal databases

Midnight Commander provides a way to fix your system terminal database without requiring root privileges. Midnight Commander searches in the system initialization file (the mc.lib file located in Midnight Commander's library directory) and in the ~/.config/mc/ini file for the section "terminal:your-terminal-name" and then for the section "terminal:general", each line of the section contains a key symbol that you want to define, followed by an equal sign and the definition for the key. You can use the special \e form to represent the escape character and the ^x to represent the control-x character.

The possible key symbols are:

f0 to f20 Function keys f0-f20

bs backspace

home home key

end end key

up up arrow key

down down arrow key

left left arrow key

right right arrow key

pgdn page down key

pgup page up key

insert the insert character

delete the delete character

complete to do completion

For example, to define the key insert to be the Escape + [+ O + p, you set this in the ini file:

```
insert=\e[Op
```

Also now you can use *extended learn keys*. For example:

```
ctrl-alt-right=\e[[1;6C
ctrl-alt-left=\e[[1;6D
```

This means that ctrl+alt+left sends a `\e[[1;6D` escape sequence and therefore Midnight Commander interprets `"\e[[1;6D"` as C-Alt-Left.

The *complete* key symbol represents the escape sequences used to invoke the completion process, this is invoked with Alt-tab, but you can define other keys to do the same work (on those keyboard with tons of nice and unused keys everywhere).

FILES

Full paths below may vary between installations. They are also affected by the **MC_DATADIR** environment variable. If it's set, its value is used instead of `/usr/local/share/mc` in the paths below.

`/usr/local/share/mc/help/mc.hlp`

The help file for the program.

`/usr/local/share/mc/mc.ext`

The default system-wide extensions file.

`~/.config/mc/mc.ext`

User's own extension, view configuration and edit configuration file. They override the contents of the system wide files if present.

`/usr/local/etc/mc/mc.ini`

`/usr/local/share/mc/mc.ini`

System-wide setup files for Midnight Commander, used only if the user doesn't have his own `~/.config/mc.ini` file. If `/usr/local/etc/mc/mc.ini` exists, `/usr/local/share/mc/mc.ini` isn't used.

`/usr/local/share/mc/mc.lib`

Global settings for Midnight Commander. Settings in this file affect all users, whether they have `~/.config/mc.ini` or not. Currently, only terminal settings are loaded from `mc.lib`.

`~/.config/mc/ini`

User's own setup. If this file is present then the setup is loaded from here instead of the system-wide startup file.

`/usr/local/share/mc/hints/mc.hint`

This file contains the hints displayed by the program.

`/usr/local/share/mc/mc.menu`

This file contains the default system-wide applications menu.

`~/.config/mc/menu`

User's own application menu. If this file is present it is used instead of the system-wide applications menu.

`~/.cache/mc/Tree`

The directory list for the directory tree and tree view features.

`~/.local/share/mc.menu`

Local user-defined menu. If this file is present, it is used instead of the home or system-wide applications menu.

To change default root directory of MC, you can use **MC_PROFILE_ROOT** environment variable. The value of **MC_PROFILE_ROOT** must be an absolute path. If **MC_PROFILE_ROOT** is unset or empty, **HOME** variable is used. If **HOME** is unset or empty, MC directories are get from GLib library.

LICENSE

This program is distributed under the terms of the GNU General Public License as published by the Free Software Foundation. See the built-in help for details on the License and the lack of warranty.

AVAILABILITY

The latest version of this program can be found at <http://ftp.midnight-commander.org/>.

SEE ALSO

`ed(1)`, `gpm(1)`, `terminfo(1)`, `view(1)`, `sh(1)`, `bash(1)`, `tcsh(1)`, `zsh(1)`.

Midnight Commander's page on the World Wide Web:

<http://www.midnight-commander.org/>

AUTHORS

Authors and contributors are listed in the **AUTHORS** file in the source distribution.

BUGS

See the file **TODO** in the distribution for information on what remains to be done.

If you want to report a problem with the program, please create bugreport at <http://www.midnight-commander.org/>.

Provide a detailed description of the bug, the version of the program you are running (*mc -V* displays this information), the operating system you are running the program on. If the program crashes, we would appreciate a stack trace.

NAME

`mcedit` – Internal file editor of GNU Midnight Commander.

SYNOPSIS

`mcedit` [`-bcDfhstVx?`] [`+lineno`] [`file1`] [`file2`] ...

`mcedit` [`-bcDfhstVx?`] `file1:lineno[:]` `file2:lineno[:]` ...

DESCRIPTION

`mcedit` is a link to **mc**, the main GNU Midnight Commander executable. Executing GNU Midnight Commander under this name runs the internal editor and opens files specified on the command line. The editor is based on the terminal version of **cooledit** – standalone editor for X Window System.

OPTIONS

`+lineno`

Go to the line specified by number (do not put a space between the + sign and the number). Several line numbers are allowed but only the last one will be used, and it will be applied to the first file only.

`-b` Force black and white display.

`-c` Force ANSI color mode on terminals that don't seem to have color support.

`-C` `<keyword>=<fgcolor>,<bgcolor>,<attributes>:<keyword>= ...`
Specify a different color set. See the **Colors** section in `mc(1)` for more information.

`-d` Disable mouse support.

`-f` Display the compiled-in search path for GNU Midnight Commander data files.

`-t` Force using termcap database instead of terminfo. This option is only applicable if GNU Midnight Commander was compiled with S-Lang library with terminfo support.

`-V` Display the version of the program.

`-x` Force xterm mode. Used when running on xterm-capable terminals (two screen modes, and able to send mouse escape sequences).

FEATURES

The internal file editor is a full-featured windowed editor. It can edit several files at the same time. Maximum size of each file is 64 megabytes. It is possible to edit binary files. The features it presently supports are: block copy, move, delete, cut, paste; key for key undo; pull-down menus; file insertion; macro commands; regular expression search and replace; shift-arrow text highlighting (if supported by the terminal); insert-overwrite toggle; autoindent; tunable tab size; syntax highlighting for various file types; and an option to pipe text blocks through shell commands like `indent` and `ispell`.

Each file is opened in its own window in full-screen mode. Window control in `mcedit` is similar to the window control in other multi-window program: double click on window title maximizes the window to full-screen or restores window size and position; left-click on window title and mouse drag moves the window in editor area; left-click on low-right frame corner and mouse drag resizes the window. These actions can be made using "Window" menu.

KEYS

The editor is easy to use and can be used without learning. The pull-down menu is invoked by pressing F9. You can learn other keys from the menu and from the button bar labels.

In addition to that, Shift combined with arrows does text highlighting (if supported by the terminal): **Ctrl-Ins** copies to the file `~/cache/mc/mcedit/mcedit.clip`, **Shift-Ins** pastes from `~/cache/mc/mcedit/mcedit.clip`, **Shift-Del** cuts to `~/cache/mc/mcedit/mcedit.clip`, and **Ctrl-Del** deletes highlighted text. Mouse highlighting also works on some terminals. To use the standard mouse support provided by your terminal, hold the Shift key. Please note that the mouse support in the terminal doesn't share the clipboard with **mcedit**.

The completion key (usually **Meta-Tab** or **Escape Tab**) completes the word under the cursor using the words used in the file.

MACRO

To define a macro, press **Ctrl-R** and then type out the keys you want to be executed. Press **Ctrl-R** again when finished. The macro can be assigned to any key by pressing that key. The macro is executed when you press the assigned key.

The macro commands are stored in section **[editor]** in the file `~/.local/share/mc/mc.macros`.

External scripts (filters) can be assigned into the any hotkey by edit **mc.macros** like following:

```
[editor]
ctrl-W=ExecuteScript:25;
```

This means that `ctrl-W` hotkey initiates the *ExecuteScript(25)* action, then editor handler translates this into execution of `~/.local/share/mc/mcedit/macros.d/macro.25.sh` shell script.

External scripts are stored in `~/.local/share/mc/mcedit/macros.d/` directory and must be named as **macro.XXXX.sh** where **XXXX** is the number from 0 to 9999. See **Edit Menu File** for more detail about format of the script.

Following macro definition and directives can be used:

#silent If this directive is set, then script starts without interactive subshell.

%c The cursor column position number.

%i The indent of blank space, equal the cursor column.

%y The syntax type of current file.

%b The block file name.

%f The current file name.

%n Only the current file name without extension.

%x The extension of current file name.

%d The current directory name.

%F The current file in the unselected panel.

%D The directory name of the unselected panel.

%t The currently tagged files.

%T The tagged files in the unselected panel.

%u and **%U**

Similar to the **%t** and **%T** macros, but in addition the files are untagged. You can use this macro only once per menu file entry or extension file entry, because next time there will be no tagged files.

%s and **%S**

The selected files: The tagged files if there are any. Otherwise the current file.

Feel free to edit this files, if you need. Here is a sample external script:

```
1 comment selection
   TMPFILE='mktemp ${MC_TMPDIR:-/tmp}/up.XXXXXX' || exit 1
   echo #if 0 > $TMPFILE
   cat %b >> $TMPFILE
   echo #endif >> $TMPFILE
   cat $TMPFILE > %b
   rm -f $TMPFILE
```

If some keys don't work, you can use **Learn Keys** in the **Options** menu.

CODE NAVIGATION

mcedit can be used for navigation through code with tags files created by `etags` or `ctags` commands. If there is no TAGS file code navigation will not work. For example, in case of `exuberant-ctags` for C language command will be:

```
ctags -e --language-force=C -R ./
```

Meta-Enter shows list box to select item under cursor (cursor should stand at the end of the word).

Meta-Minus where minus is symbol "-" goes to previous function in navigation list (like browser's Back button).

Meta-Equal where equal is symbol "=" goes to next function in navigation list (like browser's Forward button).

SYNTAX HIGHLIGHTING

mcedit supports syntax highlighting. This means that keywords and contexts (like C comments, string constants, etc) are highlighted in different colors. The following section explains the format of the file `~/.config/mc/mcedit/Syntax`. If this file is missing, system-wide `/usr/local/share/mc/syntax/Syntax` is used. The file `~/.config/mc/mcedit/Syntax` is rescanned on opening of every new editor file. The file contains rules for highlighting, each of which is given on a separate line, and define which keywords will be highlighted with what color.

The file is divided into sections, each beginning with a line with the **file** command. The sections are normally put into separate files using the **include** command.

The **file** command has three arguments. The first argument is a regular expression that is applied to the file name to determine if the following section applies to the file. The second argument is the description of the file type. It is used in **cooledit**; future versions of **mcedit** may use it as well. The third optional argument is a regular expression to match the first line of text of the file. The rules in the following section apply if either the file name or the first line of text matches.

A section ends with the start of another section. Each section is divided into contexts, and each context contains rules. A context is a scope within the text that a particular set of rules belongs to. For instance, the text within a C style comment (i.e. between `/*` and `*/`) has its own color. This is a context, although it has no further rules inside it because there is probably nothing that we want highlighted within a C comment.

A trivial C programming section might look like this:

```
file .*\\c C\\sProgram\\sFile (#include|/\\\\*)
```

```
wholechars abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ_
```

```
# default colors
```

```
define comment brown
```

```
context default
```

```
keyword whole if yellow
keyword whole else yellow
keyword whole for yellow
keyword whole while yellow
keyword whole do yellow
keyword whole switch yellow
keyword whole case yellow
keyword whole static yellow
keyword whole extern yellow
keyword { brightcyan
keyword } brightcyan
keyword '*' green
```

```
# C comments
context /\* \*/ comment
```

```
# C preprocessor directives
context linestart # \n red
keyword \\n brightred
```

```
# C string constants
context " " green
keyword %d brightgreen
keyword %s brightgreen
keyword %c brightgreen
keyword \" brightgreen
```

Each context starts with a line of the form:

```
context [exclusive] [whole|wholeright|wholeleft] [linestart] delim [linestart] delim [foreground] [background] [attributes]
```

The first context is an exception. It must start with the command

```
context default [foreground] [background] [attributes]
```

otherwise **mcedit** will report an error. The **linestart** option specifies that *delim* must start at the beginning of a line. The **whole** option tells that *delim* must be a whole word. To specify that a word must begin on the word boundary only on the left side, you can use the **wholeleft** option, and similarly a word that must end on the word boundary is specified by **wholeright**.

The set of characters that constitute a whole word can be changed at any point in the file with the **wholechars** command. The left and right set of characters can be set separately with

```
wholechars [left|right] characters
```

The **exclusive** option causes the text between the delimiters to be highlighted, but not the delimiters themselves.

Each rule is a line of the form:

```
keyword [whole|wholeright|wholeleft] [linestart] string foreground [background] [attributes]
```

Context or keyword strings are interpreted, so that you can include tabs and spaces with the sequences `\t` and `\s`. Newlines and backslashes are specified with `\n` and `\\` respectively. Since whitespace is used as a separator, it may not be used as is. Also, `*` must be used to specify an asterisk. The `*` itself is a wildcard that matches any length of characters. For example,

```
keyword      '* '    green
```

colors all C single character constants green. You also could use

```
keyword      "*"    green
```

to color string constants, but the matched string would not be allowed to span across multiple newlines. The wildcard may be used within context delimiters as well, but you cannot have a wildcard as the last or first character.

Important to note is the line

```
keyword \\n brightgreen
```

This line defines a keyword containing the backslash and newline characters. Since the keywords are matched before the context delimiters, this keyword prevents the context from ending at the end of the lines that end in a backslash, thus allowing C preprocessor directive to continue across multiple lines.

The possible colors are: black, gray, red, brightred, green, brightgreen, brown, yellow, blue, brightblue, magenta, brightmagenta, cyan, brightcyan, lightgray and white. The special keyword "default" means the terminal's default. Another special keyword "base" means mc's main colors, it is useful as a placeholder if

you want to specify attributes without modifying the background color. When 256 colors are available, they can be specified either as color16 to color255, or as rgb000 to rgb555 and gray0 to gray23.

If the syntax file is shared with **cooledit**, it is possible to specify different colors for **mcedit** and **cooledit** by separating them with a slash, e.g.

```
keyword #include red/Orange
```

mcedit uses the color before the slash. See cooledit(1) for supported **cooledit** colors.

Attributes can be any of bold, italic, underline, reverse and blink, appended by a plus sign if more than one are desired.

Comments may be put on a separate line starting with the hash sign (#).

If you are describing case insensitive language you need to use **caseinsensitive** directive. It should be specified at the beginning of syntax file.

Because of the simplicity of the implementation, there are a few intricacies that will not be dealt with correctly but these are a minor irritation. On the whole, a broad spectrum of quite complicated situations are handled with these simple rules. It is a good idea to take a look at the syntax file to see some of the nifty tricks you can do with a little imagination. If you cannot get by with the rules I have coded, and you think you have a rule that would be useful, please email me with your request. However, do not ask for regular expression support, because this is flatly impossible.

A useful hint is to work with as much as possible with the things you can do rather than try to do things that this implementation cannot deal with. Also remember that the aim of syntax highlighting is to make programming less prone to error, not to make code look pretty.

The syntax highlighting can be toggled using Ctrl-s shortcut.

COLORS

The default colors may be changed by appending to the **MC_COLOR_TABLE** environment variable. Foreground and background colors pairs may be specified for example with:

```
MC_COLOR_TABLE="$MC_COLOR_TABLE:\
editnormal=lightgray,black:\
editbold=yellow,black:\
editmarked=black,cyan"
```

OPTIONS

Most options can be set from Options dialog box. See the **Options** menu. The following options are defined in **./config/mc/ini** and have obvious counterparts in the dialog box. You can modify them to change the editor behavior, by editing the file. Unless specified, a 1 sets the option to on, and a 0 sets it to off, as usual.

use_internal_edit

This option is ignored when invoking **mcedit**.

editor_tab_spacing

Interpret the tab character as being of this length. Default is 8. You should avoid using other than 8 since most other editors and text viewers assume a tab spacing of 8. Use **editor_fake_half_tabs** to simulate a smaller tab spacing.

editor_fill_tabs_with_spaces

Never insert a tab character. Rather insert spaces (ascii 32) to fill to the desired tab size.

editor_return_does_auto_indent

Pressing return will tab across to match the indentation of the first line above that has text on it.

editor_backspace_through_tabs

Make a single backspace delete all the space to the left margin if there is no text between the cursor and the left margin.

editor_fake_half_tabs

This will emulate a half tab for those who want to program with a tab spacing of 4, but do not want the tab size changed from 8 (so that the code will be formatted the same when displayed by other programs). When editing between text and the left margin, moving and tabbing will be as though a tab space were 4, while actually using spaces and normal tabs for an optimal fill. When editing anywhere else, a normal tab is inserted.

editor_option_save_mode

Possible values 0, 1 and 2. The save mode (see the options menu also) allows you to change the method of saving a file. Quick save (0) saves the file immediately, truncating the disk file to zero length (i.e. erasing it) and then writing the editor contents to the file. This method is fast, but dangerous, since a system error during a file save will leave the file only partially written, possibly rendering the data irretrievable. When saving, the safe save (1) option enables creation of a temporary file into which the file contents are first written. In the event of a problem, the original file is untouched. When the temporary file is successfully written, it is renamed to the name of the original file, thus replacing it. The safest method is create backups (2): a backup file is created before any changes are made. You can specify your own backup file extension in the dialog. Note that saving twice will replace your backup as well as your original file.

editor_word_wrap_line_length

Line length to wrap at. Default is 72.

editor_backup_extension

Symbol to add to name of backup files. Default is "~".

editor_line_state

Show state line of editor. Currently it shows current line number (in the future it might show things like folding, breakpoints, etc.). M-n toggles this option.

editor_visible_spaces

Toggle "show visible trailing spaces". If editor_visible_spaces=1, they are shown as ' '.

editor_visible_tabs

Toggle "show visible tabs". If editor_visible_tabs=1, tabs are shown as '<---->'.

editor_persistent_selections

Do not remove block selection after cursor movement.

editor_drop_selection_on_copy

Reset selection after copy to clipboard.

editor_cursor_beyond_eol

Allow moving cursor beyond the end of line.

editor_cursor_after_inserted_block

Allow moving cursor after inserted block.

editor_syntax_highlighting

enable syntax highlighting.

editor_edit_confirm_save

Show confirmation dialog on save.

editor_option_ttypewriter_wrap

to be described

editor_option_auto_para_formatting

to be described

editor_option_save_position

Save file position on exit.

source_codepage

Symbol representation of codepage name for file (i.e. CP1251, ~ – default).

editor_group_undo

Combine UNDO actions for several of the same type of action (inserting/overwriting, deleting, navigating, typing)

editor_wordcompletion_collect_entire_file

Search autocomplete candidates in entire file (1) or just from beginning of file to cursor position (0).

spell_language

Spelling language (en, en-variant_0, ru, etc) installed with aspell package (a full list can be obtained using 'aspell' utility). Use **spell_language = NONE** to disable aspell support. Default value is 'en'. Option must be located in the [Misc] section.

editor_stop_format_chars

Set of characters to stop paragraph formatting. If one of those characters is found in the beginning of line, that line and all following lines of paragraph will be untouched. Default value is "-+*,\.,:;>".

editor_state_full_filename

Show full path name in the status line. If disabled (default), only base name of the file is shown.

MISCELLANEOUS

The editor also displays non-us characters (160+). When editing binary files, you should set **display bits** to 7 bits in Midnight Commander's options menu to keep the spacing clean.

FILES

/usr/local/share/mc/help/mc.hlp

The help file for the program.

/usr/local/share/mc/mc.ini

The default system-wide setup for GNU Midnight Commander, used only if the user's own *~/config/mc/ini* file is missing.

/usr/local/share/mc/mc.lib

Global settings for Midnight Commander. Settings in this file affect all users, whether they have *~/config/mc/ini* or not.

*/usr/local/share/mc/syntax/**

The default system-wide syntax files for mcedit, used only if the corresponding user's own *~/local/share/mc/mcedit/* file is missing.

~/config/mc/ini

User's own setup. If this file is present then the setup is loaded from here instead of the system-wide setup file.

~/local/share/mc/mcedit/

User's own directory where block commands are processed and saved and user's own syntax files are located.

NAME

mcview – Internal file viewer of GNU Midnight Commander.

SYNOPSIS

mcview [-bcCd fhstVx?] file

DESCRIPTION

mcview is a link to **mc**, the main GNU Midnight Commander executable. Executing GNU Midnight Commander under this name requests starting the internal viewer and opening the *file* specified on the command line.

OPTIONS

- b Force black and white display.
- c Force color mode on terminals where **mcview** defaults to black and white.
- C <keyword>=<fgcolor>,<bgcolor>,<attributes>:<keyword>= ...
Specify a different color set. See the **Colors** section in mc(1) for more information.
- d Disable mouse support.
- f Display the compiled-in search paths for Midnight Commander files.
- t Used only if the code was compiled with S-Lang and terminfo: it makes Midnight Commander use the value of the **TERMCAP** variable for the terminal information instead of the information on the system wide terminal database
- V Displays the version of the program.
- x Forces xterm mode. Used when running on xterm-capable terminals (two screen modes, and able to send mouse escape sequences).

COLORS

The default colors may be changed by appending to the **MC_COLOR_TABLE** environment variable. Foreground and background colors pairs may be specified for example with:

```
MC_COLOR_TABLE="$MC_COLOR_TABLE:\
normal=lightgray,black:\
selected=black,green"
```

FILES

/usr/local/share/mc/help/mc.hlp

The help file for the program.

/usr/local/share/mc/mc.ini

The default system-wide setup for GNU Midnight Commander, used only if the user's own *~/config/mc/ini* file is missing.

/usr/local/share/mc/mc.lib

Global settings for Midnight Commander. Settings in this file affect all users, whether they have *~/config/mc/ini* or not.

~/config/mc/ini

User's own setup. If this file is present, the setup is loaded from here instead of the system-wide startup file.

NAME

md2html – convert Markdown to HTML

SYNOPSIS

md2html [*OPTION*]... [*FILE*]

OPTIONS**General options:**

- o, --output=*OUTFILE***
Write output to *OUTFILE* instead of **stdout**(3)
- f, --full-html**
Generate full HTML document, including header
- s, --stat**
Measure time of input parsing
- h, --help**
Display help and exit
- v, --version**
Display version and exit

Markdown dialect options:

- commonmark**
CommonMark (the default)
- github**
Github Flavored Markdown

Note: dialect options are equivalent to some combination of flags below.

Markdown extension options:

- fcollapse-whitespace**
Collapse non-trivial whitespace
- fverbatim-entities**
Do not translate entities
- fpermissive-atx-headers**
Allow ATX headers without delimiting space
- fpermissive-url-autolinks**
Allow URL autolinks without "<" and ">" delimiters
- fpermissive-www-autolinks**
Allow WWW autolinks without any scheme (e.g. "www.example.com")
- fpermissive-email-autolinks**
Allow e-mail autolinks without "<", ">" and "mailto:"
- fpermissive-autolinks**
Enable all 3 of the above permissive autolinks options
- fhard-soft-breaks**
Force all soft breaks to act as hard breaks
- fno-indented-code**
Disable indented code blocks
- fno-html-blocks**
Disable raw HTML blocks
- fno-html-spans**
Disable raw HTML spans

--fno-html

Same as **--fno-html-blocks --fno-html-spans**

--ftables

Enable tables

--fstrikethrough

Enable strikethrough spans

--ftasklists

Enable task lists

NAME

md5string – filter to calculate MD5 checksum on strings

SYNOPSIS

edrc/lib/md5string [**-h** | **-V**]

stream | **md5string** [**-n**]

md5string [**-n**] < *filename*

AVAILABILITY

WA2L/edrc

DESCRIPTION

filter to calculate MD5 checksum on strings line by line.

This command is faster then using the **md5sum**(1) command in a loop if checksums for multiple strings (not files) have to be calculated.

OPTIONS

- h** usage message.
- V** print command version.
- n** no input string output beside the checksum.
- f** *filename* filename to read strings (=lines) from.

ENVIRONMENT

-

EXIT STATUS

- 0** match
- 1** cannot read from the file specified.
- 4** usage printed.

5 version printed.

FILES

-

EXAMPLES

-

SEE ALSO

edrcintro(1), **md5sum(1)**

NOTES

to calculate the md5 checksum for entire files, use the **md5sum(1)** command.

BUGS

-

AUTHOR

md5string was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

mediawiki – filter to get/put Wikipedia page

SYNOPSIS

edrc/lib/mediawiki [**-h**]

mediawiki **-a** { **put** | **get** } **-u** *url* **-p** *wikipage* [**-s** *section*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

get/put MediaWiki pages from/to a MediaWiki server. The communication does not need the MediaWiki API (**api.php**), therefore also MediaWiki servers running on older versions than 1.13 are supported.

OPTIONS

-h usage message.

-a action:

put
 put data stream to a MediaWiki page.

get
 get data stream from MediaWiki page and print it to **stdout**.

-u *url*
 MediaWiki URL. Example: *http://acme.ch/wiki*.

-p *page*
 MediaWiki page below the *url*.

-s *section*
 section number within the MediaWiki *page*.

ENVIRONMENT

\$MEDIAWIKI_USER

 user to connect to MediaWiki server.

\$MEDIAWIKI_PASSWD

password of connection user.

EXIT STATUS

- | | |
|----------|--|
| 0 | no error. |
| 1 | could not log on to <i>url</i> specified with user <i>user</i> using the <i>password</i> . |
| 2 | errors while loading data to the <i>url</i> . |
| 4 | Usage printed. |

NAME

mkuser – Initialize User's Home Directory

SYNOPSIS

mkuser **-u** *uid* **-g** *gid* **-d** *directory* [**-c** *class*] [**-m** *umask*] [**-s** *server*] [**-f**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

Used to initialize a user's home directory according to predefined classes. **mkuser** will not overwrite an existing directory, unless **-f** is given. The user's home directory is created, standard files, directories and symbolic links are copied, and the permissions are set. More than one user may be created, but all must be of the same class.

OPTIONS

- u** *uid* The user id of the desired user. If this is specified as a number, the creation will succeed, even if the user has not yet been created in the passwd map.

- g** *gid* The group id of the desired user. If this is specified as a number, the creation will succeed, even if the user has not yet been created in the passwd map.

- d** *directory* The physical path of the directory to be created. This is probably not the entry placed in the home directory field of the passwd entry, because the user's home directory will usually be mounted with automounter. Before it can be auto-mounted, it must physically exist.

- s** *server* Specify the server on which the homedir shall be created. It must be possible to reference the server via **/net/server**, and the parent directory must be exported with root permissions so that the directory may be created and ownership may be set.

- c** *class* If present, this option specifies the initialization "class" (or template) for the user. If specified, then files (.login, etc.) and directories are recursively copied from **~sfertools/classes/<class>** or from **\$CLASSES_DIR/classes/<class>** if the environment variable **\$CLASSES_DIR** is set. Otherwise, the directory is created and the ownership is set, but no other initialization takes place.

- f** Force initialization. Copies the standard configuration (according to -c option, if present) and sets permissions even if directory already exists. Useful if a user has deleted his "dot-files". If **mkuser** must overwrite a file, it will use the command **sav -D mkuser file** to backup the original version of **file**. It does not overwrite files which match the pattern **.my***.

- m** *umask* Set the umask for use when creating the directory. (Note: this is not applied to the users profile - this must be set in the corresponding initialization class).

ENVIRONMENT**\$CLASSES_DIR**

If this environment variable is set **mkuser** uses the classes files located in this directory for the initialization of the \$HOME of new users. See also section **FILES**.

EXIT STATUS

0 no error.

4 usage displayed.

EXAMPLES

-

SEE ALSO

edrcintro(1), **makeuser(1)**, **sav(1)**

FILES

~sfitools/classes/*

Files for initializing \$HOME of new users, may include subdirectories, which will be created.

\$CLASSES_DIR/classes/*

Files for initializing \$HOME of new users, may include subdirectories, which will be created.

~sfitools/defaults

SFI standard dot-files include the corresponding files from this subdirectory.

NOTES

Parts of this manpage were extracted from the documentation of the **SFI-Director** and modified to fit to the **WA2L/edrc** package. See <http://sfidirector.sourceforge.net> for more information about the **SFI-Director**.

BUGS

-

AUTHOR

mkuser was developed by Peter Stevens and integrated into **WA2L/edrc** by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

msg – write a message to screen

SYNOPSIS

edrc/lib/msg *level* "*message text*"

msg -h

AVAILABILITY

WA2L/edrc

DESCRIPTION

This command is used in scripts to write a standardized message to screen.

The message is printed to **stderr** and has the format:

<Scriptname>-<LEVEL>: <message text>

Example:

my_script-ERROR: directory '/dat/report/myreport' does not exist.

The **<Scriptname>** is derived from the **\$EDRC_SCRIPTNAME** environment variable, the **<LEVEL>** is the upper case of the *level* string given as the first option of the command. The message text is printed as received from the other options of the command.

OPTIONS

level Message level. The string given here is printed in upper case. There is no restriction in the *level* strings, a convention used in commands within WA2L/edrc is:

INFO Information messages.

ERROR

An error occurred, that questions the correct output or function of the command. An error has to be corrected to ensure that the command can complete successfully.

WARNING

A non critical malfunction of the command occurred. Often a **WARNING** can be ignored, but in some occasions a warning can also lead to a minor reduction in output quality. A warning has to be analyzed and rated by the user.

FATAL

A fatal error is a condition that has to be analyzed and that needs user intervention and correction to ensure proper functionality.

message text

message to be printed.

ENVIRONMENT

\$EDRC_SCRIPTNAME

scriptname that is printed in the **<Scriptname>** part of the output.

EXIT STATUS

0 no error.

4 usage listed.

EXAMPLES

The following examples are script cut-outs of Bourne-, Korn- or Bash shell scripts:

1) common usage

```
EDRC_SCRIPTNAME=`basename $0`; export EDRC_SCRIPTNAME
```

```
msg INFO "command started"
```

2) msg usage within a function with a return value

```
EDRC_SCRIPTNAME=`basename $0`; export EDRC_SCRIPTNAME
```

```
# is_bigger a b -- return True if a is bigger as b, else return False
#
```

```
is_bigger(){ a=$1; b=$2
    if [ $a -gt $b ]; then
        msg INFO "'$a' is bigger as '$b'"
        echo True
    else
        msg INFO "'$a' is smaller or equal as '$b'"
        echo False
    fi
}
```

```
# is_bigger
```

```
# main - main
```

```
#
```

```
main(){
    seconds=`date +%S`
    if [ `is_bigger $seconds 30` = True ]; then
        msg INFO "we are in the 2nd half of the current minute"
    else
        msg INFO "we are in the 1st half of the current minute"
    fi
}
```

```
    } # main
    main $*
```

NAME

msmtp – An SMTP client

SYNOPSIS

Sendmail mode (default):

msmtp [option...] [--] recipient...

msmtp [option...] -t [--] [recipient...]

Server information mode:

msmtp [option...] --serverinfo

Remote Message Queue Starting mode:

msmtp [option...] --rmqs=*host*[@*domain*]*#queue*

DESCRIPTION

In the default sendmail mode, msmtp reads a mail from standard input and sends it to an SMTP server for delivery.

In server information mode, msmtp prints information about an SMTP server.

In Remote Message Queue Starting mode, msmtp sends a Remote Message Queue Starting request for a host, domain, or queue to an SMTP server.

EXIT STATUS

The standard sendmail exit status codes are used, as defined in sysexits.h.

OPTIONS

Options override configuration file settings.

They are compatible with sendmail where appropriate.

General options

--version

Print version information. This includes information about the library used for TLS/SSL support (if any), the library used for authentication, the authentication mechanisms supported by this library, and the default locations of the system and user configuration files.

--help Print help.

-P, --pretend

Print the configuration settings that would be used, but do not take further action. An asterisk (*) will be printed instead of your password.

-d, --debug

Print lots of debugging information, including the whole conversation with the SMTP server. Be careful with this option: the (potentially dangerous) output will not be sanitized, and your password may get printed in an easily decodable format!

Changing the mode of operation

-S, --serverinfo

Print information about the SMTP server and exit. This includes information about supported features (mail size limit, authentication, TLS, DSN, ...) and about the TLS certificate (if TLS is active).

--rmqs=*(host*[@*domain*]*#queue)*

Send a Remote Message Queue Starting request for the given host, domain, or queue to the SMTP server and exit.

Configuration options

-C, --file=*filename*

Use the given file instead of ~/.msmtprc as the user configuration file.

-a, --account=*account_name*

Use the given account instead of the account named "default". The settings of this account may be changed with command line options. This option cannot be used together

with the **--host** option.

--host=hostname

Use this SMTP server with settings from the command line; do not use any configuration file data. This option cannot be used together with the **--account** option.

--port=number

Set the port number to connect to. See the **port** command below.

--timeout=(off|seconds)

Set a network timeout. See the **timeout** command below. For compatibility with older versions, **--connect-timeout** is accepted as an alias for this option.

--protocol=(smtp|lmtp)

Set the protocol to use. See the **protocol** command below.

--auth[=(on|off|method)]

Enable or disable authentication. You can optionally choose the method. See the **auth** command below.

--user=[username]

Set or unset the user name for authentication. See the **user** command below.

--tls[=(on|off)]

Enable or disable TLS/SSL encryption. See the **tls** command below.

--tls-starttls[=(on|off)]

Enable or disable STARTTLS for TLS encryption. See the **tls_starttls** command below.

--tls-trust-file=[file]

Set or unset a trust file for TLS encryption. See the **tls_trust_file** command below.

--tls-crl-file=[file]

Set or unset a certificate revocation list (CRL) file for TLS. See the **tls_crl_file** command below.

--tls-key-file=[file]

Set or unset a key file for TLS encryption. See the **tls_key_file** command below.

--tls-cert-file=[file]

Set or unset a cert file for TLS encryption. See the **tls_cert_file** command below.

--tls-certcheck[=(on|off)]

Enable or disable server certificate checks for TLS encryption. See the **tls_certcheck** command below.

--tls-force-ssl3[=(on|off)]

Force TLS/SSL version SSLv3. See the **tls_force_ssl3** command below.

--tls-min-dh-prime-bits=[bits]

Set or unset minimum bit size of the Diffie-Hellman (DH) prime. See the **tls_min_dh_prime_bits** command below.

--tls-priorities=[priorities]

Set or unset TLS priorities. See the **tls_priorities** command below.

--domain=[string]

Set the argument of the SMTP EHLO (or LMTP LHLO) command. See the **domain** command below.

Options specific to sendmail mode

--auto-from[=(on|off)]

Enable or disable automatic envelope-from addresses. The default is off. See the **auto_from** command below.

- f, --from=*address*
Set the envelope-from address. It is only used when *auto_from* is off.
If no account was chosen yet (with **--account** or **--host**), this option will choose the first account that has the given envelope-from address (set with the **from** command). If no such account is found, "default" is used.
- maildomain=*domain*
Set the domain part for generated envelope-from addresses. It is only used when *auto_from* is on. See the **maildomain** command below.
- N, --dsn-notify=(*off|cond*)
Set or unset DSN notification conditions. See the **dsn_notify** command below.
- R, --dsn-return=(*off|ret*)
Set or unset the DSN notification amount. See the **dsn_return** command below. Note that *hdrs* is accepted as an alias for *headers* to be compatible with sendmail.
- keepbcc[=(*on|off*)]
Enable or disable the preservation of the Bcc header. See the **keepbcc** command below.
- X, --logfile=*file*
Set or unset the log file. See the **logfile** command below.
- syslog[=(*on|off|facility*)]
Enable or disable syslog logging. See the **syslog** command below.
- t, --read-recipients
Read recipient addresses from the To, Cc, and Bcc headers of the mail in addition to the recipients given on the command line. If any Resent- headers are present, then the addresses from any Resent-To, Resent-Cc, and Resent-Bcc headers in the first block of Resent- headers are used instead.
- read-envelope-from
Read the envelope from address from the From header of the mail.
- This marks the end of options. All following arguments will be treated as recipient addresses, even if they start with a *'*.

The following options are accepted but ignored for sendmail compatibility:

-Btype, **-bm**, **-Fname**, **-G**, **-hN**, **-i**, **-L tag**, **-m**, **-n**, **-O option=value**, **-ox value**, **-v**

USAGE

Normally, a system wide configuration file and/or a user configuration file contain information about which SMTP server to use (and how to use it), but almost all settings can also be configured on the command line.

Information about SMTP servers is organized in *accounts*. Each account describes one SMTP server: host name, authentication settings, TLS settings, and so on. Each configuration file can define multiple accounts.

In sendmail mode, an envelope-from address is necessary to send mail. This is the mail address that will be presented to the SMTP server as the originator of the mail. Envelope-from addresses can be generated automatically (when *auto_from* is enabled) or set explicitly with the **from** command or **--from** option. When *auto_from* is enabled, an envelope-from address of the form *user@domain* will be generated. The local part will be set to **USER** or, if that fails, to **LOGNAME** or, if that fails, to the login name of the current user. The domain part can be set with the **maildomain** command. If the maildomain is empty, the envelope-from address will only consist of the user name and not have a domain part.

The user can choose which account to use in one of three ways:

--account=id

Use the given account. Command line settings override configuration file settings.

`--host=hostname`

Use only the settings from the command line; do not use any configuration file data.

`--from=address` or `--read-envelope-from`

Choose the first account from the system or user configuration file that has a matching envelope-from address as specified by a **from** command. This works only when neither **--account** nor **--host** is used.

If none of the above options is used (or if no account has a matching **from** command), then the account "default" is used.

Skip to the EXAMPLES section for a quick start.

CONFIGURATION FILES

If it exists and is readable, a system wide configuration file `SYSCONFDIR/msmtpc` will be loaded, where `SYSCONFDIR` depends on your platform. Use **--version** to find out which directory is used.

If it exists and is readable, a user configuration file will be loaded (`~/msmtpc` by default). Accounts defined in the user configuration file override accounts from the system configuration file. The user configuration file must have no more permissions than user read/write. Configuration data from either file can be changed by command line options.

A configuration file is a simple text file. Empty lines and comment lines (whose first non-blank character is '#') are ignored.

Every other line must contain a command and may contain an argument to that command.

The argument may be enclosed in double quotes ("), for example if its first or last character is a blank.

If the first character of a filename is the tilde (~), this tilde will be replaced by HOME. If a command accepts the argument *on*, it also accepts an empty argument and treats that as if it was *on*.

Commands form groups. Each group begins with the **account** command and defines the settings for one SMTP server.

Skip to the EXAMPLES section for a quick start.

Commands are as follows:

defaults

Set defaults. The following configuration commands will set default values for all following account definitions in the current configuration file.

account *name* [:*account*[...]]

Start a new account definition with the given name. The current default values are filled in.

If a colon and a list of previously defined accounts is given after the account name, the new account, with the filled in default values, will inherit all settings from the accounts in the list.

host *hostname*

The SMTP server to send the mail to. The argument may be a host name or a network address. Every account definition must contain this command.

port *number*

The port that the SMTP server listens on. The default port will be acquired from your operating system's service database: for SMTP, the service is "smtp" (default port 25), unless TLS without STARTTLS is used, in which case it is "ssmtp" (465). For LMTP, it is "lmtp".

timeout (*off*|*seconds*)

Set or unset a network timeout, in seconds. The argument *off* means that no timeout will be set, which means that the operating system default will be used.

For compatibility with older versions, **connect_timeout** is accepted as an alias for this command.

protocol (*smtp*|*lmtp*)

Set the protocol to use. Currently only SMTP and LMTP are supported. SMTP is the default. See the **port** command above for default ports.

`auto_from [(on|off)]`

Enable or disable automatic envelope-from addresses. The default is off. When enabled, an envelope-from address of the form `user@domain` will be generated. The local part will be set to **USER** or, if that fails, to **LOGNAME** or, if that fails, to the login name of the current user. The domain part can be set with the **maildomain** command. If the maildomain is empty, the envelope-from address will only consist of the user name and not have a domain part. When `auto_from` is disabled, the envelope-from address must be set explicitly.

`from envelope_from`

Set the envelope-from address. This address will only be used when `auto_from` is off.

`maildomain [domain]`

Set a domain part for the generation of an envelope-from address. This is only used when `auto_from` is on. The domain may be empty.

`auth [(on|off){method}]`

This command enables or disables SMTP authentication. You should not need to set the method yourself; with the argument *on*, `msmtp` will choose the best one available for you (see below).

You probably need to set a username (with **user**) and password (with **password**). If no password is set but one is needed during authentication, `msmtp` will try to find it in `~/netrc`. If that fails, it will try to find it in `SYSCONFDIR/netrc` (use **--version** to find out what `SYSCONFDIR` is on your platform). If that fails, it will try to get it from a system specific keychain (if available). If that fails but a controlling terminal is available, `msmtp` will prompt you for it.

Currently supported keychains are the GNOME keychain and the Mac OS X keychain. See the **EXAMPLES** section below.

Available methods are *plain*, *cram-md5*, *digest-md5*, *gssapi*, *external*, *login*, and *ntlm*. Note that one or more of these methods may be unavailable due to lack of support in the underlying authentication library. Use the **--version** option to find out which methods are supported.

The *plain* and *login* methods send your authentication data in cleartext over the net, and the *ntlm* method may be vulnerable to attacks. These methods should therefore only be used together with the **tls** command.

If you don't choose the method yourself, `msmtp` chooses the best secure method that the SMTP server supports. Secure means that your authentication data will not be sent in cleartext over the net. For TLS encrypted connections, every authentication method is secure in this sense. If TLS is not active, only *gssapi*, *digest-md5*, and *cram-md5* are secure in this sense.

The *external* is special: the actual authentication happens outside of the SMTP protocol, typically by sending a TLS client certificate (see the **tls_cert_file** command). The *external* method merely confirms that this authentication succeeded for the given user (or, if no user name is given, confirms that authentication succeeded). This authentication method is not chosen automatically; you have to request it manually.

`user [username]`

Set your user name for SMTP authentication. An empty argument unsets the user name. Authentication must be activated with the **auth** command.

`password [secret]`

Set your password for SMTP authentication. An empty argument unsets the password. Authentication must be activated with the **auth** command. If no password is set but one is needed during authentication, `msmtp` will try to find it in `~/netrc`. If that fails, it will try to find it in `SYSCONFDIR/netrc` (use **--version** to find out what `SYSCONFDIR` is on your platform). If that fails, it will try to get it from a system specific keychain (if available). If that fails but a controlling terminal is available, `msmtp` will prompt you for it.

`ntlm_domain [domain]`

Set a domain for the *ntlm* authentication method. The default is to use no domain (equivalent to an empty argument), but some servers seem to require one, even if it is an arbitrary string.

tls [(on|off)]

This command enables or disables TLS (also known as SSL) encrypted connections to the SMTP server. Not every server supports TLS.

With TLS/SSL, the connection with the SMTP server will be protected against eavesdroppers and man-in-the-middle attacks. To use TLS/SSL, it is required to either use the **tls_trust_file** command (highly recommended) or to disable **tls_certcheck**.

tls_starttls [(on|off)]

By default, TLS encryption is activated using the STARTTLS SMTP command. By disabling this, TLS encryption is immediately started instead (this is known as SMTP tunneled through TLS/SSL). The default port is set to 465 for this mode of operation.

For compatibility with older versions, **tls_nostarttls** is accepted as an alias for **tls_starttls off**.

tls_trust_file [file]

This command activates strict server certificate verification.

The filename must be the absolute path name of a file in PEM format containing one or more certificates of trusted Certification Authorities (CAs).

On Debian based systems, you can install the **ca-certificates** package and use the file **/etc/ssl/certs/ca-certificates.crt**.

tls_crl_file [file]

This command sets or unsets a certificate revocation list (CRL) file for TLS, to be used during strict server certificate verification as enabled by the **tls_trust_file** command. This allows the verification procedure to detect revoked certificates.

tls_key_file [file]

This command (together with the **tls_cert_file** command) enables msmtp to send a client certificate to the SMTP server if requested. The file must contain the private key of a certificate in PEM format. An empty argument disables this feature.

tls_cert_file [file]

This command (together with the **tls_key_file** command) enables msmtp to send a client certificate to the SMTP server if requested. The file must contain a certificate in PEM format. An empty argument disables this feature.

tls_certcheck [(on|off)]

This command enables or disables checks for the server certificate.

WARNING: When the checks are disabled, TLS/SSL sessions will be vulnerable to man-in-the-middle attacks!

For compatibility with older versions, **tls_nocertcheck** is accepted as an alias for **tls_certcheck off**.

tls_force_sslv3 [(on|off)]

Force TLS/SSL version SSLv3. This might be needed to use SSL with some old and broken servers. Do not use this unless you have to.

tls_min_dh_prime_bits [bits]

Set or unset the minimum number of Diffie-Hellman (DH) prime bits that msmtp will accept for TLS sessions. The default is set by the TLS library and can be selected by using an empty argument to this command. Only lower the default (for example to 512 bits) if there is no other way to make TLS work with the remote server.

tls_priorities [priorities]

Set the priorities for TLS sessions. The default is set by the TLS library and can be selected by using an empty argument to this command. Currently this command only works with sufficiently recent GnuTLS releases. See the GnuTLS documentation of the **gnutls_priority_init** function for a description of the *priorities* string.

dsn_notify (*off*|*condition*)

This command sets the condition(s) under which the mail system should send DSN (Delivery Status Notification) messages. The argument *off* disables explicit DSN requests, which means the mail system decides when to send DSN messages. This is the default. The *condition* must be *never*, to never request notification, or a comma separated list (no spaces!) of one or more of the following: *failure*, to request notification on transmission failure, *delay*, to be notified of message delays, *success*, to be notified of successful transmission. The SMTP server must support the DSN extension.

dsn_return (*off*|*amount*)

This command controls how much of a mail should be returned in DSN (Delivery Status Notification) messages. The argument *off* disables explicit DSN requests, which means the mail system decides how much of a mail it returns in DSN messages. This is the default. The *amount* must be *headers*, to just return the message headers, or *full*, to return the full mail. The SMTP server must support the DSN extension.

domain *argument*

Use this command to set the argument of the SMTP EHLO (or LMTP LHLO) command. The default is *localhost* (stupid, but working). Possible choices are the domain part of your mail address (provider.example for joe@provider.example) or the fully qualified domain name of your host (if available).

keepbcc [(*on*|*off*)]

This command controls whether to remove or keep the Bcc header when sending a mail. The default is to remove it.

logfile [*file*]

An empty argument disables logging (this is the default).

When logging is enabled by choosing a log file, msmtp will append one line to the log file for each mail it tries to send via the account that this log file was chosen for.

The line will include the following information: date and time, host name of the SMTP server, whether TLS was used, whether authentication was used, authentication user name (only if authentication is used), envelope-from address, recipient addresses, size of the mail as transferred to the server (only if the delivery succeeded), SMTP status code and SMTP error message (only in case of failure and only if available), error message (only in case of failure and only if available), exit code (from sysexits.h; EX_OK indicates success).

If the filename is a dash (-), msmtp prints the log line to the standard output.

syslog [(*on*|*off*|*facility*)]

Enable or disable syslog logging. The facility can be one of LOG_USER, LOG_MAIL, LOG_LOCAL0, ..., LOG_LOCAL7. The default is LOG_USER.

Each time msmtp tries to send a mail via the account that contains this syslog command, it will log one entry to the syslog service with the chosen facility.

The line will include the following information: host name of the SMTP server, whether TLS was used, whether authentication was used, envelope-from address, recipient addresses, size of the mail as transferred to the server (only if the delivery succeeded), SMTP status code and SMTP error message (only in case of failure and only if available), error message (only in case of failure and only if available), exit code (from sysexits.h; EX_OK indicates success).

EXAMPLES**Configuration file**

Set default values for all following accounts.

defaults

tls on

tls_trust_file /etc/ssl/certs/ca-certificates.crt

logfile ~/.msmtp.log

A freemail service

```

account freemail
host smtp.freemail.example
from joe_smith@freemail.example
auth on
user joe.smith
password secret

# A second mail address at the same freemail service
account freemail2 : freemail
from joey@freemail.example

# The SMTP server of the provider.
account provider
host mail.provider.example
from smithjoe@provider.example
auth on
user 123456789
password my_password

# Set a default account
account default : provider

```

Manually finding the right CA certificate for `tls_trust_file`

The following example works as of 2007-04-18.

For the Gmail SMTP server, you first issue the following command:

```
msmtp --serverinfo --host=smtp.gmail.com --tls=on --port=587 --tls-certcheck=off
```

The option `--port=587` is specific to Gmail and should not be used with other servers. The option `--tls-certcheck=off` allows msmtp to accept any certificate, so that it can print some information about it.

According to the output of this command, the common name of the server certificate issuer is "Thawte Premium Server CA". This means that you have to trust the Thawte CA to use full TLS security. You can download the Thawte CA certificate bundle from <http://thawte.com/roots>. You get a ZIP file with different certificates. The one you need for the `tls_trust_file` command is *Thawte Server Roots/ThawtePremiumServerCA_b64.txt*.

The following command should now succeed:

```
msmtp --serverinfo --host=smtp.gmail.com --tls=on --port=587 --tls-trust-file="Thawte Server Roots/ThawtePremiumServerCA_b64.txt"
```

Using msmtp with Mutt

Create a configuration file for msmtp and add the following lines to your Mutt configuration file:

```

set sendmail="/path/to/msmtp"
set use_from=yes
set realname="Your Name"
set from=you@example.com
set envelope_from=yes

```

The `envelope_from=yes` option lets Mutt use the `-f` option of msmtp. Therefore msmtp chooses the first account that matches the from address `you@example.com`.

Alternatively, you can use the `-a` option:

```
set sendmail="/path/to/msmtp -a my-account"
```

Or set everything from the command line:

```
set sendmail="/path/to/msmtp --host=mailhub -f me@example.com --tls"
```

If you have multiple mail accounts in your msmtp configuration file and let Mutt use the `-f` option to choose the right one, you can easily switch accounts in Mutt with the following Mutt configuration lines:

```
macro generic "<esc>1" "":set from=you@example.com"
macro generic "<esc>2" "":set from=you@your-employer.example"
macro generic "<esc>3" "":set from=you@some-other-provider.example"
```

Using msmtp with mail

Define a default account, and put the following in your ~/.mailrc:

```
set sendmail="/path/to/msmtp"
```

Using the Mac OS X Keychain

A Mac OS X user can store a password in a keychain item using the Keychain Access GUI application. The *account name* is simply the value of the msmtp **user** argument. However, the *keychain item name* is **smtp://<hostname>** where **<hostname>** matches the msmtp **host** argument. Using **smtp://** is needed so that the item is created of kind *internet password*. For example, selecting *File->Get Info* on a keychain item that corresponds to **host smtp.freemail.example** and **user joe.smith** will show:

Name: smtp.freemail.example

Kind: Internet password

Account: joe.smith

Where: smtp://smtp.freemail.example

FILES

SYSCONFDIR/msmtpc

System configuration file. Use **--version** to find out what SYSCONFDIR is on your platform.

~/.msmtpc

User configuration file.

~/.netrc and **SYSCONFDIR/netrc**

The netrc file contains login information. If a password is not found in the configuration file, msmtp will search it in ~/.netrc and SYSCONFDIR/netrc before prompting the user for it. The syntax of netrc files is described in **netrc(5)** or **ftp(1)**.

ENVIRONMENT

USER, LOGNAME

These variables override the user's login name when constructing an envelope-from address. LOGNAME is only used if USER is unset.

TMPDIR

Directory to create temporary files in. If this is unset, a system specific default directory is used.

A temporary file is only created when the **-t/--read-recipients** or **--read-envelope-from** option is used. The file is then used to buffer the headers of the mail (but not the body, so the file won't get very large).

EMAIL, SMTPSERVER

These environment variables are used only if neither **--host** nor **--account** is used and there is no default account defined in the configuration files. In this case, the host name is taken from SMTPSERVER, and the envelope from address is taken from EMAIL, unless overridden by **--from** or **--read-envelope-from**. Currently SMTPSERVER must contain a plain host name (no URL), and EMAIL must contain a plain address (no names or additional information).

AUTHORS

msmtp was written by Martin Lambers <marlam@marlam.de>.

Other authors are listed in the AUTHORS file in the source distribution.

NAME

name – print description of a file or directory examined from the file header

SYNOPSIS

edrc/bin/name [*selection*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

Print a description of a selection of files or directories in the current working directory examined from the file header.

This helps to get a quick overview of the purpose of files and directories located in a certain directory.

The file header must have the (very simple to remember) format:

filename - the description text

or:

path/filename - the description text

Between the *filename*, the - and *the description text* has to be only one space each.

The *filename* has to be identical to the real **filename**. See also **scripthheadersync**(1) to see how to efficiently synchronize file headers with the real file name.

If you do hard- or symbolic links to a file, each name of the file has to have an own description line in the header.

If the original file does not have a header entry of the symlinked file, the header entry of the original file is displayed.

If the file has been saved using the **sav**(3) command or if it is a backedup recovery script file as found in the **.sav** directories of a recovery script tree handled by **edrc**(1m), the **name** command can also display the header information.

If all the methods above do not succeed or if it is a directory, the index file **..name_index** is consulted for the file header information.

Binary files are not scanned for file header patterns.

OPTIONS

selection selection as known from the **ls** command to select a subset of files or directories from the current working directory.

ENVIRONMENT

-

EXIT STATUS

- | | |
|----------|--|
| 0 | no error. |
| 2 | operating system is not supported, yet. See osid (3) if you get this error. |
| 4 | usage printed. |

FILES

..name_index****

list of file or directory header descriptions for a certain directory. If this file exists and the file header cannot be resolved from the file itself the **name** command will return the matching description from that file. This might be the cause, if the file does not allow comment entries, or the file is based on a 3rd party source and it is not wished to change the file. The format is identical to the file header.

etc/name.index

global list of file header descriptions. This file is read if neither the name can be resolved from the file itself, nor from the **..**name_index**** file.

EXAMPLES

1) Shellsript header

```
#!/bin/sh
#
# busy - keep the line open
#
# [00] 28.02.2001 CWa    Initial Version
#
```

2) Configuration file header

```
#
# /etc/hosts - internet host names
#
# [00] 28.02.2001 CWa    Initial Version
#
#
127.0.0.1      localhost
192.168.75.1   rh7mzv7t001
```

3) Configuration file header

```

;
; /etc/samba/smb.conf - samba configuration file
;
; [00] 28.02.2001 CWa    Initial Version
;
;
[global]
    workgroup = MYGROUP
    server string = %h

```

4) SQL script header

```

--
-- TopTen.sql - Reports lists DB statistics
--
-- [00] 31.1.2003 CBi    Initial
--
select
    a.tablespace_name,
    a.bytes/1024 as total_kbytes,

```

5) Manpage file header

```

.\"
.\" name.1 - manpage for name
.\"
.\" [00] 30.11.2003 CWa Initial Version
.\"

```

NAME

nano – Nano's ANOther editor, an enhanced free Pico clone

SYNOPSIS

nano [*OPTIONS*] [[*+LINE,COLUMN*] *FILE*]...

DESCRIPTION

This manual page briefly documents the **nano** command.

nano is a small, free and friendly editor which aims to replace Pico, the default editor included in the non-free Pine package. Rather than just copying Pico's look and feel, **nano** also implements some missing (or disabled by default) features in Pico, such as "search and replace" and "go to line and column number".

OPTIONS

+LINE,COLUMN

Places cursor at line number *LINE* and column number *COLUMN* (at least one of which must be specified) on startup, instead of the default of line 1, column 1.

-? Same as **-h** (**--help**).

-A (**--smarthome**)

Make the Home key smarter. When Home is pressed anywhere but at the very beginning of non-whitespace characters on a line, the cursor will jump to that beginning (either forwards or backwards). If the cursor is already at that position, it will jump to the true beginning of the line.

-B (**--backup**)

When saving a file, back up the previous version of it to the current filename suffixed with a `~`.

-C dir (**--backupdir=dir**)

Set the directory where **nano** puts unique backup files if file backups are enabled.

-D (**--boldtext**)

Use bold text instead of reverse video text.

-E (**--tabstospaces**)

Convert typed tabs to spaces.

-F (**--multibuffer**)

Enable multiple file buffers, if available.

-H (**--historylog**)

Log search and replace strings to `%.nano_history`, so they can be retrieved in later sessions, if nanorc support is available.

-I (**--ignorercfiles**)

Don't look at `SYSCONFDIR/nanorc` or `%.nanorc`, if nanorc support is available.

-K (**--rebindkeypad**)

Interpret the numeric keypad keys so that they all work properly. You should only need to use this option if they don't, as mouse support won't work properly with this option enabled.

-L (**--nonewlines**)

Don't add newlines to the ends of files.

-N (**--noconvert**)

Disable automatic conversion of files from DOS/Mac format.

-O (**--morespace**)

Use the blank line below the titlebar as extra editing space.

- Q *str* (--quotestr=*str*)**
Set the quoting string for justifying. The default is "`^[\t]*[#:>\\|])`" if extended regular expression support is available, or ">" otherwise. Note that `\t` stands for a Tab.
- R (--restricted)**
Restricted mode: don't read or write to any file not specified on the command line; read any `nanorc` files; allow suspending; allow a file to be appended to, prepended to, or saved under a different name if it already has one; or use backup files or spell checking. Also accessible by invoking **nano** with any name beginning with 'r' (e.g. "rnano").
- S (--smooth)**
Enable smooth scrolling. Text will scroll line-by-line, instead of the usual chunk-by-chunk behavior.
- T *cols* (--tabsize=*cols*)**
Set the size (width) of a tab to *cols* columns. The value of *cols* must be greater than 0. The default value is 8.
- U (---quickblank)**
Do quick statusbar blanking. Statusbar messages will disappear after 1 keystroke instead of 25. Note that **-c** overrides this.
- V (--version)**
Show the current version number and exit.
- W (--wordbounds)**
Detect word boundaries more accurately by treating punctuation characters as part of a word.
- Y *str* (---syntax=*str*)**
Specify a specific syntax highlighting from the *nanorc* to use, if available.
- c (--const)**
Constantly show the cursor position. Note that this overrides **-U**.
- d (--rebinddelete)**
Interpret the Delete key differently so that both Backspace and Delete work properly. You should only need to use this option if Backspace acts like Delete on your system.
- h (--help)**
Show a summary of command line options and exit.
- i (--autoindent)**
Indent new lines to the previous line's indentation. Useful when editing source code.
- k (--cut)**
Enable cut from cursor to end of line.
- l (--nofollow)**
If the file being edited is a symbolic link, replace the link with a new file instead of following it. Good for editing files in */tmp*, perhaps?
- m (--mouse)**
Enable mouse support, if available for your system. When enabled, mouse clicks can be used to place the cursor, set the mark (with a double click), and execute shortcuts. The mouse will work in the X Window System, and on the console when *gpm* is running.
- o *dir* (--operatingdir=*dir*)**
Set operating directory. Makes **nano** set up something similar to a chroot.
- p (--preserve)**
Preserve the XON and XOFF sequences (`^Q` and `^S`) so they will be caught by the terminal.
- r *cols* (---fill=*cols*)**
Wrap lines at column *cols*. If this value is 0 or less, wrapping will occur at the width of the screen less *cols* columns, allowing the wrap point to vary along with the width of the screen if the screen

is resized. The default value is -8.

-s *prog* (**--speller=prog**)

Enable alternative spell checker command.

-t (**--tempfile**)

Always save changed buffer without prompting. Same as Pico's **-t** option.

-v (**--view**)

View file (read only) mode.

-w (**--nowrap**)

Disable wrapping of long lines.

-x (**--nohelp**)

Disable help screen at bottom of editor.

-z (**--suspend**)

Enable suspend ability.

-a, -b, -e, -f, -g, -j

Ignored, for compatibility with Pico.

INITIALIZATION FILE

nano will read initialization files in the following order: *SYSCONFDIR/nanorc*, then *~/nanorc*. Please see **nanorc(4)** and the example file **nanorc.sample**, both of which should be provided with **nano**.

NOTES

If no alternative spell checker command is specified on the command line or in one of the nanorc files, **nano** will check the **SPELL** environment variable for one.

In some cases **nano** will try to dump the buffer into an emergency file. This will happen mainly if **nano** receives a SIGHUP or SIGTERM or runs out of memory. It will write the buffer into a file named *nano.save* if the buffer didn't have a name already, or will add a ".save" suffix to the current filename. If an emergency file with that name already exists in the current directory, it will add ".save" plus a number (e.g. ".save.1") to the current filename in order to make it unique. In multibuffer mode, **nano** will write all the open buffers to their respective emergency files.

BUGS

Please send any comments or bug reports to **nano@nano-editor.org**.

The **nano** mailing list is available from **nano-devel@gnu.org**.

To subscribe, email to **nano-devel-request@gnu.org** with a subject of "subscribe".

NAME

nanorc – GNU nano's rcfile

DESCRIPTION

This manual page briefly documents GNU **nano**'s rcfile.

nano is a small, free and friendly editor which aims to replace Pico, the default editor included in the non-free Pine package. Rather than just copying Pico's look and feel, **nano** also implements some missing (or disabled by default) features in Pico, such as "search and replace" and "go to line and column number".

The *nanorc* file contains the default settings for **nano**. It should not be in DOS or Mac format. During startup, **nano** will first read its system-wide settings from *SYSCONFDIR/nanorc*, and then user-specific settings from *~/.nanorc*.

OPTIONS

The configuration file accepts a series of **set** and **unset** commands, which can be used to configure nano on startup without using the command line options. Additionally, the **syntax**, **color**, and **icolor** keywords are used to define syntax highlighting rules for different text patterns. **nano** will read one command per line.

Options in nanorc files take precedence over nano's defaults, and command line options override nanorc settings. Also, options are unset by default, except for those that take arguments.

Quotes inside string parameters don't have to be escaped with backslashes. The last double quote in the string will be treated as its end. For example, for the **brackets** option, `"")>]]"` will match `"`, `'`, `)`, `>`, `]`, and `]`.

The supported commands and arguments are:

set/unset autoindent

Use auto-indentation.

set/unset backup

Create backup files in *filename~*.

set backupdir *directory*

Set the directory where **nano** puts unique backup files if file backups are enabled.

set/unset backwards

Do backwards searches by default.

set/unset boldtext

Use bold text instead of reverse video text.

set brackets *string*

Set the characters treated as closing brackets when justifying paragraphs. They cannot contain blank characters. Only closing punctuation, optionally followed by closing brackets, can end sentences. The default value is `"")>]]"`.

set/unset casesensitive

Do case sensitive searches by default.

set/unset const

Constantly display the cursor position in the status bar.

set/unset cut

Use cut to end of line by default.

set fill *n*

Wrap lines at column number *n*. If *n* is 0 or less, the maximum line length will be the screen width less *n* columns. The default value is -8.

set/unset historylog

Enable `~/.nano_history` for saving and reading search/replace strings.

set matchbrackets *string*

Set the opening and closing brackets that can be found by bracket searches. They cannot contain blank characters. The former set must come before the latter set, and both must be in the same order. The default value is "`(<[{}>])`".

set/unset morespace

Use the blank line below the titlebar as extra editing space.

set/unset mouse

Enable mouse support, if available for your system. When enabled, mouse clicks can be used to place the cursor, set the mark (with a double click), and execute shortcuts. The mouse will work in the X Window System, and on the console when gpm is running.

set/unset multibuffer

Allow inserting files into their own buffers.

set/unset noconvert

Don't convert files from DOS/Mac format.

set/unset nofollow

Don't follow symlinks when writing files.

set/unset nohelp

Don't display the help lists at the bottom of the screen.

set/unset nonewlines

Don't add newlines to the ends of files.

set/unset nowrap

Don't wrap text at all.

set operatingdir *directory*

nano will only read and write files inside *directory* and its subdirectories. Also, the current directory is changed to here, so files are inserted from this directory. By default, the operating directory feature is turned off.

set/unset preserve

Preserve the XON and XOFF keys (^Q and ^S).

set punct *string*

Set the characters treated as closing punctuation when justifying paragraphs. They cannot contain blank characters. Only closing punctuation, optionally followed by closing brackets, can end sentences. The default value is "`!.?>`".

set/unset quickblank

Do quick statusbar blanking. Statusbar messages will disappear after 1 keystroke instead of 25.

set quotestr *string*

The email-quote string, used to justify email-quoted paragraphs. This is an extended regular expression if your system supports them, otherwise a literal string. The default value is "`^[\t]*[#:]>[\t]*`" if you have extended regular expression support, or "`>`" otherwise. Note that `\t` stands for a literal Tab character.

set/unset rebinddelete

Interpret the Delete key differently so that both Backspace and Delete work properly. You should only need to use this option if Backspace acts like Delete on your system.

set/unset rebindkeypad

Interpret the numeric keypad keys so that they all work properly. You should only need to use this option if they don't, as mouse support won't work properly with this option enabled.

set/unset regexp

Do extended regular expression searches by default.

set/unset smarthome

Make the Home key smarter. When Home is pressed anywhere but at the very beginning of non-white-space characters on a line, the cursor will jump to that beginning (either forwards or backwards). If the cursor is already at that position, it will jump to the true beginning of the line.

set/unset smooth

Use smooth scrolling by default.

set speller *spellprog*

Use spelling checker *spellprog* instead of the built-in one, which calls *spell*.

set/unset suspend

Allow **nano** to be suspended.

set tabsize *n*

Use a tab size of *n* columns. The value of *n* must be greater than 0. The default value is 8.

set/unset tabstospaces

Convert typed tabs to spaces.

set/unset tempfile

Save automatically on exit, don't prompt.

set/unset view

Disallow file modification.

set whitespace *string*

Set the two characters used to display the first characters of tabs and spaces. They must be single-column characters.

set/unset wordbounds

Detect word boundaries more accurately by treating punctuation characters as parts of words.

syntax *str* ["*fileregex*" ...]

Defines a syntax named *str* which can be activated via the -Y/--syntax command line option, or will be automatically activated if the current filename matches the extended regular expression *fileregex*. All following **color** and **icolor** statements will apply to *syntax* until a new syntax is defined.

The *none* syntax is reserved; specifying it on the command line is the same as not having a syntax at all. The *default* syntax is special: it takes no *fileregex*, and applies to files that don't match any other syntax's *fileregex*.

color *fgcolor,bgcolor regex* ...

For the currently defined syntax, display all expressions matching the extended regular expression *regex* with foreground color *fgcolor* and background color *bgcolor*, at least one of which must be specified. Legal colors for foreground and background color are: white, black, red, blue, green, yellow, magenta, and cyan. You may use the prefix "bright" to force a stronger color highlight for the foreground. If your terminal supports transparency, not specifying a *bgcolor* tells **nano** to attempt to use a transparent background.

icolor *fgcolor,bgcolor regex* ...

Same as above, except that the expression matching is case insensitive.

color *fgcolor,bgcolor start="sr" end="er"*

Display expressions which start with the extended regular expression *sr* and end with the extended regular expression *er* with foreground color *fgcolor* and background color *bgcolor*, at least one of which must be specified. This allows syntax highlighting to span multiple lines. Note that all subsequent instances of *sr* after an initial *sr* is found will be highlighted until the first instance of *er*.

icolor *fgcolor,bgcolor* **start="sr" end="er"**

Same as above, except that the expression matching is case insensitive.

include *syntaxfile*

Read in self-contained color syntaxes from *syntaxfile*. Note that *syntaxfile* can only contain **syntax**, **color**, and **icolor** commands.

NAME

nc – GNU Netcat Manual

SYNOPSIS

nc [options] hostname port [port] ...

nc -l -p port [options] [hostname] [port] ...

nc -L hostname:port -p port [options] ...

DESCRIPTION

nc is a simple Unix utility which reads and writes data across network connections, using TCP or UDP protocol. It is designed to be a reliable “back-end” tool that can be used directly or easily driven by other programs and scripts. At the same time, it is a feature-rich network debugging and exploration tool, since it can create almost any kind of connection you would need and has several interesting built-in capabilities. nc, or “nc” as the original program was named, should have been supplied long ago as another one of those cryptic but standard Unix tools.

nc has three main modes of functionality. These are the connect mode, the listen mode, and the tunnel mode.

The most common mode is the connect mode, which for example allows the output of a locally called command to be redirected for example to a remote nc listening or to any other kind of daemon waiting for a connection.

On the other hand, the listen mode can be used to obtain some kind of stream of data from a remote site.

The most new feature is the tunnel mode, which is a powerful and reliable mode that allows tunneling a remote site towards any other remote site, allowing to specify for example from which interface create the connection and from which port.

OPTIONS**Basic Startup Options**

-V

--version

Display the version of nc and exit.

-h

--help

Print a help message describing most common nc’s command-line switches and a short description.

-v

--verbose

Prints status messages, usually needed for using nc as user front-end. All messages are printed to stderr in order not to affect the data stream.

Use this option double to get more messages.

Protocol and Interface Options

-t

--tcp

Selects the TCP protocol, this is the default. It may be useful (see Tunnel Mode) to specify this option after for example the UDP option in order to allow a cross-protocol bridge between TCP and UDP.

-u

--udp

Selects the UDP protocol. See the **--tcp** option.

-p NUM

--local-port=NUM

Selects the local port. In listen and tunnel mode, it specifies which port to use for listening, while in connect mode it specifies the source port (the port from which originating the connection).

If this option is not specified, the OS will assign a random available port.

-s ADDRESS

--source=ADDRESS

Specifies the source address used for creating sockets. In listen mode and tunnel mode this switch specifies the bound address, and it is generally a good idea not to specify this, which causes nc to bind to a generic interface. In the connect mode, this switch is used to specify the source address for connecting to the outside world. Again, if it's not specified a proper address for the destination route will be used.

-P NUM

--tunnel-port=NUM

Same as **--port**, but affects only the connect phase (thus this option has no effect in listen mode). This switch is useful in tunnel mode for specifying the source port for the connecting socket.

-S ADDRESS

--tunnel-source=ADDRESS

Same as **--source**, but affects only the connect phase (thus this has no effects in listen mode). This switch is useful in tunnel mode for specifying the source address for the connecting socket.

Advanced Options

-i SECS

--interval SECS

sets the buffering output delay time. This affects all the current modes and makes the connection sock to buffer outgoing data. This means that in tunnel mode everything received from the listening socket is buffered for the connect socket.

-n

--dont-resolve

Don't do DNS lookups on any of the specified addresses or hostnames, or names of port numbers from `/etc/services`.

-r

--randomize

Randomizes the target remote ports ranges. If more than one range is specified it will randomize the ports in the whole global range.

-w

--wait=SECS

Specifies the starting inactivity delay after which nc will exit with an error status. In connect mode and in tunnel mode this specifies the timeout for the connecting socket, while in listen mode it specifies the time to wait for a VALID incoming connection (see listen mode).

-T

--telnet

Answers the telnet codes as described in RFC0854. This makes possible to use nc to script telnet sessions. The incoming telnet codes are parsed inside the receiving queue and are stripped off before forwarding the data as they were never received, so the application doesn't have to parse the codes itself (this behaviour can be disabled at compile time with **--enable-oldtelnet** or with **--enable-compat**).

-z

--zero

Sets the zero I/O flag for the selected mode. In connect mode it means that as soon as the port is open it is immediately shutdown and closed. This may be useful for probing or scanning (even if there are faster portscanners out there, but this may be useful for scripting purposes). In listen mode, it makes nc refusing all the incoming connections thus running in timeout (if set), or waiting forever. In both cases, no data is transferred.

This option is incompatible with the tunnel mode.

NAME

nginx - HTTP and reverse proxy server, mail proxy server

SYNOPSIS

lib/nginx [**-?hqtVv**] [**-c** *file*] [**-g** *directives*] [**-p** *prefix*] [**-s** *signal*]

DESCRIPTION

nginx (pronounced engine x) is an HTTP and reverse proxy server, as well as a mail proxy server. It is known for its high performance, stability, rich feature set, simple configuration, and low resource consumption.

OPTIONS

-h, -? Print help.

-c *file* Use an alternative configuration *file* .

-g *directives*
Set global configuration directives. See **EXAMPLES** for details.

-p *prefix* Set the prefix path. The default value is `%%PREFIX%%` .

-q Suppress non-error messages during configuration testing.

-s *signal* Send a signal to the master process. The argument *signal* can be one of: **stop** , **quit** , **reopen** , **reload** .

The following table shows the corresponding system signals:

```
stop SIGTERM
quit SIGQUIT
reopen SIGUSR1
reload SIGHUP
```

-t Do not run, just test the configuration file. **nginx** checks the configuration file syntax and then tries to open files referenced in the configuration file.

-V Print the **nginx** version, compiler version, and *configure* script parameters.

-v Print the **nginx** version.

SIGNALS

The master process of **nginx** can handle the following signals:

SIGINT, SIGTERM

Shut down quickly.

SIGHUP Reload configuration, start the new worker process with a new configuration, and gracefully shut down old worker processes.

SIGQUIT Shut down gracefully.

SIGUSR1 Reopen log files.

SIGUSR2 Upgrade the **nginx** executable on the fly.

SIGWINCH

Shut down worker processes gracefully.

While there is no need to explicitly control worker processes normally, they support some signals too:

SIGTERM

Shut down quickly.

SIGQUIT Shut down gracefully.

SIGUSR1 Reopen log files.

DEBUGGING LOG

To enable a debugging log, reconfigure **nginx** to build with debugging:

```
./configure --with-debug ...
```

and then set the **debug** level of the **error_log** :

```
error_log /path/to/log debug;
```

It is also possible to enable the debugging for a particular IP address:

```
events {
    debug_connection 127.0.0.1;
}
```

ENVIRONMENT

The **\$NGINX** environment variable is used internally by **nginx** and should not be set directly by the user.

FILES

%%PID_PATH%

Contains the process ID of **nginx** . The contents of this file are not sensitive, so it can be world-readable.

%%CONF_PATH%

The main configuration file.

%%ERROR_LOG_PATH%

Error log file.

EXIT STATUS

Exit status is **0** on success, or **1** if the command fails.

EXAMPLES

Test configuration file **~/mynginx.cfg** with global directives for PID and quantity of worker processes:

```
nginx -t -c ~/mynginx.conf \  
-g "pid /var/run/mynginx.pid; worker_processes 2;"
```

SEE ALSO

Documentation at <http://nginx.org/en/docs/> .

For questions and technical support, please refer to <http://nginx.org/en/support.html> .

HISTORY

Development of **nginx** started in 2002, with the first public release on October 4, 2004.

AUTHORS

Igor Sysoev <igor@sysoev.ru> .

This manual page was originally written by Sergey A. Osokin <osa@FreeBSD.org.ru> as a result of compiling many **nginx** documents from all over the world.

NAME

nmap – Network exploration tool and security / port scanner

SYNOPSIS

nmap [*Scan Type...*] [*Options*] {*target specification*}

DESCRIPTION

Nmap (Network Mapper) is an open source tool for network exploration and security auditing. It was designed to rapidly scan large networks, although it works fine against single hosts. Nmap uses raw IP packets in novel ways to determine what hosts are available on the network, what services (application name and version) those hosts are offering, what operating systems (and OS versions) they are running, what type of packet filters/firewalls are in use, and dozens of other characteristics. While Nmap is commonly used for security audits, many systems and network administrators find it useful for routine tasks such as network inventory, managing service upgrade schedules, and monitoring host or service uptime.

The output from Nmap is a list of scanned targets, with supplemental information on each depending on the options used. Key among that information is the “interesting ports table”.. That table lists the port number and protocol, service name, and state. The state is either open, filtered, closed, or unfiltered. Open. means that an application on the target machine is listening for connections/packets on that port. Filtered. means that a firewall, filter, or other network obstacle is blocking the port so that Nmap cannot tell whether it is open or closed. Closed. ports have no application listening on them, though they could open up at any time. Ports are classified as unfiltered. when they are responsive to Nmap's probes, but Nmap cannot determine whether they are open or closed. Nmap reports the state combinations open|filtered. and closed|filtered. when it cannot determine which of the two states describe a port. The port table may also include software version details when version detection has been requested. When an IP protocol scan is requested (**-sO**), Nmap provides information on supported IP protocols rather than listening ports.

In addition to the interesting ports table, Nmap can provide further information on targets, including reverse DNS names, operating system guesses, device types, and MAC addresses.

A typical Nmap scan is shown in Example 1. The only Nmap arguments used in this example are **-A**, to enable OS and version detection, script scanning, and traceroute; **-T4** for faster execution; and then the two target hostnames.

Example 1. A representative Nmap scan

```
# nmap -A -T4 scanme.nmap.org
```

```
Nmap scan report for scanme.nmap.org (74.207.244.221)
Host is up (0.029s latency).

Nmap done: 1 IP address (1 host up) scanned in 14.40 seconds

The newest version of Nmap can be obtained from <http://nmap.org>. The newest version of this man page is available at <http://nmap.org/book/man.html>. It is also included as a chapter of Nmap Network Scanning: The Official Nmap Project Guide to Network Discovery and Security Scanning (see <http://nmap.org/book/>).

OPTIONS SUMMARY

This options summary is printed when Nmap is run with no arguments, and the latest version is always available at <https://svn.nmap.org/nmap/docs/nmap.usage.txt>. It helps people remember the most common options, but is no substitute for the in-depth documentation in the rest of this manual. Some obscure options aren't even included here.

Nmap 6.25 (<http://nmap.org>)

Usage: nmap [Scan Type(s)] [Options] {target specification}

TARGET SPECIFICATION:

Can pass hostnames, IP addresses, networks, etc.

Ex: scanme.nmap.org, microsoft.com/24, 192.168.0.1; 10.0.0-255.1-254

-iL <inputfilename>: Input from list of hosts/networks

-iR <num hosts>: Choose random targets

--exclude <host1[,host2][,host3],...>: Exclude hosts/networks

--excludefile <exclude_file>: Exclude list from file

HOST DISCOVERY:

-sL: List Scan - simply list targets to scan

-sn: Ping Scan - disable port scan

-Pn: Treat all hosts as online -- skip host discovery

-PS/PA/PU/PY[portlist]: TCP SYN/ACK, UDP or SCTP discovery to given ports

-PE/PP/PM: ICMP echo, timestamp, and netmask request discovery probes

-PO[protocol list]: IP Protocol Ping

-n/-R: Never do DNS resolution/Always resolve [default: sometimes]

--dns-servers <serv1[,serv2],...>: Specify custom DNS servers

--system-dns: Use OS's DNS resolver

--traceroute: Trace hop path to each host

SCAN TECHNIQUES:

-sS/sT/sA/sW/sM: TCP SYN/Connect()/ACK/Window/Maimon scans

-sU: UDP Scan

-sN/sF/sX: TCP Null, FIN, and Xmas scans

--scanflags <flags>: Customize TCP scan flags

-sI <zombie host[:probeport]>: Idle scan

-sY/sZ: SCTP INIT/COOKIE-ECHO scans

-sO: IP protocol scan

-b <FTP relay host>: FTP bounce scan

PORT SPECIFICATION AND SCAN ORDER:

-p <port ranges>: Only scan specified ports

Ex: -p22; -p1-65535; -p U:53,111,137,T:21-25,80,139,8080,S:9

-F: Fast mode - Scan fewer ports than the default scan

-r: Scan ports consecutively - don't randomize

--top-ports <number>: Scan <number> most common ports

--port-ratio <ratio>: Scan ports more common than <ratio>

SERVICE/VERSION DETECTION:

-sV: Probe open ports to determine service/version info

--version-intensity <level>: Set from 0 (light) to 9 (try all probes)
 --version-light: Limit to most likely probes (intensity 2)
 --version-all: Try every single probe (intensity 9)
 --version-trace: Show detailed version scan activity (for debugging)

SCRIPT SCAN:

-sC: equivalent to --script=default
 --script=<Lua scripts>: <Lua scripts> is a comma separated list of directories, script-files or script-categories
 --script-args=<n1=v1,[n2=v2,...]>: provide arguments to scripts
 --script-args-file=filename: provide NSE script args in a file
 --script-trace: Show all data sent and received
 --script-updatedb: Update the script database.
 --script-help=<Lua scripts>: Show help about scripts.
 <Lua scripts> is a comma separated list of script-files or script-categories.

OS DETECTION:

-O: Enable OS detection
 --osscan-limit: Limit OS detection to promising targets
 --osscan-guess: Guess OS more aggressively

TIMING AND PERFORMANCE:

Options which take <time> are in seconds, or append 'ms' (milliseconds), 's' (seconds), 'm' (minutes), or 'h' (hours) to the value (e.g. 30m).
 -T<0-5>: Set timing template (higher is faster)
 --min-hostgroup/max-hostgroup <size>: Parallel host scan group sizes
 --min-parallelism/max-parallelism <numprobes>: Probe parallelization
 --min-rtt-timeout/max-rtt-timeout/initial-rtt-timeout <time>: Specifies probe round trip time.
 --max-retries <tries>: Caps number of port scan probe retransmissions.
 --host-timeout <time>: Give up on target after this long
 --scan-delay/--max-scan-delay <time>: Adjust delay between probes
 --min-rate <number>: Send packets no slower than <number> per second
 --max-rate <number>: Send packets no faster than <number> per second

FIREWALL/IDS EVASION AND SPOOFING:

-f; --mtu <val>: fragment packets (optionally w/given MTU)
 -D <decoy1,decoy2[,ME],...>: Cloak a scan with decoys
 -S <IP_Address>: Spoof source address
 -e <iface>: Use specified interface
 -g/--source-port <portnum>: Use given port number
 --data-length <num>: Append random data to sent packets
 --ip-options <options>: Send packets with specified ip options
 --ttl <val>: Set IP time-to-live field
 --spoof-mac <mac address/prefix/vendor name>: Spoof your MAC address
 --badsum: Send packets with a bogus TCP/UDP/SCTP checksum

OUTPUT:

-oN/-oX/-oS/-oG <file>: Output scan in normal, XML, s|<rlpt klddi3, and Grepable format, respectively, to the given filename.
 -oA <basename>: Output in the three major formats at once
 -v: Increase verbosity level (use -vv or more for greater effect)
 -d: Increase debugging level (use -dd or more for greater effect)
 --reason: Display the reason a port is in a particular state
 --open: Only show open (or possibly open) ports
 --packet-trace: Show all packets sent and received
 --iflist: Print host interfaces and routes (for debugging)
 --log-errors: Log errors/warnings to the normal-format output file

--append-output: Append to rather than clobber specified output files
 --resume <filename>: Resume an aborted scan
 --stylesheet <path/URL>: XSL stylesheet to transform XML output to HTML
 --webxml: Reference stylesheet from Nmap.Org for more portable XML
 --no-stylesheet: Prevent associating of XSL stylesheet w/XML output

MISC:

-6: Enable IPv6 scanning
 -A: Enable OS detection, version detection, script scanning, and traceroute
 --datadir <dirname>: Specify custom Nmap data file location
 --send-eth/--send-ip: Send using raw ethernet frames or IP packets
 --privileged: Assume that the user is fully privileged
 --unprivileged: Assume the user lacks raw socket privileges
 -V: Print version number
 -h: Print this help summary page.

EXAMPLES:

```
nmap -v -A scanme.nmap.org
nmap -v -sn 192.168.0.0/16 10.0.0.0/8
nmap -v -iR 10000 -Pn -p 80
```

SEE THE MAN PAGE (<http://nmap.org/book/man.html>) FOR MORE OPTIONS AND EXAMPLES

TARGET SPECIFICATION

Everything on the Nmap command-line that isn't an option (or option argument) is treated as a target host specification. The simplest case is to specify a target IP address or hostname for scanning.

Sometimes you wish to scan a whole network of adjacent hosts. For this, Nmap supports CIDR-style addressing. You can append */numbits* to an IPv4 address or hostname and Nmap will scan every IP address for which the first *numbits* are the same as for the reference IP or hostname given. For example, 192.168.10.0/24 would scan the 256 hosts between 192.168.10.0 (binary: 11000000 10101000 00001010 00000000) and 192.168.10.255 (binary: 11000000 10101000 00001010 11111111), inclusive. 192.168.10.40/24 would scan exactly the same targets. Given that the host scanme.nmap.org. is at the IP address 64.13.134.52, the specification scanme.nmap.org/16 would scan the 65,536 IP addresses between 64.13.0.0 and 64.13.255.255. The smallest allowed value is /0, which targets the whole Internet. The largest value is /32, which scans just the named host or IP address because all address bits are fixed.

CIDR notation is short but not always flexible enough. For example, you might want to scan 192.168.0.0/16 but skip any IPs ending with .0 or .255 because they may be used as subnet network and broadcast addresses. Nmap supports this through octet range addressing. Rather than specify a normal IP address, you can specify a comma-separated list of numbers or ranges for each octet. For example, 192.168.0-255.1-254 will skip all addresses in the range that end in .0 or .255, and 192.168.3-5.7.1 will scan the four addresses 192.168.3.1, 192.168.4.1, 192.168.5.1, and 192.168.7.1. Either side of a range may be omitted; the default values are 0 on the left and 255 on the right. Using - by itself is the same as 0-255, but remember to use 0- in the first octet so the target specification doesn't look like a command-line option. Ranges need not be limited to the final octets: the specifier 0-255.0-255.13.37 will perform an Internet-wide scan for all IP addresses ending in 13.37. This sort of broad sampling can be useful for Internet surveys and research.

IPv6 addresses can only be specified by their fully qualified IPv6 address or hostname. CIDR and octet ranges aren't yet supported for IPv6.

IPv6 addresses with non-global scope need to have a zone ID suffix. On Unix systems, this is a percent sign followed by an interface name; a complete address might be fe80::a8bb:ccff:fedd:eeff%eth0. On Windows, use an interface index number in place of an interface name: fe80::a8bb:ccff:fedd:eeff%1. You can see a list of interface indexes by running the command **netsh.exe interface ipv6 show interface**.

Nmap accepts multiple host specifications on the command line, and they don't need to be the same type. The command **nmap scanme.nmap.org 192.168.0.0/8 10.0.0.1,3-7.-** does what you would expect.

While targets are usually specified on the command lines, the following options are also available to control target selection:

-iL *inputfilename* (Input from list) .

Reads target specifications from *inputfilename*. Passing a huge list of hosts is often awkward on the command line, yet it is a common desire. For example, your DHCP server might export a list of 10,000 current leases that you wish to scan. Or maybe you want to scan all IP addresses *except* for those to locate hosts using unauthorized static IP addresses. Simply generate the list of hosts to scan and pass that filename to Nmap as an argument to the **-iL** option. Entries can be in any of the formats accepted by Nmap on the command line (IP address, hostname, CIDR, IPv6, or octet ranges). Each entry must be separated by one or more spaces, tabs, or newlines. You can specify a hyphen (-) as the filename if you want Nmap to read hosts from standard input rather than an actual file.

The input file may contain comments that start with # and extend to the end of the line.

-iR *num hosts* (Choose random targets) .

For Internet-wide surveys and other research, you may want to choose targets at random. The *num hosts* argument tells Nmap how many IPs to generate. Undesirable IPs such as those in certain private, multicast, or unallocated address ranges are automatically skipped. The argument 0 can be specified for a never-ending scan. Keep in mind that some network administrators bristle at unauthorized scans of their networks and may complain. Use this option at your own risk! If you find yourself really bored one rainy afternoon, try the command **nmap -Pn -sS -p 80 -iR 0 --open** to locate random web servers for browsing.

--exclude *host1[,host2[,...]]* (Exclude hosts/networks) .

Specifies a comma-separated list of targets to be excluded from the scan even if they are part of the overall network range you specify. The list you pass in uses normal Nmap syntax, so it can include hostnames, CIDR netblocks, octet ranges, etc. This can be useful when the network you wish to scan includes untouchable mission-critical servers, systems that are known to react adversely to port scans, or subnets administered by other people.

--excludefile *exclude_file* (Exclude list from file) .

This offers the same functionality as the **--exclude** option, except that the excluded targets are provided in a newline-, space-, or tab-delimited *exclude_file* rather than on the command line.

The exclude file may contain comments that start with # and extend to the end of the line.

HOST DISCOVERY

One of the very first steps in any network reconnaissance mission is to reduce a (sometimes huge) set of IP ranges into a list of active or interesting hosts. Scanning every port of every single IP address is slow and usually unnecessary. Of course what makes a host interesting depends greatly on the scan purposes. Network administrators may only be interested in hosts running a certain service, while security auditors may care about every single device with an IP address. An administrator may be comfortable using just an ICMP ping to locate hosts on his internal network, while an external penetration tester may use a diverse set of dozens of probes in an attempt to evade firewall restrictions.

Because host discovery needs are so diverse, Nmap offers a wide variety of options for customizing the techniques used. Host discovery is sometimes called ping scan, but it goes well beyond the simple ICMP echo request packets associated with the ubiquitous ping tool. Users can skip the ping step entirely with a list scan (**-sL**) or by disabling ping (**-Pn**), or engage the network with arbitrary combinations of multi-port TCP SYN/ACK, UDP, SCTP INIT and ICMP probes. The goal of these probes is to solicit responses which demonstrate that an IP address is actually active (is being used by a host or network device). On many networks, only a small percentage of IP addresses are active at any given time. This is particularly common with private address space such as 10.0.0.0/8. That network has 16 million IPs, but I have seen it used by companies with less than a thousand machines. Host discovery can find those machines in a sparsely allocated sea of IP addresses.

If no host discovery options are given, Nmap sends an ICMP echo request, a TCP SYN packet to port 443, a TCP ACK packet to port 80, and an ICMP timestamp request. (For IPv6, the ICMP timestamp request is omitted because it is not part of ICMPv6.) These defaults are equivalent to the **-PE -PS443 -PA80 -PP** options. The exceptions to this are the ARP (for IPv4) and Neighbor Discovery. (for IPv6) scans which are

used for any targets on a local ethernet network. For unprivileged Unix shell users, the default probes are a SYN packet to ports 80 and 443 using the **connect** system call.. This host discovery is often sufficient when scanning local networks, but a more comprehensive set of discovery probes is recommended for security auditing.

The **-P*** options (which select ping types) can be combined. You can increase your odds of penetrating strict firewalls by sending many probe types using different TCP ports/flags and ICMP codes. Also note that ARP/Neighbor Discovery (**-PR**) is done by default against targets on a local ethernet network even if you specify other **-P*** options, because it is almost always faster and more effective.

By default, Nmap does host discovery and then performs a port scan against each host it determines is online. This is true even if you specify non-default host discovery types such as UDP probes (**-PU**). Read about the **-sn** option to learn how to perform only host discovery, or use **-Pn** to skip host discovery and port scan all target hosts. The following options control host discovery:

-sL (List Scan) .

The list scan is a degenerate form of host discovery that simply lists each host of the network(s) specified, without sending any packets to the target hosts. By default, Nmap still does reverse-DNS resolution on the hosts to learn their names. It is often surprising how much useful information simple hostnames give out. For example, fw.chi is the name of one company's Chicago firewall. Nmap also reports the total number of IP addresses at the end. The list scan is a good sanity check to ensure that you have proper IP addresses for your targets. If the hosts sport domain names you do not recognize, it is worth investigating further to prevent scanning the wrong company's network.

Since the idea is to simply print a list of target hosts, options for higher level functionality such as port scanning, OS detection, or ping scanning cannot be combined with this. If you wish to disable ping scanning while still performing such higher level functionality, read up on the **-Pn** (skip ping) option.

-sn (No port scan) .

This option tells Nmap not to do a port scan after host discovery, and only print out the available hosts that responded to the scan. This is often known as a "ping scan", but you can also request that traceroute and NSE host scripts be run. This is by default one step more intrusive than the list scan, and can often be used for the same purposes. It allows light reconnaissance of a target network without attracting much attention. Knowing how many hosts are up is more valuable to attackers than the list provided by list scan of every single IP and host name.

Systems administrators often find this option valuable as well. It can easily be used to count available machines on a network or monitor server availability. This is often called a ping sweep, and is more reliable than pinging the broadcast address because many hosts do not reply to broadcast queries.

The default host discovery done with **-sn** consists of an ICMP echo request, TCP SYN to port 443, TCP ACK to port 80, and an ICMP timestamp request by default. When executed by an unprivileged user, only SYN packets are sent (using a **connect** call) to ports 80 and 443 on the target. When a privileged user tries to scan targets on a local ethernet network, ARP requests are used unless **--send-ip** was specified. The **-sn** option can be combined with any of the discovery probe types (the **-P*** options, excluding **-Pn**) for greater flexibility. If any of those probe type and port number options are used, the default probes are overridden. When strict firewalls are in place between the source host running Nmap and the target network, using those advanced techniques is recommended. Otherwise hosts could be missed when the firewall drops probes or their responses.

In previous releases of Nmap, **-sn** was known as **-sP**..

-Pn (No ping) .

This option skips the Nmap discovery stage altogether. Normally, Nmap uses this stage to determine active machines for heavier scanning. By default, Nmap only performs heavy probing such as port scans, version detection, or OS detection against hosts that are found to be up. Disabling host discovery with **-Pn** causes Nmap to attempt the requested scanning functions against *every* target IP

address specified. So if a class B target address space (/16) is specified on the command line, all 65,536 IP addresses are scanned. Proper host discovery is skipped as with the list scan, but instead of stopping and printing the target list, Nmap continues to perform requested functions as if each target IP is active. To skip ping scan *and* port scan, while still allowing NSE to run, use the two options **-Pn** **-sn** together.

For machines on a local ethernet network, ARP scanning will still be performed (unless **--disable-arp-ping** or **--send-ip** is specified) because Nmap needs MAC addresses to further scan target hosts. In previous versions of Nmap, **-Pn** was **-P0**. and **-PN**..

-PS *port list* (TCP SYN Ping) .

This option sends an empty TCP packet with the SYN flag set. The default destination port is 80 (configurable at compile time by changing `DEFAULT_TCP_PROBE_PORT_SPEC`. in `nmap.h`).. Alternate ports can be specified as a parameter. The syntax is the same as for the **-p** except that port type specifiers like T: are not allowed. Examples are **-PS22** and **-PS22-25,80,113,1050,35000**. Note that there can be no space between **-PS** and the port list. If multiple probes are specified they will be sent in parallel.

The SYN flag suggests to the remote system that you are attempting to establish a connection. Normally the destination port will be closed, and a RST (reset) packet sent back. If the port happens to be open, the target will take the second step of a TCP three-way-handshake. by responding with a SYN/ACK TCP packet. The machine running Nmap then tears down the nascent connection by responding with a RST rather than sending an ACK packet which would complete the three-way-handshake and establish a full connection. The RST packet is sent by the kernel of the machine running Nmap in response to the unexpected SYN/ACK, not by Nmap itself.

Nmap does not care whether the port is open or closed. Either the RST or SYN/ACK response discussed previously tell Nmap that the host is available and responsive.

On Unix boxes, only the privileged user root. is generally able to send and receive raw TCP packets.. For unprivileged users, a workaround is automatically employed. whereby the **connect** system call is initiated against each target port. This has the effect of sending a SYN packet to the target host, in an attempt to establish a connection. If **connect** returns with a quick success or an ECONNREFUSED failure, the underlying TCP stack must have received a SYN/ACK or RST and the host is marked available. If the connection attempt is left hanging until a timeout is reached, the host is marked as down.

-PA *port list* (TCP ACK Ping) .

The TCP ACK ping is quite similar to the just-discussed SYN ping. The difference, as you could likely guess, is that the TCP ACK flag is set instead of the SYN flag. Such an ACK packet purports to be acknowledging data over an established TCP connection, but no such connection exists. So remote hosts should always respond with a RST packet, disclosing their existence in the process.

The **-PA** option uses the same default port as the SYN probe (80) and can also take a list of destination ports in the same format. If an unprivileged user tries this, the **connect** workaround discussed previously is used. This workaround is imperfect because **connect** is actually sending a SYN packet rather than an ACK.

The reason for offering both SYN and ACK ping probes is to maximize the chances of bypassing firewalls. Many administrators configure routers and other simple firewalls to block incoming SYN packets except for those destined for public services like the company web site or mail server. This prevents other incoming connections to the organization, while allowing users to make unobstructed outgoing connections to the Internet. This non-stateful approach takes up few resources on the firewall/router and is widely supported by hardware and software filters. The Linux Netfilter/iptables. firewall software offers the **--syn** convenience option to implement this stateless approach. When stateless firewall rules such as this are in place, SYN ping probes (**-PS**) are likely to be blocked when

sent to closed target ports. In such cases, the ACK probe shines as it cuts right through these rules.

Another common type of firewall uses stateful rules that drop unexpected packets. This feature was initially found mostly on high-end firewalls, though it has become much more common over the years. The Linux Netfilter/iptables system supports this through the **--state** option, which categorizes packets based on connection state. A SYN probe is more likely to work against such a system, as unexpected ACK packets are generally recognized as bogus and dropped. A solution to this quandary is to send both SYN and ACK probes by specifying **-PS** and **-PA**.

-PU *port list* (UDP Ping) .

Another host discovery option is the UDP ping, which sends a UDP packet to the given ports. For most ports, the packet will be empty, though for a few a protocol-specific payload will be sent that is more likely to get a response.. The payload database is described at <http://nmap.org/book/nmap-payloads.html>.

The **--data-length** option can be used to send a fixed-length random payload to every port or (if you specify a value of 0) to disable payloads. You can also disable payloads by specifying **--data-length 0**.

The port list takes the same format as with the previously discussed **-PS** and **-PA** options. If no ports are specified, the default is 40125.. This default can be configured at compile-time by changing *DEFAULT_UDP_PROBE_PORT_SPEC*. in *nmap.h*.. A highly uncommon port is used by default because sending to open ports is often undesirable for this particular scan type.

Upon hitting a closed port on the target machine, the UDP probe should elicit an ICMP port unreachable packet in return. This signifies to Nmap that the machine is up and available. Many other types of ICMP errors, such as host/network unreachables or TTL exceeded are indicative of a down or unreachable host. A lack of response is also interpreted this way. If an open port is reached, most services simply ignore the empty packet and fail to return any response. This is why the default probe port is 40125, which is highly unlikely to be in use. A few services, such as the Character Generator (chargen) protocol, will respond to an empty UDP packet, and thus disclose to Nmap that the machine is available.

The primary advantage of this scan type is that it bypasses firewalls and filters that only screen TCP. For example, I once owned a Linksys BEFW11S4 wireless broadband router. The external interface of this device filtered all TCP ports by default, but UDP probes would still elicit port unreachable messages and thus give away the device.

-PY *port list* (SCTP INIT Ping) .

This option sends an SCTP packet containing a minimal INIT chunk. The default destination port is 80 (configurable at compile time by changing *DEFAULT_SCTP_PROBE_PORT_SPEC*. in *nmap.h*). Alternate ports can be specified as a parameter. The syntax is the same as for the **-p** except that port type specifiers like *S:* are not allowed. Examples are **-PY22** and **-PY22,80,179,5060**. Note that there can be no space between **-PY** and the port list. If multiple probes are specified they will be sent in parallel.

The INIT chunk suggests to the remote system that you are attempting to establish an association. Normally the destination port will be closed, and an ABORT chunk will be sent back. If the port happens to be open, the target will take the second step of an SCTP four-way-handshake. by responding with an INIT-ACK chunk. If the machine running Nmap has a functional SCTP stack, then it tears down the nascent association by responding with an ABORT chunk rather than sending a COOKIE-ECHO chunk which would be the next step in the four-way-handshake. The ABORT packet is sent by the kernel of the machine running Nmap in response to the unexpected INIT-ACK, not by Nmap itself.

Nmap does not care whether the port is open or closed. Either the ABORT or INIT-ACK response

discussed previously tell Nmap that the host is available and responsive.

On Unix boxes, only the privileged user root. is generally able to send and receive raw SCTP packets.. Using SCTP INIT Pings is currently not possible for unprivileged users..

-PE; -PP; -PM (ICMP Ping Types) .

In addition to the unusual TCP, UDP and SCTP host discovery types discussed previously, Nmap can send the standard packets sent by the ubiquitous ping program. Nmap sends an ICMP type 8 (echo request) packet to the target IP addresses, expecting a type 0 (echo reply) in return from available hosts.. Unfortunately for network explorers, many hosts and firewalls now block these packets, rather than responding as required by [RFC 1122](#)^[2].. For this reason, ICMP-only scans are rarely reliable enough against unknown targets over the Internet. But for system administrators monitoring an internal network, they can be a practical and efficient approach. Use the **-PE** option to enable this echo request behavior.

While echo request is the standard ICMP ping query, Nmap does not stop there. The ICMP standards ([RFC 792](#)^[3]. and [RFC 950](#)^[4]. “a host SHOULD NOT implement these messages”. Timestamp and address mask queries can be sent with the **-PP** and **-PM** options, respectively. A timestamp reply (ICMP code 14) or address mask reply (code 18) discloses that the host is available. These two queries can be valuable when administrators specifically block echo request packets while forgetting that other ICMP queries can be used for the same purpose.

-PO *protocol list* (IP Protocol Ping) .

One of the newer host discovery options is the IP protocol ping, which sends IP packets with the specified protocol number set in their IP header. The protocol list takes the same format as do port lists in the previously discussed TCP, UDP and SCTP host discovery options. If no protocols are specified, the default is to send multiple IP packets for ICMP (protocol 1), IGMP (protocol 2), and IP-in-IP (protocol 4). The default protocols can be configured at compile-time by changing `DEFAULT_PROTO_PROBE_PORT_SPEC.` in `nmap.h`. Note that for the ICMP, IGMP, TCP (protocol 6), UDP (protocol 17) and SCTP (protocol 132), the packets are sent with the proper protocol headers. while other protocols are sent with no additional data beyond the IP header (unless the **---data-length.** option is specified).

This host discovery method looks for either responses using the same protocol as a probe, or ICMP protocol unreachable messages which signify that the given protocol isn't supported on the destination host. Either type of response signifies that the target host is alive.

-PR (ARP Ping) .

One of the most common Nmap usage scenarios is to scan an ethernet LAN. On most LANs, especially those using private address ranges specified by [RFC 1918](#)^[5], the vast majority of IP addresses are unused at any given time. When Nmap tries to send a raw IP packet such as an ICMP echo request, the operating system must determine the destination hardware (ARP) address corresponding to the target IP so that it can properly address the ethernet frame. This is often slow and problematic, since operating systems weren't written with the expectation that they would need to do millions of ARP requests against unavailable hosts in a short time period.

ARP scan puts Nmap and its optimized algorithms in charge of ARP requests. And if it gets a response back, Nmap doesn't even need to worry about the IP-based ping packets since it already knows the host is up. This makes ARP scan much faster and more reliable than IP-based scans. So it is done by default when scanning ethernet hosts that Nmap detects are on a local ethernet network. Even if different ping types (such as **-PE** or **-PS**) are specified, Nmap uses ARP instead for any of the targets which are on the same LAN. If you absolutely don't want to do an ARP scan, specify **---disable-arp-ping.**

For IPv6 (**-6** option), **-PR** uses ICMPv6 Neighbor Discovery instead of ARP. Neighbor Discovery, defined in RFC 4861, can be seen as the IPv6 equivalent of ARP.

---disable-arp-ping (No ARP or ND Ping) .

Nmap normally does ARP or IPv6 Neighbor Discovery (ND) discovery of locally connected ethernet hosts, even if other host discovery options such as **-Pn** or **-PE** are used. To disable this implicit behavior, use the **---disable-arp-ping** option.

The default behavior is normally faster, but this option is useful on networks using proxy ARP, in which a router speculatively replies to all ARP requests, making every target appear to be up according to ARP scan.

---traceroute (Trace path to host) .

Traceroutes are performed post-scan using information from the scan results to determine the port and protocol most likely to reach the target. It works with all scan types except connect scans (**-sT**) and idle scans (**-sI**). All traces use Nmap's dynamic timing model and are performed in parallel.

Traceroute works by sending packets with a low TTL (time-to-live) in an attempt to elicit ICMP Time Exceeded messages from intermediate hops between the scanner and the target host. Standard traceroute implementations start with a TTL of 1 and increment the TTL until the destination host is reached. Nmap's traceroute starts with a high TTL and then decrements the TTL until it reaches zero. Doing it backwards lets Nmap employ clever caching algorithms to speed up traces over multiple hosts. On average Nmap sends 5–10 fewer packets per host, depending on network conditions. If a single subnet is being scanned (i.e. 192.168.0.0/24) Nmap may only have to send two packets to most hosts.

-n (No DNS resolution) .

Tells Nmap to *never* do reverse DNS resolution on the active IP addresses it finds. Since DNS can be slow even with Nmap's built-in parallel stub resolver, this option can slash scanning times.

-R (DNS resolution for all targets) .

Tells Nmap to *always* do reverse DNS resolution on the target IP addresses. Normally reverse DNS is only performed against responsive (online) hosts.

---system-dns (Use system DNS resolver) .

By default, Nmap resolves IP addresses by sending queries directly to the name servers configured on your host and then listening for responses. Many requests (often dozens) are performed in parallel to improve performance. Specify this option to use your system resolver instead (one IP at a time via the **getnameinfo** call). This is slower and rarely useful unless you find a bug in the Nmap parallel resolver (please let us know if you do). The system resolver is always used for IPv6 scans.

---dns-servers *server1[,server2[,...]]* (Servers to use for reverse DNS queries) .

By default, Nmap determines your DNS servers (for rDNS resolution) from your **resolv.conf** file (Unix) or the Registry (Win32). Alternatively, you may use this option to specify alternate servers. This option is not honored if you are using **---system-dns** or an IPv6 scan. Using multiple DNS servers is often faster, especially if you choose authoritative servers for your target IP space. This option can also improve stealth, as your requests can be bounced off just about any recursive DNS server on the Internet.

This option also comes in handy when scanning private networks. Sometimes only a few name servers provide proper rDNS information, and you may not even know where they are. You can scan the network for port 53 (perhaps with version detection), then try Nmap list scans (**-sL**) specifying each name server one at a time with **---dns-servers** until you find one which works.

PORT SCANNING BASICS

While Nmap has grown in functionality over the years, it began as an efficient port scanner, and that remains its core function. The simple command **nmap target** scans 1,000 TCP ports on the host *target*. While many port scanners have traditionally lumped all ports into the open or closed states, Nmap is much more granular. It divides ports into six states: open, closed, filtered, unfiltered, open|filtered, or closed|filtered.

These states are not intrinsic properties of the port itself, but describe how Nmap sees them. For example,

an Nmap scan from the same network as the target may show port 135/tcp as open, while a scan at the same time with the same options from across the Internet might show that port as filtered.

The six port states recognized by Nmap

An application is actively accepting TCP connections, UDP datagrams or SCTP associations on this port. Finding these is often the primary goal of port scanning. Security-minded people know that each open port is an avenue for attack. Attackers and pen-testers want to exploit the open ports, while administrators try to close or protect them with firewalls without thwarting legitimate users. Open ports are also interesting for non-security scans because they show services available for use on the network.

A closed port is accessible (it receives and responds to Nmap probe packets), but there is no application listening on it. They can be helpful in showing that a host is up on an IP address (host discovery, or ping scanning), and as part of OS detection. Because closed ports are reachable, it may be worth scanning later in case some open up. Administrators may want to consider blocking such ports with a firewall. Then they would appear in the filtered state, discussed next.

Nmap cannot determine whether the port is open because packet filtering prevents its probes from reaching the port. The filtering could be from a dedicated firewall device, router rules, or host-based firewall software. These ports frustrate attackers because they provide so little information. Sometimes they respond with ICMP error messages such as type 3 code 13 (destination unreachable: communication administratively prohibited), but filters that simply drop probes without responding are far more common. This forces Nmap to retry several times just in case the probe was dropped due to network congestion rather than filtering. This slows down the scan dramatically.

The unfiltered state means that a port is accessible, but Nmap is unable to determine whether it is open or closed. Only the ACK scan, which is used to map firewall rulesets, classifies ports into this state. Scanning unfiltered ports with other scan types such as Window scan, SYN scan, or FIN scan, may help resolve whether the port is open.

Nmap places ports in this state when it is unable to determine whether a port is open or filtered. This occurs for scan types in which open ports give no response. The lack of response could also mean that a packet filter dropped the probe or any response it elicited. So Nmap does not know for sure whether the port is open or being filtered. The UDP, IP protocol, FIN, NULL, and Xmas scans classify ports this way.

This state is used when Nmap is unable to determine whether a port is closed or filtered. It is only used for the IP ID idle scan.

PORT SCANNING TECHNIQUES

As a novice performing automotive repair, I can struggle for hours trying to fit my rudimentary tools (hammer, duct tape, wrench, etc.) to the task at hand. When I fail miserably and tow my jalopy to a real mechanic, he invariably fishes around in a huge tool chest until pulling out the perfect gizmo which makes the job seem effortless. The art of port scanning is similar. Experts understand the dozens of scan techniques and choose the appropriate one (or combination) for a given task. Inexperienced users and script kiddies, on the other hand, try to solve every problem with the default SYN scan. Since Nmap is free, the only barrier to port scanning mastery is knowledge. That certainly beats the automotive world, where it may take great skill to determine that you need a strut spring compressor, then you still have to pay thousands of dollars for it.

Most of the scan types are only available to privileged users.. This is because they send and receive raw packets, which requires root access on Unix systems. Using an administrator account on Windows is recommended, though Nmap sometimes works for unprivileged users on that platform when WinPcap has already been loaded into the OS. Requiring root privileges was a serious limitation when Nmap was released in 1997, as many users only had access to shared shell accounts. Now, the world is different. Computers are cheaper, far more people have always-on direct Internet access, and desktop Unix systems (including Linux and Mac OS X) are prevalent. A Windows version of Nmap is now available, allowing it to run on even more desktops. For all these reasons, users have less need to run Nmap from limited shared shell accounts. This is fortunate, as the privileged options make Nmap far more powerful and flexible.

While Nmap attempts to produce accurate results, keep in mind that all of its insights are based on packets returned by the target machines (or firewalls in front of them). Such hosts may be untrustworthy and send responses intended to confuse or mislead Nmap. Much more common are non-RFC-compliant hosts that do not respond as they should to Nmap probes. FIN, NULL, and Xmas scans are particularly susceptible to this problem. Such issues are specific to certain scan types and so are discussed in the individual scan type entries.

This section documents the dozen or so port scan techniques supported by Nmap. Only one method may be used at a time, except that UDP scan (**-sU**) and any one of the SCTP scan types (**-sY**, **-sZ**) may be combined with any one of the TCP scan types. As a memory aid, port scan type options are of the form **-sC**, where *C* is a prominent character in the scan name, usually the first. The one exception to this is the deprecated FTP bounce scan (**-b**). By default, Nmap performs a SYN Scan, though it substitutes a connect scan if the user does not have proper privileges to send raw packets (requires root access on Unix). Of the scans listed in this section, unprivileged users can only execute connect and FTP bounce scans.

-sS (TCP SYN scan) .

SYN scan is the default and most popular scan option for good reasons. It can be performed quickly, scanning thousands of ports per second on a fast network not hampered by restrictive firewalls. It is also relatively unobtrusive and stealthy since it never completes TCP connections. SYN scan works against any compliant TCP stack rather than depending on idiosyncrasies of specific platforms as Nmap's FIN/NULL/Xmas, Maimon and idle scans do. It also allows clear, reliable differentiation between the open, closed, and filtered states.

This technique is often referred to as half-open scanning, because you don't open a full TCP connection. You send a SYN packet, as if you are going to open a real connection and then wait for a response. A SYN/ACK indicates the port is listening (open), while a RST (reset) is indicative of a non-listener. If no response is received after several retransmissions, the port is marked as filtered. The port is also marked filtered if an ICMP unreachable error (type 3, code 1, 2, 3, 9, 10, or 13) is received. The port is also considered open if a SYN packet (without the ACK flag) is received in response. This can be due to an extremely rare TCP feature known as a simultaneous open or split handshake connection (see <http://nmap.org/misc/split-handshake.pdf>).

-sT (TCP connect scan) .

TCP connect scan is the default TCP scan type when SYN scan is not an option. This is the case when a user does not have raw packet privileges. Instead of writing raw packets as most other scan types do, Nmap asks the underlying operating system to establish a connection with the target machine and port by issuing the **connect** system call. This is the same high-level system call that web browsers, P2P clients, and most other network-enabled applications use to establish a connection. It is part of a programming interface known as the Berkeley Sockets API. Rather than read raw packet responses off the wire, Nmap uses this API to obtain status information on each connection attempt.

When SYN scan is available, it is usually a better choice. Nmap has less control over the high level **connect** call than with raw packets, making it less efficient. The system call completes connections to open target ports rather than performing the half-open reset that SYN scan does. Not only does this take longer and require more packets to obtain the same information, but target machines are more likely to log the connection. A decent IDS will catch either, but most machines have no such alarm system. Many services on your average Unix system will add a note to syslog, and sometimes a cryptic error message, when Nmap connects and then closes the connection without sending data. Truly pathetic services crash when this happens, though that is uncommon. An administrator who sees a bunch of connection attempts in her logs from a single system should know that she has been connect scanned.

-sU (UDP scans) .

While most popular services on the Internet run over the TCP protocol, **UDP**^[6] services are widely deployed. DNS, SNMP, and DHCP (registered ports 53, 161/162, and 67/68) are three of the most common. Because UDP scanning is generally slower and more difficult than TCP, some security auditors ignore these ports. This is a mistake, as exploitable UDP services are quite common and

attackers certainly don't ignore the whole protocol. Fortunately, Nmap can help inventory UDP ports.

UDP scan is activated with the **-sU** option. It can be combined with a TCP scan type such as SYN scan (**-sS**) to check both protocols during the same run.

UDP scan works by sending a UDP packet to every targeted port. For some common ports such as 53 and 161, a protocol-specific payload is sent, but for most ports the packet is empty.. The **--data-length** option can be used to send a fixed-length random payload to every port or (if you specify a value of 0) to disable payloads. If an ICMP port unreachable error (type 3, code 3) is returned, the port is closed. Other ICMP unreachable errors (type 3, codes 1, 2, 9, 10, or 13) mark the port as filtered. Occasionally, a service will respond with a UDP packet, proving that it is open. If no response is received after retransmissions, the port is classified as open|filtered. This means that the port could be open, or perhaps packet filters are blocking the communication. Version detection (**-sV**) can be used to help differentiate the truly open ports from the filtered ones.

A big challenge with UDP scanning is doing it quickly. Open and filtered ports rarely send any response, leaving Nmap to time out and then conduct retransmissions just in case the probe or response were lost. Closed ports are often an even bigger problem. They usually send back an ICMP port unreachable error. But unlike the RST packets sent by closed TCP ports in response to a SYN or connect scan, many hosts rate limit ICMP port unreachable messages by default. Linux and Solaris are particularly strict about this. For example, the Linux 2.4.20 kernel limits destination unreachable messages to one per second (in net/ipv4/icmp.c).

Nmap detects rate limiting and slows down accordingly to avoid flooding the network with useless packets that the target machine will drop. Unfortunately, a Linux-style limit of one packet per second makes a 65,536-port scan take more than 18 hours. Ideas for speeding your UDP scans up include scanning more hosts in parallel, doing a quick scan of just the popular ports first, scanning from behind the firewall, and using **--host-timeout** to skip slow hosts.

-sY (SCTP INIT scan) .

SCTP^[7] is a relatively new alternative to the TCP and UDP protocols, combining most characteristics of TCP and UDP, and also adding new features like multi-homing and multi-streaming. It is mostly being used for SS7/SIGTRAN related services but has the potential to be used for other applications as well. SCTP INIT scan is the SCTP equivalent of a TCP SYN scan. It can be performed quickly, scanning thousands of ports per second on a fast network not hampered by restrictive firewalls. Like SYN scan, INIT scan is relatively unobtrusive and stealthy, since it never completes SCTP associations. It also allows clear, reliable differentiation between the open, closed, and filtered states.

This technique is often referred to as half-open scanning, because you don't open a full SCTP association. You send an INIT chunk, as if you are going to open a real association and then wait for a response. An INIT-ACK chunk indicates the port is listening (open), while an ABORT chunk is indicative of a non-listener. If no response is received after several retransmissions, the port is marked as filtered. The port is also marked filtered if an ICMP unreachable error (type 3, code 1, 2, 3, 9, 10, or 13) is received.

-sN; -sF; -sX (TCP NULL, FIN, and Xmas scans) .

These three scan types (even more are possible with the **--scanflags** option described in the next section) exploit a subtle loophole in the **TCP RFC**^[8] to differentiate between open and closed ports. Page 65 of RFC 793 says that "if the [destination] port state is CLOSED an incoming segment not containing a RST causes a RST to be sent in response." Then the next page discusses packets sent to open ports without the SYN, RST, or ACK bits set, stating that: "you are unlikely to get here, but if you do, drop the segment, and return."

When scanning systems compliant with this RFC text, any packet not containing SYN, RST, or ACK bits will result in a returned RST if the port is closed and no response at all if the port is open. As long

as none of those three bits are included, any combination of the other three (FIN, PSH, and URG) are OK. Nmap exploits this with three scan types:

Null scan (**-sN**)

Does not set any bits (TCP flag header is 0)

FIN scan (**-sF**)

Sets just the TCP FIN bit.

Xmas scan (**-sX**)

Sets the FIN, PSH, and URG flags, lighting the packet up like a Christmas tree.

These three scan types are exactly the same in behavior except for the TCP flags set in probe packets. If a RST packet is received, the port is considered closed, while no response means it is open|filtered. The port is marked filtered if an ICMP unreachable error (type 3, code 1, 2, 3, 9, 10, or 13) is received.

The key advantage to these scan types is that they can sneak through certain non-stateful firewalls and packet filtering routers. Another advantage is that these scan types are a little more stealthy than even a SYN scan. Don't count on this though—most modern IDS products can be configured to detect them. The big downside is that not all systems follow RFC 793 to the letter. A number of systems send RST responses to the probes regardless of whether the port is open or not. This causes all of the ports to be labeled closed. Major operating systems that do this are Microsoft Windows, many Cisco devices, BSDI, and IBM OS/400. This scan does work against most Unix-based systems though. Another downside of these scans is that they can't distinguish open ports from certain filtered ones, leaving you with the response open|filtered.

-sA (TCP ACK scan) .

This scan is different than the others discussed so far in that it never determines open (or even open|filtered) ports. It is used to map out firewall rulesets, determining whether they are stateful or not and which ports are filtered.

The ACK scan probe packet has only the ACK flag set (unless you use **--scanflags**). When scanning unfiltered systems, open and closed ports will both return a RST packet. Nmap then labels them as unfiltered, meaning that they are reachable by the ACK packet, but whether they are open or closed is undetermined. Ports that don't respond, or send certain ICMP error messages back (type 3, code 1, 2, 3, 9, 10, or 13), are labeled filtered.

-sW (TCP Window scan) .

Window scan is exactly the same as ACK scan except that it exploits an implementation detail of certain systems to differentiate open ports from closed ones, rather than always printing unfiltered when a RST is returned. It does this by examining the TCP Window field of the RST packets returned. On some systems, open ports use a positive window size (even for RST packets) while closed ones have a zero window. So instead of always listing a port as unfiltered when it receives a RST back, Window scan lists the port as open or closed if the TCP Window value in that reset is positive or zero, respectively.

This scan relies on an implementation detail of a minority of systems out on the Internet, so you can't always trust it. Systems that don't support it will usually return all ports closed. Of course, it is possible that the machine really has no open ports. If most scanned ports are closed but a few common port numbers (such as 22, 25, 53) are filtered, the system is most likely susceptible. Occasionally, systems will even show the exact opposite behavior. If your scan shows 1,000 open ports and three closed or filtered ports, then those three may very well be the truly open ones.

-sM (TCP Maimon scan) .

The Maimon scan is named after its discoverer, Uriel Maimon.. He described the technique in Phrack Magazine issue #49 (November 1996).. Nmap, which included this technique, was released two issues later. This technique is exactly the same as NULL, FIN, and Xmas scans, except that the probe is FIN/ACK. According to [RFC 793](#)^[8] (TCP), a RST packet should be generated in response to such a

probe whether the port is open or closed. However, Uriel noticed that many BSD-derived systems simply drop the packet if the port is open.

--scanflags (Custom TCP scan) .

Truly advanced Nmap users need not limit themselves to the canned scan types offered. The **--scanflags** option allows you to design your own scan by specifying arbitrary TCP flags.. Let your creative juices flow, while evading intrusion detection systems. whose vendors simply paged through the Nmap man page adding specific rules!

The **--scanflags** argument can be a numerical flag value such as 9 (PSH and FIN), but using symbolic names is easier. Just mash together any combination of URG, ACK, PSH, RST, SYN, and FIN. For example, **--scanflags URGACKPSHRSTSYNFIN** sets everything, though it's not very useful for scanning. The order these are specified in is irrelevant.

In addition to specifying the desired flags, you can specify a TCP scan type (such as **-sA** or **-sF**). That base type tells Nmap how to interpret responses. For example, a SYN scan considers no-response to indicate a filtered port, while a FIN scan treats the same as open|filtered. Nmap will behave the same way it does for the base scan type, except that it will use the TCP flags you specify instead. If you don't specify a base type, SYN scan is used.

-sZ (SCTP COOKIE ECHO scan) .

SCTP COOKIE ECHO scan is a more advanced SCTP scan. It takes advantage of the fact that SCTP implementations should silently drop packets containing COOKIE ECHO chunks on open ports, but send an ABORT if the port is closed. The advantage of this scan type is that it is not as obvious a port scan than an INIT scan. Also, there may be non-stateful firewall rulesets blocking INIT chunks, but not COOKIE ECHO chunks. Don't be fooled into thinking that this will make a port scan invisible; a good IDS will be able to detect SCTP COOKIE ECHO scans too. The downside is that SCTP COOKIE ECHO scans cannot differentiate between open and filtered ports, leaving you with the state open|filtered in both cases.

-sI *zombie host[:probeport]* (idle scan) .

This advanced scan method allows for a truly blind TCP port scan of the target (meaning no packets are sent to the target from your real IP address). Instead, a unique side-channel attack exploits predictable IP fragmentation ID sequence generation on the zombie host to glean information about the open ports on the target. IDS systems will display the scan as coming from the zombie machine you specify (which must be up and meet certain criteria). This fascinating scan type is too complex to fully describe in this reference guide, so I wrote and posted an informal paper with full details at <http://nmap.org/book/idlescan.html>.

Besides being extraordinarily stealthy (due to its blind nature), this scan type permits mapping out IP-based trust relationships between machines. The port listing shows open ports *from the perspective of the zombie host*. So you can try scanning a target using various zombies that you think might be trusted. (via router/packet filter rules).

You can add a colon followed by a port number to the zombie host if you wish to probe a particular port on the zombie for IP ID changes. Otherwise Nmap will use the port it uses by default for TCP pings (80).

-sO (IP protocol scan) .

IP protocol scan allows you to determine which IP protocols (TCP, ICMP, IGMP, etc.) are supported by target machines. This isn't technically a port scan, since it cycles through IP protocol numbers rather than TCP or UDP port numbers. Yet it still uses the **-p** option to select scanned protocol numbers, reports its results within the normal port table format, and even uses the same underlying scan engine as the true port scanning methods. So it is close enough to a port scan that it belongs here.

Besides being useful in its own right, protocol scan demonstrates the power of open-source software. While the fundamental idea is pretty simple, I had not thought to add it nor received any requests for

such functionality. Then in the summer of 2000, Gerhard Rieger conceived the idea, wrote an excellent patch implementing it, and sent it to the nmap-hackers mailing list. I incorporated that patch into the Nmap tree and released a new version the next day. Few pieces of commercial software have users enthusiastic enough to design and contribute their own improvements!

Protocol scan works in a similar fashion to UDP scan. Instead of iterating through the port number field of a UDP packet, it sends IP packet headers and iterates through the eight-bit IP protocol field. The headers are usually empty, containing no data and not even the proper header for the claimed protocol. The exceptions are TCP, UDP, ICMP, SCTP, and IGMP. A proper protocol header for those is included since some systems won't send them otherwise and because Nmap already has functions to create them. Instead of watching for ICMP port unreachable messages, protocol scan is on the lookout for ICMP *protocol* unreachable messages. If Nmap receives any response in any protocol from the target host, Nmap marks that protocol as open. An ICMP protocol unreachable error (type 3, code 2) causes the protocol to be marked as closed. Other ICMP unreachable errors (type 3, code 1, 3, 9, 10, or 13) cause the protocol to be marked filtered (though they prove that ICMP is open at the same time). If no response is received after retransmissions, the protocol is marked open|filtered.

-b *FTP relay host* (FTP bounce scan) .

An interesting feature of the FTP protocol ([RFC 959](#)^[9]) is support for so-called proxy FTP connections. This allows a user to connect to one FTP server, then ask that files be sent to a third-party server. Such a feature is ripe for abuse on many levels, so most servers have ceased supporting it. One of the abuses this feature allows is causing the FTP server to port scan other hosts. Simply ask the FTP server to send a file to each interesting port of a target host in turn. The error message will describe whether the port is open or not. This is a good way to bypass firewalls because organizational FTP servers are often placed where they have more access to other internal hosts than any old Internet host would. Nmap supports FTP bounce scan with the **-b** option. It takes an argument of the form *username:password@server:port*. *Server* is the name or IP address of a vulnerable FTP server. As with a normal URL, you may omit *username:password*, in which case anonymous login credentials (user: anonymous password:-wwwuser@) are used. The port number (and preceding colon) may be omitted as well, in which case the default FTP port (21) on *server* is used.

This vulnerability was widespread in 1997 when Nmap was released, but has largely been fixed. Vulnerable servers are still around, so it is worth trying when all else fails. If bypassing a firewall is your goal, scan the target network for port 21 (or even for any FTP services if you scan all ports with version detection) and use the ftp-bounce. NSE script. Nmap will tell you whether the host is vulnerable or not. If you are just trying to cover your tracks, you don't need to (and, in fact, shouldn't) limit yourself to hosts on the target network. Before you go scanning random Internet addresses for vulnerable FTP servers, consider that sysadmins may not appreciate you abusing their servers in this way.

PORT SPECIFICATION AND SCAN ORDER

In addition to all of the scan methods discussed previously, Nmap offers options for specifying which ports are scanned and whether the scan order is randomized or sequential. By default, Nmap scans the most common 1,000 ports for each protocol.

-p *port ranges* (Only scan specified ports) .

This option specifies which ports you want to scan and overrides the default. Individual port numbers are OK, as are ranges separated by a hyphen (e.g. 1-1023). The beginning and/or end values of a range may be omitted, causing Nmap to use 1 and 65535, respectively. So you can specify **-p-** to scan ports from 1 through 65535. Scanning port zero. is allowed if you specify it explicitly. For IP protocol scanning (**-sO**), this option specifies the protocol numbers you wish to scan for (0-255).

When scanning a combination of protocols (e.g. TCP and UDP), you can specify a particular protocol by preceding the port numbers by T: for TCP, U: for UDP, S: for SCTP, or P: for IP Protocol. The qualifier lasts until you specify another qualifier. For example, the argument **-p U:53,111,137,T:21-25,80,139,8080** would scan UDP ports 53, 111, and 137, as well as the listed TCP

ports. Note that to scan both UDP and TCP, you have to specify **-sU** and at least one TCP scan type (such as **-sS**, **-sF**, or **-sT**). If no protocol qualifier is given, the port numbers are added to all protocol lists. Ports can also be specified by name according to what the port is referred to in the `nmap-services`. You can even use the wildcards `*` and `?` with the names. For example, to scan FTP and all ports whose names begin with "http", use **-p ftp,http***. Be careful about shell expansions and quote the argument to **-p** if unsure.

Ranges of ports can be surrounded by square brackets to indicate ports inside that range that appear in `nmap-services`. For example, the following will scan all ports in `nmap-services` equal to or below 1024: **-p [-1024]**. Be careful with shell expansions and quote the argument to **-p** if unsure.

-F (Fast (limited port) scan) .

Specifies that you wish to scan fewer ports than the default. Normally Nmap scans the most common 1,000 ports for each scanned protocol. With **-F**, this is reduced to 100.

Nmap needs an `nmap-services` file with frequency information in order to know which ports are the most common. If port frequency information isn't available, perhaps because of the use of a custom `nmap-services` file, Nmap scans all named ports plus ports 1–1024. In that case, **-F** means to scan only ports that are named in the services file.

-r (Don't randomize ports) .

By default, Nmap randomizes the scanned port order (except that certain commonly accessible ports are moved near the beginning for efficiency reasons). This randomization is normally desirable, but you can specify **-r** for sequential (sorted from lowest to highest) port scanning instead.

--port-ratio *ratio*<decimal number between 0 and 1>

Scans all ports in `nmap-services` file with a ratio greater than the one given. *ratio* must be between 0.0 and 1.1.

--top-ports *n*

Scans the *n* highest-ratio ports found in `nmap-services` file. *n* must be 1 or greater.

SERVICE AND VERSION DETECTION

Point Nmap at a remote machine and it might tell you that ports 25/tcp, 80/tcp, and 53/udp are open. Using its `nmap-services` database of about 2,200 well-known services, Nmap would report that those ports probably correspond to a mail server (SMTP), web server (HTTP), and name server (DNS) respectively. This lookup is usually accurate—the vast majority of daemons listening on TCP port 25 are, in fact, mail servers. However, you should not bet your security on this! People can and do run services on strange ports.

Even if Nmap is right, and the hypothetical server above is running SMTP, HTTP, and DNS servers, that is not a lot of information. When doing vulnerability assessments (or even simple network inventories) of your companies or clients, you really want to know which mail and DNS servers and versions are running. Having an accurate version number helps dramatically in determining which exploits a server is vulnerable to. Version detection helps you obtain this information.

After TCP and/or UDP ports are discovered using one of the other scan methods, version detection interrogates those ports to determine more about what is actually running. The `nmap-service-probes` database contains probes for querying various services and match expressions to recognize and parse responses. Nmap tries to determine the service protocol (e.g. FTP, SSH, Telnet, HTTP), the application name (e.g. ISC BIND, Apache httpd, Solaris telnetd), the version number, hostname, device type (e.g. printer, router), the OS family (e.g. Windows, Linux). When possible, Nmap also gets the Common Platform Enumeration (CPE) representation of this information. Sometimes miscellaneous details like whether an X server is open to connections, the SSH protocol version, or the KaZaA user name, are available. Of course, most services don't provide all of this information. If Nmap was compiled with OpenSSL support, it will connect to SSL servers to deduce the service listening behind that encryption layer. Some UDP ports are left in the open|filtered state after a UDP port scan is unable to determine whether the port is open or filtered. Version detection will try to elicit a response from these ports (just as it does with open ports), and change the state to open if it succeeds. open|filtered TCP ports are treated the

same way. Note that the Nmap **-A** option enables version detection among other things. A paper documenting the workings, usage, and customization of version detection is available at <http://nmap.org/book/vscan.html>.

When RPC services are discovered, the Nmap RPC grinder. is automatically used to determine the RPC program and version numbers. It takes all the TCP/UDP ports detected as RPC and floods them with SunRPC program NULL commands in an attempt to determine whether they are RPC ports, and if so, what program and version number they serve up. Thus you can effectively obtain the same info as **rpcinfo -p** even if the target's portmapper is behind a firewall (or protected by TCP wrappers). Decoys do not currently work with RPC scan..

When Nmap receives responses from a service but cannot match them to its database, it prints out a special fingerprint and a URL for you to submit if to if you know for sure what is running on the port. Please take a couple minutes to make the submission so that your find can benefit everyone. Thanks to these submissions, Nmap has about 6,500 pattern matches for more than 650 protocols such as SMTP, FTP, HTTP, etc..

Version detection is enabled and controlled with the following options:

-sV (Version detection) .

Enables version detection, as discussed above. Alternatively, you can use **-A**, which enables version detection among other things.

-sR. is an alias for **-sV**. Prior to March 2011, it was used to active the RPC grinder separately from version detection, but now these options are always combined.

--allports (Don't exclude any ports from version detection) .

By default, Nmap version detection skips TCP port 9100 because some printers simply print anything sent to that port, leading to dozens of pages of HTTP GET requests, binary SSL session requests, etc. This behavior can be changed by modifying or removing the Exclude directive in `nmap-service-probes`, or you can specify **--allports** to scan all ports regardless of any Exclude directive.

--version-intensity *intensity* (Set version scan intensity) .

When performing a version scan (**-sV**), Nmap sends a series of probes, each of which is assigned a rarity value between one and nine. The lower-numbered probes are effective against a wide variety of common services, while the higher-numbered ones are rarely useful. The intensity level specifies which probes should be applied. The higher the number, the more likely it is the service will be correctly identified. However, high intensity scans take longer. The intensity must be between 0 and 9.. The default is 7.. When a probe is registered to the target port via the `nmap-service-probes` ports directive, that probe is tried regardless of intensity level. This ensures that the DNS probes will always be attempted against any open port 53, the SSL probe will be done against 443, etc.

--version-light (Enable light mode) .

This is a convenience alias for **--version-intensity 2**. This light mode makes version scanning much faster, but it is slightly less likely to identify services.

--version-all (Try every single probe) .

An alias for **--version-intensity 9**, ensuring that every single probe is attempted against each port.

--version-trace (Trace version scan activity) .

This causes Nmap to print out extensive debugging info about what version scanning is doing. It is a subset of what you get with **--packet-trace**.

OS DETECTION

One of Nmap's best-known features is remote OS detection using TCP/IP stack fingerprinting. Nmap sends a series of TCP and UDP packets to the remote host and examines practically every bit in the responses. After performing dozens of tests such as TCP ISN sampling, TCP options support and ordering, IP ID sampling, and the initial window size check, Nmap compares the results to its `nmap-os-db`. database of more than 2,600 known OS fingerprints and prints out the OS details if there is a match. Each fingerprint includes a freeform textual description of the OS, and a classification which provides the vendor name (e.g.

Sun), underlying OS (e.g. Solaris), OS generation (e.g. 10), and device type (general purpose, router, switch, game console, etc). Most fingerprints also have a Common Platform Enumeration (CPE) representation, like `cpe:/o:linux:linux_kernel:2.6`.

If Nmap is unable to guess the OS of a machine, and conditions are good (e.g. at least one open port and one closed port were found), Nmap will provide a URL you can use to submit the fingerprint if you know (for sure) the OS running on the machine. By doing this you contribute to the pool of operating systems known to Nmap and thus it will be more accurate for everyone.

OS detection enables some other tests which make use of information that is gathered during the process anyway. One of these is TCP Sequence Predictability Classification. This measures approximately how hard it is to establish a forged TCP connection against the remote host. It is useful for exploiting source-IP based trust relationships (rlogin, firewall filters, etc) or for hiding the source of an attack. This sort of spoofing is rarely performed any more, but many machines are still vulnerable to it. The actual difficulty number is based on statistical sampling and may fluctuate. It is generally better to use the English classification such as “worthy challenge” or “trivial joke”. This is only reported in normal output in verbose (`-v`) mode. When verbose mode is enabled along with `-O`, IP ID sequence generation is also reported. Most machines are in the “incremental” class, which means that they increment the ID field in the IP header for each packet they send. This makes them vulnerable to several advanced information gathering and spoofing attacks.

Another bit of extra information enabled by OS detection is a guess at a target's uptime. This uses the TCP timestamp option ([RFC 1323](#)^[10]) to guess when a machine was last rebooted. The guess can be inaccurate due to the timestamp counter not being initialized to zero or the counter overflowing and wrapping around, so it is printed only in verbose mode.

A paper documenting the workings, usage, and customization of OS detection is available at <http://nmap.org/book/osdetect.html>.

OS detection is enabled and controlled with the following options:

-O (Enable OS detection) .

Enables OS detection, as discussed above. Alternatively, you can use `-A` to enable OS detection along with other things.

--osscan-limit (Limit OS detection to promising targets) .

OS detection is far more effective if at least one open and one closed TCP port are found. Set this option and Nmap will not even try OS detection against hosts that do not meet this criteria. This can save substantial time, particularly on `-Pn` scans against many hosts. It only matters when OS detection is requested with `-O` or `-A`.

--osscan-guess; --fuzzy (Guess OS detection results) .

When Nmap is unable to detect a perfect OS match, it sometimes offers up near-matches as possibilities. The match has to be very close for Nmap to do this by default. Either of these (equivalent) options make Nmap guess more aggressively. Nmap will still tell you when an imperfect match is printed and display its confidence level (percentage) for each guess.

--max-os-tries (Set the maximum number of OS detection tries against a target) .

When Nmap performs OS detection against a target and fails to find a perfect match, it usually repeats the attempt. By default, Nmap tries five times if conditions are favorable for OS fingerprint submission, and twice when conditions aren't so good. Specifying a lower **--max-os-tries** value (such as 1) speeds Nmap up, though you miss out on retries which could potentially identify the OS. Alternatively, a high value may be set to allow even more retries when conditions are favorable. This is rarely done, except to generate better fingerprints for submission and integration into the Nmap OS database.

NMAP SCRIPTING ENGINE (NSE)

The Nmap Scripting Engine (NSE) is one of Nmap's most powerful and flexible features. It allows users to write (and share) simple scripts (using the [Lua programming language](#)^[11],

Tasks we had in mind when creating the system include network discovery, more sophisticated version

detection, vulnerability detection. NSE can even be used for vulnerability exploitation.

To reflect those different uses and to simplify the choice of which scripts to run, each script contains a field associating it with one or more categories. Currently defined categories are auth, broadcast, default, discovery, dos, exploit, external, fuzzer, intrusive, malware, safe, version, and vuln. These are all described at <http://nmap.org/book/nse-usage.html#nse-categories>.

Scripts are not run in a sandbox and thus could accidentally or maliciously damage your system or invade your privacy. Never run scripts from third parties unless you trust the authors or have carefully audited the scripts yourself.

The Nmap Scripting Engine is described in detail at <http://nmap.org/book/nse.html>

and is controlled by the following options:

-sC .

Performs a script scan using the default set of scripts. It is equivalent to **--script=default**. Some of the scripts in this category are considered intrusive and should not be run against a target network without permission.

--script filename|category|directory|expression[,...] .

Runs a script scan using the comma-separated list of filenames, script categories, and directories. Each element in the list may also be a Boolean expression describing a more complex set of scripts. Each element is interpreted first as an expression, then as a category, and finally as a file or directory name.

There are two special features for advanced users only. One is to prefix script names and expressions with + to force them to run even if they normally wouldn't (e.g. the relevant service wasn't detected on the target port). The other is that the argument all may be used to specify every script in Nmap's database. Be cautious with this because NSE contains dangerous scripts such as exploits, brute force authentication crackers, and denial of service attacks.

File and directory names may be relative or absolute. Absolute names are used directly. Relative paths are looked for in the scripts of each of the following places until found:

--datadir

\$NMAPDIR.

`~/nmap` (not searched on Windows).

`HOME\AppData\Roaming\nmap` (only on Windows).

the directory containing the nmap executable

the directory containing the nmap executable, followed by `./share/nmap`

NMAPDATADIR.

the current directory.

When a directory name is given, Nmap loads every file in the directory whose name ends with `.nse`. All other files are ignored and directories are not searched recursively. When a filename is given, it does not have to have the `.nse` extension; it will be added automatically if necessary. Nmap scripts are stored in a scripts subdirectory of the Nmap data directory by default (see <http://nmap.org/book/data-files.html>).

For efficiency, scripts are indexed in a database stored in `scripts/script.db.` which lists the category or categories in which each script belongs. When referring to scripts from `script.db` by name, you can use a shell-style `*` wildcard.

nmap --script "http-*

Loads all scripts whose name starts with `http-`, such as `http-auth` and `http-open-proxy`. The argument to **--script** had to be in quotes to protect the wildcard from the shell.

More complicated script selection can be done using the and, or, and not operators to build Boolean

expressions. The operators have the same [precedence](#)^[12] as in Lua: not is the highest, followed by and and then or. You can alter precedence by using parentheses. Because expressions contain space characters it is necessary to quote them.

nmap --script "not intrusive"

Loads every script except for those in the intrusive category.

nmap --script "default or safe"

This is functionally equivalent to **nmap --script "default,safe"**. It loads all scripts that are in the default category or the safe category or both.

nmap --script "default and safe"

Loads those scripts that are in *both* the default and safe categories.

nmap --script "(default or safe or intrusive) and not http-"

Loads scripts in the default, safe, or intrusive categories, except for those whose names start with http-.

--script-args n1=v1,n2={n3=v3},n4={v4,v5} .

Lets you provide arguments to NSE scripts. Arguments are a comma-separated list of name=value pairs. Names and values may be strings not containing whitespace or the characters '{', '}', '=', or ';'. To include one of these characters in a string, enclose the string in single or double quotes. Within a quoted string, '\ ' escapes a quote. A backslash is only used to escape quotation marks in this special case; in all other cases a backslash is interpreted literally. Values may also be tables enclosed in {}, just as in Lua. A table may contain simple string values or more name-value pairs, including nested tables. Many scripts qualify their arguments with the script name, as in xmpp-info.server_name. You may use that full qualified version to affect just the specified script, or you may pass the unqualified version (server_name in this case) to affect all scripts using that argument name. A script will first check for its fully qualified argument name (the name specified in its documentation) before it accepts an unqualified argument name. A complex example of script arguments is **--script-args 'user=foo,pass="{ }=bar",whois={whodb=nofollow+ripe},xmpp-info.server_name=localhost'**. The online NSE Documentation Portal at <http://nmap.org/nsedoc/> lists the arguments that each script accepts.

--script-args-file filename .

Lets you load arguments to NSE scripts from a file. Any arguments on the command line supersede ones in the file. The file can be an absolute path, or a path relative to Nmap's usual search path (NMAPDIR, etc.) Arguments can be comma-separated or newline-separated, but otherwise follow the same rules as for **--script-args**, without requiring special quoting and escaping, since they are not parsed by the shell.

--script-help filename|category|directory|expression|all[,...] .

Shows help about scripts. For each script matching the given specification, Nmap prints the script name, its categories, and its description. The specifications are the same as those accepted by **--script**; so for example if you want help about the ftp-anon script, you would run **nmap --script-help ftp-anon**. In addition to getting help for individual scripts, you can use this as a preview of what scripts will be run for a specification, for example with **nmap --script-help default**.

--script-trace .

This option does what **--packet-trace** does, just one ISO layer higher. If this option is specified all incoming and outgoing communication performed by a script is printed. The displayed information includes the communication protocol, the source, the target and the transmitted data. If more than 5% of all transmitted data is not printable, then the trace output is in a hex dump format. Specifying **--packet-trace** enables script tracing too.

--script-updatedb .

This option updates the script database found in scripts/script.db which is used by Nmap to determine the available default scripts and categories. It is only necessary to update the database if you have added or removed NSE scripts from the default scripts directory or if you have changed the categories of any script. This option is generally used by itself: **nmap --script-updatedb**.

TIMING AND PERFORMANCE

One of my highest Nmap development priorities has always been performance. A default scan (**nmap hostname**) of a host on my local network takes a fifth of a second. That is barely enough time to blink, but adds up when you are scanning hundreds or thousands of hosts. Moreover, certain scan options such as UDP scanning and version detection can increase scan times substantially. So can certain firewall configurations, particularly response rate limiting. While Nmap utilizes parallelism and many advanced algorithms to accelerate these scans, the user has ultimate control over how Nmap runs. Expert users carefully craft Nmap commands to obtain only the information they care about while meeting their time constraints.

Techniques for improving scan times include omitting non-critical tests, and upgrading to the latest version of Nmap (performance enhancements are made frequently). Optimizing timing parameters can also make a substantial difference. Those options are listed below.

Some options accept a time parameter. This is specified in seconds by default, though you can append 'ms', 's', 'm', or 'h' to the value to specify milliseconds, seconds, minutes, or hours. So the **--host-timeout** arguments 900000ms, 900, 900s, and 15m all do the same thing.

--min-hostgroup numhosts; **--max-hostgroup numhosts** (Adjust parallel scan group sizes) .

Nmap has the ability to port scan or version scan multiple hosts in parallel. Nmap does this by dividing the target IP space into groups and then scanning one group at a time. In general, larger groups are more efficient. The downside is that host results can't be provided until the whole group is finished. So if Nmap started out with a group size of 50, the user would not receive any reports (except for the updates offered in verbose mode) until the first 50 hosts are completed.

By default, Nmap takes a compromise approach to this conflict. It starts out with a group size as low as five so the first results come quickly and then increases the groupsize to as high as 1024. The exact default numbers depend on the options given. For efficiency reasons, Nmap uses larger group sizes for UDP or few-port TCP scans.

When a maximum group size is specified with **--max-hostgroup**, Nmap will never exceed that size. Specify a minimum size with **--min-hostgroup** and Nmap will try to keep group sizes above that level. Nmap may have to use smaller groups than you specify if there are not enough target hosts left on a given interface to fulfill the specified minimum. Both may be set to keep the group size within a specific range, though this is rarely desired.

These options do not have an effect during the host discovery phase of a scan. This includes plain ping scans (**-sn**). Host discovery always works in large groups of hosts to improve speed and accuracy.

The primary use of these options is to specify a large minimum group size so that the full scan runs more quickly. A common choice is 256 to scan a network in Class C sized chunks. For a scan with many ports, exceeding that number is unlikely to help much. For scans of just a few port numbers, host group sizes of 2048 or more may be helpful.

--min-parallelism numprobes; **--max-parallelism numprobes** (Adjust probe parallelization) .

These options control the total number of probes that may be outstanding for a host group. They are used for port scanning and host discovery. By default, Nmap calculates an ever-changing ideal parallelism based on network performance. If packets are being dropped, Nmap slows down and allows fewer outstanding probes. The ideal probe number slowly rises as the network proves itself worthy. These options place minimum or maximum bounds on that variable. By default, the ideal parallelism can drop to one if the network proves unreliable and rise to several hundred in perfect conditions.

The most common usage is to set **--min-parallelism** to a number higher than one to speed up scans of poorly performing hosts or networks. This is a risky option to play with, as setting it too high may affect accuracy. Setting this also reduces Nmap's ability to control parallelism dynamically based on network conditions. A value of 10 might be reasonable, though I only adjust this value as a last resort.

The **--max-parallelism** option is sometimes set to one to prevent Nmap from sending more than one probe at a time to hosts. The **--scan-delay** option, discussed later, is another way to do this.

--min-rtt-timeout *time*, **--max-rtt-timeout** *time*, **--initial-rtt-timeout** *time* (Adjust probe timeouts)

Nmap maintains a running timeout value for determining how long it will wait for a probe response before giving up or retransmitting the probe. This is calculated based on the response times of previous probes.

If the network latency shows itself to be significant and variable, this timeout can grow to several seconds. It also starts at a conservative (high) level and may stay that way for a while when Nmap scans unresponsive hosts.

Specifying a lower **--max-rtt-timeout** and **--initial-rtt-timeout** than the defaults can cut scan times significantly. This is particularly true for pingless (**-Pn**) scans, and those against heavily filtered networks. Don't get too aggressive though. The scan can end up taking longer if you specify such a low value that many probes are timing out and retransmitting while the response is in transit.

If all the hosts are on a local network, 100 milliseconds (**--max-rtt-timeout 100ms**) is a reasonable aggressive value. If routing is involved, ping a host on the network first with the ICMP ping utility, or with a custom packet crafter such as Nping. That is more likely to get through a firewall. Look at the maximum round trip time out of ten packets or so. You might want to double that for the **--initial-rtt-timeout** and triple or quadruple it for the **--max-rtt-timeout**. I generally do not set the maximum RTT below 100 ms, no matter what the ping times are. Nor do I exceed 1000 ms.

--min-rtt-timeout is a rarely used option that could be useful when a network is so unreliable that even Nmap's default is too aggressive. Since Nmap only reduces the timeout down to the minimum when the network seems to be reliable, this need is unusual and should be reported as a bug to the nmap-dev mailing list.

--max-retries *numtries* (Specify the maximum number of port scan probe retransmissions) .

When Nmap receives no response to a port scan probe, it could mean the port is filtered. Or maybe the probe or response was simply lost on the network. It is also possible that the target host has rate limiting enabled that temporarily blocked the response. So Nmap tries again by retransmitting the initial probe. If Nmap detects poor network reliability, it may try many more times before giving up on a port. While this benefits accuracy, it also lengthens scan times. When performance is critical, scans may be sped up by limiting the number of retransmissions allowed. You can even specify **--max-retries 0** to prevent any retransmissions, though that is only recommended for situations such as informal surveys where occasional missed ports and hosts are acceptable.

The default (with no **-T** template) is to allow ten retransmissions. If a network seems reliable and the target hosts aren't rate limiting, Nmap usually only does one retransmission. So most target scans aren't even affected by dropping **--max-retries** to a low value such as three. Such values can substantially speed scans of slow (rate limited) hosts. You usually lose some information when Nmap gives up on ports early, though that may be preferable to letting the **--host-timeout** expire and losing all information about the target.

--host-timeout *time* (Give up on slow target hosts) .

Some hosts simply take a *long* time to scan. This may be due to poorly performing or unreliable networking hardware or software, packet rate limiting, or a restrictive firewall. The slowest few percent of the scanned hosts can eat up a majority of the scan time. Sometimes it is best to cut your losses and skip those hosts initially. Specify **--host-timeout** with the maximum amount of time you are willing to wait. For example, specify 30m to ensure that Nmap doesn't waste more than half an hour on a single host. Note that Nmap may be scanning other hosts at the same time during that half an hour, so it isn't a complete loss. A host that times out is skipped. No port table, OS detection, or version detection results are printed for that host.

--scan-delay *time*; **--max-scan-delay** *time* (Adjust delay between probes) .

This option causes Nmap to wait at least the given amount of time between each probe it sends to a given host. This is particularly useful in the case of rate limiting.. Solaris machines (among many others) will usually respond to UDP scan probe packets with only one ICMP message per second. Any more than that sent by Nmap will be wasteful. A **--scan-delay** of 1s will keep Nmap at that slow rate. Nmap tries to detect rate limiting and adjust the scan delay accordingly, but it doesn't hurt to specify it explicitly if you already know what rate works best.

When Nmap adjusts the scan delay upward to cope with rate limiting, the scan slows down dramatically. The **--max-scan-delay** option specifies the largest delay that Nmap will allow. A low **--max-scan-delay** can speed up Nmap, but it is risky. Setting this value too low can lead to wasteful packet retransmissions and possible missed ports when the target implements strict rate limiting.

Another use of **--scan-delay** is to evade threshold based intrusion detection and prevention systems (IDS/IPS)..

--min-rate *number*; **--max-rate** *number* (Directly control the scanning rate) .

Nmap's dynamic timing does a good job of finding an appropriate speed at which to scan. Sometimes, however, you may happen to know an appropriate scanning rate for a network, or you may have to guarantee that a scan will be finished by a certain time. Or perhaps you must keep Nmap from scanning too quickly. The **--min-rate** and **--max-rate** options are designed for these situations.

When the **--min-rate** option is given Nmap will do its best to send packets as fast as or faster than the given rate. The argument is a positive real number representing a packet rate in packets per second. For example, specifying **--min-rate 300** means that Nmap will try to keep the sending rate at or above 300 packets per second. Specifying a minimum rate does not keep Nmap from going faster if conditions warrant.

Likewise, **--max-rate** limits a scan's sending rate to a given maximum. Use **--max-rate 100**, for example, to limit sending to 100 packets per second on a fast network. Use **--max-rate 0.1** for a slow scan of one packet every ten seconds. Use **--min-rate** and **--max-rate** together to keep the rate inside a certain range.

These two options are global, affecting an entire scan, not individual hosts. They only affect port scans and host discovery scans. Other features like OS detection implement their own timing.

There are two conditions when the actual scanning rate may fall below the requested minimum. The first is if the minimum is faster than the fastest rate at which Nmap can send, which is dependent on hardware. In this case Nmap will simply send packets as fast as possible, but be aware that such high rates are likely to cause a loss of accuracy. The second case is when Nmap has nothing to send, for example at the end of a scan when the last probes have been sent and Nmap is waiting for them to time out or be responded to. It's normal to see the scanning rate drop at the end of a scan or in between hostgroups. The sending rate may temporarily exceed the maximum to make up for unpredictable delays, but on average the rate will stay at or below the maximum.

Specifying a minimum rate should be done with care. Scanning faster than a network can support may lead to a loss of accuracy. In some cases, using a faster rate can make a scan take *longer* than it would with a slower rate. This is because Nmap's

adaptive retransmission algorithms will detect the network congestion caused by an excessive scanning rate and increase the number of retransmissions in order to improve accuracy. So even though packets are sent at a higher rate, more packets are sent overall. Cap the number of retransmissions with the **--max-retries** option if you need to set an upper limit on total scan time.

--defeat-rst-ratelimit .

Many hosts have long used rate limiting. to reduce the number of ICMP error messages (such as

port-unreachable errors) they send. Some systems now apply similar rate limits to the RST (reset) packets they generate. This can slow Nmap down dramatically as it adjusts its timing to reflect those rate limits. You can tell Nmap to ignore those rate limits (for port scans such as SYN scan which *don't* treat non-responsive ports as open) by specifying **--defeat-rst-ratelimit**.

Using this option can reduce accuracy, as some ports will appear non-responsive because Nmap didn't wait long enough for a rate-limited RST response. With a SYN scan, the non-response results in the port being labeled filtered rather than the closed state we see when RST packets are received. This option is useful when you only care about open ports, and distinguishing between closed and filtered ports isn't worth the extra time.

--nsock-engine epoll|kqueue|poll|select .

Enforce use of a given nsock IO multiplexing engine. Only the select(2)-based fallback engine is guaranteed to be available on your system. Engines are named after the name of the IO management facility they leverage. Engines currently implemented are epoll, kqueue, poll, and select, but not all will be present on any platform. Use **nmap -V** to see which engines are supported.

-T paranoid|sneaky|polite|normal|aggressive|insane (Set a timing template) .

While the fine-grained timing controls discussed in the previous section are powerful and effective, some people find them confusing. Moreover, choosing the appropriate values can sometimes take more time than the scan you are trying to optimize. So Nmap offers a simpler approach, with six timing templates. You can specify them with the **-T** option and their number (0-5) or their name. The template names are **paranoid (0)**, **sneaky (1)**, **polite (2)**, **normal (3)**, **aggressive (4)**, and **insane (5)**. The first two are for IDS evasion. Polite mode slows down the scan to use less bandwidth and target machine resources. Normal mode is the default and so **-T3** does nothing. Aggressive mode speeds scans up by making the assumption that you are on a reasonably fast and reliable network. Finally insane mode. assumes that you are on an extraordinarily fast network or are willing to sacrifice some accuracy for speed.

These templates allow the user to specify how aggressive they wish to be, while leaving Nmap to pick the exact timing values. The templates also make some minor speed adjustments for which fine-grained control options do not currently exist. For example, **-T4** prohibits the dynamic scan delay from exceeding 10 ms for TCP ports and **-T5** caps that value at 5 ms. Templates can be used in combination with fine-grained controls, and the fine-grained controls will you specify will take precedence over the timing template default for that parameter. I recommend using **-T4** when scanning reasonably modern and reliable networks. Keep that option even when you add fine-grained controls so that you benefit from those extra minor optimizations that it enables.

If you are on a decent broadband or ethernet connection, I would recommend always using **-T4**. Some people love **-T5** though it is too aggressive for my taste. People sometimes specify **-T2** because they think it is less likely to crash hosts or because they consider themselves to be polite in general. They often don't realize just how slow **-T polite** really is. Their scan may take ten times longer than a default scan. Machine crashes and bandwidth problems are rare with the default timing options (**-T3**) and so I normally recommend that for cautious scanners. Omitting version detection is far more effective than playing with timing values at reducing these problems.

While **-T0** and **-T1** may be useful for avoiding IDS alerts, they will take an extraordinarily long time to scan thousands of machines or ports. For such a long scan, you may prefer to set the exact timing values you need rather than rely on the canned **-T0** and **-T1** values.

The main effects of **T0** are serializing the scan so only one port is scanned at a time, and waiting five minutes between sending each probe. **T1** and **T2** are similar but they only wait 15 seconds and 0.4 seconds, respectively, between probes. **T3** is Nmap's default behavior, which includes parallelization. **-T4** does the equivalent of **--max-rtt-timeout 1250ms --initial-rtt-timeout 500ms --max-retries 6** and sets the maximum TCP scan delay to 10 milliseconds. **T5** does the equivalent of **--max-rtt-timeout 300ms --min-rtt-timeout 50ms --initial-rtt-timeout 250ms**

--max-retries 2 --host-timeout 15m as well as setting the maximum TCP scan delay to 5 ms.

FIREWALL/IDS EVASION AND SPOOFING

Many Internet pioneers envisioned a global open network with a universal IP address space allowing virtual connections between any two nodes. This allows hosts to act as true peers, serving and retrieving information from each other. People could access all of their home systems from work, changing the climate control settings or unlocking the doors for early guests. This vision of universal connectivity has been stifled by address space shortages and security concerns. In the early 1990s, organizations began deploying firewalls for the express purpose of reducing connectivity. Huge networks were cordoned off from the unfiltered Internet by application proxies, network address translation, and packet filters. The unrestricted flow of information gave way to tight regulation of approved communication channels and the content that passes over them.

Network obstructions such as firewalls can make mapping a network exceedingly difficult. It will not get any easier, as stifling casual reconnaissance is often a key goal of implementing the devices. Nevertheless, Nmap offers many features to help understand these complex networks, and to verify that filters are working as intended. It even supports mechanisms for bypassing poorly implemented defenses. One of the best methods of understanding your network security posture is to try to defeat it. Place yourself in the mind-set of an attacker, and deploy techniques from this section against your networks. Launch an FTP bounce scan, idle scan, fragmentation attack, or try to tunnel through one of your own proxies.

In addition to restricting network activity, companies are increasingly monitoring traffic with intrusion detection systems (IDS). All of the major IDSs ship with rules designed to detect Nmap scans because scans are sometimes a precursor to attacks. Many of these products have recently morphed into intrusion *prevention* systems (IPS). that actively block traffic deemed malicious. Unfortunately for network administrators and IDS vendors, reliably detecting bad intentions by analyzing packet data is a tough problem. Attackers with patience, skill, and the help of certain Nmap options can usually pass by IDSs undetected. Meanwhile, administrators must cope with large numbers of false positive results where innocent activity is misdiagnosed and alerted on or blocked.

Occasionally people suggest that Nmap should not offer features for evading firewall rules or sneaking past IDSs. They argue that these features are just as likely to be misused by attackers as used by administrators to enhance security. The problem with this logic is that these methods would still be used by attackers, who would just find other tools or patch the functionality into Nmap. Meanwhile, administrators would find it that much harder to do their jobs. Deploying only modern, patched FTP servers is a far more powerful defense than trying to prevent the distribution of tools implementing the FTP bounce attack.

There is no magic bullet (or Nmap option) for detecting and subverting firewalls and IDS systems. It takes skill and experience. A tutorial is beyond the scope of this reference guide, which only lists the relevant options and describes what they do.

-f (fragment packets); **--mtu** (using the specified MTU) .

The **-f** option causes the requested scan (including ping scans) to use tiny fragmented IP packets. The idea is to split up the TCP header over several packets to make it harder for packet filters, intrusion detection systems, and other annoyances to detect what you are doing. Be careful with this! Some programs have trouble handling these tiny packets. The old-school sniffer named Sniffit segmentation faulted immediately upon receiving the first fragment. Specify this option once, and Nmap splits the packets into eight bytes or less after the IP header. So a 20-byte TCP header would be split into three packets. Two with eight bytes of the TCP header, and one with the final four. Of course each fragment also has an IP header. Specify **-f** again to use 16 bytes per fragment (reducing the number of fragments).. Or you can specify your own offset size with the **--mtu** option. Don't also specify **-f** if you use **--mtu**. The offset must be a multiple of eight. While fragmented packets won't get by packet filters and firewalls that queue all IP fragments, such as the `CONFIG_IP_ALWAYS_DEFRAG` option in the Linux kernel, some networks can't afford the performance hit this causes and thus leave it disabled. Others can't enable this because fragments may take different routes into their networks. Some source systems defragment outgoing packets in the kernel. Linux with the iptables. connection tracking module is one such example. Do a scan while a sniffer such as Wireshark. is running to ensure that sent packets are fragmented. If your host OS is causing problems, try the **--send-eth**. option to

bypass the IP layer and send raw ethernet frames.

Fragmentation is only supported for Nmap's raw packet features, which includes TCP and UDP port scans (except connect scan and FTP bounce scan) and OS detection. Features such as version detection and the Nmap Scripting Engine generally don't support fragmentation because they rely on your host's TCP stack to communicate with target services.

-D *decoy1[,decoy2][,ME][,...]* (Cloak a scan with decoys) .

Causes a decoy scan to be performed, which makes it appear to the remote host that the host(s) you specify as decoys are scanning the target network too. Thus their IDS might report 5–10 port scans from unique IP addresses, but they won't know which IP was scanning them and which were innocent decoys. While this can be defeated through router path tracing, response–dropping, and other active mechanisms, it is generally an effective technique for hiding your IP address.

Separate each decoy host with commas, and you can optionally use ME. as one of the decoys to represent the position for your real IP address. If you put ME in the sixth position or later, some common port scan detectors (such as Solar Designer's. excellent Scanlogd). are unlikely to show your IP address at all. If you don't use ME, Nmap will put you in a random position. You can also use RND. to generate a random, non–reserved IP address, or RND:*number* to generate *number* addresses.

Note that the hosts you use as decoys should be up or you might accidentally SYN flood your targets. Also it will be pretty easy to determine which host is scanning if only one is actually up on the network. You might want to use IP addresses instead of names (so the decoy networks don't see you in their nameserver logs).

Decoys are used both in the initial ping scan (using ICMP, SYN, ACK, or whatever) and during the actual port scanning phase. Decoys are also used during remote OS detection (**-O**). Decoys do not work with version detection or TCP connect scan. When a scan delay is in effect, the delay is enforced between each batch of spoofed probes, not between each individual probe. Because decoys are sent as a batch all at once, they may temporarily violate congestion control limits.

It is worth noting that using too many decoys may slow your scan and potentially even make it less accurate. Also, some ISPs will filter out your spoofed packets, but many do not restrict spoofed IP packets at all.

-S *IP_Address* (Spoof source address) .

In some circumstances, Nmap may not be able to determine your source address (Nmap will tell you if this is the case). In this situation, use **-S** with the IP address of the interface you wish to send packets through.

Another possible use of this flag is to spoof the scan to make the targets think that *someone else* is scanning them. Imagine a company being repeatedly port scanned by a competitor! The **-e** option and **-Pn** are generally required for this sort of usage. Note that you usually won't receive reply packets back (they will be addressed to the IP you are spoofing), so Nmap won't produce useful reports.

-e *interface* (Use specified interface) .

Tells Nmap what interface to send and receive packets on. Nmap should be able to detect this automatically, but it will tell you if it cannot.

--source-port *portnumber*; **-g** *portnumber* (Spoof source port number) .

One surprisingly common misconfiguration is to trust traffic based only on the source port number. It is easy to understand how this comes about. An administrator will set up a shiny new firewall, only to be flooded with complaints from ungrateful users whose applications stopped working. In particular, DNS may be broken because the UDP DNS replies from external servers can no longer enter the network. FTP is another common example. In active FTP transfers, the remote server tries to establish a connection back to the client to transfer the requested file.

Secure solutions to these problems exist, often in the form of application-level proxies or protocol-parsing firewall modules. Unfortunately there are also easier, insecure solutions. Noting that DNS replies come from port 53 and active FTP from port 20, many administrators have fallen into the trap of simply allowing incoming traffic from those ports. They often assume that no attacker would notice and exploit such firewall holes. In other cases, administrators consider this a short-term stop-gap measure until they can implement a more secure solution. Then they forget the security upgrade.

Overworked network administrators are not the only ones to fall into this trap. Numerous products have shipped with these insecure rules. Even Microsoft has been guilty. The IPsec filters that shipped with Windows 2000 and Windows XP contain an implicit rule that allows all TCP or UDP traffic from port 88 (Kerberos). In another well-known case, versions of the Zone Alarm personal firewall up to 2.1.25 allowed any incoming UDP packets with the source port 53 (DNS) or 67 (DHCP).

Nmap offers the **-g** and **--source-port** options (they are equivalent) to exploit these weaknesses. Simply provide a port number and Nmap will send packets from that port where possible. Most scanning operations that use raw sockets, including SYN and UDP scans, support the option completely. The option notably doesn't have an effect for any operations that use normal operating system sockets, including DNS requests, TCP **connect** scan, version detection, and script scanning. Setting the source port also doesn't work for OS detection, because Nmap must use different port numbers for certain OS detection tests to work properly.

--data-length *number* (Append random data to sent packets) .

Normally Nmap sends minimalist packets containing only a header. So its TCP packets are generally 40 bytes and ICMP echo requests are just 28. Some UDP ports and IP protocols get a custom payload by default. This option tells Nmap to append the given number of random bytes to most of the packets it sends, and not to use any protocol-specific payloads. (Use **--data-length 0** for no random or protocol-specific payloads.. OS detection (**-O**) packets are not affected. because accuracy there requires probe consistency, but most pinging and portscan packets support this. It slows things down a little, but can make a scan slightly less conspicuous.

--ip-options *S*[*R* [*route*]]*L* [*route*]]*T**U* ... ; **--ip-options** *hex string* (Send packets with specified ip options) .

The **IP protocol**^[13] offers several options which may be placed in packet headers. Unlike the ubiquitous TCP options, IP options are rarely seen due to practicality and security concerns. In fact, many Internet routers block the most dangerous options such as source routing. Yet options can still be useful in some cases for determining and manipulating the network route to target machines. For example, you may be able to use the record route option to determine a path to a target even when more traditional traceroute-style approaches fail. Or if your packets are being dropped by a certain firewall, you may be able to specify a different route with the strict or loose source routing options.

The most powerful way to specify IP options is to simply pass in values as the argument to **--ip-options**. Precede each hex number with \x then the two digits. You may repeat certain characters by following them with an asterisk and then the number of times you wish them to repeat. For example, \x01\x07\x04\x00*36\x01 is a hex string containing 36 NUL bytes.

Nmap also offers a shortcut mechanism for specifying options. Simply pass the letter R, T, or U to request record-route, record-timestamp, or both options together, respectively. Loose or strict source routing may be specified with an L or S followed by a space and then a space-separated list of IP addresses.

If you wish to see the options in packets sent and received, specify **--packet-trace**. For more information and examples of using IP options with Nmap, see <http://seclists.org/nmap-dev/2006/q3/52>.

--ttl *value* (Set IP time-to-live field) .

Sets the IPv4 time-to-live field in sent packets to the given value.

--randomize-hosts (Randomize target host order) .

Tells Nmap to shuffle each group of up to 16384 hosts before it scans them. This can make the scans less obvious to various network monitoring systems, especially when you combine it with slow timing options. If you want to randomize over larger group sizes, increase *PING_GROUP_SZ.* in *nmap.h.* and recompile. An alternative solution is to generate the target IP list with a list scan (**-sL -n -oN filename**), randomize it with a Perl script, then provide the whole list to Nmap with **-iL.**

--spoof-mac *MAC address, prefix, or vendor name* (Spoof MAC address) .

Asks Nmap to use the given MAC address for all of the raw ethernet frames it sends. This option implies **--send-eth.** to ensure that Nmap actually sends ethernet-level packets. The MAC given can take several formats. If it is simply the number 0, Nmap chooses a completely random MAC address for the session. If the given string is an even number of hex digits (with the pairs optionally separated by a colon), Nmap will use those as the MAC. If fewer than 12 hex digits are provided, Nmap fills in the remainder of the six bytes with random values. If the argument isn't a zero or hex string, Nmap looks through *nmap-mac-prefixes* to find a vendor name containing the given string (it is case insensitive). If a match is found, Nmap uses the vendor's OUI (three-byte prefix). and fills out the remaining three bytes randomly. Valid **--spoof-mac** argument examples are Apple, 0, 01:02:03:04:05:06, deadbeefcfe, 0020F2, and Cisco. This option only affects raw packet scans such as SYN scan or OS detection, not connection-oriented features such as version detection or the Nmap Scripting Engine.

--badsum (Send packets with bogus TCP/UDP checksums) .

Asks Nmap to use an invalid TCP, UDP or SCTP checksum for packets sent to target hosts. Since virtually all host IP stacks properly drop these packets, any responses received are likely coming from a firewall or IDS that didn't bother to verify the checksum. For more details on this technique, see <http://nmap.org/p60-12.html>

--adler32 (Use deprecated Adler32 instead of CRC32C for SCTP checksums) .

Asks Nmap to use the deprecated Adler32 algorithm for calculating the SCTP checksum. If **--adler32** is not given, CRC-32C (Castagnoli) is used. [RFC 2960](#)^[14] originally defined Adler32 as checksum algorithm for SCTP; [RFC 4960](#)^[7] later redefined the SCTP checksums to use CRC-32C. Current SCTP implementations should be using CRC-32C, but in order to elicit responses from old, legacy SCTP implementations, it may be preferable to use Adler32.

OUTPUT

Any security tool is only as useful as the output it generates. Complex tests and algorithms are of little value if they aren't presented in an organized and comprehensible fashion. Given the number of ways Nmap is used by people and other software, no single format can please everyone. So Nmap offers several formats, including the interactive mode for humans to read directly and XML for easy parsing by software.

In addition to offering different output formats, Nmap provides options for controlling the verbosity of output as well as debugging messages. Output types may be sent to standard output or to named files, which Nmap can append to or clobber. Output files may also be used to resume aborted scans.

Nmap makes output available in five different formats. The default is called interactive output, and it is sent to standard output (stdout).. There is also normal output, which is similar to interactive except that it displays less runtime information and warnings since it is expected to be analyzed after the scan completes rather than interactively.

XML output. is one of the most important output types, as it can be converted to HTML, easily parsed by programs such as Nmap graphical user interfaces, or imported into databases.

The two remaining output types are the simple grepable output. which includes most information for a target host on a single line, and sCRiPt KiDDi3 OutPUt. for users who consider themselves |<-r4d.

While interactive output is the default and has no associated command-line options, the other four format options use the same syntax. They take one argument, which is the filename that results should be stored in. Multiple formats may be specified, but each format may only be specified once. For example, you may

wish to save normal output for your own review while saving XML of the same scan for programmatic analysis. You might do this with the options **-oX myscan.xml -oN myscan.nmap**. While this chapter uses the simple names like myscan.xml for brevity, more descriptive names are generally recommended. The names chosen are a matter of personal preference, though I use long ones that incorporate the scan date and a word or two describing the scan, placed in a directory named after the company I'm scanning.

While these options save results to files, Nmap still prints interactive output to stdout as usual. For example, the command **nmap -oX myscan.xml target** prints XML to myscan.xml and fills standard output with the same interactive results it would have printed if **-oX** wasn't specified at all. You can change this by passing a hyphen character as the argument to one of the format types. This causes Nmap to deactivate interactive output, and instead print results in the format you specified to the standard output stream. So the command **nmap -oX - target** will send only XML output to stdout.. Serious errors may still be printed to the normal error stream, stderr..

Unlike some Nmap arguments, the space between the logfile option flag (such as **-oX**) and the filename or hyphen is mandatory. If you omit the flags and give arguments such as **-oG-** or **-oXscan.xml**, a backwards compatibility feature of Nmap will cause the creation of *normal format* output files named G- and Xscan.xml respectively.

All of these arguments support **strftime**-like conversions in the filename. %H, %M, %S, %m, %d, %y, and %Y are all exactly the same as in **strftime**. %T is the same as %H%M%S, %R is the same as %H%M, and %D is the same as %m%d%y. A % followed by any other character just yields that character (%% gives you a percent symbol). So **-oX 'scan-%T-%D.xml'** will use an XML file with a name in the form of scan-144840-121307.xml.

Nmap also offers options to control scan verbosity and to append to output files rather than clobbering them. All of these options are described below.

Nmap Output Formats

-oN *filespec* (normal output) .

Requests that normal output be directed to the given filename. As discussed above, this differs slightly from interactive output.

-oX *filespec* (XML output) .

Requests that XML output be directed to the given filename. Nmap includes a document type definition (DTD) which allows XML parsers to validate Nmap XML output. While it is primarily intended for programmatic use, it can also help humans interpret Nmap XML output. The DTD defines the legal elements of the format, and often enumerates the attributes and values they can take on. The latest version is always available from <https://svn.nmap.org/nmap/docs/nmap.dtd>.

XML offers a stable format that is easily parsed by software. Free XML parsers are available for all major computer languages, including C/C++, Perl, Python, and Java. People have even written bindings for most of these languages to handle Nmap output and execution specifically. Examples are [Nmap::Scanner](#)^[15] and [Nmap::Parser](#)^[16] in Perl CPAN. In almost all cases that a non-trivial application interfaces with Nmap, XML is the preferred format.

The XML output references an XSL stylesheet which can be used to format the results as HTML. The easiest way to use this is simply to load the XML output in a web browser such as Firefox or IE. By default, this will only work on the machine you ran Nmap on (or a similarly configured one) due to the hard-coded nmap.xsl filesystem path. Use the **---webxml** or **---stylesheet** options to create portable XML files that render as HTML on any web-connected machine.

-oS *filespec* (ScRipT KIdd|3 oUTpuT) .

Script kiddie output is like interactive output, except that it is post-processed to better suit the 133t HaXXorZ who previously looked down on Nmap due to its consistent capitalization and spelling. Humor impaired people should note that this option is making fun of the script kiddies before flaming me for supposedly "helping them".

-oG *filespec* (greppable output) .

This output format is covered last because it is deprecated. The XML output format is far more powerful, and is nearly as convenient for experienced users. XML is a standard for which dozens of excellent parsers are available, while grepable output is my own simple hack. XML is extensible to support new Nmap features as they are released, while I often must omit those features from grepable output for lack of a place to put them.

Nevertheless, grepable output is still quite popular. It is a simple format that lists each host on one line and can be trivially searched and parsed with standard Unix tools such as `grep`, `awk`, `cut`, `sed`, `diff`, and `Perl`. Even I usually use it for one-off tests done at the command line. Finding all the hosts with the SSH port open or that are running Solaris takes only a simple `grep` to identify the hosts, piped to an `awk` or `cut` command to print the desired fields.

Grepable output consists of comments (lines starting with a pound (#)). and target lines. A target line includes a combination of six labeled fields, separated by tabs and followed with a colon. The fields are Host, Ports, Protocols, Ignored State, OS, Seq Index, IP ID, and Status.

The most important of these fields is generally Ports, which gives details on each interesting port. It is a comma separated list of port entries. Each port entry represents one interesting port, and takes the form of seven slash (/) separated subfields. Those subfields are: Port number, State, Protocol, Owner, Service, SunRPC info, and Version info.

As with XML output, this man page does not allow for documenting the entire format. A more detailed look at the Nmap grepable output format is available from <http://nmap.org/book/output-formats-grepable-output.html>.

-oA *basename* (Output to all formats) .

As a convenience, you may specify **-oA** *basename* to store scan results in normal, XML, and grepable formats at once. They are stored in *basename.nmap*, *basename.xml*, and *basename.gnmap*, respectively. As with most programs, you can prefix the filenames with a directory path, such as `~/nmaplogs/foocorp/` on Unix or `c:\hacking\sco` on Windows.

Verbosity and debugging options

-v (Increase verbosity level) .

Increases the verbosity level, causing Nmap to print more information about the scan in progress. Open ports are shown as they are found and completion time estimates are provided when Nmap thinks a scan will take more than a few minutes. Use it twice or more for even greater verbosity: **-vv**, or give a verbosity level directly, for example **-v3**.

Most changes only affect interactive output, and some also affect normal and script kiddie output. The other output types are meant to be processed by machines, so Nmap can give substantial detail by default in those formats without fatiguing a human user. However, there are a few changes in other modes where output size can be reduced substantially by omitting some detail. For example, a comment line in the grepable output that provides a list of all ports scanned is only printed in verbose mode because it can be quite long.

-d (Increase debugging level) .

When even verbose mode doesn't provide sufficient data for you, debugging is available to flood you with much more! As with the verbosity option (**-v**), debugging is enabled with a command-line flag (**-d**) and the debug level can be increased by specifying it multiple times, as in **-dd**, or by setting a level directly. For example, **-d9** sets level nine. That is the highest effective level and will produce thousands of lines unless you run a very simple scan with very few ports and targets.

Debugging output is useful when a bug is suspected in Nmap, or if you are simply confused as to what Nmap is doing and why. As this feature is mostly intended for developers, debug lines aren't always self-explanatory. You may get something like: Timeout vals: srtr: -1 rttvar: -1 to: 1000000 delta 14987 ==> srtr: 14987 rttvar: 14987 to: 100000. If you don't understand a line, your only recourse is

to ignore it, look it up in the source code, or request help from the development list (nmap-dev).. Some lines are self explanatory, but the messages become more obscure as the debug level is increased.

--reason (Host and port state reasons) .

Shows the reason each port is set to a specific state and the reason each host is up or down. This option displays the type of the packet that determined a port or hosts state. For example, A RST packet from a closed port or an echo reply from an alive host. The information Nmap can provide is determined by the type of scan or ping. The SYN scan and SYN ping (**-sS** and **-PS**) are very detailed, but the TCP connect scan (**-sT**) is limited by the implementation of the **connect** system call. This feature is automatically enabled by the debug option (**-d**). and the results are stored in XML log files even if this option is not specified.

--stats-every time (Print periodic timing stats) .

Periodically prints a timing status message after each interval of *time*. The time is a specification of the kind described in the section called "TIMING AND PERFORMANCE"; so for example, use **--stats-every 10s** to get a status update every 10 seconds. Updates are printed to interactive output (the screen) and XML output.

--packet-trace (Trace packets and data sent and received) .

Causes Nmap to print a summary of every packet sent or received. This is often used for debugging, but is also a valuable way for new users to understand exactly what Nmap is doing under the covers. To avoid printing thousands of lines, you may want to specify a limited number of ports to scan, such as **-p20-30**. If you only care about the goings on of the version detection subsystem, use **--version-trace** instead. If you only care about script tracing, specify **--script-trace**. With **--packet-trace**, you get all of the above.

--open (Show only open (or possibly open) ports) .

Sometimes you only care about ports you can actually connect to (open ones), and don't want results cluttered with closed, filtered, and closed|filtered ports. Output customization is normally done after the scan using tools such as grep, awk, and Perl, but this feature was added due to overwhelming requests. Specify **--open** to only see hosts with at least one open, open|filtered, or unfiltered port, and only see ports in those states. These three states are treated just as they normally are, which means that open|filtered and unfiltered may be condensed into counts if there are an overwhelming number of them.

--iflist (List interfaces and routes) .

Prints the interface list and system routes as detected by Nmap. This is useful for debugging routing problems or device mischaracterization (such as Nmap treating a PPP connection as ethernet).

Miscellaneous output options

--append-output (Append to rather than clobber output files) .

When you specify a filename to an output format flag such as **-oX** or **-oN**, that file is overwritten by default. If you prefer to keep the existing content of the file and append the new results, specify the **--append-output** option. All output filenames specified in that Nmap execution will then be appended to rather than clobbered. This doesn't work well for XML (**-oX**) scan data as the resultant file generally won't parse properly until you fix it up by hand.

--resume filename (Resume aborted scan) .

Some extensive Nmap runs take a very long time—on the order of days. Such scans don't always run to completion. Restrictions may prevent Nmap from being run during working hours, the network could go down, the machine Nmap is running on might suffer a planned or unplanned reboot, or Nmap itself could crash. The administrator running Nmap could cancel it for any other reason as well, by pressing ctrl-C. Restarting the whole scan from the beginning may be undesirable. Fortunately, if normal (**-oN**) or grepable (**-oG**) logs were kept, the user can ask Nmap to resume scanning with the target it was working on when execution ceased. Simply specify the **--resume** option and pass the normal/grepable output file as its argument. No other arguments are permitted, as Nmap parses the output file to use the same ones specified previously. Simply call Nmap as **nmap --resume**

logfile. Nmap will append new results to the data files specified in the previous execution. Resumption does not support the XML output format because combining the two runs into one valid XML file would be difficult.

--stylesheet *path or URL* (Set XSL stylesheet to transform XML output) .

Nmap ships with an XSL stylesheet named `nmap.xsl` for viewing or translating XML output to HTML. The XML output includes an `xml-stylesheet` directive which points to `nmap.xml` where it was initially installed by Nmap. Run the XML file through an XSLT processor such as [xsltproc](#)^[17] to produce an HTML file. Directly opening the XML file in a browser no longer works well because modern browsers limit the locations a stylesheet may be loaded from. If you wish to use a different stylesheet, specify it as the argument to **--stylesheet**. You must pass the full pathname or URL. One common invocation is **--stylesheet http://nmap.org/svn/docs/nmap.xsl**. This tells an XSLT processor to load the latest version of the stylesheet from Nmap.Org. The **--webxml** option does the same thing with less typing and memorization. Loading the XSL from Nmap.Org makes it easier to view results on a machine that doesn't have Nmap (and thus `nmap.xsl`) installed. So the URL is often more useful, but the local filesystem location of `nmap.xsl` is used by default for privacy reasons.

--webxml (Load stylesheet from Nmap.Org) .

This is a convenience option, nothing more than an alias for **--stylesheet http://nmap.org/svn/docs/nmap.xsl**.

--no-stylesheet (Omit XSL stylesheet declaration from XML) .

Specify this option to prevent Nmap from associating any XSL stylesheet with its XML output. The `xml-stylesheet` directive is omitted.

MISCELLANEOUS OPTIONS

This section describes some important (and not-so-important) options that don't really fit anywhere else.

-6 (Enable IPv6 scanning) .

Nmap has IPv6 support for its most popular features. Ping scanning, port scanning, version detection, and the Nmap Scripting Engine all support IPv6. The command syntax is the same as usual except that you also add the **-6** option. Of course, you must use IPv6 syntax if you specify an address rather than a hostname. An address might look like `3ffe:7501:4819:2000:210:f3ff:fe03:14d0`, so hostnames are recommended. The output looks the same as usual, with the IPv6 address on the "interesting ports" line being the only IPv6 giveaway.

While IPv6 hasn't exactly taken the world by storm, it gets significant use in some (usually Asian) countries and most modern operating systems support it. To use Nmap with IPv6, both the source and target of your scan must be configured for IPv6. If your ISP (like most of them) does not allocate IPv6 addresses to you, free tunnel brokers are widely available and work fine with Nmap. I use the free IPv6 tunnel broker service at <http://www.tunnelbroker.net>. Other tunnel brokers are [listed at Wikipedia](#)^[18]. 6to4 tunnels are another popular, free approach.

On Windows, raw-socket IPv6 scans are supported only on ethernet devices (not tunnels), and only on Windows Vista and later. Use the **--unprivileged** option in other situations.

-A (Aggressive scan options) .

This option enables additional advanced and aggressive options. I haven't decided exactly which it stands for yet. Presently this enables OS detection (**-O**), version scanning (**-sV**), script scanning (**-sC**) and traceroute (**--traceroute**). More features may be added in the future. The point is to enable a comprehensive set of scan options without people having to remember a large set of flags. However, because script scanning with the default set is considered intrusive, you should not use **-A** against target networks without permission. This option only enables features, and not timing options (such as **-T4**) or verbosity options (**-v**) that you might want as well.

--datadir *directoryname* (Specify custom Nmap data file location) .

Nmap obtains some special data at runtime in files named `nmap-service-probes`, `nmap-services`, `nmap-protocols`, `nmap-rpc`, `nmap-mac-prefixes`, and `nmap-os-db`. If the location of any of these files has been specified (using the **--servicedb** or **--versiondb** options), that location is used for that

file. After that, Nmap searches these files in the directory specified with the **---datadir** option (if any). Any files not found there, are searched for in the directory specified by the **NMAPDIR** environment variable. Next comes `~/nmap` for real and effective UIDs; or on Windows, `HOME\AppData\Roaming\nmap` (where *HOME* is the user's home directory, like `C:\Users\user`). This is followed by the location of the nmap executable and the same location with `../share/nmap` appended. Then a compiled-in location such as `/usr/local/share/nmap` or `/usr/share/nmap`.

---servicedb *services file* (Specify custom services file) .

Asks Nmap to use the specified services file rather than the `nmap-services` data file that comes with Nmap. Using this option also causes a fast scan (**-F**) to be used. See the description for **---datadir** for more information on Nmap's data files.

---versiondb *service probes file* (Specify custom service probes file) .

Asks Nmap to use the specified service probes file rather than the `nmap-service-probes` data file that comes with Nmap. See the description for **---datadir** for more information on Nmap's data files.

---send-eth (Use raw ethernet sending) .

Asks Nmap to send packets at the raw ethernet (data link) layer rather than the higher IP (network) layer. By default, Nmap chooses the one which is generally best for the platform it is running on. Raw sockets (IP layer) are generally most efficient for Unix machines, while ethernet frames are required for Windows operation since Microsoft disabled raw socket support. Nmap still uses raw IP packets on Unix despite this option when there is no other choice (such as non-ethernet connections).

---send-ip (Send at raw IP level) .

Asks Nmap to send packets via raw IP sockets rather than sending lower level ethernet frames. It is the complement to the **---send-eth** option discussed previously.

---privileged (Assume that the user is fully privileged) .

Tells Nmap to simply assume that it is privileged enough to perform raw socket sends, packet sniffing, and similar operations that usually require root privileges. on Unix systems. By default Nmap quits if such operations are requested but `geteuid` is not zero. **---privileged** is useful with Linux kernel capabilities and similar systems that may be configured to allow unprivileged users to perform raw-packet scans. Be sure to provide this option flag before any flags for options that require privileges (SYN scan, OS detection, etc.). The **NMAP_PRIVILEGED** environment variable may be set as an equivalent alternative to **---privileged**.

---unprivileged (Assume that the user lacks raw socket privileges) .

This option is the opposite of **---privileged**. It tells Nmap to treat the user as lacking network raw socket and sniffing privileges. This is useful for testing, debugging, or when the raw network functionality of your operating system is somehow broken. The **NMAP_UNPRIVILEGED** environment variable may be set as an equivalent alternative to **---unprivileged**.

---release-memory (Release memory before quitting) .

This option is only useful for memory-leak debugging. It causes Nmap to release allocated memory just before it quits so that actual memory leaks are easier to spot. Normally Nmap skips this as the OS does this anyway upon process termination.

-V; **---version** (Print version number) .

Prints the Nmap version number and exits.

-h; **---help** (Print help summary page) .

Prints a short help screen with the most common command flags. Running Nmap without any arguments does the same thing.

RUNTIME INTERACTION

During the execution of Nmap, all key presses are captured. This allows you to interact with the program without aborting and restarting it. Certain special keys will change options, while any other keys will print out a status message telling you about the scan. The convention is that *lowercase letters increase* the amount of printing, and *uppercase letters decrease* the printing. You may also press `?` for help.

v / V

Increase / decrease the verbosity level

d / D

Increase / decrease the debugging Level

p / P

Turn on / off packet tracing

?

Print a runtime interaction help screen

Anything else

Print out a status message like this:

Stats: 0:00:07 elapsed; 20 hosts completed (1 up), 1 undergoing Service Scan

Service scan Timing: About 33.33% done; ETC: 20:57 (0:00:12 remaining)

EXAMPLES

Here are some Nmap usage examples, from the simple and routine to a little more complex and esoteric. Some actual IP addresses and domain names are used to make things more concrete. In their place you should substitute addresses/names from *your own network*. While I don't think port scanning other networks is or should be illegal, some network administrators don't appreciate unsolicited scanning of their networks and may complain. Getting permission first is the best approach.

For testing purposes, you have permission to scan the host scanme.nmap.org.. This permission only includes scanning via Nmap and not testing exploits or denial of service attacks. To conserve bandwidth, please do not initiate more than a dozen scans against that host per day. If this free scanning target service is abused, it will be taken down and Nmap will report Failed to resolve given hostname/IP: scanme.nmap.org. These permissions also apply to the hosts scanme2.nmap.org, scanme3.nmap.org, and so on, though those hosts do not currently exist.

nmap -v scanme.nmap.org

This option scans all reserved TCP ports on the machine scanme.nmap.org . The **-v** option enables verbose mode.

nmap -sS -O scanme.nmap.org/24

Launches a stealth SYN scan against each machine that is up out of the 256 IPs on the class C sized network where Scanme resides. It also tries to determine what operating system is running on each host that is up and running. This requires root privileges because of the SYN scan and OS detection.

nmap -sV -p 22,53,110,143,4564 198.116.0-255.1-127

Launches host enumeration and a TCP scan at the first half of each of the 255 possible eight-bit subnets in the 198.116 class B address space. This tests whether the systems run SSH, DNS, POP3, or IMAP on their standard ports, or anything on port 4564. For any of these ports found open, version detection is used to determine what application is running.

nmap -v -iR 100000 -Pn -p 80

Asks Nmap to choose 100,000 hosts at random and scan them for web servers (port 80). Host enumeration is disabled with **-Pn** since first sending a couple probes to determine whether a host is up is wasteful when you are only probing one port on each target host anyway.

nmap -Pn -p80 -oX logs/pb-port80scan.xml -oG logs/pb-port80scan.gnmap 216.163.128.20/20

This scans 4096 IPs for any web servers (without pinging them) and saves the output in grepable and XML formats.

NMAP BOOK

While this reference guide details all material Nmap options, it can't fully demonstrate how to apply those features to quickly solve real-world tasks. For that, we released Nmap Network Scanning: The Official Nmap Project Guide to Network Discovery and Security Scanning. Topics include subverting firewalls and intrusion detection systems, optimizing Nmap performance, and automating common networking tasks

with the Nmap Scripting Engine. Hints and instructions are provided for common Nmap tasks such as taking network inventory, penetration testing, detecting rogue wireless access points, and quashing network worm outbreaks. Examples and diagrams show actual communication on the wire. More than half of the book is available free online. See <http://nmap.org/book> for more information.

BUGS

Like its author, Nmap isn't perfect. But you can help make it better by sending bug reports or even writing patches. If Nmap doesn't behave the way you expect, first upgrade to the latest version available from <http://nmap.org>. If the problem persists, do some research to determine whether it has already been discovered and addressed. Try searching for the error message on our search page at <http://insecure.org/search.html> or at Google. Also try browsing the nmap-dev archives at <http://seclists.org/>. Read this full manual page as well. If nothing comes of this, mail a bug report to nmap-dev@insecure.org. Please include everything you have learned about the problem, as well as what version of Nmap you are running and what operating system version it is running on. Problem reports and Nmap usage questions sent to nmap-dev@insecure.org are far more likely to be answered than those sent to Fyodor directly. If you subscribe to the nmap-dev list before posting, your message will bypass moderation and get through more quickly. Subscribe at <http://cgi.insecure.org/mailman/listinfo/nmap-dev>.

Code patches to fix bugs are even better than bug reports. Basic instructions for creating patch files with your changes are available at <https://svn.nmap.org/nmap/HACKING>. Patches may be sent to nmap-dev@insecure.org (recommended) or to Fyodor directly.

AUTHOR

Gordon "Fyodor" Lyon fyodor@insecure.org (<http://insecure.org>)

Hundreds of people have made valuable contributions to Nmap over the years. These are detailed in the CHANGELOG. file which is distributed with Nmap and also available from <http://nmap.org/changelog.html>.

LEGAL NOTICES

Nmap Copyright and Licensing

The Nmap Security Scanner is (C) 1996–2012 Insecure.Com LLC. Nmap is also a registered trademark of Insecure.Com LLC. This program is free software; you may redistribute and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation; Version 2 with the clarifications and exceptions described below. This guarantees your right to use, modify, and redistribute this software under certain conditions. If you wish to embed Nmap technology into proprietary software, we sell alternative licenses (contact sales@insecure.com). Dozens of software vendors already license Nmap technology such as host discovery, port scanning, OS detection, and version detection.

Note that the GPL places important restrictions on "derived works", yet it does not provide a detailed definition of that term. To avoid misunderstandings, we consider an application to constitute a "derivative work" for the purpose of this license if it does any of the following:

- Integrates source code from Nmap
- Reads or includes Nmap copyrighted data files, such as `nmap-os-db` or `nmap-service-probes`.
- Executes Nmap and parses the results (as opposed to typical shell or execution-menu apps, which simply display raw Nmap output and so are not derivative works.)
- Integrates/includes/aggregates Nmap into a proprietary executable installer, such as those produced by InstallShield.
- Links to a library or executes a program that does any of the above.

The term "Nmap" should be taken to also include any portions or derived works of Nmap. This list is not exclusive, but is meant to clarify our interpretation of derived works with some common examples. Our interpretation applies only to Nmap—we don't speak for other people's GPL works.

If you have any questions about the GPL licensing restrictions on using Nmap in non-GPL works, we would be happy to help. As mentioned above, we also offer alternative license to integrate Nmap into

proprietary applications and appliances. These contracts have been sold to many security vendors, and generally include a perpetual license as well as providing for priority support and updates as well as helping to fund the continued development of Nmap technology. Please email sales@insecure.com for further information.

As a special exception to the GPL terms, Insecure.Com LLC grants permission to link the code of this program with any version of the OpenSSL library which is distributed under a license identical to that listed in the included COPYING.OpenSSL file, and distribute linked combinations including the two.. You must obey the GNU GPL in all respects for all of the code used other than OpenSSL. If you modify this file, you may extend this exception to your version of the file, but you are not obligated to do so.

If you received these files with a written license agreement or contract stating terms other than the terms above, then that alternative license agreement takes precedence over these comments.

Creative Commons License for this Nmap Guide

This Nmap Reference Guide is (C) 2005–2012 Insecure.Com LLC. It is hereby placed under version 3.0 of the [Creative Commons Attribution License](#)^[19]. This allows you redistribute and modify the work as you desire, as long as you credit the original source. Alternatively, you may choose to treat this document as falling under the same license as Nmap itself (discussed previously).

Source Code Availability and Community Contributions

Source is provided to this software because we believe users have a right to know exactly what a program is going to do before they run it. This also allows you to audit the software for security holes (none have been found so far).

Source code also allows you to port Nmap to new platforms, fix bugs, and add new features. You are highly encouraged to send your changes to nmap-dev@insecure.org for possible incorporation into the main distribution. By sending these changes to Fyodor or one of the Insecure.Org development mailing lists, it is assumed that you are offering the Nmap Project (Insecure.Com LLC) the unlimited, non-exclusive right to reuse, modify, and relicense the code. Nmap will always be available open source,. but this is important because the inability to relicense code has caused devastating problems for other Free Software projects (such as KDE and NASM). We also occasionally relicense the code to third parties as discussed above. If you wish to specify special license conditions of your contributions, just say so when you send them.

No Warranty.

This program is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU General Public License v2.0 for more details at <http://www.gnu.org/licenses/gpl-2.0.html>, or in the COPYING file included with Nmap.

It should also be noted that Nmap has occasionally been known to crash poorly written applications, TCP/IP stacks, and even operating systems.. While this is extremely rare, it is important to keep in mind. *Nmap should never be run against mission critical systems* unless you are prepared to suffer downtime. We acknowledge here that Nmap may crash your systems or networks and we disclaim all liability for any damage or problems Nmap could cause.

Inappropriate Usage

Because of the slight risk of crashes and because a few black hats like to use Nmap for reconnaissance prior to attacking systems, there are administrators who become upset and may complain when their system is scanned. Thus, it is often advisable to request permission before doing even a light scan of a network.

Nmap should never be installed with special privileges (e.g. `sudo` root).. That would open up a major security vulnerability as other users on the system (or attackers) could use it for privilege escalation.

Third-Party Software and Funding Notices

This product includes software developed by the [Apache Software Foundation](#)^[20]. A modified version of the [Libpcap portable packet capture library](#)^[21], is distributed along with Nmap. The Windows version of Nmap utilized the Libpcap-derived [WinPcap library](#)^[22], instead. Regular expression support is provided by the [PCRE library](#)^[23], which is open-source software, written by Philip Hazel.. Certain raw networking functions use the [Libdnet](#)^[24], networking library, which was written by Dug Song.. A

modified version is distributed with Nmap. Nmap can optionally link with the [OpenSSL cryptography toolkit](#)^[25] for SSL version detection support. The Nmap Scripting Engine uses an embedded version of the [Lua programming language](#)^[26]. The [Liblinear linear classification library](#)^[27] is used for our [IPv6 OS detection machine learning techniques](#)^[28].

All of the third-party software described in this paragraph is freely redistributable under BSD-style software licenses.

Binary packages for Windows and Mac OS X include support libraries necessary to run Zenmap and Ndiff with Python and PyGTK. (Unix platforms commonly make these libraries easy to install, so they are not part of the packages.) A listing of these support libraries and their licenses is included in the LICENSES files.

This software was supported in part through the [Google Summer of Code](#)^[29] and the [DARPA CINDER program](#)^[30] (DARPA-BAA-10-84).

United States Export Control.

Nmap only uses encryption when compiled with the optional OpenSSL support and linked with OpenSSL. When compiled without OpenSSL support, Insecure.Com LLC believes that Nmap is not subject to U.S. [Export Administration Regulations \(EAR\)](#)^[31] export control. As such, there is no applicable ECCN (export control classification number) and exportation does not require any special license, permit, or other governmental authorization.

When compiled with OpenSSL support or distributed as source code, Insecure.Com LLC believes that Nmap falls under U.S. ECCN [5D002](#)^[32] ("Information Security Software"). We distribute Nmap under the TSU exception for publicly available encryption software defined in [EAR 740.13\(e\)](#)^[33].

NAME

nping – Network packet generation tool / ping utility

SYNOPSIS

nping [*Options*] {*targets*}

DESCRIPTION

Nping is an open-source tool for network packet generation, response analysis and response time measurement. Nping allows users to generate network packets of a wide range of protocols, letting them tune virtually any field of the protocol headers. While Nping can be used as a simple ping utility to detect active hosts, it can also be used as a raw packet generator for network stack stress tests, ARP poisoning, Denial of Service attacks, route tracing, and other purposes.

Additionally, Nping offers a special mode of operation called the "Echo Mode", that lets users see how the generated probes change in transit, revealing the differences between the transmitted packets and the packets received at the other end. See section "Echo Mode" for details.

The output from Nping is a list of the packets that are being sent and received. The level of detail depends on the options used.

A typical Nping execution is shown in Example 1. The only Nping arguments used in this example are **-c**, to specify the number of times to target each host, **---tcp** to specify TCP Probe Mode, **-p 80,433** to specify the target ports; and then the two target hostnames.

Example 1. A representative Nping execution

```
# nping -c 1 ---tcp -p 80,433 scanme.nmap.org google.com
```

Starting Nping (<http://nmap.org/nping>)

```
SENT (0.0120s) TCP 96.16.226.135:50091 > 64.13.134.52:80 S ttl=64 id=52072 iplen=40 seq=1077657388 win=1480
RCVD (0.1810s) TCP 64.13.134.52:80 > 96.16.226.135:50091 SA ttl=53 id=0 iplen=44 seq=4158134847 win=5840 <m
SENT (1.0140s) TCP 96.16.226.135:50091 > 74.125.45.100:80 S ttl=64 id=13932 iplen=40 seq=1077657388 win=1480
RCVD (1.1370s) TCP 74.125.45.100:80 > 96.16.226.135:50091 SA ttl=52 id=52913 iplen=44 seq=2650443864 win=57:

```

Statistics for host scanme.nmap.org (64.13.134.52):

```
| Probes Sent: 2 | Rcvd: 1 | Lost: 1 (50.00%)
|_ Max rtt: 169.720ms | Min rtt: 169.720ms | Avg rtt: 169.720ms
```

Statistics for host google.com (74.125.45.100):

```
| Probes Sent: 2 | Rcvd: 1 | Lost: 1 (50.00%)
|_ Max rtt: 122.686ms | Min rtt: 122.686ms | Avg rtt: 122.686ms
```

Raw packets sent: 4 (160B) | Rcvd: 2 (92B) | Lost: 2 (50.00%)

Tx time: 3.00296s | Tx bytes/s: 53.28 | Tx pkts/s: 1.33

Rx time: 3.00296s | Rx bytes/s: 30.64 | Rx pkts/s: 0.67

Nping done: 2 IP addresses pinged in 4.01 seconds

OPTIONS SUMMARY

This options summary is printed when Nping is run with no arguments. It helps people remember the most common options, but is no substitute for the in-depth documentation in the rest of this manual. Some obscure options aren't even included here.

Nping 0.5.59BETA1 (<http://nmap.org/nping>)

Usage: nping [Probe mode] [Options] {target specification}

TARGET SPECIFICATION:

Targets may be specified as hostnames, IP addresses, networks, etc.

Ex: scanme.nmap.org, microsoft.com/24, 192.168.0.1; 10.0.0–255.1–254

PROBE MODES:

--tcp-connect : Unprivileged TCP connect probe mode.
 --tcp : TCP probe mode.
 --udp : UDP probe mode.
 --icmp : ICMP probe mode.
 --arp : ARP/RARP probe mode.
 --tr, --traceroute : Traceroute mode (can only be used with TCP/UDP/ICMP modes).

TCP CONNECT MODE:

-p, --dest-port <port spec> : Set destination port(s).
 -g, --source-port <portnumber> : Try to use a custom source port.

TCP PROBE MODE:

-g, --source-port <portnumber> : Set source port.
 -p, --dest-port <port spec> : Set destination port(s).
 --seq <seqnumber> : Set sequence number.
 --flags <flag list> : Set TCP flags (ACK,PSH,RST,SYN,FIN...)
 --ack <acknumber> : Set ACK number.
 --win <size> : Set window size.
 --badsum : Use a random invalid checksum.

UDP PROBE MODE:

-g, --source-port <portnumber> : Set source port.
 -p, --dest-port <port spec> : Set destination port(s).
 --badsum : Use a random invalid checksum.

ICMP PROBE MODE:

--icmp-type <type> : ICMP type.
 --icmp-code <code> : ICMP code.
 --icmp-id <id> : Set identifier.
 --icmp-seq <n> : Set sequence number.
 --icmp-redirect-addr <addr> : Set redirect address.
 --icmp-param-pointer <pnt> : Set parameter problem pointer.
 --icmp-advert-lifetime <time> : Set router advertisement lifetime.
 --icmp-advert-entry <IP,pref> : Add router advertisement entry.
 --icmp-orig-time <timestamp> : Set originate timestamp.
 --icmp-recv-time <timestamp> : Set receive timestamp.
 --icmp-trans-time <timestamp> : Set transmit timestamp.

ARP/RARP PROBE MODE:

--arp-type <type> : Type: ARP, ARP-reply, RARP, RARP-reply.
 --arp-sender-mac <mac> : Set sender MAC address.
 --arp-sender-ip <addr> : Set sender IP address.
 --arp-target-mac <mac> : Set target MAC address.
 --arp-target-ip <addr> : Set target IP address.

IPv4 OPTIONS:

-S, --source-ip : Set source IP address.
 --dest-ip <addr> : Set destination IP address (used as an alternative to {target specification}).
 --tos <tos> : Set type of service field (8bits).
 --id <id> : Set identification field (16 bits).
 --df : Set Don't Fragment flag.
 --mf : Set More Fragments flag.
 --ttl <hops> : Set time to live [0-255].
 --badsum-ip : Use a random invalid checksum.
 --ip-options <S[R [route]]L [route]]T[U ...> : Set IP options
 --ip-options <hex string> : Set IP options
 --mtu <size> : Set MTU. Packets get fragmented if MTU is small enough.

IPv6 OPTIONS:

-6, --IPv6 : Use IP version 6.
 --dest-ip : Set destination IP address (used as an alternative to {target specification}).
 --hop-limit : Set hop limit (same as IPv4 TTL).
 --traffic-class <class> : Set traffic class.
 --flow <label> : Set flow label.

ETHERNET OPTIONS:

--dest-mac <mac> : Set destination mac address. (Disables ARP resolution)
 --source-mac <mac> : Set source MAC address.
 --ether-type <type> : Set EtherType value.

PAYLOAD OPTIONS:

--data <hex string> : Include a custom payload.
 --data-string <text> : Include a custom ASCII text.
 --data-length <len> : Include len random bytes as payload.

ECHO CLIENT/SERVER:

--echo-client <passphrase> : Run Nping in client mode.
 --echo-server <passphrase> : Run Nping in server mode.
 --echo-port <port> : Use custom <port> to listen or connect.
 --no-crypto : Disable encryption and authentication.
 --once : Stop the server after one connection.
 --safe-payloads : Erase application data in echoed packets.

TIMING AND PERFORMANCE:

Options which take <time> are in seconds, or append 'ms' (milliseconds), 's' (seconds), 'm' (minutes), or 'h' (hours) to the value (e.g. 30m, 0.25h).

--delay <time> : Adjust delay between probes.
 --rate <rate> : Send num packets per second.

MISC:

-h, --help : Display help information.
 -V, --version : Display current version number.
 -c, --count <n> : Stop after <n> rounds.
 -e, --interface <name> : Use supplied network interface.
 -H, --hide-sent : Do not display sent packets.
 -N, --no-capture : Do not try to capture replies.
 --privileged : Assume user is fully privileged.
 --unprivileged : Assume user lacks raw socket privileges.
 --send-eth : Send packets at the raw ethernet layer.
 --send-ip : Send packets using raw IP sockets.
 --bpf-filter <filter spec> : Specify custom BPF filter.

OUTPUT:

-v : Increment verbosity level by one.
 -v[level] : Set verbosity level. E.g: -v4
 -d : Increment debugging level by one.
 -d[level] : Set debugging level. E.g: -d3
 -q : Decrease verbosity level by one.
 -q[N] : Decrease verbosity level N times
 --quiet : Set verbosity and debug level to minimum.
 --debug : Set verbosity and debug to the max level.

EXAMPLES:

nping scanme.nmap.org
 nping --tcp -p 80 --flags rst --ttl 2 192.168.1.1
 nping --icmp --icmp-type time --delay 500ms 192.168.254.254
 nping --echo-server "public" -e wlan0 -vvv

```
nping --echo-client "public" echo.nmap.org --tcp -p1-1024 --flags ack
```

SEE THE MAN PAGE FOR MANY MORE OPTIONS, DESCRIPTIONS, AND EXAMPLES

TARGET SPECIFICATION

Everything on the Nping command line that isn't an option or an option argument is treated as a target host specification. Nping uses the same syntax for target specifications that Nmap does. The simplest case is a single target given by IP address or hostname.

Nping supports CIDR-style addressing. You can append */numbits* to an IPv4 address or hostname and Nping will send probes to every IP address for which the first *numbits* are the same as for the reference IP or hostname given. For example, 192.168.10.0/24 would send probes to the 256 hosts between 192.168.10.0 (binary: 11000000 10101000 00001010 00000000) and 192.168.10.255 (binary: 11000000 10101000 00001010 11111111), inclusive. 192.168.10.40/24 would ping exactly the same targets. Given that the host scanme.nmap.org. is at the IP address 64.13.134.52, the specification scanme.nmap.org/16 would send probes to the 65,536 IP addresses between 64.13.0.0 and 64.13.255.255. The smallest allowed value is /0, which targets the whole Internet. The largest value is /32, which targets just the named host or IP address because all address bits are fixed.

CIDR notation is short but not always flexible enough. For example, you might want to send probes to 192.168.0.0/16 but skip any IPs ending with .0 or .255 because they may be used as subnet network and broadcast addresses. Nping supports this through octet range addressing. Rather than specify a normal IP address, you can specify a comma-separated list of numbers or ranges for each octet. For example, 192.168.0-255.1-254 will skip all addresses in the range that end in .0 or .255, and 192.168.3-5.7.1 will target the four addresses 192.168.3.1, 192.168.4.1, 192.168.5.1, and 192.168.7.1. Either side of a range may be omitted; the default values are 0 on the left and 255 on the right. Using - by itself is the same as 0-255, but remember to use 0- in the first octet so the target specification doesn't look like a command-line option. Ranges need not be limited to the final octets: the specifier 0-.-.13.37 will send probes to all IP addresses on the Internet ending in .13.37. This sort of broad sampling can be useful for Internet surveys and research.

IPv6 addresses can only be specified by their fully qualified IPv6 address or hostname. CIDR and octet ranges aren't supported for IPv6 because they are rarely useful.

Nping accepts multiple host specifications on the command line, and they don't need to be the same type. The command **nping scanme.nmap.org 192.168.0.0/8 10.0.0.1,3-7.-** does what you would expect.

OPTION SPECIFICATION

Nping is designed to be very flexible and fit a wide variety of needs. As with most command-line tools, its behavior can be adjusted using command-line options. These general principles apply to option arguments, unless stated otherwise.

Options that take integer numbers can accept values specified in decimal, octal or hexadecimal base. When a number starts with 0x, it will be treated as hexadecimal; when it simply starts with 0, it will be treated as octal. Otherwise, Nping will assume the number has been specified in base 10. Virtually all numbers that can be supplied from the command line are unsigned so, as a general rule, the minimum value is zero.

Users may also specify the word random or rand to make Nping generate a random value within the expected range.

IP addresses may be given as IPv4 addresses (e.g. 192.168.1.1), IPv6 addresses (e.g. 2001:db8:85a3::8e4c:760:7146), or hostnames, which will be resolved using the default DNS server configured in the host system.

Options that take MAC addresses accept the usual colon-separated 6 hex byte format (e.g. 00:50:56:d4:01:98). Hyphens may also be used instead of colons (e.g. 00-50-56-c0-00-08). The special word random or rand sets a random address and the word broadcast or bcast sets ff:ff:ff:ff:ff:ff.

GENERAL OPERATION

Unlike other ping and packet generation tools, Nping supports multiple target host and port specifications. While this provides great flexibility, it is not obvious how Nping handles situations where there is more than one host and/or more than one port to send probes to. This section explains how Nping behaves in these cases.

When multiple target hosts are specified, Nping rotates among them in round-robin fashion. This gives slow hosts more time to send their responses before another probe is sent to them. Ports are also scheduled using round robin. So, unless only one port is specified, Nping never sends two probes to the same target host and port consecutively.

The loop around targets is the “inner loop” and the loop around ports is the “outer loop”. All targets will be sent a probe for a given port before moving on to the next port. Between probes, Nping waits a configurable amount of time called the “inter-probe delay”, which is controlled by the **--delay** option. These examples show how it works.

```
# nping --tcp -c 2 1.1.1.1 -p 100-102
```

```
Starting Nping ( http://nmap.org/nping )
SENT (0.0210s) TCP 192.168.1.77 > 1.1.1.1:100

SENT (4.0330s) TCP 192.168.0.21 > 3.3.3.3:139
```

PROBE MODES

Nping supports a wide variety of protocols. Although in some cases Nping can automatically determine the mode from the options used, it is generally a good idea to specify it explicitly.

--tcp-connect (TCP Connect mode) .

TCP connect mode is the default mode when a user does not have raw packet privileges. Instead of writing raw packets as most other modes do, Nping asks the underlying operating system to establish a connection with the target machine and port by issuing the connect system call. This is the same high-level system call that web browsers, P2P clients, and most other network-enabled applications use to establish a connection. It is part of a programming interface known as the Berkeley Sockets

API. Rather than read raw packet responses off the wire, Nping uses this API to obtain status information on each connection attempt. For this reason, you will not be able to see the contents of the packets that are sent or received but only status information about the TCP connection establishment taking place.

--tcp (TCP mode) .

TCP is the mode that lets users create and send any kind of TCP packet. TCP packets are sent embedded in IP packets that can also be tuned. This mode can be used for many different purposes. For example you could try to discover open ports by sending TCP SYN messages without completing the three-way handshake. This technique is often referred to as half-open scanning, because you don't open a full TCP connection. You send a SYN packet, as if you are going to open a real connection and then wait for a response. A SYN/ACK indicates the port is open, while a RST indicates it's closed. If no response is received one could assume that some intermediate network device is filtering the responses. Another use could be to see how a remote TCP/IP stack behaves when it receives a non-RFC-compliant packet, like one with both SYN and RST flags set. One could also do some evil by creating custom RST packets using an spoofed IP address with the intent of closing an active TCP connection.

--udp (UDP mode) .

UDP mode can have two different behaviours. Under normal circumstances, it lets users create custom IP/UDP packets. However, if Nping is run by a user without raw packet privileges and no changes to the default protocol headers are requested, then Nping enters the unprivileged UDP mode which basically sends UDP packets to the specified target hosts and ports using the `sendto` system call. Note that in this unprivileged mode it is not possible to see low-level header information of the packets on the wire but only status information about the amount of bytes that are being transmitted and received. UDP mode can be used to interact with any UDP-based server. Examples are DNS servers, streaming servers, online gaming servers, and port knocking/single-packet authorization daemons.

--icmp (ICMP mode) .

ICMP mode is the default mode when the user runs Nping with raw packet privileges. Any kind of ICMP message can be created. The default ICMP type is Echo, i.e., ping. ICMP mode can be used for many different purposes, from a simple request for a timestamp or a netmask to the transmission of fake destination unreachable messages, custom redirects, and router advertisements.

--arp (ARP/RARP mode) .

ARP lets you create and send a few different ARP-related packets. These include ARP, RARP, DRARP, and InARP requests and replies. This mode can be used to perform low-level host discovery, and conduct ARP-cache poisoning attacks.

--traceroute (Traceroute mode) .

Traceroute is not a mode by itself but a complement to TCP, UDP, and ICMP modes. When this option is specified Nping will set the IP TTL value of the first probe to 1. When the next router receives the packet it will drop it due to the expiration of the TTL and it will generate an ICMP destination unreachable message. The next probe will have a TTL of 2 so now the first router will forward the packet while the second router will be the one that drops the packet and generates the ICMP message. The third probe will have a TTL value of 3 and so on. By examining the source addresses of all those ICMP Destination Unreachable messages it is possible to determine the path that the probes take until they reach their final destination.

TCP CONNECT MODE

-p *port_spec*, **--dest-port** *port_spec* (Target ports) .

This option specifies which ports you want to try to connect to. It can be a single port, a comma-separated list of ports (e.g. 80,443,8080), a range (e.g. 1-1023), and any combination of those (e.g. 21-25,80,443,1024-2048). The beginning and/or end values of a range may be omitted, causing Nping to use 1 and 65535, respectively. So you can specify `-p-` to target ports from 1 through 65535. Using port zero is allowed if you specify it explicitly.

-g *portnumber*, **--source-port** *portnumber* (Spoof source port) .

This option asks Nping to use the specified port as source port for the TCP connections. Note that this

might not work on all systems or may require root privileges. Specified value must be an integer in the range [0–65535].

TCP MODE

-p *port_spec*, **--dest-port** *port_spec* (Target ports)

This option specifies which destination ports you want to send probes to. It can be a single port, a comma-separated list of ports (e.g. 80,443,8080), a range (e.g. 1–1023), and any combination of those (e.g. 21–25,80,443,1024–2048). The beginning and/or end values of a range may be omitted, causing Nping to use 1 and 65535, respectively. So you can specify **-p** to target ports from 1 through 65535. Using port zero is allowed if you specify it explicitly.

-g *portnumber*, **--source-port** *portnumber* (Spoof source port)

This option asks Nping to use the specified port as source port for the TCP connections. Note that this might not work on all systems or may require root privileges. Specified value must be an integer in the range [0–65535].

--seq *seqnumber* (Sequence Number) .

Specifies the TCP sequence number. In SYN packets this is the initial sequence number (ISN). In a normal transmission this corresponds to the sequence number of the first byte of data in the segment. *seqnumber* must be a number in the range [0–4294967295].

--flags *flags* (TCP Flags) .

This option specifies which flags should be set in the TCP packet. *flags* may be specified in three different ways:

1. As a comma-separated list of flags, e.g. **--flags syn,ack,rst**
2. As a list of one-character flag initials, e.g. **--flags SAR** tells Nping to set flags SYN, ACK, and RST.
3. As an 8-bit hexadecimal number, where the supplied number is the exact value that will be placed in the flags field of the TCP header. The number should start with the prefix 0x and should be in the range [0x00–0xFF], e.g. **--flags 0x20** sets the URG flag as 0x20 corresponds to binary 00100000 and the URG flag is represented by the third bit.

There are 8 possible flags to set: CWR, ECN, URG, ACK, PSH, RST, SYN, and FIN. The special value ALL means to set all flags. NONE means to set no flags. It is important that if you don't want any flag to be set, you request it explicitly because in some cases the SYN flag may be set by default. Here is a brief description of the meaning of each flag:

CWR (Congestion Window Reduced) .

Set by an ECN-Capable sender when it reduces its congestion window (due to a retransmit timeout, a fast retransmit or in response to an ECN notification).

ECN (Explicit Congestion Notification) .

During the three-way handshake it indicates that sender is capable of performing explicit congestion notification. Normally it means that a packet with the IP Congestion Experienced flag set was received during normal transmission. See RFC 3168. for more information.

URG (Urgent) .

Segment is urgent and the urgent pointer field carries valid information.

ACK (Acknowledgement) .

The segment carries an acknowledgement and the value of the acknowledgement number field is valid and contains the next sequence number that is expected from the receiver.

PSH (Push) .

The data in this segment should be immediately pushed to the application layer on arrival.

RST (Reset) .

There was some problem and the sender wants to abort the connection.

SYN (Synchronize) .

The segment is a request to synchronize sequence numbers and establish a connection. The sequence number field contains the sender's initial sequence number.

FIN (Finish) .

The sender wants to close the connection.

--win size (Window Size) .

Specifies the TCP window size, this is, the number of octets the sender of the segment is willing to accept from the receiver at one time. This is usually the size of the reception buffer that the OS allocates for a given connection. *size* must be a number in the range [0–65535].

--badsum (Invalid Checksum) .

Asks Nping to use an invalid TCP checksum for the packets sent to target hosts. Since virtually all host IP stacks properly drop these packets, any responses received are likely coming from a firewall or an IDS that didn't bother to verify the checksum. For more details on this technique, see

<http://nmap.org/p60-12.html>.

UDP MODE

--p port_spec, --dest-port port_spec (Target ports) .

This option specifies which ports you want UDP datagrams to be sent to. It can be a single port, a comma-separated list of ports (e.g. 80,443,8080), a range (e.g. 1–1023), and any combination of those (e.g. 21–25,80,443,1024–2048). The beginning and/or end values of a range may be omitted, causing Nping to use 1 and 65535, respectively. So you can specify **--p** to target ports from 1 through 65535. Using port zero is allowed if you specify it explicitly.

--g portnumber, --source-port portnumber (Spoof source port) .

This option asks Nping to use the specified port as source port for the transmitted datagrams. Note that this might not work on all systems or may require root privileges. Specified value must be an integer in the range [0–65535].

--badsum (Invalid Checksum)

Asks Nping to use an invalid UDP checksum for the packets sent to target hosts. Since virtually all host IP stacks properly drop these packets, any responses received are likely coming from a firewall or an IDS that didn't bother to verify the checksum. For more details on this technique, see

<http://nmap.org/p60-12.html>.

ICMP MODE

--icmp-type type (ICMP type) .

This option specifies which type of ICMP messages should be generated. *type* can be supplied in two different ways. You can use the [official type numbers assigned by IANA](#)^[1] (e.g. **--icmp-type 8** for ICMP Echo Request), or you can use any of the mnemonics listed in the section called “ICMP Types”.

--icmp-code code (ICMP code) .

This option specifies which ICMP code should be included in the generated ICMP messages. *code* can be supplied in two different ways. You can use the [official code numbers assigned by IANA](#)^[1] (e.g. **--icmp-code 1** for Fragment Reassembly Time Exceeded), or you can use any of the mnemonics listed in the section called “ICMP Codes”.

--icmp-id id (ICMP identifier) .

This option specifies the value of the identifier used in some of the ICMP messages. In general it is used to match request and reply messages. *id* must be a number in the range [0–65535].

--icmp-seq seq (ICMP sequence) .

This option specifies the value of the sequence number field used in some ICMP messages. In general it is used to match request and reply messages. *id* must be a number in the range [0–65535].

--icmp-redirect-addr addr (ICMP Redirect address) .

This option sets the address field in ICMP Redirect messages. In other words, it sets the IP address of the router that should be used when sending IP datagrams to the original destination. *addr* can be either an IPv4 address or a hostname.

--icmp-param-pointer pointer (ICMP Parameter Problem pointer) .

This option specifies the pointer that indicates the location of the problem in ICMP Parameter Problem messages. *pointer* should be a number in the range [0–255]. Normally this option is only used when ICMP code is set to 0 ("Pointer indicates the error").

--icmp-advert-lifetime *ttl* (ICMP Router Advertisement Lifetime) .

This option specifies the router advertisement lifetime, this is, the number of seconds the information carried in an ICMP Router Advertisement can be considered valid for. *ttl* must be a positive integer in the range [0–65535].

--icmp-advert-entry *addr,pref* (ICMP Router Advertisement Entry) .

This option adds a Router Advertisement entry to an ICMP Router Advertisement message. The parameter must be two values separated by a comma. *addr* is the router's IP and can be specified either as an IP address in dot-decimal notation or as a hostname. *pref* is the preference level for the specified IP. It must be a number in the range [0–4294967295]. An example is **--icmp-advert-entry 192.168.128.1,3**.

--icmp-orig-time *timestamp* (ICMP Originate Timestamp) .

This option sets the Originate Timestamp in ICMP Timestamp messages. The Originate Timestamp is expressed as the number of milliseconds since midnight UTC and it corresponds to the time the sender last touched the Timestamp message before its transmission. *timestamp* can be specified as a regular time (e.g. 10s, 3h, 1000ms), or the special string now. You can add or subtract values from now, for example **--icmp-orig-time now-2s**, **--icmp-orig-time now+1h**, **--icmp-orig-time now+200ms**.

--icmp-recv-time *timestamp* (ICMP Receive Timestamp) .

This option sets the Receive Timestamp in ICMP Timestamp messages. The Receive Timestamp is expressed as the number of milliseconds since midnight UTC and it corresponds to the time the echoer first touched the Timestamp message on receipt. *timestamp* is as with **--icmp-orig-time**.

--icmp-trans-time *timestamp* (ICMP Transmit Timestamp) .

This option sets the Transmit Timestamp in ICMP Timestamp messages. The Transmit Timestamp is expressed as the number of milliseconds since midnight UTC and it corresponds to the time the echoer last touched the Timestamp message before its transmission. *timestamp* is as with **--icmp-orig-time**.

ICMP Types

These identifiers may be used as mnemonics for the ICMP type numbers given to the **--icmp-type** option. In general there are three forms of each identifier: the full name (e.g. destination-unreachable), the short name (e.g. dest-unr), or the initials (e.g. du). In ICMP types that request something, the word "request" is omitted.

echo-reply, echo-rep, er

Echo Reply (type 0). This message is sent in response to an Echo Request message.

destination-unreachable, dest-unr, du

Destination Unreachable (type 3). This message indicates that a datagram could not be delivered to its destination.

source-quench, sour-que, sq

Source Quench (type 4). This message is used by a congested IP device to tell other device that is sending packets too fast and that it should slow down.

redirect, redi, r

Redirect (type 5). This message is normally used by routers to inform a host that there is a better route to use for sending datagrams. See also the **--icmp-redirect-addr** option.

echo-request, echo, e

Echo Request (type 8). This message is used to test the connectivity of another device on a network.

router-advertisement, rout-adv, ra

Router Advertisement (type 9). This message is used by routers to let hosts know of their existence and capabilities. See also the **--icmp-advert-lifetime** option.

router-solicitation, rout-sol, rs

Router Solicitation (type 10). This message is used by hosts to request Router Advertisement messages from any listening routers.

time-exceeded, time-exc, te

Time Exceeded (type 11). This message is generated by some intermediate device (normally a router) to indicate that a datagram has been discarded before reaching its destination because the IP TTL expired.

parameter-problem, member-pro, pp

Parameter Problem (type 12). This message is used when a device finds a problem with a parameter in an IP header and it cannot continue processing it. See also the **--icmp-param-pointer** option.

timestamp, time, tm

Timestamp Request (type 13). This message is used to request a device to send a timestamp value for propagation time calculation and clock synchronization. See also the **--icmp-orig-time**, **--icmp-recv-time**, and **--icmp-trans-time**.

timestamp-reply, time-rep, tr

Timestamp Reply (type 14). This message is sent in response to a Timestamp Request message.

information, info, i

Information Request (type 15). This message is now obsolete but it was originally used to request configuration information from another device.

information-reply, info-rep, ir

Information Reply (type 16). This message is now obsolete but it was originally sent in response to an Information Request message to provide configuration information.

mask-request, mask, m

Address Mask Request (type 17). This message is used to ask a device to send its subnet mask.

mask-reply, mask-rep, mr

Address Mask Reply (type 18). This message contains a subnet mask and is sent in response to a Address Mask Request message.

traceroute, trace, tc

Traceroute (type 30). This message is normally sent by an intermediate device when it receives an IP datagram with a traceroute option. ICMP Traceroute messages are still experimental, see RFC 1393. for more information.

ICMP Codes

These identifiers may be used as mnemonics for the ICMP code numbers given to the **--icmp-code** option. They are listed by the ICMP type they correspond to.

Destination Unreachable

network-unreachable, netw-unr, net

Code 0. Datagram could not be delivered to its destination network (probably due to some routing problem).

host-unreachable, host-unr, host

Code 1. Datagram was delivered to the destination network but it was impossible to reach the specified host (probably due to some routing problem).

protocol-unreachable, prot-unr, proto

Code 2. The protocol specified in the Protocol field of the IP datagram is not supported by the host to which the datagram was delivered.

port-unreachable, port-unr, port

Code 3. The TCP/UDP destination port was invalid.

needs-fragmentation, need-fra, frag

Code 4. Datagram had the DF bit set but it was too large for the MTU of the next physical

network so it had to be dropped.

source-route-failed, sour-rou, routefail

Code 5. IP datagram had a Source Route option but a router couldn't pass it to the next hop.

network-unknown, netw-unk, net?

Code 6. Destination network is unknown. This code is never used. Instead, Network Unreachable is used.

host-unknown, host-unk, host?

Code 7. Specified host is unknown. Usually generated by a router local to the destination host to inform of a bad address.

host-isolated, host-iso, isolated

Code 8. Source Host Isolated. Not used.

network-prohibited, netw-pro, !net

Code 9. Communication with destination network is administratively prohibited (source device is not allowed to send packets to the destination network).

host-prohibited, host-pro, !host

Code 10. Communication with destination host is administratively prohibited. (The source device is allowed to send packets to the destination network but not to the destination device.)

network-tos, unreachable-network-tos, netw-tos, tosnet

Code 11. Destination network unreachable because it cannot provide the type of service specified in the IP TOS field.

host-tos, unreachable-host-tos, toshost

Code 12. Destination host unreachable because it cannot provide the type of service specified in the IP TOS field.

communication-prohibited, comm-pro, !comm

Code 13. Datagram could not be forwarded due to filtering that blocks the message based on its contents.

host-precedence-violation, precedence-violation, prec-vio, violation

Code 14. Precedence value in the IP TOS field is not permitted.

precedence-cutoff, prec-cut, cutoff

Code 15. Precedence value in the IP TOS field is lower than the minimum allowed for the network.

Redirect

redirect-network, redi-net, net

Code 0. Redirect all future datagrams with the same destination network as the original datagram, to the router specified in the Address field. The use of this code is prohibited by RFC 1812..

redirect-host, redi-host, host

Code 1. Redirect all future datagrams with the same destination host as the original datagram, to the router specified in the Address field.

redirect-network-tos, redi-ntos, redir-ntos

Code 2. Redirect all future datagrams with the same destination network and IP TOS value as the original datagram, to the router specified in the Address field. The use of this code is prohibited by RFC 1812.

redirect-host-tos, redi-htos, redir-htos

Code 3. Redirect all future datagrams with the same destination host and IP TOS value as the original datagram, to the router specified in the Address field.

Router Advertisement

normal-advertisement, norm-adv, normal, zero, default, def

Code 0. Normal router advertisement. In Mobile IP: Mobility agent can act as a router for IP datagrams not related to mobile nodes.

not-route-common-traffic, not-rou, mobile-ip, !route, !commontraffic

Code 16. Used for Mobile IP. The mobility agent does not route common traffic. All foreign agents must forward to a default router any datagrams received from a registered mobile node

Time Exceeded

ttl-exceeded-in-transit, ttl-exc, ttl-transit

Code 0. IP Time To Live expired during transit.

fragment-reassembly-time-exceeded, frag-exc, frag-time

Code 1. Fragment reassembly time has been exceeded.

Parameter Problem

pointer-indicates-error, poin-ind, pointer

Code 0. The pointer field indicates the location of the problem. See the **--icmp-param-pointer** option.

missing-required-option, miss-option, option-missing

Code 1. IP datagram was expected to have an option that is not present.

bad-length, bad-len, badlen

Code 2. The length of the IP datagram is incorrect.

ARP MODE

--arp-type *type* (ICMP Type) .

This option specifies which type of ARP messages should be generated. *type* can be supplied in two different ways. You can use the [official numbers assigned by IANA](#)^[2] (e.g. **--arp-type 1** for ARP Request), or you can use one of the mnemonics from the section called “ARP Types”.

--arp-sender-mac *mac* (Sender MAC address) .

This option sets the Sender Hardware Address field of the ARP header. Although ARP supports many types of link layer addresses, currently Nping only supports MAC addresses. *mac* must be specified using the traditional MAC notation (e.g. 00:0a:8a:32:f4:ae). You can also use hyphens as separators (e.g. 00-0a-8a-32-f4-ae).

--arp-sender-ip *addr* (Sender IP address) .

This option sets the Sender IP field of the ARP header. *addr* can be given as an IPv4 address or a hostname.

--arp-target-mac *mac* (target MAC address) .

This option sets the Target Hardware Address field of the ARP header.

--arp-target-ip *addr* (target ip address) .

This option sets the Target IP field of the ARP header.

ARP Types

These identifiers may be used as mnemonics for the ARP type numbers given to the **--arp-type** option.

arp-request, arp, a

ARP Request (type 1). ARP requests are used to translate network layer addresses (normally IP addresses) to link layer addresses (usually MAC addresses). Basically, an ARP request is a broadcasted message that asks the host in the same network segment that has a given IP address to provide its MAC address.

arp-reply, arp-rep, ar

ARP Reply (type 2). An ARP reply is a message that a host sends in response to an ARP request to provide its link layer address.

rarp-request, rarp, r

RARP Requests (type 3). RARP requests are used to translate a link layer address (normally a MAC

address) to a network layer address (usually an IP address). Basically a RARP request is a broadcasted message sent by a host that wants to know his own IP address because it doesn't have any. It was the first protocol designed to solve the bootstrapping problem. However, RARP is now obsolete and DHCP is used instead. For more information about RARP see RFC 903..

rarp-reply, rarp-rep, rr

RARP Reply (type 4). A RARP reply is a message sent in response to a RARP request to provide an IP address to the host that sent the RARP request in the first place.

drarp-request, drarp, d

Dynamic RARP Request (type 5). Dynamic RARP is an extension to RARP used to obtain or assign a network layer address from a fixed link layer address. DRARP was used mainly in Sun Microsystems platforms in the late 90's but now it's no longer used. See RFC 1931. for more information.

drarp-reply, drarp-rep, dr

Dynamic RARP Reply (type 6). A DRARP reply is a message sent in response to a RARP request to provide network layer address.

drarp-error, drarp-err, de

DRARP Error (type 7). DRARP Error messages are usually sent in response to DRARP requests to inform of some error. In DRARP Error messages, the Target Protocol Address field is used to carry an error code (usually in the first byte). The error code is intended to tell why no target protocol address is being returned. For more information see RFC 1931.

inarp-request, inarp, i

Inverse ARP Request (type 8). InARP requests are used to translate a link layer address to a network layer address. It is similar to RARP request but in this case, the sender of the InARP request wants to know the network layer address of another node, not its own address. InARP is mainly used in Frame Relay and ATM networks. For more information see RFC 2390..

inarp-reply, inarp-rep, ir

Inverse ARP Reply (type 9). InARP reply messages are sent in response to InARP requests to provide the network layer address associated with the host that has a given link layer address.

arp-nak, an

ARP NAK (type 10). ARP NAK messages are an extension to the ATMARF protocol and they are used to improve the robustness of the ATMARF server mechanism. With ARP NAK, a client can determine the difference between a catastrophic server failure and an ATMARF table lookup failure. See RFC 1577. for more information.

IPV4 OPTIONS

-S *addr*, --source-ip *addr* (Source IP Address) .

Sets the source IP address. This option lets you specify a custom IP address to be used as source IP address in sent packets. This allows spoofing the sender of the packets. *addr* can be an IPv4 address or a hostname.

--dest-ip *addr* (Destination IP Address) .

Adds a target to Nping's target list. This option is provided for consistency but its use is deprecated in favor of plain target specifications. See the section called "TARGET SPECIFICATION".

--tos *tos* (Type of Service) .

Sets the IP TOS field. The TOS field is used to carry information to provide quality of service features. It is normally used to support a technique called Differentiated Services. See RFC 2474. for more information. *tos* must be a number in the range [0–255].

--id *id* (Identification) .

Sets the IPv4 Identification field. The Identification field is a 16-bit value that is common to all fragments belonging to a particular message. The value is used by the receiver to reassemble the original message from the fragments received. *id* must be a number in the range [0–65535].

--df (Don't Fragment) .

Sets the Don't Fragment bit in sent packets. When an IP datagram has its DF flag set, intermediate

devices are not allowed to fragment it so if it needs to travel across a network with a MTU smaller than datagram length the datagram will have to be dropped. Normally an ICMP Destination Unreachable message is generated and sent back to the sender.

--md (More Fragments) .

Sets the More Fragments bit in sent packets. The MF flag is set to indicate the receiver that the current datagram is a fragment of some larger datagram. When set to zero it indicates that the current datagram is either the last fragment in the set or that it is the only fragment.

--ttl *hops* (Time To Live) .

Sets the IPv4 Time-To-Live (TTL) field in sent packets to the given value. The TTL field specifies how long the datagram is allowed to exist on the network. It was originally intended to represent a number of seconds but it actually represents the number of hops a packet can traverse before being dropped. The TTL tries to avoid a situation in which undeliverable datagrams keep being forwarded from one router to another endlessly. *hops* must be a number in the range [0–255].

--badsum-ip (Invalid IP checksum) .

Asks Nping to use an invalid IP checksum for packets sent to target hosts. Note that some systems (like most Linux kernels), may fix the checksum before placing the packet on the wire, so even if Nping shows the incorrect checksum in its output, the packets may be transparently corrected by the kernel.

--ip-options *S*[*R* [*route*]]*L* [*route*]]*T**U* ..., **--ip-options** *hex string* (IP Options) .

The IP protocol offers several options which may be placed in packet headers. Unlike the ubiquitous TCP options, IP options are rarely seen due to practicality and security concerns. In fact, many Internet routers block the most dangerous options such as source routing. Yet options can still be useful in some cases for determining and manipulating the network route to target machines. For example, you may be able to use the record route option to determine a path to a target even when more traditional traceroute-style approaches fail. Or if your packets are being dropped by a certain firewall, you may be able to specify a different route with the strict or loose source routing options.

The most powerful way to specify IP options is to simply pass in hexadecimal data as the argument to **--ip-options**. Precede each hex byte value with \x. You may repeat certain characters by following them with an asterisk and then the number of times you wish them to repeat. For example, \x01\x07\x04\x00*4 is the same as \x01\x07\x04\x00\x00\x00\x00.

Note that if you specify a number of bytes that is not a multiple of four, an incorrect IP header length will be set in the IP packet. The reason for this is that the IP header length field can only express multiples of four. In those cases, the length is computed by dividing the header length by 4 and rounding down. This will affect the way the header that follows the IP header is interpreted, showing bogus information in Nping or in the output of any sniffer. Although this kind of situation might be useful for some stack stress tests, users would normally want to specify explicit padding, so the correct header length is set.

Nping also offers a shortcut mechanism for specifying options. Simply pass the letter R, T, or U to request record-route, record-timestamp, or both options together, respectively. Loose or strict source routing may be specified with an L or S followed by a space and then a space-separated list of IP addresses.

For more information and examples of using IP options with Nping, see the mailing list post at <http://seclists.org/nmap-dev/2006/q3/0052.html>.

--mtu *size* (Maximum Transmission Unit) .

This option sets a fictional MTU in Nping so IP datagrams larger than *size* are fragmented before transmission. *size* must be specified in bytes and corresponds to the number of octets that can be carried on a single link-layer frame.

IPV6 OPTIONS

-6, --ipv6 (Use IPv6) .

Tells Nping to use IP version 6 instead of the default IPv4. It is generally a good idea to specify this option as early as possible in the command line so Nping can parse it soon and know in advance that the rest of the parameters refer to IPv6. The command syntax is the same as usual except that you also add the **-6** option. Of course, you must use IPv6 syntax if you specify an address rather than a hostname. An address might look like **3ffe:7501:4819:2000:210:f3ff:fe03:14d0**, so hostnames are recommended.

While IPv6 hasn't exactly taken the world by storm, it gets significant use in some (usually Asian) countries and most modern operating systems support it. To use Nping with IPv6, both the source and target of your packets must be configured for IPv6. If your ISP (like most of them) does not allocate IPv6 addresses to you, free tunnel brokers are widely available and work fine with Nping. You can use the free IPv6 tunnel broker service at <http://www.tunnelbroker.net>.

Please note that IPv6 support is still highly experimental and many modes and options may not work with it.

-S addr, --source-ip addr (Source IP Address) .

Sets the source IP address. This option lets you specify a custom IP address to be used as source IP address in sent packets. This allows spoofing the sender of the packets. *addr* can be an IPv6 address or a hostname.

--dest-ip addr (Destination IP Address) .

Adds a target to Nping's target list. This option is provided for consistency but its use is deprecated in favor of plain target specifications. See the section called "TARGET SPECIFICATION".

--flow label (Flow Label) .

Sets the IPv6 Flow Label. The Flow Label field is 20 bits long and is intended to provide certain quality-of-service properties for real-time datagram delivery. However, it has not been widely adopted, and not all routers or endpoints support it. Check RFC 2460. for more information. *label* must be an integer in the range [0-1048575].

--traffic-class class (Traffic Class) .

Sets the IPv6 Traffic Class. This field is similar to the TOS field in IPv4, and is intended to provide the Differentiated Services method, enabling scalable service discrimination in the Internet without the need for per-flow state and signaling at every hop. Check RFC 2474. for more information. *class* must be an integer in the range [0-255].

--hop-limit hops (Hop Limit) .

Sets the IPv6 Hop Limit field in sent packets to the given value. The Hop Limit field specifies how long the datagram is allowed to exist on the network. It represents the number of hops a packet can traverse before being dropped. As with the TTL in IPv4, IPv6 Hop Limit tries to avoid a situation in which undeliverable datagrams keep being forwarded from one router to another endlessly. *hops* must be a number in the range [0-255].

ETHERNET OPTIONS

In most cases Nping sends packets at the raw IP level. This means that Nping creates its own IP packets and transmits them through a raw socket. However, in some cases it may be necessary to send packets at the raw Ethernet level. This happens, for example, when Nping is run under Windows (as Microsoft has disabled raw socket support since Windows XP SP2), or when Nping is asked to send ARP packets. Since in some cases it is necessary to construct ethernet frames, Nping offers some options to manipulate the different fields.

--dest-mac mac (Ethernet Destination MAC Address) .

This option sets the destination MAC address that should be set in outgoing Ethernet frames. This is useful in case Nping can't determine the next hop's MAC address or when you want to route probes through a router other than the configured default gateway. The MAC address should have the usual format of six colon-separated bytes, e.g. 00:50:56:d4:01:98. Alternatively, hyphens may be used

instead of colons. Use the word random or rand to generate a random address, and broadcast or bcast to use ff:ff:ff:ff:ff:ff. If you set up a bogus destination MAC address your probes may not reach the intended targets.

--source-mac *mac* (Ethernet Source MAC Address) .

This option sets the source MAC address that should be set in outgoing Ethernet frames. This is useful in case Nping can't determine your network interface MAC address or when you want to inject traffic into the network while hiding your network card's real address. The syntax is the same as for **--dest-mac**. If you set up a bogus source MAC address you may not receive probe replies.

--ether-type *type* (Ethertype) .

This option sets the Ethertype field of the ethernet frame. The Ethertype is used to indicate which protocol is encapsulated in the payload. *type* can be supplied in two different ways. You can use the [official numbers listed by the IEEE](#)^[3] (e.g. **--ether-type 0x0800** for IP version 4), or one of the mnemonics from the section called "Ethernet Types".

Ethernet Types

These identifiers may be used as mnemonics for the Ethertype numbers given to the **--arp-type** option.

ipv4, ip, 4

Internet Protocol version 4 (type 0x0800).

ipv6, 6

Internet Protocol version 6 (type 0x86DD).

arp

Address Resolution Protocol (type 0x0806).

rarp

Reverse Address Resolution Protocol (type 0x8035).

frame-relay, frelay, fr

Frame Relay (type 0x0808).

ppp

Point-to-Point Protocol (type 0x880B).

gsmpp

General Switch Management Protocol (type 0x880C).

mpls

Multiprotocol Label Switching (type 0x8847).

mps-ual, mps

Multiprotocol Label Switching with Upstream-assigned Label (type 0x8848).

mcap

Multicast Channel Allocation Protocol (type 0x8861).

pppoe-discovery, pppoe-d

PPP over Ethernet Discovery Stage (type 0x8863).

pppoe-session, pppoe-s

PPP over Ethernet Session Stage (type 0x8864).

ctag

Customer VLAN Tag Type (type 0x8100).

epon

Ethernet Passive Optical Network (type 0x8808).

pbnac

Port-based network access control (type 0x888E).

stag

Service VLAN tag identifier (type 0x88A8).

ethexp1
Local Experimental Ethertype 1 (type 0x88B5).

ethexp2
Local Experimental Ethertype 2 (type 0x88B6).

ethoui
OUI Extended Ethertype (type 0x88B7).

preauth
Pre-Authentication (type 0x88C7).

lldp
Link Layer Discovery Protocol (type 0x88CC).

mac-security, mac-sec, macsec
Media Access Control Security (type 0x88E5).

mvrp
Multiple VLAN Registration Protocol (type 0x88F5).

mmrp
Multiple Multicast Registration Protocol (type 0x88F6).

frrr
Fast Roaming Remote Request (type 0x890D).

PAYLOAD OPTIONS

--data *hex string* (Append custom binary data to sent packets) .
This option lets you include binary data as payload in sent packets. *hex string* may be specified in any of the following formats: 0xAABBCCDDEEFF..., AABBCCDDEEFF... or \xAA\xBB\xCC\xDD\xEE\xFF.... Examples of use are **--data 0xdeadbeef** and **--data \xCA\xFE\x09**. Note that if you specify a number like 0x00ff no byte-order conversion is performed. Make sure you specify the information in the byte order expected by the receiver.

--data-string *string* (Append custom string to sent packets) .
This option lets you include a regular string as payload in sent packets. *string* can contain any string. However, note that some characters may depend on your system's locale and the receiver may not see the same information. Also, make sure you enclose the string in double quotes and escape any special characters from the shell. Example: **--data-string "Jimmy Jazz..."**.

--data-length *len* (Append random data to sent packets) .
This option lets you include *len* random bytes of data as payload in sent packets. *len* must be an integer in the range [0-65400]. However, values higher than 1400 are not recommended because it may not be possible to transmit packets due to network MTU limitations.

ECHO MODE

The "Echo Mode" is a novel technique implemented by Nping which lets users see how network packets change in transit, from the host where they originated to the target machine. Basically, the Echo mode turns Nping into two different pieces: the Echo server and the Echo client. The Echo server is a network service that has the ability to capture packets from the network and send a copy ("echo them") to the originating client through a side TCP channel. The Echo client is the part that generates such network packets, transmits them to the server, and receives their echoed version through a side TCP channel that it has previously established with the Echo server.

This scheme lets the client see the differences between the packets that it sends and what is actually received by the server. By having the server send back copies of the received packets through the side channel, things like NAT devices become immediately apparent to the client because it notices the changes in the source IP address (and maybe even source port). Other devices like those that perform traffic shaping, changing TCP window sizes or adding TCP options transparently between hosts, turn up too.

The Echo mode is also useful for troubleshooting routing and firewall issues. Among other things, it can be used to determine if the traffic generated by the Nping client is being dropped in transit and never gets to its

destination or if the responses are the ones that don't get back to it.

Internally, client and server communicate over an encrypted and authenticated channel, using the Nping Echo Protocol (NEP), whose technical specification can be found in <http://nmap.org/svn/nping/docs/EchoProtoRFC.txt>

The following paragraphs describe the different options available in Nping's Echo mode.

--ec *passphrase*, --echo-client *passphrase* (Run Echo client) .

This option tells Nping to run as an Echo client. *passphrase* is a sequence of ASCII characters that is used to generate the cryptographic keys needed for encryption and authentication in a given session. The passphrase should be a secret that is also known by the server, and it may contain any number of printable ASCII characters. Passphrases that contain whitespace or special characters must be enclosed in double quotes.

When running Nping as an Echo client, most options from the regular raw probe modes apply. The client may be configured to send specific probes using flags like **--tcp**, **--icmp** or **--udp**. Protocol header fields may be manipulated normally using the appropriate options (e.g. **--ttl**, **--seq**, **--icmp-type**, etc.). The only exceptions are ARP-related flags, which are not supported in Echo mode, as protocols like ARP are closely related to the data link layer and its probes can't pass through different network segments.

--es *passphrase*, --echo-server *passphrase* (Run Echo server) .

This option tells Nping to run as an Echo server. *passphrase* is a sequence of ASCII characters that is used to generate the cryptographic keys needed for encryption and authentication in a given session. The passphrase should be a secret that is also known by the clients, and it may contain any number of printable ASCII characters. Passphrases that contain whitespace or special characters must be enclosed in double quotes. Note that although it is not recommended, it is possible to use empty passphrases, supplying **--echo-server ""**. However, if what you want is to set up an open Echo server, it is better to use option **--no-crypto**. See below for details.

--ep *port*, --echo-port *port* (Set Echo TCP port number) .

This option asks Nping to use the specified TCP port number for the Echo side channel connection. If this option is used with **--echo-server**, it specifies the port on which the server listens for connections. If it is used with **--echo-client**, it specifies the port to connect to on the remote host. By default, port number 9929 is used.

--nc, --no-crypto (Disable encryption and authentication) .

This option asks Nping not to use any cryptographic operations during an Echo session. In practical terms, this means that the Echo side channel session data will be transmitted in the clear, and no authentication will be performed by the server or client during the session establishment phase. When **--no-crypto** is used, the passphrase supplied with **--echo-server** or **--echo-client** is ignored.

This option must be specified if Nping was compiled without openssl support. Note that, for technical reasons, a passphrase still needs to be supplied after the **--echo-client** or **--echo-server** flags, even though it will be ignored.

The **--no-crypto** flag might be useful when setting up a public Echo server, because it allows users to connect to the Echo without the need for any passphrase or shared secret. However, it is strongly recommended to not use **--no-crypto** unless absolutely necessary. Public Echo servers should be configured to use the passphrase "public" or the empty passphrase (**--echo-server ""**) as the use of cryptography does not only provide confidentiality and authentication but also message integrity.

--once (Serve one client and quit) .

This option asks the Echo server to quit after serving one client. This is useful when only a single Echo session wants to be established as it eliminates the need to access the remote host to shutdown the server.

--safe-payloads (Zero application data before echoing a packet) .

This option asks the Echo server to erase any application layer data found in client packets before echoing them. When the option is enabled, the Echo server parses the packets received from Echo clients and tries to determine if they contain data beyond the transport layer. If such data is found, it is overwritten with zeroes before transmitting the packets to the appropriate Echo client.

Echo servers can handle multiple simultaneous clients running multiple echo sessions in parallel. In order to determine which packet needs to be echoed to which client and through which session, the Echo server uses an heuristic algorithm. Although we have taken every security measure that we could think of to prevent that a client receives an echoed packet that it did not generate, there is always a risk that our algorithm makes a mistake and delivers a packet to the wrong client. The **--safe-payloads** option is useful for public echo servers or critical deployments where that kind of mistake cannot be afforded.

The following examples illustrate how Nping's Echo mode can be used to discover intermediate devices.

Example 2. Discovering NAT devices

```
# nping --echo-client "public" echo.nmap.org --udp
```

Starting Nping (<http://nmap.org/nping>)

```
SENT (1.0970s) UDP 10.1.20.128:53 > 178.79.165.17:40125 ttl=64 id=32523 iplen=28
CAPT (1.1270s) UDP 80.38.10.21:45657 > 178.79.165.17:40125 ttl=54 id=32523 iplen=28
RCVD (1.1570s) ICMP 178.79.165.17 > 10.1.20.128 Port unreachable (type=3/code=3) ttl=49 id=16619 iplen=56
[...]
SENT (5.1020s) UDP 10.1.20.128:53 > 178.79.165.17:40125 ttl=64 id=32523 iplen=28
CAPT (5.1335s) UDP 80.38.10.21:45657 > 178.79.165.17:40125 ttl=54 id=32523 iplen=28
RCVD (5.1600s) ICMP 178.79.165.17 > 10.1.20.128 Port unreachable (type=3/code=3) ttl=49 id=16623 iplen=56
```

```
Max rtt: 60.628ms | Min rtt: 58.378ms | Avg rtt: 59.389ms
Raw packets sent: 5 (140B) | Rcvd: 5 (280B) | Lost: 0 (0.00%) | Echoed: 5 (140B)
Tx time: 4.00459s | Tx bytes/s: 34.96 | Tx pkts/s: 1.25
Rx time: 5.00629s | Rx bytes/s: 55.93 | Rx pkts/s: 1.00
Nping done: 1 IP address pinged in 6.18 seconds
```

The output clearly shows the presence of a NAT device in the client's local network. Note how the captured packet (CAPT) differs from the SENT packet: the source address for the original packets is in the reserved 10.0.0.0/8 range, while the address seen by the server is 80.38.10.21, the Internet side address of the NAT device. The source port was also modified by the device. The line starting with RCVD corresponds to the responses generated by the TCP/IP stack of the machine where the Echo server is run.

Example 3. Discovering a transparent proxy

```
# nping --echo-client "public" echo.nmap.org --tcp -p80
```

Starting Nping (<http://nmap.org/nping>)

```
SENT (1.2160s) TCP 10.0.1.77:41659 > 178.79.165.17:80 S ttl=64 id=3317 iplen=40 seq=567704200 win=1480
RCVD (1.2180s) TCP 178.79.165.17:80 > 10.0.1.77:41659 SA ttl=128 id=13177 iplen=44 seq=3647106954 win=163;
SENT (2.2150s) TCP 10.0.1.77:41659 > 178.79.165.17:80 S ttl=64 id=3317 iplen=40 seq=567704200 win=1480

```

```
Max rtt: 2.062ms | Min rtt: 2.062ms | Avg rtt: 2.062ms
Raw packets sent: 5 (200B) | Rcvd: 1 (46B) | Lost: 4 (80.00%) | Echoed: 0 (0B)
Tx time: 4.00504s | Tx bytes/s: 49.94 | Tx pkts/s: 1.25
```

```
Rx time: 5.00618s | Rx bytes/s: 9.19 | Rx pkts/s: 0.20
Nping done: 1 IP address pinged in 6.39 seconds
```

In this example, the output is a bit more tricky. The absence of error messages shows that the Echo client has successfully established an Echo session with the server. However, no CAPT packets can be seen in the output. This means that none of the transmitted packets reached the server. Interestingly, a TCP SYN-ACK packet was received in response to the first TCP-SYN packet (and also, it is known that the target host does not have port 80 open). This behavior reveals the presence of a transparent web proxy cache server (which in this case is an old MS ISA server).

TIMING AND PERFORMANCE OPTIONS

--delay *time* (Delay between probes) .

This option lets you control for how long will Nping wait before sending the next probe. Like in many other ping tools, the default delay is one second. *time* must be a positive integer or floating point number. By default it is specified in seconds, however you can give an explicit unit by appending ms for milliseconds, s for seconds, m for minutes, or h for hours (e.g. 2.5s, 45m, 2h).

--rate *rate* (Send probes at a given rate) .

This option specifies the number of probes that Nping should send per second. This option and **--delay** are inverses; **--rate 20** is the same as **--delay 0.05**. If both options are used, only the last one in the parameter list counts.

MISCELLANEOUS OPTIONS

-h, --help (Display help) .

Displays help information and exits.

-V, --version (Display version) .

Displays the program's version number and quits.

-c *rounds*, **--count** *rounds* (Stop after a given number of rounds) .

This option lets you specify the number of times that Nping should loop over target hosts (and in some cases target ports). Nping calls these “rounds”. In a basic execution with only one target (and only one target port in TCP/UDP modes), the number of rounds matches the number of probes sent to the target host. However, in more complex executions where Nping is run against multiple targets and multiple ports, the number of rounds is the number of times that Nping sends a complete set of probes that covers all target IPs and all target ports. For example, if Nping is asked to send TCP SYN packets to hosts 192.168.1.0–255 and ports 80 and 433, then $256 \times 2 = 512$ packets are sent in one round. So if you specify **-c 100**, Nping will loop over the different target hosts and ports 100 times, sending a total of $256 \times 2 \times 100 = 51200$ packets. By default Nping runs for 5 rounds. If a value of 0 is specified, Nping will run continuously.

-e *name*, **--interface** *name* (Set the network interface to be used) .

This option tells Nping what interface should be used to send and receive packets. Nping should be able to detect this automatically, but it will tell you if it cannot. *name* must be the name of an existing network interface with an assigned IP address.

--privileged (Assume that the user is fully privileged) .

Tells Nping to simply assume that it is privileged enough to perform raw socket sends, packet sniffing, and similar operations that usually require special privileges. By default Nping quits if such operations are requested by a user that has no root or administrator privileges. This option may be useful on Linux, BSD or similar systems that can be configured to allow unprivileged users to perform raw-packet transmissions. The **NPING_PRIVILEGED** environment variable may be set as an alternative to using **--privileged**.

--unprivileged (Assume that the user lacks raw socket privileges) .

This option is the opposite of **--privileged**. It tells Nping to treat the user as lacking network raw socket and sniffing privileges. This is useful for testing, debugging, or when the raw network functionality of your operating system is somehow broken. The **NPING_UNPRIVILEGED** environment variable may be set as an alternative to using **--unprivileged**.

--send-eth (Use raw ethernet sending) .

Asks Nping to send packets at the raw ethernet (data link) layer rather than the higher IP (network) layer. By default, Nping chooses the one which is generally best for the platform it is running on. Raw sockets (IP layer) are generally most efficient for Unix machines, while ethernet frames are required for Windows operation since Microsoft disabled raw socket support. Nping still uses raw IP packets despite this option when there is no other choice (such as non-ethernet connections).

--send-ip (Send at raw IP level) .

Asks Nping to send packets via raw IP sockets rather than sending lower level ethernet frames. It is the complement to the **--send-eth** option.

--bpf-filter filter spec --filter filter spec (Set custom BPF filter) .

This option lets you use a custom BPF filter. By default Nping chooses a filter that is intended to capture most common responses to the particular probes that are sent. For example, when sending TCP packets, the filter is set to capture packets whose destination port matches the probe's source port or ICMP error messages that may be generated by the target or any intermediate device as a result of the probe. If for some reason you expect strange packets in response to sent probes or you just want to sniff a particular kind of traffic, you can specify a custom filter using the BPF syntax used by tools like tcpdump.. See the documentation at <http://www.tcpdump.org/> for more information.

-H, --hide-sent (Do not display sent packets) .

This option tells Nping not to print information about sent packets. This can be useful when using very short inter-probe delays (i.e., when flooding), because printing information to the standard output has a computational cost and disabling it can probably speed things up a bit. Also, it may be useful when using Nping to detect active hosts or open ports (e.g. sending probes to all TCP ports in a /24 subnet). In that case, users may not want to see thousands of sent probes but just the replies generated by active hosts.

-N, --no-capture (Do not attempt to capture replies) .

This option tells Nping to skip packet capture. This means that packets in response to sent probes will not be processed or displayed. This can be useful when doing flooding and network stack stress tests. Note that when this option is specified, most of the statistics shown at the end of the execution will be useless. This option does not work with TCP Connect mode.

OUTPUT OPTIONS**-v[level], --verbose [level]** (Increase or set verbosity level) .

Increases the verbosity level, causing Nping to print more information during its execution. There are 9 levels of verbosity (-4 to 4). Every instance of **-v** increments the verbosity level by one (from its default value, level 0). Every instance of option **-q** decrements the verbosity level by one.

Alternatively you can specify the level directly, as in **-v3** or **-v-1**. These are the available levels:

Level â4

No output at all. In some circumstances you may not want Nping to produce any output (like when one of your work mates is watching over your shoulder). In that case level â4 can be useful because although you won't see any response packets, probes will still be sent.

Level â3

Like level â4 but displays fatal error messages so you can actually see if Nping is running or it failed due to some error.

Level â2

Like level â3 but also displays warnings and recoverable errors.

Level â1

Displays traditional run-time information (version, start time, statistics, etc.) but does not display sent or received packets.

Level 0

This is the default verbosity level. It behaves like level â1 but also displays sent and received packets and some other important information.

Level 1

Like level 0 but it displays detailed information about timing, flags, protocol details, etc.

Level 2

Like level 1 but displays very detailed information about sent and received packets and other interesting information.

Level 3

Like level 2 but also displays the raw hexadecimal dump of sent and received packets.

Level 4 and higher

Same as level 3.

-q[level], --reduce-verbosity [level] (Decrease verbosity level) .

Decreases the verbosity level, causing Nping to print less information during its execution.

-d[level] (Increase or set debugging level) .

When even verbose mode doesn't provide sufficient data for you, debugging is available to flood you with much more! As with the **-v**, debugging is enabled with a command-line flag **-d** and the debug level can be increased by specifying it multiple times. There are 7 debugging levels (0 to 6). Every instance of **-d** increments debugging level by one. Provide an argument to **-d** to set the level directly; for example **-d4**.

Debugging output is useful when you suspect a bug in Nping, or if you are simply confused as to what Nping is doing and why. As this feature is mostly intended for developers, debug lines aren't always self-explanatory. You may get something like

```
NSOCK (1.0000s) Callback: TIMER SUCCESS for EID 12; tcpconnect_event_handler(): Received callback of type
```

If you don't understand a line, your only recourses are to ignore it, look it up in the source code, or request help from the development list (nmap-dev). Some lines are self-explanatory, but the messages become more obscure as the debug level is increased. These are the available levels:

Level 0

Level 0. No debug information at all. This is the default level.

Level 1

In this level, only very important or high-level debug information will be printed.

Level 2

Like level 1 but also displays important or medium-level debug information

Level 3

Like level 2 but also displays regular and low-level debug information.

Level 4

Like level 3 but also displays messages only a real Nping freak would want to see.

Level 5

Like level 4 but it enables basic debug information related to external libraries like Nsock..

Level 6

Like level 5 but it enables full, very detailed, debug information related to external libraries like Nsock.

BUGS

Like its author, Nping isn't perfect. But you can help make it better by sending bug reports or even writing patches. If Nping doesn't behave the way you expect, first upgrade to the latest Nmap version available from <http://nmap.org/download.html>. If the problem persists, do some research to determine whether it has already been discovered and addressed. Try searching for the error message on our search page at <http://insecure.org/search.html> or at Google. Also try browsing the nmap-dev archives at <http://seclists.org/>. Read this full manual page as well. If nothing comes out of this, mail a bug report to

nmap-dev@insecure.org. Please include everything you have learned about the problem, as well as what version of Nping you are running and what operating system version it is running on. Problem reports and Nping usage questions sent to nmap-dev@insecure.org are far more likely to be answered than those sent to Fyodor directly. If you subscribe to the nmap-dev list before posting, your message will bypass moderation and get through more quickly. Subscribe at <http://cgi.insecure.org/mailman/listinfo/nmap-dev>.

Code patches to fix bugs are even better than bug reports. Basic instructions for creating patch files with your changes are available at <https://svn.nmap.org/nmap/HACKING>. Patches may be sent to nmap-dev (recommended) or to any of the authors listed in the next section directly.

NAME

omniutil – collection of HP DataProtector enhancement utilities

SYNOPSIS

edrc/lib/omniutil [**-h**]

omniutil **-a pd_create** **-i ora_sid** **-d basedir** [**-v ora_vers**]

omniutil **-a pd_link** **-i ora_sid** **-d basedir**

AVAILABILITY

WA2L/edrc

DESCRIPTION

omniutil is a collection of HP DataProtector enhancement tools.

The different tools can be started using the **-a action** option.

The remaining options are dependent of the selected *action*.

For a description of the functionality of the different *actions* see section **OPTIONS**.

OPTIONS

-h usage message.

-a action :

pd_create

create a pointer directory structure. This is a structure mainly consisting of symbolic links that will point to an **\$ORACLE_HOME** after invoking **-a pd_link** later.

This enables DataProtector to backup databases, that have no own **\$ORACLE_HOME** installation. The **\$ORACLE_HOME** setting in DataProtector can be set to this "pretended" **\$ORACLE_HOME**.

To allow a pseudo-dynamic setup, after invoking **-a pd_create** ... the two symbolic links (**.ora_home** and **.network_admin**) in the applied structure have to be set accordingly using **-a pd_link**

See also section **EXAMPLES**.

pd_link

the structure applied using **-a pd_create** ... mainly contains symbolic links that first point to the two main symbolic links (**.ora_home** and **.network_admin**). This two links then should point to the real **\$ORACLE_HOME**. This indirect symbolic link structure enables an automated update of the structure if an Oracle installation is patched creating a new **\$ORACLE_HOME** with the applied patches. Normally the directory structure after installing a patch is identical, but the binaries etc. might change. If a patch is applied using this method it is only needed to update the two symbolic links **.ora_home** and **.network_admin** using the **-a pd_link** ... option.

In the configuration file **omniutil.cfg** the command to resolve the current **\$ORACLE_HOME** and **\$TNS_ADMIN** can be specified in the **ORACLE_ENV_CMD** setting. If it is not possible to resolve this environment variables, they can be set manually previous to the **omniutil** command invocation using **export ORACLE_HOME=path** and **export TNS_ADMIN=path**.

To ensure that the described symbolic links always point to the most recent **\$ORACLE_HOME** the **~edrc/bin/omniutil -a pd_link -i ora_sid -d basedir** can be defined as **PRE_EXEC** script in the DataProtector Barlist for the related database backup.

See also section **EXAMPLES**.

-i ora_sid Oracle SID.

-d basedir Base directory of the pointer directory structure.

-v ora_version

Database version (=template file **ora_version.tar.gz** located in **edrc/var/omniutil/pd/**).

ENVIRONMENT

-

EXIT STATUS

- | | |
|-----------|---|
| 0 | no error. |
| 2 | operating system not supported, see osid(3) if you get this error. |
| 4 | usage listed. |
| 6 | configuration file omniutil.cfg does not exist. |
| 10 | template for the specified Oracle version (ora_vers) does not exist. |
| 11 | DataProtector Oracle pointer directory (<basedir>/<ora_sid>) already exists. |

- 12 template does not contain the directory for the specified Oracle version (*ora_vers*).
- 13 cannot write to the specified *basedir*.
- 21 DataProtector pointer directory **<basedir>/<ora_sid>** does not exist.
- 23 cannot write to the specified *basedir*.

FILES

edrc/etc/omniutil.cfg

configuration file for **omniutil**.

edrc/var/omniutil/pd/<ora_vers>/

template files for the pointer directory structure.

edrc/var/omniutil/pd/<ora_vers>.tar.gz

packed template files for the pointer directory structure. For easy distribution of the template structure, always the packed version of the structure template should be used.

<basedir>/<ora_sid>/

applied template pointer directory structure

<basedir>/<ora_sid>/ora_home

main symbolic link of applied template pointer directory structure pointing to the **\$ORACLE_HOME** directory of the installed Oracle software for a certain database (*ora_sid*).

<basedir>/<ora_sid>/network_admin

main symbolic link of applied template pointer directory structure pointing to the **\$TNS_ADMIN** directory of the installed Oracle software for a certain database (*ora_sid*).

EXAMPLES

1) create a pointer directory structure

This example shows how to create a pointer directory structure for the database *FS90DMO* in the directory **/data_ps1/dat/omni/** that will be used as **\$ORACLE_HOME** for this database in DataProtector. The **\$ORACLE_HOME** that is used by the database itself is located in **/ora/product/10204**.

1.1) create the directory structure

Create the generic pointer directory structure for the database version *10gR2* :

```
[ /data_ps1/dat/omni ]
[ root@acme001 ] [-sh]: ~edrc/bin/omniutil -a pd_create -i FS90DMO \
                        -d /data_ps1/dat/omni -v 10gR2
```

omniutil - DataProtector Utilities

```
create OBII Oracle pointer directory structure ...
  create /data_ps1/dat/omni/FS90DMO ... done.
  create structure ...
    using template: /opt/edrc/var/omniutil/pd/10gR2.tar.gz
    /data_ps1/dat/omni/FS90DMO/.patch_storage
    /data_ps1/dat/omni/FS90DMO/OPatch
    /data_ps1/dat/omni/FS90DMO/assistants
    /data_ps1/dat/omni/FS90DMO/bin
    /data_ps1/dat/omni/FS90DMO/cdata
    /data_ps1/dat/omni/FS90DMO/cfgtoollogs
    /data_ps1/dat/omni/FS90DMO/clone
    /data_ps1/dat/omni/FS90DMO/config
    /data_ps1/dat/omni/FS90DMO/crs
    /data_ps1/dat/omni/FS90DMO/css
    /data_ps1/dat/omni/FS90DMO/ctx
    /data_ps1/dat/omni/FS90DMO/dbs
    /data_ps1/dat/omni/FS90DMO/demo
    /data_ps1/dat/omni/FS90DMO/diagnostics
    /data_ps1/dat/omni/FS90DMO/has
    /data_ps1/dat/omni/FS90DMO/hs
    /data_ps1/dat/omni/FS90DMO/install
    /data_ps1/dat/omni/FS90DMO/inventory
  :
  :
    /data_ps1/dat/omni/FS90DMO/sqlj
    /data_ps1/dat/omni/FS90DMO/sqlplus
    /data_ps1/dat/omni/FS90DMO/srvn
    /data_ps1/dat/omni/FS90DMO/sysman
    /data_ps1/dat/omni/FS90DMO/tg4ifmx
    /data_ps1/dat/omni/FS90DMO/tg4ingr
    /data_ps1/dat/omni/FS90DMO/tg4sybs
    /data_ps1/dat/omni/FS90DMO/tg4tera
    /data_ps1/dat/omni/FS90DMO/uix
    /data_ps1/dat/omni/FS90DMO/wwg
    /data_ps1/dat/omni/FS90DMO/xdk
    /data_ps1/dat/omni/FS90DMO/.network_admin
    /data_ps1/dat/omni/FS90DMO/.ora_home
    0 blocks
  done.
done.
```

1.2) set the directory structure link

Update the symbolic links to point to the **\$ORACLE_HOME** for the given database:

```
[ /data_ps1/dat/omni/FS90DMO ]
[ root@acme001 ][-sh]: ~edrc/bin/omniutil -a pd_link -i FS90DMO \
                        -d /data_ps1/dat/omni
```

omniutil - DataProtector Utilities

```
update OBII Oracle pointer directory symlinks ...
```

```
in directory /data_psl/dat/omni/FS90DMO ...
omniutil-INFO: symlink '.network_admin -> /ora/product/10204/netw
omniutil-INFO: symlink '.ora_home -> /ora/product/10204' created
done
done.
```

NAME

omniutil.cfg – configuration file for omniutil

SYNOPSIS

edrc/etc/omniutil.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **omniutil** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS

LOG Log output dir of **omniutil**. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation.

Example: LOG=/var/opt/omni/log

Default: LOG='approot'/var/log

OBII_DEFAULT_ORACLE_VERSION

Default Oracle version if no version is specified in the command line. This setting specifies the template used in **edrc/var/omniutil/pd**.

Example: OBII_DEFAULT_ORACLE_VERSION=Oracle9i

Default: OBII_DEFAULT_ORACLE_VERSION=Oracle8

ORACLE_ENV_CMD

Command used to evaluate the current **\$TNS_ADMIN** and **\$ORACLE_HOME** of a database. The variables **\$OBII_ORACLE_VERSION** and **\$OBII_ORACLE_INSTANCE** can be used as options in the **ORACLE_ENV_CMD**.

Example: ORACLE_ENV_CMD='./usr/local/bin/sid \$OBII_ORACLE_INSTANCE'

Default: ORACLE_ENV_CMD='ini.ksh \$OBII_ORACLE_VERSION'

EXEC_SHELL

Shell to execute the **ORACLE_ENV_CMD**.

Example: EXEC_SHELL=/bin/ksh

Default: EXEC_SHELL=/bin/ksh

NAME

`os_wrapper` – wrap operating system dependent binaries

SYNOPSIS

`edrc/bin/command -> .os_wrapper`

`edrc/lib/command -> .os_wrapper`

AVAILABILITY

WA2L/edrc

DESCRIPTION

wrap operating system dependent binaries to allow transparent command startup.

If a binary for the related operating system (OSID) is installed in WA2L/edrc this binary is started. When the binary is not installed in WA2L/edrc, but the operating system provides it, it is started from the operating system.

This default *command* startup behaviour can be altered in the configuration file **lib/os_wrapper/command.cfg** for each *command* started thru the **.os_wrapper**.

The concept behind the default startup behaviour is, that on certain operating systems some commands are not installed by default. Therefore only for those operating systems the "missing" commands have to be distributed with WA2L/edrc, in this case the command provided in WA2L/edrc complements the commands provided by the operating system.

Furthermore it might also be the case that some variants of commands provided by a certain operating systems do not provide the needed functionality, in this case the command variant provided in WA2L/edrc over-locks the one installed by the operating system.

An example for over-locking is the **cpio** command for HP-UX, where the operating system command lacks some options and is not able to copy files bigger then 2 GByte.

An example for complementing is the **traceroute** command for SunOS, where it was not installed by default on early Solaris releases.

When a binary that is provided in WA2L/edrc is started thru the **.os_wrapper** the **\$LD_LIBRARY_PATH** and based on the underlying operating system, the **\$SHLIB_PATH** environment variables are expanded with **lib/<OSID>/libs/**.

To start a new command thru the **.os_wrapper**, follow the following steps:

- 1.) create a symlink to the new command in the **edrc/bin/** or **edrc/lib/** directory depending on your needs:

```
[ /opt/edrc/bin ]
[ root@acme001 ] [*edrc*/bash]: ln -s .os_wrapper new_cmd
```

- 2.) install the command binary in the **edrc/bin/<OSID>/** or **edrc/lib/<OSID>/** directory depending on your needs and set the correct file ownership (0:3) and permissions (*executable*):

```
[ /opt/edrc/lib/Linux ]
[ root@acme001 ][*edrc*/bash]: chown root:3 new_cmd

[ /opt/edrc/lib/Linux ]
[ root@acme001 ][*edrc*/bash]: chmod 755 new_cmd
```

OPTIONS

-

ENVIRONMENT

-

EXIT STATUS

- 103** user calling the command has no permission to access/execute the called *daemon_command*.
- 106** the operating system id (OSID) is not supported, yet. If you get this error, the *command* is neither installed in WA2L/edrc, nor on the underlying operating system.
- 107** the **.os_wrapper** was called directly.
- other** exit status of the started *command*.

FILES

- lib/os_wrapper/command.cfg**
configuration file for the *command* started thru the **.os_wrapper**. If this file is missing for a *command*, the default startup behaviour applies.
- bin/<OSID>/command**
location of the provided *command* for a certain operating system id (OSID).
- bin/<OSID>/<GLIBC>/command**
location of the provided *command* for a certain operating system id (OSID) and for a specific GLIBC version.

The GLIBC version can be resolved using the **glibc.version(3)**, the **ldd --version** or the **get-conf GNU_LIBC_VERSION** command.
- lib/<OSID>/command**
location of the provided *command* for a certain operating system id (OSID).

lib/<OSID>/<GLIBC>/command

location of the provided *command* for a certain operating system id (OSID) and for a specific GLIBC version.

The GLIBC version can be resolved using the **glibc.version(3)** or the **ldd --version** command.

lib/<OSID>/libs/

location of the provided shared libraries for a certain operating system id (OSID).

lib/<OSID>/<GLIBC>/libs/

location of the provided shared libraries for a certain operating system id (OSID) and for a specific GLIBC version.

NAME

osid – evaluate the system's operating system id

SYNOPSIS

edrc/lib/osid [**-h** | **-p** | **-s** | **-e**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

osid generates an unique identifier for each combination of OS release (**uname -r**) and OS version (**uname -s**). This identifier is used, particularly by **sysconfig**, to identify the appropriate files for system configuration. Furthermore many scripts use **osid** to make it compatible to multiple operating systems.

This tool is necessary because the OS alone is not sufficient to uniquely identify the proper configuration files for an OS. For example, both Solaris 1.x and 2.x call themselves "SunOS". But because Solaris 1.x is a BSD release and Solaris 2.x is a System V release, they require completely different configuration files.

To minimize the risk of damaging a future, incompatible release of an existing operating system, **osid** will only return a value different from *unknown* if the entry in **osid.dat** exactly matches the values returned by **uname -rs**.

If two releases of an Operating System are sufficiently similar (for instance HP-UX v9.01 and v9.03), they may of course be mapped to the same OSID in **osid.dat**.

If the file **/etc/sfi/OSID** exists, the value from this file is returned by **osid**. If this file does not exist, the current OSID is resolved from the **edrc/etc/osid.dat** file.

OPTIONS

- h** print **osid** usage.
- p** print the OSID definitions as an unordered list identical to the sequence in the **osid.dat** file. This output can also be used to debug the definitions in an **osid.dat** file due to the fact that OSID of the first matching entry will be returned as the resolved OSID.
- s** print the OSID definitions as an ordered list.
- e** print a line in the **osid.dat** format based on the current operating system. This option helps to quickly add a line to the related **osid.dat** file. The fields *unknown* and *<Comment>* have to be replaced by the correct values.

EXIT STATUS

- 0** the operating system id could be resolved.

- 1 the operating system id could not be resolved. In this case **osid** returns *unknown* as OS-id. If you receive this return value you should check the configuration file **edrc/etc/osid.dat** if the entry for the current operating system is missing. If two releases on an operating system are sufficient similar, they should be mapped to the same OS-id.
- 2 the option **-p** or **-s** has been invoked.
- 4 usage listed.
- 5 the option **-e** has been invoked.

EXAMPLES

- 1) HOWTO use osid to write a multiple os compatible script

```

:
:

case "`osid`" in
    Solaris)
        DF="df -k"
        AWK=nawk
        ECHO=echo
        ;;
    HP-10|HP-11)
        DF="bdf"
        AWK=awk
        ECHO=echo
        ;;
    Linux)
        DF="df -k"
        AWK=awk
        ECHO="echo -e"
        ;;
    unknown)
        echo "example-FATAL: OS not defined"
        exit 2
        ;;
    *)
        echo "example-FATAL: OS not supported"
        exit 2
        ;;
esac

:
:

cd /
$DF | $AWK '{ printf("%10d | %10d | %s\n", $3, $4, $6)}'

edrcintro(1), **mandir**(4), **osid.cfg**(4), **osid.dat**(4), **osid.probe**(3), **rosid**(3), **sysconfig**(1)

FILES

/etc/sfi/OSID

operating system id on a system configured by **rmtconfig** of the **SFI-Director**.

edrc/etc/osid.cfg

optional configuration file for **osid**. See **osid.cfg**(4) for more information.

edrc/etc/osid.dat

mapfile of **uname -rs** or **uname -rsm** to OS-id. See **osid.dat**(4) for more information.

edrc/lib/OSID/osid.probe

the **osid.probe** command is a C-program that is compiled for each OSID. It is used to probe if the binary related to the resolved OSID is able to run on the system. If the **osid.probe** binary can't be executed it is assumed that also the other binaries related to the OSID aren't compatible to the system architecture and *unknown* is returned by the **osid** command
If the **osid.probe** command does not exist the binary compatibility is not checked.

NOTES

Parts of this manpage were extracted from the documentation of the **SFI-Director** and modified to fit to the **WA2L/edrc** package. See <http://sfidirector.sourceforge.net> for more information about the **SFI-Director**.

Due to the fact that certain operating system vendors started to distribute identical operating system releases (**uname -r**) on different platforms, the need came up to even distinguish within identical operating system releases between the platforms. Therefore the machine (hardware) type (**uname -m**) can be considered too. This lead into an extended format of the **osid.dat** file, that usage can be configured in the **osid.cfg** configuration file, if needed.

BUGS

-

AUTHOR

osid was initially developed by Peter Stevens. The version included in **WA2L/edrc** has been rewritten by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net .

NAME

osid.cfg – configuration file for osid

SYNOPSIS

edrc/etc/osid.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the optional configuration file for the **osid** command.

FILEFORMAT

Rows starting with a **#** are considered as comments.

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the **=** and the **VALUE** are no spaces.

You should not comment out any **OPTION**. If you like to use default settings simply do not specify a **VALUE**.

OPTIONS**OSID_DAT_FORMAT**

Format of the **osid.dat** file.

The **SFI** format as known from the SFI Director in the years 1996-2008 is:
OS:release:OSID:Comment

The extended **WA2L** format starting from 2008 is: *OS:release:machine:OSID:Comment*

See **osid.dat(4)** for more information.

Default is the **SFI** format. The **SFI** format also applies when the **osid.cfg** file does not exist.

Example: **OSID_DAT_FORMAT=WA2L**

Default: **OSID_DAT_FORMAT=SFI**

OSID_DAT_FILE

Name of the **osid.dat** file in the **edrc/etc** directory.

The default if the specified file does not exist or if the **osid.cfg** file does not exist is **osid.dat**.

Example: OSID_DAT_FILE=osid.dat.wa2l

Default: OSID_DAT_FILE=osid.dat

PROBE_BINARY

With this setting the probing of binaries for the resolved OSID can be turned off. Currently I cannot imagine a reason why to set this option to False, but you never know.

Example: PROBE_BINARY=False

Default: PROBE_BINARY=True

DISABLE_REGEX

If the **OSID_DAT_FORMAT** is set to **WA2L**, the first three fields in the specified **OSID_DAT_FILE** (<OS>:<release>:<machine>:) are treated as regular expressions. To disable this feature, set **DISABLE_REGEX** to **True**.

Example: DISABLE_REGEX=True

Default: DISABLE_REGEX=False

NAME

osid.dat – operating system versions map for osid

SYNOPSIS

edrc/etc/osid.dat
edrc/etc/osid.dat.WA2L

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the OSID map file for the **osid** command.

There are two formats of the **osid.dat** file possible. One (the file format known from the SFI-Director, that suited the requirements for more then ten years from 1996 to 2008) considers the **uname -rs** combinations. The new slightly extended format (needed due to the operating system vendors started to distribute identical operating system versions on different platforms) considers the **uname -rsm** combinations.

The used format and the **osid.dat** file to be used for your environment can be configured in the **osid.cfg(4)** configuration file.

The default is still the **SFI** format.

SFI FORMAT

This list defines a unique identifier for each combination of OS release (**uname -r**) and OS version (**uname -s**). It maps these two values to OSID. This is defined to separate different OS and release levels. If two different releases are sufficiently close to each other, they may be mapped into the same OSID. The command **osid** processes a **uname -rs** and compares the result with the contents of **edrc/etc/osid.dat**. If the result matches to an entry, the corresponding OSID is returned.

WA2L FORMAT

This list defines a unique identifier for each combination of OS release (**uname -r**), OS version (**uname -s**) and machine type (**uname -m**). It maps these three values to OSID. This is defined to separate different OS, release levels and platform types. If two different releases are sufficiently close to each other, they may be mapped into the same OSID. The command **osid** processes a **uname -rsm** and compares the result with the contents of **edrc/etc/osid.dat**. If the result matches to an entry, the corresponding OSID is returned.

Due to the fact, that especially on Linux operating systems, the **uname -r** output changes also when patches are installed and not only on operating system release upgrades as on Solaris or HP-UX, the first three fields of the **edrc/etc/osid.dat** file in the **WA2L** format are treated as regular expressions, by default. This enables, to resolve the OSID more reliable.

Be aware, that all regular expressions in the file are correct, else the OSID resolution might fail.

Definition example using regular expressions:

```
Linux:2.6.35.[0-9][0-9]-[0-9][0-9].fc14.i686:i686:Linux:Fedora Core 14:
```

This definition does the job, but is not completely correct due to the fact that a dot (.) allows to be replaced by any character and therefore should be escaped using the backslash (\). However, the danger to map a wrong OSID to the operating system not escaping the dots might often be low and you have to decide by your own, if it is more important to have a more easy to read definition, not escaping the dots, or to have a more correct definition, by escaping the dots. For more info to regular expressions **regexintro(4)**.

Definition example using regular expressions strictly:

```
Linux:2\.6\.35\.[0-9][0-9]-[0-9][0-9]\.fc14\.i686:i686:Linux:Fedora Core 14
```

Definition example not using regular expressions:

```
Linux:2.6.35.11-89.fc14.i686:i686:Linux:Fedora Core 14:
Linux:2.6.35.12-90.fc14.i686:i686:Linux:Fedora Core 14:
Linux:2.6.35.13-91.fc14.i686:i686:Linux:Fedora Core 14:
```

FILEFORMAT

Rows starting with a # are considered as comments.

SFI FORMAT

OS:release:OSID:Comment

WA2L FORMAT

OS:release:machine:OSID:Comment

KEYS

| | |
|----------------|---|
| <i>OS</i> | Name of the operating system, output of uname -s . |
| <i>release</i> | Operating system release level, output of uname -r . |
| <i>machine</i> | machine (hardware) type, output of uname -m . |
| <i>OSID</i> | Operating system identifier, defined by the WA2L/edrc package or the SFI Director. There might be a file named /etc/sfi/OSID on each host maintained by the SFI Director, containing the OSID from ~sfiadmin/osid.dat . |
| <i>Comment</i> | An optional comment. This comment is currently not resolved and is only used for human reading. |

NAME

osid.probe – probe if chosen OSID matches to binary format

SYNOPSIS

edrc/lib/osid.probe
edrc/lib/<OSID>/osid.probe

AVAILABILITY

WA2L/edrc

DESCRIPTION

The **osid.probe** is a simple compiled C program that is called by the **osid** command to check, if the chosen OSID matches to the binary format. If the **osid.probe** command can be executed, it's intended that the resolved OSID is correct.

osid.probe returns True, if the **OSID_PROBE** environment variable is not set.

OPTIONS

-

ENVIRONMENT**\$OSID_PROBE**

if the environment variable is set to **False**, the text and return-code as if the binary format is not compatible to the operating system is returned. This environment variable is intended to simulate incompatibility.

EXIT STATUS

0 no error.

1 cannot execute binary file. The chosen OSID is not correct, due to the fact that the probe command **osid.probe** cannot be executed.

NAME

osup – start edrc with a special Operation Support configuration

SYNOPSIS

edrc/bin/osup [**-h** | **-V**]

osup [**-s**] [**-t**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

Short start of **edrc** with an other configuration which points to an own script tree. Internally **osup** calls **edrc -c edrc.osup.cfg -n OSUP_@ID@** .

osup stands for "Operation SUPport".

The session name (as shown in the menu) is automatically set to **OSUP_<id>** . Where **<id>** is the process id of the started **edrc** instance if not already a session with the same name exists, if so the **<id>** is set to a random number.

If additional short starts are needed, create a symlink from the new short start command to **sat** (see section **EXAMPLES**).

OPTIONS

-h usage message.

-V print version and patch level of **edrc**. For an explanation of the release numbering system see **edrcrevision(1)**.

-s silent startup. Startup without showing the EDRC banner.

-t no terminal initialization. Sometimes the terminal initialization causes unwanted behavior. To skip terminal initialization, invoke **edrc** with this option.

ENVIRONMENT

-

EXIT STATUS

see **edrc**(1m).

FILES

etc/edrc.osup.cfg

configuration file of **osup**, see **edrc.cfg**(4) for more information.

Other files see section **FILES** in **edrc**(1m).

EXAMPLES**1) create a new short start**

This creates a new short start command **new_shortstart** that will load the configuration file **edrc.new_shortstart.cfg**. The session name will automatically be set to **NEW_SHORTSTART_<id>** .

```
[ /root ]
[ root@rh7mzv7t001 ] [bash]: cd ~edrc/bin

[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ] [bash]: ln -s sat new_shortstart
```

NAME

outex – produce contrib.doc OUTPUT-EXAMPLE output from logfile

SYNOPSIS

edrc/bin/outex [**-h**]

outex [*logfile*]

outex last

AVAILABILITY

WA2L/edrc

DESCRIPTION

produce output of a selected logfile (without path) that is saved in **edrc/var/log/** that can be used in **contrib.doc**(1m) in the **OUTPUT-EXAMPLE** section.

The intension is to use the **outex** *logfile* command directly from within **vi** when editing a recovery script, as:

```
# D: Restore database.
#
~
~
~
: . !outex 2020-06-02_10.52.05__db_restore.log
```

This will include the contents of the logfile **edrc/var/log/2020-06-02_10.52.05__db_restore.log** (without logfile header) into the **vi** session. Each line will be prepended by the **# O:** documentation tag.

The specified *logfile* can also be a gzipped file, as: **2020-06-02_10.52.05__db_restore.log.gz**

Furthermore if the specified logfile **2020-06-02_10.52.05__db_restore.log** does not exist, but the **2020-06-02_10.52.05__db_restore.log.gz** does, the contents of the compressed file is included and vice versa.

After receiving the log data in **vi**, press **[Ctrl] + [L]** to redraw the terminal.

OPTIONS

-h usage message.

 specify the *logfile* interactively.

logfile logfile to be read.

The file path must not be specified, due to the fact that **outex** only computes log files from the **edrc/var/log/** directory; if a path is specified, the path part of the input is ignored.

The *logfile* can be a gnu-zipped log file (**file.log.gz**) as supported by **edrc**, it is not needed to decompress the file. Furthermore if the specified *file.log* does not exist, but the *file.log.gz* does, the *.**gz** file is loaded and vice versa.

last load the last (newest) available recovery script **logfile** from **edrc/var/log**.

ENVIRONMENT

-

EXIT STATUS

| | |
|----------|--------------------------------|
| 4 | usage printed. |
| 1 | <i>logfile</i> not found. |
| 2 | <i>logfile</i> cannot be read. |

NAME

pack – pack an application to a software package

SYNOPSIS

edrc/bin/pack [**-h**]

pack [**-a** *app*] [**-f**] [**-s**] [**-d** *outdir*] [**-o** *package_format*] [**-c** *config_file*] [**-t**]

pack [**-a** *app*] [**-f**] [**-s**] [**-d** *outdir*] [**-o** *package_format*] [**-c** *config_file*] **-p** *version*

pack -L [**-a** *app*] [**-c** *config_file*] [**-p** *version*]

pack -l [**-c** *config_file*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

Create a software package of an installed application.

A software package should not contain logfiles, backup files, lock files etc. To support this, it can be defined in the configfile of **pack** which files should be excluded from the software package.

pack enables the user to pack an application that has been installed (and probably configured) back to an installable package without the need of manually copy and remove certain files. Furthermore the user does not need to know all fine details of the application e.g. which files are needed for a correct operation, which files can be deleted, which files would harm a correct operation on an other system if packed.

It is possible to create a full RELEASE or a PATCH of the current state to a certain version.

A RELEASE is created if the **-p version** option is not specified and contains all files of the application.

A PATCH is created if the **-p version** option is specified and contains all files that are newer then the point in time when the RELEASE has been created for a specific *version* of the application.

In this context it is important to realize that if files are added to an application which are older then the timestamp of the last RELEASE, those files are not added to the PATCH. This is often the case if **.tar.gz** files are downloaded and the untared files are added to the application due to the fact that the file timestamps are preserved. To ensure that those files are added to the PATCH a **touch filename** should be issued for all files added to the application. It might also be advisable to check the filepermissions and the ownership of the files.

OPTIONS

Despite of the many options available, it is often not needed to provide any option to **pack** due to the fact that a developer should define in the **default** application setting the common case for the application package creation. Issue **pack -l** to list all available definitions.

- h** usage message.
- a** *application* application handle. If this option is not specified *default* is used as the application handle.
- s** split package also in pieces of 1400000 bytes which fit to a diskette. This option can also be used to mail the package when mail size restrictions apply on sender or receiver side.

If this option is selected beside the pieces a setup script is provided to concatenate the pieces together in the correct order and to check if all pieces are available. Furthermore some instructions to the user are printed.
- f** force overwriting of output file if a file with the identical name already exists in the output directory.
- p** *version* patch application to the specified version. The timestamp for the version specified has to exist. A timestamp is always written if a **RELEASE** is generated and the **-t** option is specified. To install a patch, use the **patchinstall(3)** command.
- l** list all applications defined in the configuration file. The available timestamps to create patches are listed, too.
- L** list files to be packed into the software package without actually creating the package file. This option is useful to verify if your settings of **EXCLUDE_LIST** in the configuration file are correct.
- d** *output_dir* directory where to put the package file. If not specified this defaults to the setting made in **OUTPUT_DIRECTORY** of the related application specified with the **-a** *application* option.
- o** *package_format* format of the software package to be created. If not specified the software package format defaults to **shar**.
 - shar** generic installable shell archive. A shell archive is a file that contains the setup procedure and the software data. This can be compared with a **setup.exe** program often used on the Microsoft Windows (TM) operating system. See section **EXAMPLES** or issue **pack -h** for an example usage of a shell archive.
 - depot** HP-UX software depot. This format is used on Hewlett Packard HP-UX systems. The installation of a **depot** package is done with the **swinstall** command on HP-UX. The generation of this package format is currently not implemented.
 - pkg** Solaris package. This format is used on Sun Solaris systems. The installation of a **pkg** package is done with the **pkgadd** command on Solaris. The generation of this package format is currently not implemented.
 - rpm** RedHat package format. This format is mainly used on Linux systems. The installation of a **rpm** package is done with the **rpm** command. The generation of this package format is currently not implemented.

- c** *config_file*
configuration file for **pack**. If this option is not specified, the configuration file **edrc/etc/pack.cfg** is used.
- t**
the timestamp is updated when a RELEASE is generated (= if **pack** is called without the **-p version** option). It makes sense to use this option to produce productive RELEASES. In development cases this options won't be used.

ENVIRONMENT

\$EDRC_DEBUG_PACK_EXCLUDE

when set to **True** all regular expressions defined in the **EXCLUDE_LIST** of the **pack** configuration file and the matched files by the related regular expression are recorded to the **/tmp/pack.<DATETIME>.exclude** file.

This allows to identify which regular expression of the configuration file excludes what files.

EXIT STATUS

- 0** no error.
- 1** no application defined in configuration file.
- 2** operating system not supported. See **osid(3)** if you get this error.
- 3** application is not defined in configuration file.
- 4** usage displayed.
- 5** command aborted.
- 6** configuration file does not exist.
- 7** package format is not supported yet.
- 8** cannot write to logfile.
- 9** cannot write to output directory.
- 10** application cannot be patched against version specified. This is the case if no RELEASE of the specified application exists for the version specified.
- 11** a temporary directory could not be claimed or created in **/tmp**. Check the system temporary directory **/tmp** if you get this error, it is an indicator of system intrusion.

- 12** a temporary output directory could not be claimed or created in the output directory.
- 99** creation of package format is not implemented yet.

FILES

edrc/etc/pack.cfg

default configuration file of **pack**.

edrc/var/pack/ts/<APPLICATION>-<VERSION>

timestamp of an APPLICATION for the related VERSION. Be aware that the timestamp is saved in GMT regardless of the local time zone setting.

edrc/var/pack/sadm/<APPLICATION>-<VERSION>-<DATETIME>.gz

software admin file for a RELEASE of an APPLICATION for the related VERSION. This file contains all information about the creation of a software package created on the DATE at the TIME.

edrc/var/pack/sadm/<APPLICATION>-<VERSION>-<DATETIME>-PATCH-<PATCHVERSION>.gz

software admin file for a PATCH of an APPLICATION for the related VERSION to a PATCHVERSION. This file contains all information about the creation of a software package created on the DATE at the TIME.

edrc/lib/<PACKAGE_COMPONENTS>/

package components used to generate a certain package format.

edrc/lib/<PACKAGE_COMPONENTS>/shar.header

header file for the shell archive software package. This header is displayed when installing the produced shell archive.

edrc/lib/<PACKAGE_COMPONENTS>/shar.setup

root setup script for a shell archive.

edrc/lib/<PACKAGE_COMPONENTS>/shar.install.tar.gz

install script structure for a shell archive.

edrc/lib/<PACKAGE_COMPONENTS>/piece.setup

setup script to concatenate a splitted archive.

edrc/lib/<PACKAGE_COMPONENTS>/rpm.specification

rpm specification template to generate a rpm archive.

EXAMPLES

0) create a package of the default application

In this example usage the application timestamp is not updated. This is useful if an installed application has to be packed to be installed on an other host.

```
[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ][bash]: ./pack

pack - create application package, by Chr. Walther

create package of application in '/opt/edrc' ...
  application information ...
    APPLICATION ..... : default
    APPLICATION_PREFIX ... : edrc
    APPLICATION_NAME ..... : WA2L/edrc
    APPLICATION_RELEASE .. : 1.5.02
    DESCRIPTION ..... : WA2L/edrc complete
  done.
  package information ...
    format ..... : shar
    type ..... : RELEASE
    file ..... : /tmp/edrc-1.5.02-200705172007.sh
  done.
  write sadm file ...(/opt/edrc/var/pack/sadm/edrc-1.5.02-200705172007.
  evaluate files to be packed ...(11699 files)... done.
  evaluate properties of files to be packed ... done.
  pack files to package file ...(28262.7 kBytes)... done.
done.
```

1) create a RELEASE of the default application

```
[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ][bash]: ./pack -t \
                                -d /dat/sw/apps/edrc-1.5.02

pack - create application package, by Chr. Walther

create package of application in '/opt/edrc' ...
  application information ...
    APPLICATION ..... : default
    APPLICATION_PREFIX ... : edrc
    APPLICATION_NAME ..... : WA2L/edrc
    APPLICATION_RELEASE .. : 1.5.02
    DESCRIPTION ..... : WA2L/edrc complete
  done.
  package information ...
    format ..... : shar
    type ..... : RELEASE
    file ..... : /dat/sw/apps/edrc-1.5.02/edrc-1.5.02-200
  done.
  write timestamp ...(/opt/edrc/var/pack/ts/edrc-1.5.02)... done.
  write sadm file ...(/opt/edrc/var/pack/sadm/edrc-1.5.02-200705172007.
  evaluate files to be packed ...(11699 files)... done.
  evaluate properties of files to be packed ... done.
```

```
pack files to package file ...(28262.7 kBytes)... done.
done.
```

2) create a PATCH of the current situation to version 1.5.01

```
[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ] [bash]: ./pack -p 1.5.01

pack - create application package, by Chr. Walther

create package of application in '/opt/edrc' ...
application information ...
  APPLICATION ..... : default
  APPLICATION_PREFIX ... : edrc
  APPLICATION_NAME ..... : WA2L/edrc
  APPLICATION_RELEASE .. : 1.5.02
  DESCRIPTION ..... : WA2L/edrc complete
done.
package information ...
  format ..... : shar
  type ..... : PATCH (to version 1.5.01)
  file ..... : /tmp/edrc-1.5.02-200705172015-PATCH-1.5.
done.
write sadm file ...(/opt/edrc/var/pack/sadm/edrc-1.5.02-200705172015-
evaluate files to be packed ...(3501 files)... done.
evaluate properties of files to be packed ... done.
pack files to package file ...(9038.8 kBytes)... done.
done.
```

3) list files that would be part of a PATCH of the default application to version 1.5.01

```
[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ] [bash]: ./pack -p 1.5.01 -L

pack - create application package, by Chr. Walther

list files to be packed of application in '/opt/edrc' ...
application information ...
  APPLICATION ..... : default
  APPLICATION_PREFIX ... : edrc
  APPLICATION_NAME ..... : WA2L/edrc
  APPLICATION_RELEASE .. : 1.5.02
  DESCRIPTION ..... : WA2L/edrc complete
done.
package information ...
  format ..... : shar
  type ..... : PATCH (to version 1.5.01)
  file ..... : NONE
done.
evaluate files to be packed ...(3500 files)... done.
files in package
  edrc/
  edrc/bin/
  edrc/bin/apply2sw_inventory
```

```

edrc/bin/asup
edrc/bin/bunzip2
:
:
edrc/var/sysconfig/tools/default/
edrc/var/sysconfig/tools/HP-11/
edrc/var/sysconfig/tools/HP-11i
edrc/var/sysconfig/tools/Linux/
edrc/var/sysconfig/tools/Solaris/
done.
done.

```

4) create a RELEASE of the default application and split also the outputfile

Here in addition to the complete shell archive **edrc-1.5.02-200705172019.sh** the splitted files **edrc-1.5.02-200705172019.sh.piece_aa ... edrc-1.5.02-200705172019.sh.piece_au** and the setup script **edrc-1.5.02-200705172019.sh.piece.sh** is generated.

```

[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ] [bash]: ./pack -t -s \
                                -d /dat/sw/apps/edrc-1.5.02

pack - create application package, by Chr. Walther

create package of application in '/opt/edrc' ...
application information ...
  APPLICATION ..... : default
  APPLICATION_PREFIX ... : edrc
  APPLICATION_NAME ..... : WA2L/edrc
  APPLICATION_RELEASE .. : 1.5.02
  DESCRIPTION ..... : WA2L/edrc complete
done.
package information ...
  format ..... : shar
  type ..... : RELEASE
  file ..... : /dat/sw/apps/edrc-1.5.02/edrc-1.5.02-200
done.
write timestamp ...(/opt/edrc/var/pack/ts/edrc-1.5.02)... done.
write sadm file ...(/opt/edrc/var/pack/sadm/edrc-1.5.02-200705172019.
evaluate files to be packed ...(11699 files)... done.
pack files to package file ...(28262.7 kBytes)... done.
split 'shar' package into '1400000' pieces ...
  edrc-1.5.02-200705172019.sh.piece_aa
  edrc-1.5.02-200705172019.sh.piece_ab
  edrc-1.5.02-200705172019.sh.piece_ac
  edrc-1.5.02-200705172019.sh.piece_ad
  :
  :
  edrc-1.5.02-200705172019.sh.piece_ar
  edrc-1.5.02-200705172019.sh.piece_as
  edrc-1.5.02-200705172019.sh.piece_at
  edrc-1.5.02-200705172019.sh.piece_au
  edrc-1.5.02-200705172019.sh.piece.sh
done.

```

done.

5) list all defined applications

See also **pack.cfg(4)** for the description of how to define applications.

```
[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ][bash]: ./pack -l
```

pack - create application package, by Chr. Walther

NAME

pack.cfg – configuration file for pack

SYNOPSIS

edrc/etc/pack.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **pack** command.

FILEFORMAT

The format for options is **OPTION=VALUE** .

The format of a application definition is:

```
APPLICATION_name(){
    OPTION1=VALUE
    OPTION2=VALUE
    :
    OPTIONn=VALUE
}
```

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION**. If you like to use default settings simply do not specify a *VALUE*.

Normally there are multiple application settings defined in one configuration file.

The setting **APPLICATION_default** must be defined in a configuration file.

OPTIONS**GLOBAL OPTIONS**

This options influence the general behavior of the **pack** command.

LOG Log output dir of **pack**. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation.

Example: LOG=/var/opt/edrc/log

Default: LOG=var/log

APPLICATION OPTIONS

A application definition has the following structure:

```
APPLICATION_name(){
    PACKAGE_NAME="text"
    DESCRIPTION="text"
    APPLICATION_PREFIX="text"
    APPLICATION_RELEASE="version_number"
    TIMESTAMP_PREFIX="text"
    APPLICATION_BASEDIR="directory"
    APPLICATION_COMPONENTS="directory"
    OUTPUT_DIRECTORY="directory"
    EXCLUDE_LIST="regex_list"
    CONFIGFILE_LIST="regex_list"
}
```

The options recognized in a application definition are:

name Name of the application. The name defined here has to be specified in the **-a** option in the **pack** command. The application with the name *default* is called when the **-a** option is not specified when using the **pack** command. Therefore each **pack.cfg** file should at least define a profile with the name *default*.

PACKAGE_NAME

Name of the software package. This normally correlates to the package name in the documentation/man pages.

Example: PACKAGE_NAME="WA2L/edrc"

Default: PACKAGE_NAME="?"

DESCRIPTION

Application description.

Example: DESCRIPTION="WA2L/edrc complete"

Default: DESCRIPTION=""

APPLICATION_PREFIX

This is the prefix of the application package, as:
<APPLICATION_PREFIX>-1.5.01-20070306.sh.

Example: APPLICATION_PREFIX="edrc"

Default: APPLICATION_PREFIX="myApp"

APPLICATION_RELEASE

Release number (version) of the application software.

Example: APPLICATION_RELEASE=""^`aproot`/sbin/edrc -V^`"

Default: APPLICATION_RELEASE=<has to be specified interactively>

TIMESTAMP_PREFIX

This is the prefix of the application timestamp, as:

<TIMESTAMP_PREFIX>-1.5.01. Normally the timestamp prefix should be set to <APPLICATION_PREFIX>

Example: TIMESTAMP_PREFIX="edrc"

Default: TIMESTAMP_PREFIX=""<APPLICATION_PREFIX>"

APPLICATION_BASEDIR

Directory where the software is currently installed.

Example: APPLICATION_BASEDIR=""^`aproot^`"

Default: APPLICATION_BASEDIR=""^`aproot^`"

PACKAGE_COMPONENTS

Directory in **edrc/var/pack**/**<PACKAGE_COMPONENTS>** where the additional components used for the generation of the different package formats is located. See section **FILES** in **pack**(1m) for more information.

Example: PACKAGE_COMPONENTS="edrc"

Default: PACKAGE_COMPONENTS=""<APPLICATION_PREFIX>

OUTPUT_DIRECTORY

Existing directory where the software package file is created. This directory should have at least 1.5 times the space available as the resulting software file size.

Example: OUTPUT_DIRECTORY="/dat/sw/apps"

Default: OUTPUT_DIRECTORY="/tmp"

EXCLUDE_LIST

List (regex) of files to be excluded from the software package. To verify the exclude definition invoke **pack -L** to list the files that would be packed into the software package.

Example: EXCLUDE_LIST="/.sav/ ^edrc/var/log/.+.log\$"

Default: EXCLUDE_LIST=""

CONFIGFILE_LIST

List (regex) of config files of the software to be packed. This setting is for package formats that support the special handling of configuration files. This are the formats **rpm**, **depot** and **pkg**. The **shar** format currently does not treat config files special. But for future enhancements the **CONFIGFILE_LIST** should be defined, too.

Example: `CONFIGFILE_LIST="^edrc/etc/."`

Default: `CONFIGFILE_LIST=""`

VARIABLES

Currently no official variables are provided to be used in application settings.

To avoid defining the same settings multiple times it is allowed to chain application definitions by "calling" another definition at the beginning of an application definition. In fact you should do this at least in the **APPLICATION_default** definition. Therefore it is allowed to use the application setting variables to enhance a definition. This makes especially sense to enhance an **EXCLUDE_LIST** by first including another definition and then using the **\$EXCLUDE_LIST** variable in the definition of the **EXCLUDE_LIST**. See also definitions in the `edrc/etc/pack.cfg` file and the **EXAMPLE** section for examples for the method of chaining definitions.

EXAMPLES**1) example application definition for the WA2L/edrc application**

See the "call" of **APPLICATION_edrc** in the **APPLICATION_default** and **APPLICATION_edrc_NOSECURITY** definition to chain the definitions to save definition effort.

```
# edrc: WA2L/edrc complete
#
APPLICATION_edrc() {
    PACKAGE_NAME="WA2L/edrc"
    DESCRIPTION="WA2L/edrc complete"
    APPLICATION_PREFIX="edrc"

NAME

passwdcombine – combine users into a passwd file

SYNOPSIS

edrc/bin/passwdcombine [**-h**]

passwdcombine -t *systype* **-s** *save_file*

passwdcombine -t *passwd* **-f** '*file_1 select_1*' { **-f** '*file_n select_n*' } **-o** *outfile*

passwdcombine -t *trusted* **-f** '*file_1 select_1*' { **-f** '*file_n select_n*' } **-o** *outdir*

AVAILABILITY

WA2L/edrc

DESCRIPTION

combine password files or password databases.

This is useful if you have to apply a new set of users to a system and you like to prevent a change of certain users (as system users).

OPTIONS

-h this usage message.

-t *system_type*

type of system:

passwd /etc/passwd contains all password

trusted HP Trusted System

-s *save_file*

save file (without suffix)

-f '*file_n select_n*'

file_n source file

select_n select file

ENVIRONMENT

-

EXIT STATUS

| | |
|----------|--|
| 0 | no error. |
| 1 | file specified in -f option does not exist. |
| 1 | /etc/passwd or /tcb/ does not exist. |
| 2 | operating system not supported. |
| 2 | cannot write to output file. |
| 3 | output file already exists. |
| 4 | usage printed. |
| 5 | the passwdcombine command was aborted. |

FILES

| | |
|--------------------|--|
| /etc/passwd | password file. |
| /tcb/ | password database on a trusted HP-UX system. |

EXAMPLES

-

NAME

passwdsyncd – password synchronization daemon

SYNOPSIS

edrc/bin/passwdsyncd [**-h**]

passwdsyncd -s

passwdsyncd -m { on | off }

AVAILABILITY

WA2L/edrc

DESCRIPTION

With the **passwdsyncd** it is possible to synchronize the password database over a list of systems without the need of using NIS or NIS+.

To run the **passwdsyncd** it is necessary to have the times synchronized between all participating systems.

The **passwdsyncd** has the following features implemented:

- no master server needed, all participating systems are equivalent. Therefore this solution is also preferred to use in a clustered environment where it should be ensured that all nodes are identical.
- the **passwdsyncd** can be started at any time, it will not overwrite newer password entries on participating systems.
- the daemon can be switched centrally into a maintenance mode where all synchronization between the participating systems is on hold.
- if configured, the synchronization peers can grow dynamically without the need of reconfiguration of the other systems already participating in a synchronization.
- if configured, user lockouts are not synchronized.
- the synchronization data is submitted encrypted between the participating systems.

STATES

The **passwdsyncd** has the following states which are also recorded to the logfile:

check check if there are password database entries newer then the last password synchronization attempt of the local system. After startup this is the first state.

- synch** synchronize password database entries to remote system(s).
- wait** sleep between checks. This interval can be configured with the **SYNC_INTERVAL** setting in the **passwdsyncd.cfg** file.
- maintenance_mode_on**
promote the maintenance mode to the systems participating in a synchronization.
- maintenance_mode_off**
clear the maintenance mode on all systems participating in a synchronization.
- maintenance**
the **passwdsyncd** is in maintenance mode. During maintenance mode all password synchronization is on hold.
- stop** the **passwdsyncd** has been stopped with the **-s** option.
- abort** the **passwdsyncd** has been killed with the **kill** command. This method of stopping the **passwdsyncd** is not recommended.

OPTIONS

- h** usage message.
- m** maintenance mode control:
- on** switch maintenance mode on.
- off** switch maintenance mode off.
- s** stop a running **passwdsyncd**.

SIGNALS

The following signals are handled by **passwdsyncd**. Do not use other signals as those listed below, as long as you do not really know what you are doing and what the consequences are. In general there is no need to invoke those signals by your own, this signals are used for inter process communication of the **passwdsyncd**.

- INT** interrupt from keyboard (Ctrl+C). Issuing this signal, the daemon will go to the **abort** state.
- TERM** kill the process without an argument. Issuing this signal, the daemon will go to the **abort** state.
- HUP** stop the **passwdsyncd**. This signal is issued when **passwdsyncd -s** is issued and will put the **passwdsyncd** into the **stop** state.

- USR1** set the **passwdsyncd** into maintenance mode. The state of **passwdsyncd** after receiving this signal is **maintenance**.
- USR2** clear maintenance mode of **passwdsyncd**. The state of **passwdsyncd** after receiving this signal is **check**.

EXIT STATUS

- 0** no error.
- 1** daemon started as the wrong operating system user.
- 2** operating system is not supported. See **osid(3)** if you get this error.
- 3** cannot write to the lockfile.
- 4** usage listed.
- 5** there is already a **passwdsyncd** instance running on the system.
- 6** configuration file **edrc/etc/passwdsyncd.cfg** does not exist.
- 8** cannot write to the logfile.
- 9** no permission to stop the daemon.
- 11** a temporary directory could not be claimed or created in **/var/tmp**. Check the system temporary directory **/var/tmp** if you get this error, it is an indicator of system intrusion.
- 12** no permission to handle daemon maintenance mode.
- 13** system security type not supported.

FILES

- edrc/etc/passwdsyncd.cfg**
configuration file for **passwdsyncd**.
- edrc/var/log/**
default logfile location of **passwdsyncd**.
- edrc/var/passwdsyncd/**
default spool location of **passwdsyncd** to save password information.

edrc/var/lock/

default lock directory of **passwdsyncd**.

EXAMPLES

-

SEE ALSO

edrcintro(1), **passwdsyncd.cfg**(4), **osid**(3), **passwdsyncd_apply**(3), **remote_copy**(3), **remote_shell**(3)

NOTES

currently **passwdsyncd** supports the synchronization of HP-UX trusted systems.

NAME

passwdsyncd.cfg – configuration file for passwdsyncd

SYNOPSIS

edrc/etc/passwdsyncd.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **passwdsyncd(1m)** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**START_USER**

This is the user **passwdsyncd** has to be started with.

Example: **START_USER=eroot**

Default: **START_USER=root**

SYSTEM_TYPE

Type of system the **passwdsyncd** is started on. Set **SYSTEM_TYPE** to *trusted* for HP-UX Trusted system, to *passwd* for systems with passwords in **/etc/passwd** (not implemented yet) and to *shadow* for systems with passwords in **/etc/shadow** (not implemented yet). It probably won't be possible to mix system types.

Example: **SYSTEM_TYPE=trusted**

Default: **SYSTEM_TYPE=trusted**

LOG

Log output dir of **passwdsyncd**. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation.

Example: **LOG=/var/opt/edrc/log**

Default: **LOG=var/log**

SPOOL_DIR

Spool output basedir to save the transferred password information. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation. In general it is not recommended to set the **SPOOL_DIR** within WA2L/edrc, locate it in a system own directory.

Example: SPOOL_DIR=/var/spool

Default: SPOOL_DIR=var

SYNC_HOSTLIST

Space separated list of hosts that take part on a password synchronization.

Example: SYNC_HOSTLIST="dcdbsi61 dcdbsi62 dcdbsi71"

Default: SYNC_HOSTLIST=

DYNAMIC_SYNC_EXPANSION

Expand the **SYNC_HOSTLIST** dynamically with hosts from which additional synchronizations has been received. If this option is set to *True* dynamic expansion is enabled, if it is set to *False* it is disabled.

Example: DYNAMIC_SYNC_EXPANSION=True

Default: DYNAMIC_SYNC_EXPANSION=False

LOCKOUT_SYNC

Synchronize locked users. This setting has effect on the following system types: trusted. If **LOCKOUT_SYNC** is set to *locked* users are synchronized, if set to *False* a lock of a user will remain on one system and will not be synchronized to other systems.

Example: LOCKOUT_SYNC=True

Default: LOCKOUT_SYNC=False

DIST_MODE

Comma separated list of modes used to distribute the password information. The supported modes are: *rtools* which result in the use of **r**cp and **r**sh or *OpenSSH* which results in the use of **s**cp and **s**sh for distribution. If a comma separated list is provided, the connection initiation is made in the sequence specified. A pseudo distribution mode is *default* which results in the use of the **CONNECTION_MODE** specified in the configuration files **remote_shell.cfg** and **remote_copy.cfg**. It is not allowed to specify *default* as part of a comma separated list.

Example: DIST_MODE=rtools,OpenSSH

Default: DIST_MODE=rtools

DIST_USER

User used to distribute the files in **SCRIPTS_BASEDIR**. The home of this user is considered as the root of the WA2L/edrc installation. See **edrcsetup**(1m) for information about user settings needed by WA2L/edrc.

Example: DIST_USER=edrc

Default: DIST_USER=edrc

EDRC_OWNER

Owner of the WA2L/edrc software. This is the user the EDRC environment is installed with. See **edrcsetup**(1m) for information about user settings needed by WA2L/edrc.

Example: EDRC_OWNER=root

Default: EDRC_OWNER=root

SYNC_INTERVAL

Synchronization interval in seconds. **passwdsyncd** checks in the interval specified here if passwords have changed since the last check. If so a synchronization attempt to the other hosts participating in a synchronization will take place. The **SYNC_INTERVAL** should be set to a figure that the passwords are synchronized within a "reasonable" timeframe. Due to the fact that **passwdsyncd** is not a Master-Slave construct, the more servers participate in a synchronization, the more synchronization traffic will be generated.

Example: SYNC_INTERVAL=300

Default: SYNC_INTERVAL=600

EXCLUDE_USERS

Exclude this users from synchronization.

Example: EXCLUDE_USERS=root,bin,daemon,sys,adm,uucp,lp,hpdb,sshd

Default: EXCLUDE_USERS=""

LOCKDIR

Lock dir of **passwdsyncd**. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation. In general it is not recommended to set the lockdir within WA2L/edrc, locate it in a system own directory.

Example: LOCKDIR=/var/run

Default: LOCKDIR=var/lock

SECRET Synchronization secret password. This password has to be identical on all hosts which participate in a synchronization.

Example: SECRET="myT0PsecretPa55w0rd"

Default: SECRET="wBnCYP4HOb8Xw"

SECRET_LIFETIME

Synchronization secret (**SECRET**) lifetime in 100 seconds (example: **SECRET_LIFETIME** = 1 equals to 100 seconds). After this duration the encrypted synchronization file will not be accepted by the hosts which participate in a synchronization. To disable secret ageing, set **SECRET_LIFETIME** to 0.

This setting is currently partly ignored: the secret lifetime is 100 seconds independent of the

settings made here, except it is set to 0.

Example: SECRET_LIFETIME=1

Default: SECRET_LIFETIME=1

ENCRYPTION_MODE

Mode of encryption of the transferred password information. Currently the following modes are supported: *Enigma* (simple Unix crypt. This option requires **crypt**(1) to be installed on all participating systems), *AES* (Advanced Encryption Standard. This option requires **ccrypt**(1) to be installed on all participating systems) and *NO* (no encryption. This option is not recommended for permanent solutions, but does not need **crypt**(1) or **ccrypt**(1)).

Example: ENCRYPTION_MODE=AES

Default: ENCRYPTION_MODE=Enigma

SEE ALSO

crypt(1), **ccrypt**(1), **edrcintro**(1), **passwdsyncd**(1m)

NOTES

ccrypt is distributed with WA2L/edrc.

NAME

patchinstall – patch a WA2L/edrc installation

SYNOPSIS

edrc/lib/patchinstall [**-h**]

patchinstall [**-n** | **-m**] **-f** *patch_file*

patchinstall **-i** | **-I** [*number*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

patch a WA2L/edrc installation with a *patch_file* generated by **pack**(1m).

patchinstall also cleans up corpses of previous application installations. Corpses are files and/or directories that were part of the application, but are no longer used, are out of date (as: the .PDF manual pages of older versions in the **edrc/doc/** directory or older versions of installed binaries) or are no longer needed due to design changes in the application.

In the default configuration the files to be patched and the identified corpses are backedup prior to the installation/removal of the files.

The backup behaviour, the logfile detail depth and other settings are configurable in the configuration file **patchinstall.cfg** that is read prior to the installation of the files that are part of the *patch_file*.

When **patchinstall** is invoked, the following steps are performed:

- 1.) print system information. This includes information as the *patch_file* to be installed, if **patchinstall** is invoked with the **-n** option, and other information about the system where the patch will be applied.
- 2.) print the patch meta data. This information is also available in the directory **edrc/var/pack/sadm/** for each installed patch.
- 3.) backup the files residing in the application directory to be patched. In the active configuration file **patchinstall.cfg** can be configured if the files to be patched should be backedup or not.
- 4.) purge backedup patched files. The number of kept backup file versions (generations) and if the purging of the backup files should take place at all can be configured in the **patchinstall.cfg** configuration file.
- 5.) install the patch files.

- 6.) update timestamps of symlinks that are part of the patch. This feature is not available on all operating systems. On systems where changing of symlink timestamps is not possible, the symlink will have the timestamp of the patch installation.
- 7.) evaluate corpses in the current installation. The corpses are evaluated on each system. There is no master file list used in a patch or the application to identify corpses. This makes it possible, that own added files are not rated as a corpse. If there are doubts if a certain file would be rated as a corpse by a patch to be installed, it is possible to run **patchinstall** in the NOEXECUTE mode (**patchinstall -n -f patch_file**), where no actions are performed, but all messages are printed to stdout.
- 8.) backup files that were identified as corpses. In the active configuration file **patchinstall.cfg** can be configured if the files identified as corpses should be backed up or not previous to the removal.
- 9.) purge backed up corpses. The number of kept backup file versions (generations) and if the purging of the backup files should take place at all can be configured in the **patchinstall.cfg** configuration file.
- 10.) remove the corpses from the application installation.
- 11.) re-run step 5.) and 6.) if step 5.) terminated with errors.

The backups are written to the backup directory in the ***.cpio.gz** format, that can be viewed using the **lscomp(1)**, **llcomp(1)** and **catcomp(1)** commands.

OPTIONS

- h** usage message.
- n** NOEXECUTE. This option causes that no actions are performed, but all messages are printed. This can be used to check the consequences of a patch installation.
- m** only print meta-data of the patch. This option can also be used to verify if the file is really an WA2L/edrc patch-file.
- l** only list the files contained in the patch.
- f patch_file**
patch file to be installed. The *patch_file* has to be specified with an absolute path.
- i** list installed patches based on the **patchinstall** log file.
- I** print last installed patch in record format.
- number* number of most recent patches to list; default is **1**,

ENVIRONMENT

-

EXIT STATUS

| | |
|----------|---|
| 0 | no error. |
| 1 | <i>patch_file</i> does not exist. |
| 2 | error evaluating the files that are part of the WA2L/edrc installation. |
| 3 | error evaluating the static files of the WA2L/edrc installation. |
| 4 | usage listed. |
| 5 | sadm file not found in <i>patch_file</i> , this indicates, that the <i>patch_file</i> is not a WA2L/edrc patch. |
| 6 | configuration file patchinstall.cfg does not exist. |
| 7 | command aborted, as pressing Ctrl+C. |

FILES

edrc/etc/patchinstall.cfg
configuration file for **patchinstall**.

EXAMPLES

1) remove corpses of an installation

If you want to clean up corpses on an existing installation without installing a WA2L/edrc patch of a newer version, create a patch to the current version you have installed and then install this patch you just created on the same system:

```
[ /root ]
[ root@acme001 ][*edrc*/bash]: pack -p `~edrc/sbin/edrc -V`
```

pack - create application package, by Chr. Walther

```
create package of application in '/opt/edrc' ...
application information ...
  APPLICATION ..... : default
  APPLICATION_PREFIX ... : edrc_WA2L
  APPLICATION_NAME .... : WA2L/edrc
  APPLICATION_RELEASE .. : 1.5.10
  DESCRIPTION ..... : WA2L/edrc complete
done.
```

```

package information ...
  format ..... : shar
  type ..... : PATCH (to version 1.5.10)
  file ..... : /tmp/edrc_WA2L-1.5.10-200809071349-PATCH
done.
write sadm file ...(/opt/edrc/var/pack/sadm/edrc_WA2L-1.5.10-20080907
evaluate files to be packed ...(9 files)... done.
evaluate properties of files to be packed ... done.
pack files to package file ...(6.98535 kBytes)... done.
done.

[ /root ]
[ root@acme001 ][*edrc*/bash]: patchinstall \
                                -f /tmp/edrc_WA2L-1.5.10-200809071349-P
patchinstall - patch a WAL2/edrc installation, by Chr. Walther

install patch to application in '/opt/edrc' ...
  system information ...
    :
    :
  done.
  patch meta data ...
    :
    :
  done.
  backup files to be patched ...
    :
    :
  done.
  purge backedup patched files ...
    :
    :
  done.
  install patch files ...
    :
    :
  done.
  update symlink timestamps ...
    :
    :
  done.
  backup corpses to be removed ...
    :
    :
  done.
  purge backedup corpses ...
    :
    :
  done.
  remove corpses ...
    :
    :
  done.

```

done.

SEE ALSO

edrcintro(1), **edrcsetup**(1m), **catcomp**(1), **lscomp**(1), **llcomp**(1), **pack**(1m), **patchinstall.cfg**(4), **stat**(3)

NOTES

Due to the fact, that an installation of a *patch_file* using **patchinstall** does not cause additional command invocations (as: pre- or post-exec scripts), a patch can be applied multiple times to an application installation without side effects.

BUGS

-

AUTHOR

patchinstall was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

patchinstall.cfg – configuration file for patchinstall

SYNOPSIS

edrc/etc/patchinstall.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **patchinstall** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**START_USER**

This is the user **patchinstall** has to be started with.

Example: START_USER=root

Default: START_USER=root

BACKUP_DIR

patchinstall saves all files ahead of patching the files to a backup file to this directory.

Example: BACKUP_DIR=/var/opt/edrc/backup

Default: BACKUP_DIR=var/backup

LOG

Log output dir of **patchinstall**. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation.

Example: LOG=/var/opt/edrc/log

Default: LOG=var/log

LOG_LEVEL

Level of information written to the logfile. If all messages should be logged to the logfile, set this setting to *verbose*, if only the minimum should be logged, set it to *minimal*. The *verbose* setting causes that all output as seen on the screen (stdout) will also be saved to the logfile.

Example: LOG_LEVEL=minimal

Default: LOG_LEVEL=verbose

PACKAGE_FILES_APP

Application files.

Example: PACKAGE_FILES_APP=edrc

Default: PACKAGE_FILES_APP=""

STATIC_FILES_APP

Static installed files.

Example: STATIC_FILES_APP=edrc_STATIC

Default: STATIC_FILES_APP=""

BACKUP_PATCHED_FILES

If set to *True*, the files that will be patched are backed up previous to overwriting. Else set it to *False*.

Example: BACKUP_PATCHED_FILES=False

Default: BACKUP_PATCHED_FILES=True

BACKUP_PATCHED_FILES_GENERATIONS

When this setting is set to a value other than 0, purging of old patched files backup files takes place. The number specified here is the number of most recent backup files that are kept.

Example: BACKUP_PATCHED_FILES_GENERATIONS=10

Default: BACKUP_PATCHED_FILES_GENERATIONS=0

BACKUP_CORPSES

If set to *True*, the identified corpses are backed up previous to removal. Else set it to *False*.

Example: BACKUP_CORPSES=False

Default: BACKUP_CORPSES=True

BACKUP_CORPSES_GENERATIONS

When this setting is set to a value other than 0, purging of old corpses backup files takes place. The number specified here is the number of most recent backup files that are kept.

Example: BACKUP_CORPSES_GENERATIONS=10

Default: BACKUP_CORPSES_GENERATIONS=0

NAME

perlenv – print environment needed to start perl scripts

SYNOPSIS

edrc/lib/perlenv [-n]

AVAILABILITY

WA2L/edrc

DESCRIPTION

print the environment used by **perl** to access the Perl modules bundled with WA2L/edrc.

To set the environment prior to the execution of **perl**, invoke:

```
eval `perlenv`
```

This command is **only** to be used to prepare the environment to execute Perl scripts in "Recovery Script" trees. See **perl_modules(3)** for information regarding this usage.

When writing Perl scripts for WA2L/edrc, do **not** use **perlenv**, start the script thru the **.perl_wrapper**. See **perl_wrapper(1)** for information about integrating a Perl script into WA2L/edrc.

OPTIONS

-n no **export** *VARIABLE* ... output.

ENVIRONMENT**\$PERLLIB**

this variable holds Perl module locations additional to the standard applying to an installation. This variable will be expanded with the bundled Perl module locations when executing the **perlenv** command.

\$LD_LIBRARY_PATH

path of additional shared libraries loaded by the **ld** dynamic linker. This variable will be expanded with the shared library locations for a certain Os-Id distributed with WA2L/edrc when executing the **perlenv** command.

\$SHLIB_PATH

this variable is expanded as the **\$LD_LIBRARY_PATH** is done. This variable has basically the same function as the **\$LD_LIBRARY_PATH** and is mostly active on HP/UX systems.

\$PATH command search path. This variable will be expanded with the path where the **perl** interpreter was found on the system when executing the **perlenv** command. See also **perl_wrapper(1)** for more information.

EXIT STATUS

0 always

FILES

edrc/lib/perl_wrapper.cfg
configuration file for **.perl_wrapper** and **perlenv**.

edrc/lib/perl/pm/

location of all bundled perl modules. The related directories in **edrc/lib/perl/pm/** are prepended to the **\$PERLLIB** environment variable when executing **perlenv**. The **pmdesc -h** command can also be used to display the current Perl library path.

The directory structure in **edrc/lib/perl/pm/** is:

Legacy Structure:

```
perl<rel>/<vers>/
perl<rel>/site_perl/<vers>/
perl<rel>/vendor_perl/<vers>/
perl<rel>/edrc_perl/
perl<rel>/share/<vers>/bin/
perl<rel>/share/<vers>/man/
perl<rel>/share/site_perl/<vers>/bin/
perl<rel>/share/site_perl/<vers>/man/
perl<rel>/share/vendor_perl/<vers>/bin/
perl<rel>/share/vendor_perl/<vers>/man/
```

New Structure:

```
perl<rel>/<vers>/root/
perl<rel>/edrc_perl/
```

Where **<rel>** is the major version number (e.g. 5) and **<vers>** is the whole perl version (e.g. 5.14.3).

The "Legacy Structure" and the "New Structure" can be and is mixed. However, the "Legacy Structure" will not disappear and all files will remain as they are; new modules will be installed into the more simple "New Structure". When using the **.perl_wrapper** to start a **perl** script and the **perlenv** commands to initialize the **perl** environment, scripts need no change.

See also: **perl_modules(3)**, **pmdesc(1)**.

edrc/src/perlmodules/

source packages of all bundled perl modules to enable a fast compilation exercise when having a different perl version on the system. See **README** file and use the provided **Makefile(s)** to

build and install the related module.

edrc/lib/<Os-Id>/libs/

location of operating system dependent shared libraries outside of Perl. This directory is appended to the **\$LD_LIBRARY_PATH** and the **\$SHLIB_PATH** environment variables when executing **perlenv**.

EXAMPLES

1) Start a Perl script from a recovery script

To start a Perl script that uses a bundled Perl module from a recovery script, set the Perl library path (**@INC**) using the **'eval 'perlenv''** command in the recovery script and then call the **perl** interpreter.

Recovery script:

```
#!/bin/ksh
#
# 1:ascript - A Recovery Script
#
# [00] 08.02.2009 CWa Initial Version
#
#
test "$DEBUG" = True && set -x
:
:
eval `perlenv`
perl ./perlscript
:
```

Perl script:

```
#
# perlscript - Perl script using bundled DBI module
#
# [00] 18.03.2009 CWa Initial Version
#
:
:
use DBI;
:
```

2) Start a Perl script from a recovery script using the **_env file mechanism**

Create an **_env** file (using the **env edrc** command) and start the Perl script from the recovery script.

_env file:

```
#
# _env - Environment settings for commands in /apps/eg
#
# [00] 18.03.2009 CWa Initial Version
#
#
test "$DEBUG" = True && set -x

eval `perlenv`
:
```

Recovery script:

```
#!/bin/ksh
#
# 1:ascript - A Recovery Script
#
# [00] 08.02.2009 CWa Initial Version
#
#
test "$DEBUG" = True && set -x
:
:
perl ./perlscript
:
```

Perl script:

```
#
# perlscript - Perl script using bundled DBI module
#
# [00] 18.03.2009 CWa Initial Version
#
:
:
use DBI;
:
```

3) Write a recovery script in Perl

Create an **_env** file (using the **env edrc** command) and write the recovery script in Perl.

_env file:

```
#
# _env - Environment settings for commands in /apps/eg
#
# [00] 18.03.2009 CWa Initial Version
#
#
test "$DEBUG" = True && set -x

eval `perlenv`
```

:

Perl recovery script:

```
#!/usr/bin/env perl
#
# 1:ascrip - A Recovery Script
#
# [00] 08.02.2009 CWa Initial Version
#
:
:
use DBI;
:
```

Note the use of `'#!/usr/bin/env perl'` in the magic key to start the Perl script. This ensures that the **perl** interpreter is found on the system, even when it is not installed in the default location you will normally specify. The path to the **perl** interpreter is added to the **\$PATH** using the **perlenv** command.

4) Write a perl script outside of WA2L/edrc and profit from bundled perl modules

The startup method method (see also: <https://perldoc.perl.org/perlrun>) below allows to start the **perl** interpreter from wherever it is installed and also enables to use all **perl** modules bundled with WA2L/edrc using the **perlenv** command to dynamically initialize the environment.

This method is similar to the use of the **.perl_wrapper**, but the **perl** script can be placed somewhere of your liking outside of WA2L/edrc.

Set the permissions of the script to executable:

```
chmod +x perlscrip
```

Perl script:

```
#!/bin/ksh
#
# perlscrip - Perl script using bundled modules
#
# [00] 18.03.2009 CWa Initial Version
#
eval `~edrc/lib/perlenv`
#! -*- perl -*- -p
eval 'exec perl -x -SS $0 ${1+"$@"}'
if 0;

use strict;
use warnings;
use File::Basename;
use REST::Client;
use JSON;
use DBI;
use Data::Dumper;
```

```
use Getopt::Std;
use WA2L::Util;
:
:
```

5) Test the availability of a specific perl module

Set the needed **perl** environment:

```
[ / ]
[ root@acme007 ][*edrc*/bash]: eval `perlenv`
```

Try to access the **perl** module:

```
[ / ]
[ root@acme007 ][*edrc*/bash]: perl -e "use REST::Client;"
```

If an error message like

```
Can't locate REST/Client.pm in @INC (you may need to install the REST::
(@INC contains: /etc/perl ... /usr/lib/x86_64-linux-gnu/perl-base) at -
BEGIN failed--compilation aborted at -e line 1.
```

appears, the module cannot be found, if the module can be found there is no output.

SEE ALSO

edrcintro(1), **cpanm(1)**, **ld(1)**, **osid(3)**, **perl(1)**, **perlversion(3)**, **pmdesc(1)**, **perl_modules(3)**, **perl_wrapper(1)**,
http://search.cpan.org/~mschwern/ExtUtils-MakeMaker/lib/ExtUtils/MakeMaker.pm#make_install, http://search.cpan.org/~jesse/perl/INSTALL#Coexistence_with_earlier_versions_of_perl_5, <https://perldoc.perl.org/perlrun>

NOTES

The following excellent description of the directory structure is a partial extract of http://search.cpan.org/~jesse/perl-5.17.8/INSTALL#Coexistence_with_earlier_versions_of_perl_5 which has been written by Jesse Vincent <esse+cpan@fsck.com>.

Be aware, that the **perlenv** and **.perl_wrapper** commands are a bit less strict in the resolution of the directories listed in the **\$PERLLIB** environment variable.

Coexistence with earlier versions of perl 5

Perl 5.14 is not binary compatible with earlier versions of Perl. In other words, you will have to recompile your XS modules.

In general, you can usually safely upgrade from one version of Perl (e.g. 5.X.Y) to another similar minor version (e.g. 5.X.(Y+1))) without re-compiling all of your extensions. You can also safely leave the old version around in case the new version causes you problems for some reason.

Usually, most extensions will probably not need to be recompiled to be used with a newer version of Perl.

Here is how it is supposed to work. (These examples assume you accept all the Configure defaults.)

Suppose you already have version 5.8.7 installed. The directories searched by 5.8.7 are typically like:

```
/usr/local/lib/perl5/5.8.7/$archname
/usr/local/lib/perl5/5.8.7
/usr/local/lib/perl5/site_perl/5.8.7/$archname
/usr/local/lib/perl5/site_perl/5.8.7
```

Now, suppose you install version 5.8.8. The directories searched by version 5.8.8 will be:

```
/usr/local/lib/perl5/5.8.8/$archname
/usr/local/lib/perl5/5.8.8
/usr/local/lib/perl5/site_perl/5.8.8/$archname
/usr/local/lib/perl5/site_perl/5.8.8

/usr/local/lib/perl5/site_perl/5.8.7/$archname
/usr/local/lib/perl5/site_perl/5.8.7
/usr/local/lib/perl5/site_perl/
```

Notice the last three entries -- Perl understands the default structure of the \$sitelib directories and will look back in older, compatible directories. This way, modules installed under 5.8.7 will continue to be usable by 5.8.7 but will also be accessible to 5.8.8. Further, suppose that you upgrade a module to one which requires features present only in 5.8.8. That new module will get installed into **/usr/local/lib/perl5/site_perl/5.8.8** and will be available to 5.8.8, but will not interfere with the 5.8.7 version.

The last entry, **/usr/local/lib/perl5/site_perl/**, is there so that 5.6.0 and above will look for 5.004-era pure perl modules.

Lastly, suppose you now install 5.10.0, which is not binary compatible with 5.8.x. The directories searched by 5.10.0 (if you don't change the Configure defaults) will be:

```
/usr/local/lib/perl5/5.10.0/$archname
/usr/local/lib/perl5/5.10.0
/usr/local/lib/perl5/site_perl/5.10.0/$archname
/usr/local/lib/perl5/site_perl/5.10.0

/usr/local/lib/perl5/site_perl/5.8.8

/usr/local/lib/perl5/site_perl/5.8.7

/usr/local/lib/perl5/site_perl/
```

Note that the earlier \$archname entries are now gone, but pure perl modules from earlier versions will still be found.

This way, you can choose to share compatible extensions, but also upgrade to a newer version of an extension that may be incompatible with earlier versions, without breaking the earlier versions' installations.

BUGS

NAME

perlpod – the Plain Old Documentation format

DESCRIPTION

Pod is a simple-to-use markup language used for writing documentation for Perl, Perl programs, and Perl modules.

Translators are available for converting Pod to various formats like plain text, HTML, man pages, and more.

Pod markup consists of three basic kinds of paragraphs: ordinary, verbatim, and command.

Ordinary Paragraph

Most paragraphs in your documentation will be ordinary blocks of text, like this one. You can simply type in your text without any markup whatsoever, and with just a blank line before and after. When it gets formatted, it will undergo minimal formatting, like being rewrapped, probably put into a proportionally spaced font, and maybe even justified.

You can use formatting codes in ordinary paragraphs, for **bold**, *italic*, `code-style`, hyperlinks, and more. Such codes are explained in the "Formatting Codes" section, below.

Verbatim Paragraph

Verbatim paragraphs are usually used for presenting a codeblock or other text which does not require any special parsing or formatting, and which shouldn't be wrapped.

A verbatim paragraph is distinguished by having its first character be a space or a tab. (And commonly, all its lines begin with spaces and/or tabs.) It should be reproduced exactly, with tabs assumed to be on 8-column boundaries. There are no special formatting codes, so you can't italicize or anything like that. A \ means \, and nothing else.

Command Paragraph

A command paragraph is used for special treatment of whole chunks of text, usually as headings or parts of lists.

All command paragraphs (which are typically only one line long) start with "=", followed by an identifier, followed by arbitrary text that the command can use however it pleases. Currently recognized commands are

```
=pod
=head1 Heading Text
=head2 Heading Text
=head3 Heading Text
=head4 Heading Text
=over indentlevel
=item stuff
=back
=begin format
=end format
=for format text...
=encoding type
=cut
```

To explain them each in detail:

```
=head1 Heading Text
=head2 Heading Text
=head3 Heading Text
=head4 Heading Text
```

Head1 through head4 produce headings, head1 being the highest level. The text in the rest of this paragraph is the content of the heading. For example:

```
=head2 Object Attributes
```

The text "Object Attributes" comprises the heading there. The text in these heading commands can

use formatting codes, as seen here:

```
=head2 Possible Values for C<$/>
```

Such commands are explained in the "Formatting Codes" section, below.

```
=over indentlevel
=item stuff...
=back
```

Item, over, and back require a little more explanation: “=over” starts a region specifically for the generation of a list using “=item” commands, or for indenting (groups of) normal paragraphs. At the end of your list, use “=back” to end it. The *indentlevel* option to “=over” indicates how far over to indent, generally in ems (where one em is the width of an “M” in the document’s base font) or roughly comparable units; if there is no *indentlevel* option, it defaults to four. (And some formatters may just ignore whatever *indentlevel* you provide.) In the *stuff* in *=item stuff...*, you may use formatting codes, as seen here:

```
=item Using C<$|> to Control Buffering
```

Such commands are explained in the "Formatting Codes" section, below.

Note also that there are some basic rules to using “=over” ... “=back” regions:

- Don’t use “=item”s outside of an “=over” ... “=back” region.
- The first thing after the “=over” command should be an “=item”, unless there aren’t going to be any items at all in this “=over” ... “=back” region.
- Don’t put “=head n ” commands inside an “=over” ... “=back” region.
- And perhaps most importantly, keep the items consistent: either use “=item *” for all of them, to produce bullets; or use “=item 1.”, “=item 2.”, etc., to produce numbered lists; or use “=item foo”, “=item bar”, etc.—namely, things that look nothing like bullets or numbers.

If you start with bullets or numbers, stick with them, as formatters use the first “=item” type to decide how to format the list.

```
=cut
```

To end a Pod block, use a blank line, then a line beginning with “=cut”, and a blank line after it. This lets Perl (and the Pod formatter) know that this is where Perl code is resuming. (The blank line before the “=cut” is not technically necessary, but many older Pod processors require it.)

```
=pod
```

The “=pod” command by itself doesn’t do much of anything, but it signals to Perl (and Pod formatters) that a Pod block starts here. A Pod block starts with *any* command paragraph, so a “=pod” command is usually used just when you want to start a Pod block with an ordinary paragraph or a verbatim paragraph. For example:

```
=item stuff()
```

```
This function does stuff.
```

```
=cut
```

```
sub stuff {
    ...
}
```

```
=pod
```

Remember to check its return value, as in:

```
=for comment
```

Make sure that all the available options are documented!

Some *formatnames* will require a leading colon (as in "`=for :formatname`", or "`=begin :formatname`" ... "`=end :formatname`"), to signal that the text is not raw data, but instead *is* Pod text (i.e., possibly containing formatting codes) that's just not for normal formatting (e.g., may not be a normal-use paragraph, but might be for formatting as a footnote).

```
=encoding encodingname
```

This command is used for declaring the encoding of a document. Most users won't need this; but if your encoding isn't US-ASCII, then put a `=encoding encodingname` command very early in the document so that pod formatters will know how to decode the document. For *encodingname*, use a name recognized by the Encode::Supported module. Some pod formatters may try to guess between a Latin-1 or CP-1252 versus UTF-8 encoding, but they may guess wrong. It's best to be explicit if you use anything besides strict ASCII. Examples:

```
=encoding latin1
```

```
=encoding utf8
```

```
=encoding koi8-r
```

```
=encoding ShiftJIS
```

```
=encoding big5
```

`=encoding` affects the whole document, and must occur only once.

And don't forget, all commands but `=encoding` last up until the end of its *paragraph*, not its line. So in the examples below, you can see that every command needs the blank line after it, to end its paragraph. (And some older Pod translators may require the `=encoding` line to have a following blank line as well, even though it should be legal to omit.)

Some examples of lists include:

```
=over
```

```
=item *
```

```
First item
```

```
=item *
```

```
Second item
```

```
=back
```

```
=over
```

```
=item Foo()
```

```
Description of Foo function
```

```
=item Bar()
```

```
Description of Bar function
```

```
=back
```

Formatting Codes

In ordinary paragraphs and in some command paragraphs, various formatting codes (a.k.a. “interior sequences”) can be used:

I<text> — italic text

Used for emphasis (“be I<careful!>”) and parameters (“redo I<LABEL>”)

B<text> — bold text

Used for switches (“perl's B<-n> switch”), programs (“some systems provide a B<chfn> for that”), emphasis (“be B<careful!>”), and so on (“and that feature is known as B<autovivification>”).

C<code> — code text

Renders code in a typewriter font, or gives some other indication that this represents program text (“C<gmtime (\$^T)>”) or some other form of computerese (“C<drwxr-xr-x>”).

L<name> — a hyperlink

There are various syntaxes, listed below. In the syntaxes given, text, name, and section cannot contain the characters '/' and '|'; and any '<' or '>' should be matched.

- L<name>
Link to a Perl manual page (e.g., L<Net::Ping>). Note that name should not contain spaces. This syntax is also occasionally used for references to Unix man pages, as in L<crontab(5)>.
- L<name/"sec"> or L<name/sec>
Link to a section in other manual page. E.g., L<perlsyn/"For Loops">
- L</"sec"> or L</sec>
Link to a section in this manual page. E.g., L</"Object Methods">

A section is started by the named heading or item. For example, L<perlvar/\$.> or L<perlvar/"\$."> both link to the section started by “=item \$.” in perlvar. And L<perlsyn/For Loops> or L<perlsyn/"For Loops"> both link to the section started by “=head2 For Loops” in perlsyn.

To control what text is used for display, you use “L<text | ...>”, as in:

- L<text | name>
Link this text to that manual page. E.g., L<Perl Error Messages|perldiag>
- L<text | name/"sec"> or L<text | name/sec>
Link this text to that section in that manual page. E.g., L<postfix "if"|perlsyn/"Statement Modifiers">
- L<text | /"sec"> or L<text | /sec> or L<text | "sec">
Link this text to that section in this manual page. E.g., L<the various attributes|/"Member Data">

Or you can link to a web page:

- L<scheme:...>
L<text | scheme:...>
Links to an absolute URL. For example, L<http://www.perl.org/> or L<The Perl Home Page|http://www.perl.org/>.

E<escape> — a character escape

Very similar to HTML/XML &foo; “entity references”:

- E<lt> — a literal < (less than)

- E<gt> — a literal > (greater than)
- E<verbar> — a literal | (*vertical bar*)
- E<sol> — a literal / (*solidus*)

The above four are optional except in other formatting codes, notably L<...>, and when preceded by a capital letter.

- E<htmlname>

Some non-numeric HTML entity name, such as E<eacute>, meaning the same thing as é in HTML — i.e., a lowercase e with an acute (/–shaped) accent.

- E<number>

The ASCII/Latin-1/Unicode character with that number. A leading “0x” means that *number* is hex, as in E<0x201E>. A leading “0” means that *number* is octal, as in E<075>. Otherwise *number* is interpreted as being in decimal, as in E<181>.

Note that older Pod formatters might not recognize octal or hex numeric escapes, and that many formatters cannot reliably render characters above 255. (Some formatters may even have to use compromised renderings of Latin-1/CP-1252 characters, like rendering E<eacute> as just a plain “e”.)

F<filename> — used for filenames

Typically displayed in italics. Example: "F<.cshrc>"

S<text> — text contains non-breaking spaces

This means that the words in *text* should not be broken across lines. Example: S<\$x ? \$y : \$z>.

X<topic name> — an index entry

This is ignored by most formatters, but some may use it for building indexes. It always renders as empty-string. Example: X<absolutizing relative URLs>

Z<> — a null (zero-effect) formatting code

This is rarely used. It’s one way to get around using an E<...> code sometimes. For example, instead of "NE<lt>3" (for "N<3" you could write "NZ<><3" (the "Z<>" breaks up the "N" and the "<" so they can’t be considered the part of a (fictitious) "N<...>" code).

Most of the time, you will need only a single set of angle brackets to delimit the beginning and end of formatting codes. However, sometimes you will want to put a real right angle bracket (a greater-than sign, '>') inside of a formatting code. This is particularly common when using a formatting code to provide a different font-type for a snippet of code. As with all things in Perl, there is more than one way to do it. One way is to simply escape the closing bracket using an E code:

```
C<$a E<lt>=>E<gt> $b>
```

This will produce: "\$a <=> \$b"

A more readable, and perhaps more “plain” way is to use an alternate set of delimiters that doesn’t require a single “>” to be escaped. Doubled angle brackets (“<<” and “>>”) may be used *if and only if there is whitespace right after the opening delimiter and whitespace right before the closing delimiter!* For example, the following will do the trick:

```
C<< $a <=> $b >>
```

In fact, you can use as many repeated angle-brackets as you like so long as you have the same number of them in the opening and closing delimiters, and make sure that whitespace immediately follows the last '<' of the opening delimiter, and immediately precedes the first '>' of the closing delimiter. (The whitespace is ignored.) So the following will also work:

```
C<<< $a <=> $b >>>
C<<<< $a <=> $b >>>>
```

And they all mean exactly the same as this:

```
C<$a E<lt>=E<gt> $b>
```

The multiple-bracket form does not affect the interpretation of the contents of the formatting code, only how it must end. That means that the examples above are also exactly the same as this:

```
C<< $a E<lt>=E<gt> $b >>
```

As a further example, this means that if you wanted to put these bits of code in C (code) style:

```
open(X, ">>thing.dat") || die $!
$foo->bar();
```

you could do it like so:

```
C<<< open(X, ">>thing.dat") || die $! >>>
C<< $foo->bar(); >>
```

which is presumably easier to read than the old way:

```
C<open(X, "E<gt>E<gt>thing.dat") || die $!>
C<$foo-E<gt>bar();>
```

This is currently supported by `pod2text` (`Pod::Text`), `pod2man` (`Pod::Man`), and any other `pod2xxx` or `Pod::Xxxx` translators that use `Pod::Parser 1.093` or later, or `Pod::Tree 1.02` or later.

The Intent

The intent is simplicity of use, not power of expression. Paragraphs look like paragraphs (block format), so that they stand out visually, and so that I could run them through `fmt` easily to reformat them (that's F7 in my version of **vi**, or Esc Q in my version of **emacs**). I wanted the translator to always leave the ' and ` and " quotes alone, in verbatim mode, so I could slurp in a working program, shift it over four spaces, and have it print out, er, verbatim. And presumably in a monospace font.

The Pod format is not necessarily sufficient for writing a book. Pod is just meant to be an idiot-proof common source for `nroff`, HTML, TeX, and other markup languages, as used for online documentation. Translators exist for **pod2text**, **pod2html**, **pod2man** (that's for *nroff*(1) and *troff*(1)), **pod2latex**, and **pod2fm**. Various others are available in CPAN.

Embedding Pods in Perl Modules

You can embed Pod documentation in your Perl modules and scripts. Start your documentation with an empty line, a “=head1” command at the beginning, and end it with a “=cut” command and an empty line. The **perl** executable will ignore the Pod text. You can place a Pod statement where **perl** expects the beginning of a new statement, but not within a statement, as that would result in an error. See any of the supplied library modules for examples.

If you're going to put your Pod at the end of the file, and you're using an `__END__` or `__DATA__` cut mark, make sure to put an empty line there before the first Pod command.

```
__END__
```

```
=head1 NAME
```

```
Time::Local - efficiently compute time from local and GMT time
```

Without that empty line before the “=head1”, many translators wouldn't have recognized the “=head1” as starting a Pod block.

Hints for Writing Pod

-

The **podchecker** command is provided for checking Pod syntax for errors and warnings. For example, it checks for completely blank lines in Pod blocks and for unknown commands and formatting codes. You should still also pass your document through one or more translators and proofread the result, or print out the result and proofread that. Some of the problems found may be bugs in the translators, which you may or may not wish to work around.

- If you're more familiar with writing in HTML than with writing in Pod, you can try your hand at writing documentation in simple HTML, and converting it to Pod with the experimental Pod::HTML2Pod module, (available in CPAN), and looking at the resulting code. The experimental Pod::PXML module in CPAN might also be useful.
- Many older Pod translators require the lines before every Pod command and after every Pod command (including “=cut”) to be a blank line. Having something like this:

```
# - - - - -
=item $firecracker->boom()
```

```
This noisily detonates the firecracker object.
```

```
=cut
sub boom {
    ...
```

...will make such Pod translators completely fail to see the Pod block at all.

Instead, have it like this:

```
# - - - - -
```

```
=item $firecracker->boom()
```

```
This noisily detonates the firecracker object.
```

```
=cut
```

```
sub boom {
    ...
```

- Some older Pod translators require paragraphs (including command paragraphs like “=head2 Functions”) to be separated by *completely* empty lines. If you have an apparently empty line with some spaces on it, this might not count as a separator for those translators, and that could cause odd formatting.
- Older translators might add wording around an L<> link, so that L<Foo::Bar> may become “the Foo::Bar manpage”, for example. So you shouldn't write things like the L<foo> documentation, if you want the translated document to read sensibly. Instead, write the L<Foo::Bar|Foo::Bar> documentation or L<the Foo::Bar documentation|Foo::Bar>, to control how the link comes out.
- Going past the 70th column in a verbatim block might be ungracefully wrapped by some formatters.

NAME

perl_modules – list of WA2L/edrc bundled Perl module man pages

SYNOPSIS

-

AVAILABILITY

WA2L/edrc

DESCRIPTION

This man page lists man pages of the main Perl modules that are part of WA2L/edrc package and distributed with it.

Many Perl modules need other modules to work. All modules that were identified to be needed by a certain Perl module bundled with WA2L/edrc are also included into the package.

To start a Perl script that uses a bundled Perl module from a recovery script, set the Perl library path (@INC) using the **'eval 'perlenv''** command in the recovery script and then call the **perl** interpreter:

```
#!/bin/ksh
#
# 1:ascript - A Recovery Script
#
# [00] 08.02.2009 CWa    Initial Version
#
#
test "$DEBUG" = True && set -x
:
:
eval `perlenv`
perl ./perlscript
:
```

An other possibility is to create an **_env** file (using the **env** edrc command) with the content:

```
#
# _env - Environment settings for commands in /apps/eg
#
# [00] 18.03.2009 CWa    Initial Version
#
#
test "$DEBUG" = True && set -x

eval `perlenv`
:
```

and use the bundled Perl module using the '**use module**;' clause:

```
#!/usr/bin/env perl
#
# perlscript - Perl script using bundled DBI module
#
# [00] 18.03.2009 CWa    Initial Version
#
:
:
use DBI;
:
```

With this 2nd method it is also possible to write recovery scripts in Perl that use the bundled Perl modules.

Note the use of '**#!/usr/bin/env perl**' in the magic key to start the Perl script. This ensures that the **perl** interpreter is found on the system, even when it is not installed in the default location you will normally specify.

PERL MODULE MAN PAGE REFERENCE OF WA2L/edrc

CGI(3pm) Simple Common Gateway Interface Class.

CMS::MediaWiki(3pm) Perl extension for creating, reading and updating MediaWiki pages.

DBD::SQLite(3pm) Self Contained RDBMS in a DBI Driver.

DBI(3pm) Database independent interface for Perl.

File::Tail(3pm) Perl extension for reading from continuously updated files.

HTML::Parser(3pm) HTML parser class.

MediaWiki::API(3pm) Perl interface to the MediaWiki API.

MIME::Base64(3pm) Encoding and decoding of base64 strings

MIME::Lite(3pm) Low-calorie MIME generator.

Text::vCard(3pm) a package to edit and create a single vCard (RFC 2426).

Tk(3pm) a graphical user interface toolkit for Perl.

WA2L::Util(3) General WA2L/edrc Utility Functions.

COMPILE/INSTALL BUNDLED WA2L/edrc Perl MODULES

Because often Perl modules also need to be compiled there is a good chance that on certain operating system versions this modules have to be compiled.

If you experience missing modules when using a WA2L/edrc Perl command (watch for PSCR in **compatibility(1)**) or in an own Perl script using bundled Perl modules you might be forced to compile it for your system.

To do so:

0) goto shell in edrc or start shell

The following steps have to be executed in the **shell** due to the fact that the install mechanism relay on the environment provided by the **shell** command.

```
host-001# ~edrc/bin/shell
```

1) goto source directory

All bundled Perl modules are included in WA2L/edrc as source packages to enable a quick and efficient compilation process on future systems.

```
[ /root ]
[ root@host-001 ][*eshell*/bash]: cdsrc; cd perlmodules

[ /opt/edrc/src/perlmodules ]
[ root@host-001 ][*eshell*/bash]:
```

2) list install sequence

Because often modules relay on other modules, the given sequence below helps to a successful compilation and installation of modules.

```
[ /opt/edrc/src/perlmodules ]
[ root@host-001 ][*eshell*/bash]: make list

#
# LIST MODULES
#

:
Compress::Compress-Raw-Zlib
Compress::Compress-Zlib
LWP::LWP-UserAgent
JSON::JSON
URI::URI
MediaWiki::MediaWiki-API
File::File-Tail
CMS::CMS-MediaWiki
:
```

Identify the module(s) that has been reported as missing on the output list. Often a whole chain of modules are missing, where the above sequence gives help on the compile/install order.

3) compile module

The provided **Makefile** handles all steps to compile, test and install a bundled Perl module into the WA2L/edrc structure and not to change the underlying operating system. This steps make

the related Perl module "portable" and on similar systems the modules don't have to be compiled they can simply be distributed to it using the **pack(1m)** and **patchinstall(1m)** commands of WA2L/edrc.

```
[ /opt/edrc/src/perlmodules ]
[ root@host-001 ][*eshell*/bash]:

[ /opt/edrc/src/perlmodules ]
[ root@host-001 ][*eshell*/bash]: make help

[ /opt/edrc/src/perlmodules ]
[ root@host-001 ][*eshell*/bash]: make build
```

To build a subset of the whole module list defined in the **ALL** variable in the **Makefile**, add the module to the **TST** variable and invoke:

```
[ /opt/edrc/src/perlmodules ]
[ root@host-001 ][*eshell*/bash]: make buildtst
```

4) install module into WA2L/edrc

Install the module into the WA2L/edrc structure into the **edrc/lib/perl/pm/** directory without to change the underlying operating system.

```
[ /opt/edrc/src/perlmodules ]
[ root@host-001 ][*eshell*/bash]: make install
```

5) clean up files (optional)

Clean up all produced files during the compile/test/install process. This is an optional step.

```
[ /opt/edrc/src/perlmodules ]
[ root@host-001 ][*eshell*/bash]: make clean
```

6) create a patch release of your installation (optional)

If you compiled all missing bundled Perl modules you can create a PATCH release of the WA2L/edrc package to install the produced files on all your other systems.

```
[ /opt/edrc/src/perlmodules ]
[ root@host-001 ][*eshell*/bash]: pack -d ~edrc/var/sw -a edrc_UPDATE -

pack - create application package, by Chr. Walther

create package of application in '/opt/edrc' ...
application information ...
APPLICATION ..... : edrc_UPDATE
APPLICATION_PREFIX ... : edrc_WA2L
APPLICATION_NAME ..... : WA2L/edrc
APPLICATION_RELEASE .. : 1.5.46
DESCRIPTION ..... : WA2L/edrc without recovery script-, co
done.
package information ...
format ..... : shar
type ..... : PATCH (to version 1.5.46)
file ..... : host-001:/opt/edrc/var/sw/edrc_WA2L-1.
```

```

done.
write sadm file ...(/opt/edrc/var/pack/sadm/edrc_WA2L-1.5.46-201408
evaluate files to be packed ... (729 files)... done.
evaluate properties of files to be packed ... done.
pack files to package file ... (12917 kB)... done.
done.

```

7) install the patch on all your other systems

The most convenient way to patch all your systems is to use the **edrcupgrade** contributed command in **edrc** :

```

[ /opt/edrc/src/perlmodules ]
[ root@host-001 ][*eshell*/bash]: sat

sat@host-001> edrcupgrade
(s)tart (d)ownload only (i)nstall only (c)ancel [c] :i

DEPLOY AND INSTALL AN WA2L/edrc PATCH

patchfile basedir [/opt/edrc/var/sw]:

list downloaded patch files? <ync> [y] :y

AVAILABLE EDRC PATCH files:

FROM      TO      FILENAME
-----
1.5.46    1.5.46    edrc_WA2L-1.5.46-201408231741-PATCH-1.5.46.cpio.gz
(1)

patchfile to install : edrc_WA2L-1.5.46-201408231741-PATCH-1.5.46.cpio.

:

```

You can also install the generated patch more manually first distributing the patch file using **filedist(1)** and then installing it with the **patchinstall(1m)** command on all systems using the **rcmd(1)** command.

ENVIRONMENT

-

EXIT STATUS

-

FILES

edrc/lib/perl/pm/<perl_release>/<perl_version>/

location of all bundled Perl modules. This directory is automatically pre-pended to the **@INC** array when the Perl script is started thru the **.perl_wrapper**. See also: **perl_wrapper(1)**.

edrc/src/perlmodules/

source packages of all bundled Perl modules.

edrcintro(1), **contrib.edrcupgrade(1m)**, **filedist(1)**, **lspm(1)**, **make(1)**, **pack(1m)**, **patchinstall(1m)**, **perl_wrapper(1)**, **perl(1)**, **perlenv(3)**, **pmdesc(1)**, **rcmd(1)**, **CGI(3pm)**, **CMS::MediaWiki(3pm)**, **DBD::SQLite(3pm)**, **DBI(3pm)**, **File::Tail(3pm)**, **HTML::Parser(3pm)**, **MediaWiki::API(3pm)**, **MIME::Base64(3pm)**, **MIME::Lite(3pm)**, **Tk(3pm)**, **URI(3pm)**, **WA2LUtil(3)**, **WA2L::Util(3)**

NOTES

When Perl scripts are started thru the **perl_wrapper** it is not needed to use the **perlenv** command or to set the perl **@INC** array somehow; simply put the perl script into the **lib/perl/** directory and create the symbolic link having the identical name as the Perl script file in **bin/** or **lib/** pointing to the **.perl_wrapper**.

See also **perl_wrapper(1)** for examples of integrating Perl scripts into WA2L/edrc.

NAME

perl_wrapper – wrap Perl scripts to ensure perl startup

SYNOPSIS

edrc/bin/perlscript -> **.perl_wrapper**

edrc/lib/perlscript -> **.perl_wrapper**

AVAILABILITY

WA2L/edrc

DESCRIPTION

Wrap Perl scripts to avoid using *#!/usr/bin/perl* or similar path names in the magic key. This enhances the portability of WA2L/edrc commands written in Perl to systems where **perl** is not installed in the default install locations.

perl has to be installed in **/bin/**, **/sbin/**, **/usr/local/bin/** or **/usr/contrib/bin/**.

Further **perl** locations can be configured in the config file **perl_wrapper.cfg**.

The Perl modules bundled with WA2L/edrc that are installed in **lib/perl/pm/<perl-revision>/** are included in the Perl library path (**@INC**) and the **ld** environment variables (**\$SHLIB_PATH**, **\$LD_LIBRARY_PATH**) are expanded to the directory **lib/<OS-Id>/libs/** that might contain additional needed shared libraries.

To start a new command thru the **.perl_wrapper**, follow the following steps:

- 1.) create a symlink to the new command in the **edrc/bin/** or **edrc/lib/** directory depending on your needs:

```
[ /opt/edrc/bin ]
[ root@acme001 ][*edrc*/bash]: ln -s .perl_wrapper new_cmd
```

- 2.) install the Perl script in the **edrc/lib/perl/** directory:

```
[ /opt/edrc/lib/perl ]
[ root@acme001 ][*edrc*/bash]: vi new_cmd

[ /opt/edrc/lib/perl ]
[ root@acme001 ][*edrc*/bash]: chmod 644 new_cmd
```

OPTIONS

-

ENVIRONMENT

-

EXIT STATUS

- 101** shell (**perl**) not found. If **perl** is installed on the system and you get this error, add the **perl** location in the configuration file **perl_wrapper.cfg**.
- 102** the Perl script to be started that should be located in **lib/perl/** does not exist.
- 103** user calling the command has no permission to access/execute the called *perlscript*.
- 106** configuration file **perl_wrapper.cfg** does not exist.
- 107** the **.perl_wrapper** was called directly.

FILES

- etc/perl_wrapper.cfg**
configuration file for the **.perl_wrapper** command.
- lib/perl/** location of the wrapped Perl scripts. This files should have the file permissions *644* to show, that those scripts should not be started directly.
- lib/perl/pm/<perl-revision>/**
location of the perl modules bundled with WA2L/edrc.
- lib/<OS-Id>/libs/**
locations of the provided shared libraries for a certain operating system (**OS-Id**).

NAME

perl_wrapper.cfg – configuration file for .perl_wrapper

SYNOPSIS

edrc/etc/perl_wrapper.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **.perl_wrapper** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**SEARCH_PATH**

Colon separated search path where to search for the **perl** interpreter.

Example: SEARCH_PATH="/bin:/usr/bin:/sbin:/opt/perl/bin:/usr/local/bin:/usr/contrib/bin"

Default: SEARCH_PATH="/bin:/usr/bin:/sbin:/opt/perl/bin:/usr/local/bin:/usr/contrib/bin"

MODULE_DIR

Perl Modules contributed with WA2L/edrc.

Example: MODULE_DIR=lib/perl/pm

Default: MODULE_DIR=lib/perl/pm

SEE ALSO

edrcintro(1), **perl_wrapper**(1)

NAME

pf_wrapper – start command thru sudo or RBAC if user is privileged

SYNOPSIS

edrc/pbin/edrc_command -> .pf_wrapper

AVAILABILITY

WA2L/edrc

DESCRIPTION

Wrap WA2L/edrc commands to be started thru **pfexec**(1) or **sudo**(8).

The attributes of the privileged *edrc_command* is done with the original operating system commands (**sudo**, **pfexec**) to execute it with elevated permissions.

The **pf_wrapper**(1) does simplify the startup of those commands. The user only needs to add the **~edrc/pbin/** directory into the **\$PATH** environment variable and does not need to know if a system (as Solaris or HP-UX) is configured to use RBAC (Role Based Access Control) **pfexec** to execute a command with elevated permissions or **sudo**.

To include an additional WA2L/edrc command into this mechanism, create a symlink to the **.pf_wrapper** in the **edrc/pbin/** directory.

If a system uses both startup mechanisms (RBAC and **sudo**), first it is checked if a command is configured to be started thru RBAC, then **sudo**.

OPTIONS

-

ENVIRONMENT

-

EXIT STATUS

107 direct call of **.pf_wrapper**.

126 permission denied to start a command. This error occurs, if the WA2L/edrc command is not configured to be executed thru **sudo** or **RBAC**.

127 command does not exist in WA2L/edrc (**edrc/sbin/**, **edrc/bin/** or **edrc/lib/**).

x exit status of the related command.

FILES

bin/ binary directory in WA2L/edrc where the *edrc_command* is located.

lib/ library directory in WA2L/edrc where the *edrc_command* is located.

pbins/ binary directory for commands that could be started with elevated permissions. This directory only contains symlinks to the **.pf_wrapper**.

sbin/ binary directory where the **edrc(1m)** command is located.

var/log/pf_wrapper.log
log file for the **.pf_wrapper** command.

/etc/sudoers
typical configuration file for **sudo(8)**.

/etc/security/exec_attr
execution profiles database for RBAC.

/etc/security/prof_attr
profile description database for RBAC.

/etc/user_attr
extended user attributes database for RBAC.

EXAMPLES

1) sudo configuration example

To start some commands thru **sudo**, the following lines could be added to the **/etc/sudoers** file, using the **visudo** command. To ensure, that the user has to supply the own password to execute the privileged commands, the settings in line 55 and 56 should be commented out or removed from the file.

```
[ /etc ]
[ root@host-001 ][*eshell*/bash]: sav sudoers; visudo

1  #
2  # /etc/sudoers - sudo access definition file
3  #
4  # [01] 25.02.2012 CWa  +*_EDRC_* definitions
5  #
6  ##
```

```

7  ## Sudoers allows particular users to run various commands
8  ## as the root user, without needing the root password.
9  ##
:
18 ## User Aliases
19 User_Alias    ROLE_EDRC_ADM = john, fred
20 User_Alias    ROLE_EDRC_OPS = barney
21 User_Alias    ROLE_EDRC_USR = wilma, betty
22
23 # WA2L/edrc definitions
24 #
25 ROLE_EDRC_ADM ALL = PASSWD: CMD_EDRC_USR, CMD_EDRC_OPS, CMD_EDRC
26 ROLE_EDRC_OPS ALL = PASSWD: CMD_EDRC_USR, CMD_EDRC_OPS
27 ROLE_EDRC_USR ALL = PASSWD: CMD_EDRC_USR
28 Cmnd_Alias    CMD_EDRC_ADM = /opt/edrc/bin/shell, /opt/edrc/bin/
29                                     /opt/edrc/sbin/edrc, /opt/edrc/bin/
30 Cmnd_Alias    CMD_EDRC_OPS = /opt/edrc/bin/osup
31 Cmnd_Alias    CMD_EDRC_USR = /opt/edrc/bin/asup, /opt/edrc/bin/
:
51 # In the default (unconfigured) configuration, sudo asks for the
52 # password. This allows use of an ordinary user account
53 # administration of a fresh installed system. When configuring s
54 # delete the two following lines:
55 #Defaults     targetpw      # specify passwd of target user i.e
56 #ALL          ALL=(ALL) ALL # only together with 'Defaults targe
:
~
~
~

```

The concept of the configuration example above is, that all commands that are to be used by an user are defined in the command alias **CMD_EDRC_USR**, the additional commands that are used by operational personnel are defined in the command alias **CMD_EDRC_OPS** and the additional commands that are used by administrators are listed in **CMD_EDRC_ADM**.

To build roles, the role **ROLE_EDRC_USR** consists of the **CMD_EDRC_USR** commands, the **ROLE_EDRC_OPS** consists of the **CMD_EDRC_USR** and **CMD_EDRC_OPS** commands and the **ROLE_EDRC_ADM** consists of all three **CMD_EDRC_*** command sets (**CMD_EDRC_USR**, **CMD_EDRC_OPS** **CMD_EDRC_ADM**).

Finally a role is connected to a real user using the **User_Alias** directive. In a more automated environment you most likely don't want to edit the **sudoers** file every time a change in your user base occurs, therefore a **User_Alias** can be connected to an operating system group (*%groupname*) with the setting:

```

:
18 ## User Aliases
19 User_Alias    ROLE_EDRC_ADM = %edrc_adm
20 User_Alias    ROLE_EDRC_OPS = %edrc_ops
21 User_Alias    ROLE_EDRC_USR = %edrc_usr
22
:

```

In this example the operating system groups **edrc_adm**, **edrc_ops** and **edrc_usr** represent the roles defined in the **sudoers** file.

2) RBAC configuration example

-

3) add ~edrc/pbin directory to users ~/.bashrc for Bourne again Shell

```
[ /home/fred ]
[ fred@host-001 ][bash]: vi ~/.bashrc
:
27 # Add edrc/pbin to $PATH
28 PATH=~edrc/pbin:$PATH; export PATH
~
~
```

4) add ~edrc/pbin directory to users ~/.kshrc for Korn Shell

```
[ /home/fred ]
[ fred@host-001 ][bash]: vi ~/.kshrc
:
27 # Add edrc/pbin to $PATH
28 PATH=~edrc/pbin:$PATH; export PATH
~
~
```

SEE ALSO

edrcintro(1), **edrcsetup**(1m), **sudo**(8), **sudoers**(5), **uniqupath**(3), **visudo**(8), **profiles**(1), **exec_attr**(4), **user_attr**(4), **prof_attr**(4)

NOTES

Currently the WA2L/edrc commands **asup**(1), **edrc**(1m), **lotsctl**(1), **osup**(1), **psup**(1), **sat**(1), **shell**(1) and **sys**(1) are available in the **pbin/** directory.

Be aware, that always the original command (for example: **~edrc/bin/shell**) has to be configured in **sudo** or RBAC and not the **pbin/.pf_wrapper** command.

Therefore, if you followed the suggestions how to configure **sudo**(8) in the **edrcsetup**(1m) manual page, you don't have to change anything in the **sudo** configuration.

NAME

pip – package manager for Python packages in WA2L/edrc

SYNOPSIS

edrc/bin/pip [*options*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

start the **pip** command **pip3**(1) with settings tuned for the WA2L/edrc package and the Python3 virtual environment (**venv**) distributed with the package.

See also **pip3**(1) for additional information.

OPTIONS

options all options of the **pip** command, see: **pip3**(1).

ENVIRONMENT**\$VIRTUAL_ENV**

is set to the **edrc/lib/python/pym/<OSID>/<major>.<minor>/** directory.

\$PYTHONPATH

is set to **\$VIRTUAL_ENV/lib/python<major>.<minor>/site-packages;\$PYTHONPATH**.

\$PATH

is set to **\$VIRTUAL_ENV/bin;\$PATH**.

\$PIP_DESTINATION_DIRECTORY

if not set, points to the **edrc/var/sw/** directory if write access is possible.

\$PIP_LOG_FILE

is set to **edrc/var/log/pip.log** if writeable, else to **/dev/null**.

EXIT STATUS

x exit status of **pip3**(1).

FILES

edrc/var/log/pip.log
log file of **pip**.

edrc/var/sw/
software directory for Python3 package downloads.

edrc/lib/python/pym/<OSID>/<major>.<minor>/
Python3 virtual environment (venv) distributed with WA2L/edrc.

edrc/lib/python/pym/<OSID>/<major>.<minor>/bin/pip
Python3 package manager program (**pip**) in **venv** started when invoking the **edrc/bin/pip** command.

NAME

pip3 – package manager for Python packages

SYNOPSIS

pip3 <command> [options]

DESCRIPTION

pip3 is the PyPA recommended package manager for Python packages

OPTIONS

-h, --help

Show help.

(environment variable: **PIP_HELP**)

--debug

Let unhandled exceptions propagate outside the main subroutine, instead of logging them to stderr.

(environment variable: **PIP_DEBUG**)

--isolated

Run pip in an isolated mode, ignoring environment variables and user configuration.

(environment variable: **PIP_ISOLATED**)

--require-virtualenv

Allow pip to only run in a virtual environment; exit with an error otherwise.

(environment variable: **PIP_REQUIRE_VIRTUALENV**, **PIP_REQUIRE_VENV**)

--python <python>

Run pip with the specified Python interpreter.

(environment variable: **PIP_PYTHON**)

-v, --verbose

Give more output. Option is additive, and can be used up to 3 times.

(environment variable: **PIP_VERBOSE**)

-V, --version

Show version and exit.

(environment variable: **PIP_VERSION**)

-q, --quiet

Give less output. Option is additive, and can be used up to 3 times (corresponding to WARNING, ERROR, and CRITICAL logging levels).

(environment variable: **PIP_QUIET**)

--log <path>

Path to a verbose appending log.

(environment variable: **PIP_LOG**, **PIP_LOG_FILE**, **PIP_LOCAL_LOG**)

--no-input

Disable prompting for input.

(environment variable: **PIP_NO_INPUT**)

--keyring-provider <keyring_provider>

Enable the credential lookup via the keyring library if user input is allowed. Specify which mechanism to use [disabled, import, subprocess]. (default: disabled)

(environment variable: **PIP_KEYRING_PROVIDER**)

--proxy <proxy>

Specify a proxy in the form scheme://[user:passwd@]proxy.server:port.

(environment variable: **PIP_PROXY**)

--retries <retries>

Maximum number of retries each connection should attempt (default 5 times).

(environment variable: **PIP_RETRIES**)

--timeout <sec>

Set the socket timeout (default 15 seconds).

(environment variable: **PIP_TIMEOUT**, **PIP_DEFAULT_TIMEOUT**)

--exists-action <action>

Default action when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup, (a)bort.

(environment variable: **PIP_EXISTS_ACTION**)

--trusted-host <hostname>

Mark this host or host:port pair as trusted, even though it does not have valid or any HTTPS.

(environment variable: **PIP_TRUSTED_HOST**)

--cert <path>

Path to PEM-encoded CA certificate bundle. If provided, overrides the default. See 'SSL Certificate Verification' in pip documentation for more information.

(environment variable: **PIP_CERT**)

--client-cert <path>

Path to SSL client certificate, a single file containing the private key and the certificate in PEM format.

(environment variable: **PIP_CLIENT_CERT**)

--cache-dir <dir>

Store the cache data in <dir>.

(environment variable: **PIP_CACHE_DIR**)

--no-cache-dir

Disable the cache.

(environment variable: **PIP_NO_CACHE_DIR**)

--disable-pip-version-check

Don't periodically check PyPI to determine whether a new version of pip is available for download. Implied with **--no-index**.

(environment variable: **PIP_DISABLE_PIP_VERSION_CHECK**)

--no-color

Suppress colored output.

(environment variable: **PIP_NO_COLOR**)

--no-python-version-warning

Silence deprecation warnings for upcoming unsupported Pythons.

(environment variable: **PIP_NO_PYTHON_VERSION_WARNING**)

--use-feature <feature>

Enable new functionality, that may be backward incompatible.

(environment variable: **PIP_USE_FEATURE**)

--use-deprecated <feature>

Enable deprecated functionality, that will be removed in the future.

(environment variable: **PIP_USE_DEPRECATED**)

COMMANDS**pip3-install(1)**

Install packages.

pip3-download(1)

Download packages.

pip3-uninstall(1)

Uninstall packages.

pip3-freeze(1)

Output installed packages in requirements format.

pip3-list(1)

List installed packages.

pip3-show(1)

Show information about installed packages.

pip3-check(1)

Verify installed packages have compatible dependencies.

pip3-search(1)

Search PyPI for packages.

pip3-wheel(1)

Build wheels from your requirements.

pip3-hash(1)

Compute hashes of package archives.

pip3-help(1)

Show help for pip commands.

NAME

pip3-download – description of pip3 download command

DESCRIPTION

Download packages from:

- PyPI (and other indexes) using requirement specifiers.
- VCS project urls.
- Local project directories.
- Local or remote source archives.

pip also supports downloading from "requirements files", which provide an easy way to specify a whole environment to be downloaded.

USAGE

```
python -m pip download [options] <requirement specifier> [package-index-options]
python -m pip download [options] -r <requirements file> [package-index-options] .
python -m pip download [options] <vcs project url> ...
python -m pip download [options] <local project path> ...
python -m pip download [options] <archive url/path> ...
```

OPTIONS

-c, --constraint <file>

Constrain versions using the given constraints file. This option can be used multiple times.

(environment variable: **PIP_CONSTRAINT**)

-r, --requirement <file>

Install from the given requirements file. This option can be used multiple times.

(environment variable: **PIP_REQUIREMENT**)

--no-deps

Don't install package dependencies.

(environment variable: **PIP_NO_DEPS, PIP_NO_DEPENDENCIES**)

--global-option <options>

Extra global options to be supplied to the setup.py call before the install or bdist_wheel command.

(environment variable: **PIP_GLOBAL_OPTION**)

--no-binary <format_control>

Do not use binary packages. Can be supplied multiple times, and each time adds to the existing value. Accepts either ":all:" to disable all binary packages, ":none:" to empty the set (notice the colons), or one or more package names with commas between them (no colons). Note that some packages are tricky to compile and may fail to install when this option is used on them.

(environment variable: **PIP_NO_BINARY**)

--only-binary <format_control>

Do not use source packages. Can be supplied multiple times, and each time adds to the existing value. Accepts either ":all:" to disable all source packages, ":none:" to empty the set, or one or more package names with commas between them. Packages without binary distributions will fail to install when this option is used on them.

(environment variable: **PIP_ONLY_BINARY**)

--prefer-binary

Prefer binary packages over source packages, even if the source packages are newer.

(environment variable: **PIP_PREFER_BINARY**)

--src <dir>

Directory to check out editable projects into. The default in a virtualenv is "<venv path>/src". The default for global installs is "<current dir>/src".

(environment variable: **PIP_SRC**, **PIP_SOURCE**, **PIP_SOURCE_DIR**, **PIP_SOURCE_DIRECTORY**)

--pre Include pre-release and development versions. By default, pip only finds stable versions.

(environment variable: **PIP_PRE**)

--require-hashes

Require a hash to check each requirement against, for repeatable installs. This option is implied when any package in a requirements file has a **--hash** option.

(environment variable: **PIP_REQUIRE_HASHES**)

--progress-bar <progress_bar>

Specify whether the progress bar should be used [on, off, raw] (default: on)

(environment variable: **PIP_PROGRESS_BAR**)

--no-build-isolation

Disable isolation when building a modern source distribution. Build dependencies specified by PEP 518 must be already installed if this option is used.

(environment variable: **PIP_NO_BUILD_ISOLATION**)

--use-pep517

Use PEP 517 for building source distributions (use **--no-use-pep517** to force legacy behaviour).

(environment variable: **PIP_USE_PEP517**)

--check-build-dependencies

Check the build dependencies when PEP517 is used.

(environment variable: **PIP_CHECK_BUILD_DEPENDENCIES**)

--ignore-requires-python

Ignore the Requires-Python information.

(environment variable: **PIP_IGNORE_REQUIRES_PYTHON**)

-d, --dest <dir>

Download packages into <dir>.

(environment variable: **PIP_DEST**, **PIP_DESTINATION_DIR**, **PIP_DESTINATION_DIRECTORY**)

--platform <platform>

Only use wheels compatible with <platform>. Defaults to the platform of the running system. Use this option multiple times to specify multiple platforms supported by the target interpreter.

(environment variable: **PIP_PLATFORM**)

--python-version <python_version>

The Python interpreter version to use for wheel and "Requires-Python" compatibility checks. Defaults to a version derived from the running interpreter. The version can be specified using up to three dot-separated integers (e.g. "3" for 3.0.0, "3.7" for 3.7.0, or "3.7.3"). A major-minor version can also be given as a string without dots (e.g. "37" for 3.7.0).

(environment variable: **PIP_PYTHON_VERSION**)

--implementation <implementation>

Only use wheels compatible with Python implementation <implementation>, e.g. 'pp', 'jy', 'cp', or 'ip'. If not specified, then the current interpreter implementation is used. Use 'py' to force implementation-agnostic wheels.

(environment variable: **PIP_IMPLEMENTATION**)

--abi <abi>

Only use wheels compatible with Python abi <abi>, e.g. 'pypy_41'. If not specified, then the current interpreter abi tag is used. Use this option multiple times to specify multiple abis supported by the target interpreter. Generally you will need to specify --implementation, --platform, and --python-version when using this option.

(environment variable: **PIP_ABI**)

--no-clean

Don't clean up build directories.

(environment variable: **PIP_NO_CLEAN**)

AUTHOR

NAME

pip3-freeze – description of pip3 freeze command

DESCRIPTION

Output installed packages in requirements format.

packages are listed in a case-insensitive sorted order.

USAGE

```
python -m pip freeze [options]
```

OPTIONS

-r, --requirement <file>

Use the order in the given requirements file and its comments when generating output. This option can be used multiple times.

(environment variable: **PIP_REQUIREMENT**)

-l, --local

If in a virtualenv that has global access, do not output globally-installed packages.

(environment variable: **PIP_LOCAL**)

--user Only output packages installed in user-site.

(environment variable: **PIP_USER**)

--path <path>

Restrict to the specified installation path for listing packages (can be used multiple times).

(environment variable: **PIP_PATH**)

--all Do not skip these packages in the output: pip

(environment variable: **PIP_ALL**)

--exclude-editable

Exclude editable package from output.

(environment variable: **PIP_EXCLUDE_EDITABLE**)

--exclude <package>

Exclude specified package from the output

(environment variable: **PIP_EXCLUDE**)

AUTHOR

pip developers

COPYRIGHT

The pip developers

NAME

pip3-hash – description of pip3 hash command

DESCRIPTION

Compute a hash of a local package archive.

These can be used with `--hash` in a requirements file to do repeatable installs.

USAGE

```
python -m pip hash [options] <file> ...
```

OPTIONS

-a, --algorithm <algorithm>

The hash algorithm to use: one of sha256, sha384, sha512

(environment variable: **PIP_ALGORITHM**)

AUTHOR

pip developers

COPYRIGHT

The pip developers

NAME

pip3-help – description of pip3 help command

DESCRIPTION

Show help for commands

USAGE

python -m pip help <command>

OPTIONS

-h, --help

Show help.

(environment variable: **PIP_HELP**)

--debug

Let unhandled exceptions propagate outside the main subroutine, instead of logging them to stderr.

(environment variable: **PIP_DEBUG**)

--isolated

Run pip in an isolated mode, ignoring environment variables and user configuration.

(environment variable: **PIP_ISOLATED**)

--require-virtualenv

Allow pip to only run in a virtual environment; exit with an error otherwise.

(environment variable: **PIP_REQUIRE_VIRTUALENV**, **PIP_REQUIRE_VENV**)

--python <python>

Run pip with the specified Python interpreter.

(environment variable: **PIP_PYTHON**)

-v, --verbose

Give more output. Option is additive, and can be used up to 3 times.

(environment variable: **PIP_VERBOSE**)

-V, --version

Show version and exit.

(environment variable: **PIP_VERSION**)

-q, --quiet

Give less output. Option is additive, and can be used up to 3 times (corresponding to WARNING, ERROR, and CRITICAL logging levels).

(environment variable: **PIP_QUIET**)

--log <path>

Path to a verbose appending log.

(environment variable: **PIP_LOG**, **PIP_LOG_FILE**, **PIP_LOCAL_LOG**)

--no-input

Disable prompting for input.

(environment variable: **PIP_NO_INPUT**)

--keyring-provider <keyring_provider>

Enable the credential lookup via the keyring library if user input is allowed. Specify which mechanism to use [disabled, import, subprocess]. (default: disabled)

(environment variable: **PIP_KEYRING_PROVIDER**)

--proxy <proxy>

Specify a proxy in the form scheme://[user:passwd@]proxy.server:port.

(environment variable: **PIP_PROXY**)

--retries <retries>

Maximum number of retries each connection should attempt (default 5 times).

(environment variable: **PIP_RETRIES**)

--timeout <sec>

Set the socket timeout (default 15 seconds).

(environment variable: **PIP_TIMEOUT**, **PIP_DEFAULT_TIMEOUT**)

--exists-action <action>

Default action when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup, (a)bort.

(environment variable: **PIP_EXISTS_ACTION**)

--trusted-host <hostname>

Mark this host or host:port pair as trusted, even though it does not have valid or any HTTPS.

(environment variable: **PIP_TRUSTED_HOST**)

--cert <path>

Path to PEM-encoded CA certificate bundle. If provided, overrides the default. See 'SSL Certificate Verification' in pip documentation for more information.

(environment variable: **PIP_CERT**)

--client-cert <path>

Path to SSL client certificate, a single file containing the private key and the certificate in PEM format.

(environment variable: **PIP_CLIENT_CERT**)

--cache-dir <dir>

Store the cache data in <dir>.

(environment variable: **PIP_CACHE_DIR**)

--no-cache-dir

Disable the cache.

(environment variable: **PIP_NO_CACHE_DIR**)

--disable-pip-version-check

Don't periodically check PyPI to determine whether a new version of pip is available for download. Implied with **--no-index**.

(environment variable: **PIP_DISABLE_PIP_VERSION_CHECK**)

--no-color

Suppress colored output.

(environment variable: **PIP_NO_COLOR**)

--no-python-version-warning

Silence deprecation warnings for upcoming unsupported Pythons.

(environment variable: **PIP_NO_PYTHON_VERSION_WARNING**)

--use-feature <feature>

Enable new functionality, that may be backward incompatible.

(environment variable: **PIP_USE_FEATURE**)

--use-deprecated <feature>

Enable deprecated functionality, that will be removed in the future.

(environment variable: **PIP_USE_DEPRECATED**)

NAME

pip3-install – description of pip3 install command

DESCRIPTION

Install packages from:

- PyPI (and other indexes) using requirement specifiers.
- VCS project urls.
- Local project directories.
- Local or remote source archives.

pip also supports installing from "requirements files", which provide an easy way to specify a whole environment to be installed.

USAGE

```
python -m pip install [options] <requirement specifier> [package-index-options] .
python -m pip install [options] -r <requirements file> [package-index-options] ..
python -m pip install [options] [-e] <vcs project url> ...
python -m pip install [options] [-e] <local project path> ...
python -m pip install [options] <archive url/path> ...
```

OPTIONS

-r, --requirement <file>

Install from the given requirements file. This option can be used multiple times.

(environment variable: **PIP_REQUIREMENT**)

-c, --constraint <file>

Constrain versions using the given constraints file. This option can be used multiple times.

(environment variable: **PIP_CONSTRAINT**)

--no-deps

Don't install package dependencies.

(environment variable: **PIP_NO_DEPS, PIP_NO_DEPENDENCIES**)

--pre Include pre-release and development versions. By default, pip only finds stable versions.

(environment variable: **PIP_PRE**)

-e, --editable <path/url>

Install a project in editable mode (i.e. setuptools "develop mode") from a local project path or a VCS url.

(environment variable: **PIP_EDITABLE**)

--dry-run

Don't actually install anything, just print what would be. Can be used in combination with **--ignore-installed** to 'resolve' the requirements.

(environment variable: **PIP_DRY_RUN**)

-t, --target <dir>

Install packages into <dir>. By default this will not replace existing files/folders in <dir>. Use **--upgrade** to replace existing packages in <dir> with new versions.

(environment variable: **PIP_TARGET**)

--platform <platform>

Only use wheels compatible with <platform>. Defaults to the platform of the running system. Use this option multiple times to specify multiple platforms supported by the target interpreter.

(environment variable: **PIP_PLATFORM**)

--python-version <python_version>

The Python interpreter version to use for wheel and "Requires-Python" compatibility checks. Defaults to a version derived from the running interpreter. The version can be specified using up to three dot-separated integers (e.g. "3" for 3.0.0, "3.7" for 3.7.0, or "3.7.3"). A major-minor version can also be given as a string without dots (e.g. "37" for 3.7.0).

(environment variable: **PIP_PYTHON_VERSION**)

--implementation <implementation>

Only use wheels compatible with Python implementation <implementation>, e.g. 'pp', 'jy', 'cp', or 'ip'. If not specified, then the current interpreter implementation is used. Use 'py' to force implementation-agnostic wheels.

(environment variable: **PIP_IMPLEMENTATION**)

--abi <abi>

Only use wheels compatible with Python abi <abi>, e.g. 'pypy_41'. If not specified, then the current interpreter abi tag is used. Use this option multiple times to specify multiple abis supported by the target interpreter. Generally you will need to specify **--implementation**, **--platform**, and **--python-version** when using this option.

(environment variable: **PIP_ABI**)

--user Install to the Python user install directory for your platform. Typically ~/.local/, or %APP-DATA%\Python on Windows. (See the Python documentation for site.USER_BASE for full details.)

(environment variable: **PIP_USER**)

--root <dir>

Install everything relative to this alternate root directory.

(environment variable: **PIP_ROOT**)

--prefix <dir>

Installation prefix where lib, bin and other top-level folders are placed. Note that the resulting installation may contain scripts and other resources which reference the Python interpreter of pip, and not that of **--prefix**. See also the **--python** option if the intention is to install packages into another (possibly pip-free) environment.

(environment variable: **PIP_PREFIX**)

--src <dir>

Directory to check out editable projects into. The default in a virtualenv is "<venv path>/src". The default for global installs is "<current dir>/src".

(environment variable: **PIP_SRC**, **PIP_SOURCE**, **PIP_SOURCE_DIR**, **PIP_SOURCE_DIRECTORY**)

-U, --upgrade

Upgrade all specified packages to the newest available version. The handling of dependencies depends on the upgrade-strategy used.

(environment variable: **PIP_UPGRADE**)

--upgrade-strategy <upgrade_strategy>

Determines how dependency upgrading should be handled [default: only-if-needed]. "eager" – dependencies are upgraded regardless of whether the currently installed version satisfies the requirements of the upgraded package(s). "only-if-needed" – are upgraded only when they do not satisfy the requirements of the upgraded package(s).

(environment variable: **PIP_UPGRADE_STRATEGY**)

--force-reinstall

Reinstall all packages even if they are already up-to-date.

(environment variable: **PIP_FORCE_REINSTALL**)

-I, --ignore-installed

Ignore the installed packages, overwriting them. This can break your system if the existing package is of a different version or was installed with a different package manager!

(environment variable: **PIP_IGNORE_INSTALLED**)

--ignore-requires-python

Ignore the Requires-Python information.

(environment variable: **PIP_IGNORE_REQUIRES_PYTHON**)

--no-build-isolation

Disable isolation when building a modern source distribution. Build dependencies specified by PEP 518 must be already installed if this option is used.

(environment variable: **PIP_NO_BUILD_ISOLATION**)

--use-pep517

Use PEP 517 for building source distributions (use **--no-use-pep517** to force legacy behaviour).

(environment variable: **PIP_USE_PEP517**)

--check-build-dependencies

Check the build dependencies when PEP517 is used.

(environment variable: **PIP_CHECK_BUILD_DEPENDENCIES**)

--break-system-packages

Allow pip to modify an EXTERNALLY-MANAGED Python installation

(environment variable: **PIP_BREAK_SYSTEM_PACKAGES**)

-C, --config-settings <settings>

Configuration settings to be passed to the PEP 517 build backend. Settings take the form KEY=VALUE. Use multiple **--config-settings** options to pass multiple keys to the backend.

(environment variable: **PIP_CONFIG_SETTINGS**)

--global-option <options>

Extra global options to be supplied to the setup.py call before the install or bdist_wheel command.

(environment variable: **PIP_GLOBAL_OPTION**)

--compile

Compile Python source files to bytecode

(environment variable: **PIP_COMPILE**)

--no-compile

Do not compile Python source files to bytecode

(environment variable: **PIP_NO_COMPILE**)

--no-warn-script-location

Do not warn when installing scripts outside PATH

(environment variable: **PIP_NO_WARN_SCRIPT_LOCATION**)

--no-warn-conflicts

Do not warn about broken dependencies

(environment variable: **PIP_NO_WARN_CONFLICTS**)

--no-binary <format_control>

Do not use binary packages. Can be supplied multiple times, and each time adds to the existing value. Accepts either ":all:" to disable all binary packages, ":none:" to empty the set (notice the colons), or one or more package names with commas between them (no colons). Note that some packages are tricky to compile and may fail to install when this option is used on them.

(environment variable: **PIP_NO_BINARY**)

--only-binary <format_control>

Do not use source packages. Can be supplied multiple times, and each time adds to the existing value. Accepts either ":all:" to disable all source packages, ":none:" to empty the set, or one or more package names with commas between them. Packages without binary distributions will fail to install when this option is used on them.

(environment variable: **PIP_ONLY_BINARY**)

--prefer-binary

Prefer binary packages over source packages, even if the source packages are newer.

(environment variable: **PIP_PREFER_BINARY**)

--require-hashes

Require a hash to check each requirement against, for repeatable installs. This option is implied when any package in a requirements file has a `---hash` option.

(environment variable: **PIP_REQUIRE_HASHES**)

--progress-bar <progress_bar>

Specify whether the progress bar should be used [on, off, raw] (default: on)

(environment variable: **PIP_PROGRESS_BAR**)

--root-user-action <root_user_action>

Action if pip is run as a root user [warn, ignore] (default: warn)

(environment variable: **PIP_ROOT_USER_ACTION**)

--report <file>

Generate a JSON file describing what pip did to install the provided requirements. Can be used in combination with `--dry-run` and `--ignore-installed` to 'resolve' the requirements. When `-` is used as file name it writes to stdout. When writing to stdout, please combine with the `--quiet` option to avoid mixing pip logging output with JSON output.

(environment variable: **PIP_REPORT**)

--no-clean

Don't clean up build directories.

(environment variable: **PIP_NO_CLEAN**)

NAME

pip3-list – description of pip3 list command

DESCRIPTION

List installed packages, including editables.

Packages are listed in a case-insensitive sorted order.

USAGE

```
python -m pip list [options]
```

OPTIONS**-o, --outdated**

List outdated packages

(environment variable: **PIP_OUTDATED**)

-u, --uptodate

List uptodate packages

(environment variable: **PIP_UPTODATE**)

-e, --editable

List editable projects.

(environment variable: **PIP_EDITABLE**)

-l, --local

If in a virtualenv that has global access, do not list globally-installed packages.

(environment variable: **PIP_LOCAL**)

--user Only output packages installed in user-site.

(environment variable: **PIP_USER**)

--path <path>

Restrict to the specified installation path for listing packages (can be used multiple times).

(environment variable: **PIP_PATH**)

--pre Include pre-release and development versions. By default, pip only finds stable versions.

(environment variable: **PIP_PRE**)

--format <list_format>

Select the output format among: columns (default), freeze, or json. The 'freeze' format cannot be used with the **--outdated** option.

(environment variable: **PIP_FORMAT**)

--not-required

List packages that are not dependencies of installed packages.

(environment variable: **PIP_NOT_REQUIRED**)

--exclude-editable

Exclude editable package from output.

(environment variable: **PIP_EXCLUDE_EDITABLE**)

--include-editable

Include editable package from output.

(environment variable: **PIP_INCLUDE_EDITABLE**)

--exclude <package>

Exclude specified package from the output

(environment variable: **PIP_EXCLUDE**)

NAME

pip3-uninstall – description of pip3 uninstall command

DESCRIPTION

Uninstall packages.

pip is able to uninstall most installed packages. Known exceptions are:

- Pure distutils packages installed with **python setup.py install**, which leave behind no metadata to determine what files were installed.
- Script wrappers installed by **python setup.py develop**.

USAGE

```
python -m pip uninstall [options] <package> ...
python -m pip uninstall [options] -r <requirements file> ...
```

OPTIONS

-r, --requirement <file>

Uninstall all the packages listed in the given requirements file. This option can be used multiple times.

(environment variable: **PIP_REQUIREMENT**)

-y, --yes

Don't ask for confirmation of uninstall deletions.

(environment variable: **PIP_YES**)

--root-user-action <root_user_action>

Action if pip is run as a root user [warn, ignore] (default: warn)

(environment variable: **PIP_ROOT_USER_ACTION**)

--break-system-packages

Allow pip to modify an EXTERNALLY-MANAGED Python installation

(environment variable: **PIP_BREAK_SYSTEM_PACKAGES**)

NAME

pip3-wheel – description of pip3 wheel command

DESCRIPTION

Build Wheel archives for your requirements and dependencies.

Wheel is a built-package format, and offers the advantage of not recompiling your software during every install. For more details, see the wheel docs: <https://wheel.readthedocs.io/en/latest/>

'pip wheel' uses the build system interface as described here: - <https://pip.pypa.io/en/stable/reference/build-system/>

USAGE

```
python -m pip wheel [options] <requirement specifier> ...
python -m pip wheel [options] -r <requirements file> ...
python -m pip wheel [options] [-e] <vcs project url> ...
python -m pip wheel [options] [-e] <local project path> ...
python -m pip wheel [options] <archive url/path> ...
```

OPTIONS

-w, --wheel-dir <dir>

Build wheels into <dir>, where the default is the current working directory.

(environment variable: **PIP_WHEEL_DIR**)

--no-binary <format_control>

Do not use binary packages. Can be supplied multiple times, and each time adds to the existing value. Accepts either ":all:" to disable all binary packages, ":none:" to empty the set (notice the colons), or one or more package names with commas between them (no colons). Note that some packages are tricky to compile and may fail to install when this option is used on them.

(environment variable: **PIP_NO_BINARY**)

--only-binary <format_control>

Do not use source packages. Can be supplied multiple times, and each time adds to the existing value. Accepts either ":all:" to disable all source packages, ":none:" to empty the set, or one or more package names with commas between them. Packages without binary distributions will fail to install when this option is used on them.

(environment variable: **PIP_ONLY_BINARY**)

--prefer-binary

Prefer binary packages over source packages, even if the source packages are newer.

(environment variable: **PIP_PREFER_BINARY**)

--no-build-isolation

Disable isolation when building a modern source distribution. Build dependencies specified by PEP 518 must be already installed if this option is used.

(environment variable: **PIP_NO_BUILD_ISOLATION**)

--use-pep517

Use PEP 517 for building source distributions (use **--no-use-pep517** to force legacy behaviour).

(environment variable: **PIP_USE_PEP517**)

--check-build-dependencies

Check the build dependencies when PEP517 is used.

(environment variable: **PIP_CHECK_BUILD_DEPENDENCIES**)

-c, --constraint <file>

Constrain versions using the given constraints file. This option can be used multiple times.

(environment variable: **PIP_CONSTRAINT**)

-e, --editable <path/url>

Install a project in editable mode (i.e. setuptools "develop mode") from a local project path or a VCS url.

(environment variable: **PIP_EDITABLE**)

-r, --requirement <file>

Install from the given requirements file. This option can be used multiple times.

(environment variable: **PIP_REQUIREMENT**)

--src <dir>

Directory to check out editable projects into. The default in a virtualenv is "<venv path>/src". The default for global installs is "<current dir>/src".

(environment variable: **PIP_SRC, PIP_SOURCE, PIP_SOURCE_DIR, PIP_SOURCE_DIRECTORY**)

--ignore-requires-python

Ignore the Requires-Python information.

(environment variable: **PIP_IGNORE_REQUIRES_PYTHON**)

--no-deps

Don't install package dependencies.

(environment variable: **PIP_NO_DEPS, PIP_NO_DEPENDENCIES**)

--progress-bar <progress_bar>

Specify whether the progress bar should be used [on, off, raw] (default: on)

(environment variable: **PIP_PROGRESS_BAR**)

--no-verify

Don't verify if built wheel is valid.

(environment variable: **PIP_NO_VERIFY**)

-C, --config-settings <settings>

Configuration settings to be passed to the PEP 517 build backend. Settings take the form KEY=VALUE. Use multiple --config-settings options to pass multiple keys to the backend.

(environment variable: **PIP_CONFIG_SETTINGS**)

--build-option <options>

Extra arguments to be supplied to 'setup.py bdist_wheel'.

(environment variable: **PIP_BUILD_OPTION**)

--global-option <options>

Extra global options to be supplied to the setup.py call before the install or bdist_wheel command.

(environment variable: **PIP_GLOBAL_OPTION**)

--pre Include pre-release and development versions. By default, pip only finds stable versions.

(environment variable: **PIP_PRE**)

--require-hashes

Require a hash to check each requirement against, for repeatable installs. This option is implied when any package in a requirements file has a **--hash** option.

(environment variable: **PIP_REQUIRE_HASHES**)

--no-clean

Don't clean up build directories.

(environment variable: **PIP_NO_CLEAN**)

NAME

pkg_hostname – resolve package- or host name for the current dir

SYNOPSIS

edrc/lib/pkg_hostname

AVAILABILITY

WA2L/edrc

DESCRIPTION

return cluster package name the current working directory is related to.

If the directory is not related to a package the node name as resolved by **hostname**(1) is returned.

This command can be used to set the user's prompt depending on the current working directory of the user.

OPTIONS

-

ENVIRONMENT

\$OSID osid of the operating system as resolved by **osid**(3). If **\$OSID** is not set the OS-id is resolved by the **pkg_hostname** command.

EXIT STATUS

0 always.

FILES

etc/pkg_hostname.cfg

configuration file of **pkg_hostname**. In this file the mapping between the filesystems and the related cluster package is defined.

EXAMPLES

1) usage of **pkg_hostname** in the user .profile and .kshrc

Set the user prompt dynamically to show the user on which cluster the current working

directory is located.

~/.profile:

```

:
:

PKG_HOSTNAME=~edrc/lib/pkg_hostname`
SH=${SH:=`basename $SHELL`}

case "$SH" in
    *bash*)
        PS1="[ \${PWD} ]\n[ \${LOGNAME}@\\${PKG_HOSTNAME} ] [\$SH]: "
        ;;
    *)
        PS1="[ \${PWD} ]\n[ \${LOGNAME}@\\${PKG_HOSTNAME} ] [\$SH]: "
        ;;
esac

:
:
```

~/.kshrc:

```

:
:

ksh_cd(){
    if [ $# -eq 0 ]; then
        \cd $HOME
    else
        \cd "$*" 2>/dev/null
    fi
    ksh_cd_retval=$?
    if [ $ksh_cd_retval -eq 0 ]; then
        export PKG_HOSTNAME=~edrc/lib/pkg_hostname`
    else
        echo "ksh: $*: not found" >&2
        return $ksh_cd_retval
    fi
} # ksh_cd

alias cd='ksh_cd'

:
:
```

2) usage of pkg_hostname in a script

Suppose the script with the following cut-out is located in the path **/cluster/dwh_db1/app/bin** on the cluster packages in the TEST, PREPRODUCTION and PRODUCTION environment. The script has to run against different databases and has to mail a state information to different people depending on the package the script is running.

See also **server_environment(3)** for similar purpose.

```
#!/bin/sh

# Const
Scriptname=`basename $0`
Scriptpath=`dirname $0`

case `cd $Scriptpath; pkg_hostname` in
    dwh_dbl_tst)
        Mail_to=fred.flintstone@acme.ch
        Database=DWHTST
        ;;
    dwh_dbl_pre)
        Mail_to=barney.boulder@acme.ch
        Database=DWHPRE
        ;;
    dwh_dbl_prod)
        Mail_to=pete.pepple@acme.ch
        Database=DWHPROD
        ;;
    *)
        msg ERROR "check script!"
        exit 1
        ;;
esac

:
:
```

bash(1), **edrcintro(1)**, **getfilesystem(3)**, **ksh(1)**, **pkg_hostname.cfg(4)**, **server_environment(3)**

NOTES

-

BUGS

If the **getfilesystem(3)** command does not exist for a certain operating system, a slightly less precise mechanism is used to resolve on which filesystem the current working directory is located.

AUTHOR

pkg_hostname was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

pkg_hostname.cfg – pkg_hostname configuration file

SYNOPSIS

etc/pkg_hostname.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the location definition for the **pkg_hostname** command.

FILEFORMAT

The fileformat is a list of definitions that have the format

FILESYSTEM_REGEX;HOSTNAME_REGEX;PACKAGE_NAME;

Rows starting with a **#** are considered as comments. Empty lines are allowed, too.

OPTIONS

FILESYSTEM_REGEX

regular expression to relate a filesystem (see output of the **getfilesystem(3)** command) to a cluster package name.

HOSTNAME_REGEX

regular expression to relate a filesystem on a certain host to a cluster package name.

PACKAGE_NAME

name of the cluster package. This name will be used to set the prompt when the current working directory is on a (moving) file system related to a cluster package.

EXAMPLES

```
#
# pkg_hostname.cfg - config file for pkg_hostname in PRODUCTION
#
# [00] 03.08.2004 CWa   Initial Version
#
```

```

#

SEE ALSO

edrcintro(1), **pkg_hostname(3)**, **getfilesystem(3)**

NOTES

The **pkg_hostname(3)** command and this configuration file was originated on HP-UX MC/ServiceGuard where the need came up to always show the user if he is in a directory related to a cluster package by changing the shell prompt.

However the **pkg_hostname(3)** is not dependent on HP-US or the MC/ServiceGuard cluster.

It can be used on any system where it is desired to show the user to which host (or alias) a directory on a certain file system is related by changing the prompt (better permanently show the user the information then relating to the idea that the user will read the documentation and knows the relationship of filesystems to applications/clusters/aliases).

NAME

zip, *zipcloak*, *zipnote*, *zipsplit* – package and compress (archive) files

SYNOPSIS

zip [-AcdDeEffghjklLmoqrSTuvVwXyz@\$] [-b *path*] [-n *suffixes*] [-t *mmddyy*] [*zipfile* [*file1* *file2* ...]] [-xi *list*]

zipcloak [-dhL] [-b *path*] *zipfile*

zipnote [-hwL] [-b *path*] *zipfile*

zipsplit [-hiLpst] [-n *size*] [-b *path*] *zipfile*

DESCRIPTION

zip is a compression and file packaging utility for Unix, VMS, MSDOS, OS/2, Windows NT, Minix, Atari and Macintosh. It is analogous to a combination of the UNIX commands *tar*(1) and *compress*(1) and is compatible with PKZIP (Phil Katz's ZIP for MSDOS systems).

A companion program (*unzip*(1L)), unpacks *zip* archives. The *zip* and *unzip*(1L) programs can work with archives produced by PKZIP, and PKZIP and PKUNZIP can work with archives produced by *zip*. *zip* version 2.1 is compatible with PKZIP 2.04. Note that PKUNZIP 1.10 cannot extract files produced by PKZIP 2.04 or *zip* 2.1. You must use PKUNZIP 2.04g or *unzip* 5.0p1 (or later versions) to extract them.

For a brief help on *zip* and *unzip*, run each without specifying any parameters on the command line.

The program is useful for packaging a set of files for distribution; for archiving files; and for saving disk space by temporarily compressing unused files or directories.

The *zip* program puts one or more compressed files into a single *zip* archive, along with information about the files (name, path, date, time of last modification, protection, and check information to verify file integrity). An entire directory structure can be packed into a *zip* archive with a single command. Compression ratios of 2:1 to 3:1 are common for text files. *zip* has one compression method (deflation) and can also store files without compression. *zip* automatically chooses the better of the two for each file to be compressed.

When given the name of an existing *zip* archive, *zip* will replace identically named entries in the *zip* archive or add entries for new names. For example, if *foo.zip* exists and contains *foo/file1* and *foo/file2*, and the directory *foo* contains the files *foo/file1* and *foo/file3*, then:

```
zip -r foo foo
```

will replace *foo/file1* in *foo.zip* and add *foo/file3* to *foo.zip*. After this, *foo.zip* contains *foo/file1*, *foo/file2*, and *foo/file3*, with *foo/file2* unchanged from before.

If the file list is specified as *-@*, *zip* takes the list of input files from standard input. Under UNIX, this option can be used to powerful effect in conjunction with the *find*(1) command. For example, to archive all the C source files in the current directory and its subdirectories:

```
find . -name "*.c" -print | zip source -@
```

(note that the pattern must be quoted to keep the shell from expanding it). *zip* will also accept a single dash ("-") as the *zip* file name, in which case it will write the *zip* file to standard output, allowing the output to be piped to another program. For example:

```
zip -r - . | dd of=/dev/nrst0 obs=16k
```

would write the *zip* output directly to a tape with the specified block size for the purpose of backing up the current directory.

zip also accepts a single dash ("-") as the name of a file to be compressed, in which case it will read the file from standard input, allowing *zip* to take input from another program. For example:

```
tar cf - . | zip backup -
```

would compress the output of the *tar* command for the purpose of backing up the current directory. This generally produces better compression than the previous example using the *-r* option, because *zip* can take

advantage of redundancy between files. The backup can be restored using the command

```
unzip -p backup | tar xf -
```

When no zip file name is given and stdout is not a terminal, *zip* acts as a filter, compressing standard input to standard output. For example,

```
tar cf - . | zip | dd of=/dev/nrst0 obs=16k
```

is equivalent to

```
tar cf - . | zip - - | dd of=/dev/nrst0 obs=16k
```

zip archives created in this manner can be extracted with the program *funzip* which is provided in the *unzip* package, or by *gunzip* which is provided in the *gzip* package. For example:

```
dd if=/dev/nrst0 ibs=16k | funzip | tar xvf -
```

When changing an existing *zip* archive, *zip* will write a temporary file with the new contents, and only replace the old one when the process of creating the new version has been completed without error.

If the name of the *zip* archive does not contain an extension, the extension *.zip* is added. If the name already contains an extension other than *.zip* the existing extension is kept unchanged.

OPTIONS

-A Adjust self-extracting executable archive. A self-extracting executable archive is created by prepending the SFX stub to an existing archive. The **-A** option tells *zip* to adjust the entry offsets stored in the archive to take into account this "preamble" data.

-b path

Use the specified *path* for the temporary *zip* archive. For example:

```
zip -b /tmp stuff *
```

will put the temporary *zip* archive in the directory */tmp*, copying over *stuff.zip* to the current directory when done. This option is only useful when updating an existing archive, and the file system containing this old archive does not have enough space to hold both old and new archive at the same time.

-c Add one-line comments for each file. File operations (adding, updating) are done first, and the user is then prompted for a one-line comment for each file. Enter the comment followed by return, or just return for no comment.

-d Remove (delete) entries from a *zip* archive. For example:

```
zip -d foo foo/tom/junk foo/harry/* *.o
```

will remove the entry *foo/tom/junk*, all of the files that start with *foo/harry/*, and all of the files that end with *.o* (in any path). Note that shell pathname expansion has been inhibited with backslashes, so that *zip* can see the asterisks, enabling *zip* to match on the contents of the *zip* archive instead of the contents of the current directory.

Under MSDOS, **-d** is case sensitive when it matches names in the *zip* archive. This requires that file names be entered in upper case if they were zipped by PKZIP on an MSDOS system.

-D Do not create entries in the *zip* archive for directories. Directory entries are created by default so that their attributes can be saved in the *zip* archive. The environment variable ZIPOPT can be used to change the default options. For example under Unix with sh:

```
ZIPOPT="-D"; export ZIPOPT
```

(The variable ZIPOPT can be used for any option except **-i** and **-x** and can include several options.) The option **-D** is a shorthand for **-x ""** but the latter cannot be set as default in the ZIPOPT environment variable.

-e Encrypt the contents of the *zip* archive using a password which is entered on the terminal in response to a prompt (this will not be echoed; if standard error is not a tty, *zip* will exit with an error). The password prompt is repeated to save the user from typing errors.

- f** Replace (freshen) an existing entry in the *zip* archive only if it has been modified more recently than the version already in the *zip* archive; unlike the update option (**-u**) this will not add files that are not already in the *zip* archive. For example:

```
zip -f foo
```

This command should be run from the same directory from which the original *zip* command was run, since paths stored in *zip* archives are always relative.

Note that the timezone environment variable TZ should be set according to the local timezone in order for the **-f**, **-u** and **-o** options to work correctly.

The reasons behind this are somewhat subtle but have to do with the differences between the Unix-format file times (always in GMT) and most of the other operating systems (always local time) and the necessity to compare the two. A typical TZ value is "MET-1METDST" (Middle European time with automatic adjustment for "summertime" or Daylight Savings Time).
- F** Fix the *zip* archive. This option can be used if some portions of the archive are missing. It is not guaranteed to work, so you **MUST** make a backup of the original archive first.

When doubled as in **-FF** the compressed sizes given inside the damaged archive are not trusted and *zip* scans for special signatures to identify the limits between the archive members. The single **-F** is more reliable if the archive is not too much damaged, for example if it has only been truncated, so try this option first.

Neither option will recover archives that have been incorrectly transferred in ascii mode instead of binary. After the repair, the **-t** option of *unzip* may show that some files have a bad CRC. Such files cannot be recovered; you can remove them from the archive using the **-d** option of *zip*.
- g** Grow (append to) the specified *zip* archive, instead of creating a new one. If this operation fails, *zip* attempts to restore the archive to its original state. If the restoration fails, the archive might become corrupted.
- h** Display the *zip* help information (this also appears if *zip* is run with no arguments).
- i files** Include only the specified files, as in:

```
zip -r foo . -i \*.c
```

which will include only the files that end in *.c* in the current directory and its subdirectories. (Note for PKZIP users: the equivalent command is

```
pkzip -rP foo *.c
```

PKZIP does not allow recursion in directories other than the current one.) The backslash avoids the shell filename substitution, so that the name matching is performed by *zip* at all directory levels.
- j** Store just the name of a saved file (junk the path), and do not store directory names. By default, *zip* will store the full path (relative to the current path).
- J** Strip any prepended data (e.g. a SFX stub) from the archive.
- k** Attempt to convert the names and paths to conform to MSDOS, store only the MSDOS attribute (just the user write attribute from UNIX), and mark the entry as made under MSDOS (even though it was not); for compatibility with PKUNZIP under MSDOS which cannot handle certain names such as those with two dots.
- l** Translate the Unix end-of-line character LF into the MSDOS convention CR LF. This option should not be used on binary files. This option can be used on Unix if the *zip* file is intended for PKUNZIP under MSDOS. If the input files already contain CR LF, this option adds an extra CR. This ensure that *unzip -a* on Unix will get back an exact copy of the original file, to undo the effect of *zip -l*.
- ll** Translate the MSDOS end-of-line CR LF into Unix LF. This option should not be used on binary files. This option can be used on MSDOS if the *zip* file is intended for *unzip* under Unix.

- L** Display the *zip* license.
- m** Move the specified files into the *zip* archive; actually, this deletes the target directories/files after making the specified *zip* archive. If a directory becomes empty after removal of the files, the directory is also removed. No deletions are done until *zip* has created the archive without error. This is useful for conserving disk space, but is potentially dangerous so it is recommended to use it in combination with **-T** to test the archive before removing all input files.
- n suffixes**
Do not attempt to compress files named with the given *suffixes*. Such files are simply stored (0% compression) in the output *zip* file, so that *zip* doesn't waste its time trying to compress them. The suffixes are separated by either colons or semicolons. For example:

```
zip -rn .Z:.zip:.tiff:.gif:.snd foo foo
```

will copy everything from *foo* into *foo.zip*, but will store any files that end in *.Z*, *.zip*, *.tiff*, *.gif*, or *.snd* without trying to compress them (image and sound files often have their own specialized compression methods). By default, *zip* does not compress files with extensions in the list *.Z:.zip:.zoo:.arc:.lzh:.arj*. Such files are stored directly in the output archive. The environment variable *ZIPOPT* can be used to change the default options. For example under Unix with *csh*:

```
setenv ZIPOPT "-n .gif:.zip"
```

To attempt compression on all files, use:

```
zip -n : foo
```

The maximum compression option **-9** also attempts compression on all files regardless of extension.
- o** Set the "last modified" time of the *zip* archive to the latest (oldest) "last modified" time found among the entries in the *zip* archive. This can be used without any other operations, if desired. For example:

```
zip -o foo
```

will change the last modified time of *foo.zip* to the latest time of the entries in *foo.zip*.
- q** Quiet mode; eliminate informational messages and comment prompts. (Useful, for example, in shell scripts and background tasks).
- r** Travel the directory structure recursively; for example:

```
zip -r foo foo
```

In this case, all the files and directories in *foo* are saved in a *zip* archive named *foo.zip*, including files with names starting with ".", since the recursion does not use the shell's file-name substitution mechanism. If you wish to include only a specific subset of the files in directory *foo* and its subdirectories, use the **-i** option to specify the pattern of files to be included. You should not use **-r** with the name ".*", since that matches "." which will attempt to zip up the parent directory (probably not what was intended).
- S** Include system and hidden files. This option is effective on some systems only; it is ignored on Unix.
- t mmddyy**
Do not operate on files modified prior to the specified date, where *mm* is the month (0-12), *dd* is the day of the month (1-31), and *yy* are the last two digits of the year. For example:

```
zip -rt 120791 infamy foo
```

will add all the files in *foo* and its subdirectories that were last modified on or after 7 December 1991, to the *zip* archive *infamy.zip*.
- T** Test the integrity of the new *zip* file. If the check fails, the old *zip* file is unchanged and (with the **-m** option) not input files are removed.

- u** Replace (update) an existing entry in the *zip* archive only if it has been modified more recently than the version already in the *zip* archive. For example:

```
zip -u stuff *
```

will add any new files in the current directory, and update any files which have been modified since the *zip* archive *stuff.zip* was last created/modified (note that *zip* will not try to pack *stuff.zip* into itself when you do this).

Note that the **-u** option with no arguments acts like the **-f** (freshen) option.
- v** Verbose mode or print diagnostic version info.

Normally, when applied to real operations, this option enables the display of a progress indicator during compression and requests verbose diagnostic info about zipfile structure oddities.

When **-v** is the only command line argument, and stdout is not redirected to a file, a diagnostic screen is printed. In addition to the help screen header with program name, version, and release date, some pointers to the Info-ZIP home and distribution sites are given. Then, it shows information about the target environment (compiler type and version, OS version, compilation date and the enabled optional features used to create the *zip* executable).
- V** Save VMS file attributes. This option is available on VMS only; *zip* archives created with this option will generally not be usable on other systems.
- w** Append the version number of the files to the name, including multiple versions of files. (VMS only; default: use only the most recent version of a specified file).
- x files** Explicitly exclude the specified files, as in:

```
zip -r foo foo -x \*.o
```

which will include the contents of *foo* in *foo.zip* while excluding all the files that end in *.o*. The backslash avoids the shell filename substitution, so that the name matching is performed by *zip* at all directory levels.
- X** Do not save extra file attributes (Extended Attributes on OS/2, uid/gid and file times on Unix).
- y** Store symbolic links as such in the *zip* archive, instead of compressing and storing the file referred to by the link (UNIX only).
- z** Prompt for a multi-line comment for the entire *zip* archive. The comment is ended by a line containing just a period, or an end of file condition (^D on UNIX, ^Z on MSDOS, OS/2, and VAX/VMS). The comment can be taken from a file:

```
zip -z foo < foowhat
```
- #** Regulate the speed of compression using the specified digit #, where **-0** indicates no compression (store all files), **-1** indicates the fastest compression method (less compression) and **-9** indicates the slowest compression method (optimal compression, ignores the suffix list). The default compression level is **-6**.
- @** Take the list of input files from standard input. File names containing spaces must be quoted using single quotes, as in 'file name'.
- \$** Include the volume label for the the drive holding the first file to be compressed. If you want to include only the volume label or to force a specific drive, use the drive name as first file name, as in:

```
zip -$ foo a: c:bar
```

This option is effective on some systems only (MSDOS and OS/2); it is ignored on Unix.

EXAMPLES

The simplest example:

```
zip stuff *
```

creates the archive *stuff.zip* (assuming it does not exist) and puts all the files in the current directory in it, in compressed form (the *.zip* suffix is added automatically, unless that archive name given contains a dot already; this allows the explicit specification of other suffixes).

Because of the way the shell does filename substitution, files starting with "." are not included; to include these as well:

```
zip stuff .* *
```

Even this will not include any subdirectories from the current directory.

To zip up an entire directory, the command:

```
zip -r foo foo
```

creates the archive *foo.zip*, containing all the files and directories in the directory *foo* that is contained within the current directory.

You may want to make a *zip* archive that contains the files in *foo*, without recording the directory name, *foo*. You can use the *-j* option to leave off the paths, as in:

```
zip -j foo foo/*
```

If you are short on disk space, you might not have enough room to hold both the original directory and the corresponding compressed *zip* archive. In this case, you can create the archive in steps using the *-m* option. If *foo* contains the subdirectories *tom*, *dick*, and *harry*, you can:

```
zip -rm foo foo/tom
zip -rm foo foo/dick
zip -rm foo foo/harry
```

where the first command creates *foo.zip*, and the next two add to it. At the completion of each *zip* command, the last created archive is deleted, making room for the next *zip* command to function.

PATTERN MATCHING

This section applies only to UNIX. Watch this space for details on MSDOS and VMS operation.

The UNIX shells (*sh*(1) and *csh*(1)) do filename substitution on command arguments. The special characters are:

- ?** match any single character
- *** match any number of characters (including none)
- []** match any character in the range indicated within the brackets (example: [a-f], [0-9]).

When these characters are encountered (without being escaped with a backslash or quotes), the shell will look for files relative to the current path that match the pattern, and replace the argument with a list of the names that matched.

The *zip* program can do the same matching on names that are in the *zip* archive being modified or, in the case of the *-x* (exclude) or *-i* (include) options, on the list of files to be operated on, by using backslashes or quotes to tell the shell not to do the name expansion. In general, when *zip* encounters a name in the list of files to do, it first looks for the name in the file system. If it finds it, it then adds it to the list of files to do. If it does not find it, it looks for the name in the *zip* archive being modified (if it exists), using the pattern matching characters described above, if present. For each match, it will add that name to the list of files to be processed, unless this name matches one given with the *-x* option, or does not match any name given with the *-i* option.

The pattern matching includes the path, and so patterns like **.o* match names that end in ".o", no matter what the path prefix is. Note that the backslash must precede every special character (i.e. *?*[]*), or the entire argument must be enclosed in double quotes ("").

In general, use backslash to make *zip* do the pattern matching with the *-f* (freshen) and *-d* (delete) options, and sometimes after the *-x* (exclude) option when used with an appropriate operation (add, *-u*, *-f*, or *-d*).

BUGS

zip 2.1 is not compatible with PKUNZIP 1.10. Use *zip* 1.1 to produce *zip* files which can be extracted by PKUNZIP 1.10.

zip files produced by *zip* 2.1 must not be *updated* by *zip* 1.1 or PKZIP 1.10, if they contain encrypted members or if they have been produced in a pipe or on a non-seekable device. The old versions of *zip* or PKZIP would create an archive with an incorrect format. The old versions can list the contents of the *zip* file but cannot extract it anyway (because of the new compression algorithm). If you do not use encryption and use regular disk files, you do not have to care about this problem.

Under VMS, not all of the odd file formats are treated properly. Only stream-LF format *zip* files are expected to work with *zip*. Others can be converted using Rahul Dhesi's BILF program. This version of *zip* handles some of the conversion internally. When using Kermit to transfer *zip* files from Vax to MSDOS, type "set file type block" on the Vax. When transferring from MSDOS to Vax, type "set file type fixed" on the Vax. In both cases, type "set file type binary" on MSDOS.

Under VMS, *zip* hangs for file specification that uses DECnet syntax *foo::*.**.

On OS/2, *zip* cannot match some names, such as those including an exclamation mark or a hash sign. This is a bug in OS/2 itself: the 32-bit DosFindFirst/Next don't find such names. Other programs such as GNU tar are also affected by this bug.

Under OS/2, the amount of Extended Attributes displayed by DIR is (for compatibility) the amount returned by the 16-bit version of DosQueryPathInfo(). Otherwise OS/2 1.3 and 2.0 would report different EA sizes when DIRing a file. However, the structure layout returned by the 32-bit DosQueryPathInfo() is a bit different, it uses extra padding bytes and link pointers (it's a linked list) to have all fields on 4-byte boundaries for portability to future RISC OS/2 versions. Therefore the value reported by *zip* (which uses this 32-bit-mode size) differs from that reported by DIR. *zip* stores the 32-bit format for portability, even the 16-bit MS-C-compiled version running on OS/2 1.3, so even this one shows the 32-bit-mode size.

On the Amiga, the -A option currently does not work.

Please send bug reports and comments by email to: *zip-bugs@wkuvx1.wku.edu*. For bug reports, please include the version of *zip* (see *zip-h*), the make options used to compile it (see *zip-v*), the machine and operating system in use, and as much additional information as possible.

ACKNOWLEDGEMENTS

Thanks to R. P. Byrne for his *Shrink.Pas* program, which inspired this project, and from which the shrink algorithm was stolen; to Phil Katz for placing in the public domain the *zip* file format, compression format, and .ZIP filename extension, and for accepting minor changes to the file format; to Steve Burg for clarifications on the deflate format; to Haruhiko Okumura and Leonid Broukhis for providing some useful ideas for the compression algorithm; to Keith Petersen, Rich Wales, Hunter Goatley and Mark Adler for providing a mailing list and *ftp* site for the INFO-ZIP group to use; and most importantly, to the INFO-ZIP group itself (listed in the file *infozip.who*) without whose tireless testing and bug-fixing efforts a portable *zip* would not have been possible. Finally we should thank (blame) the first INFO-ZIP moderator, David Kirschbaum, for getting us into this mess in the first place. The manual page was rewritten for UNIX by R. P. C. Rodgers.

NAME

pid – Invoke ps With The "Right" Switches and grep For a Pattern

SYNOPSIS

edrc/bin/pid [*process-name*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

invokes a **ps** with the "right" switches and makes a **grep** for the given pattern. The whole line of **ps** is printed to standard output.

OPTIONS

process-name

Process name which has to be checked.

EXIT STATUS

0 always

EXAMPLES

-

SEE ALSO

Name

pl

Synopsis

```
pl -prefab prefabname parm=value .. [-options]
.. OR ..
pl scriptfile [-options]
```

Description

pl is the primary component of the 'ploticus' data display package

pl is a program that produces plots and charts from data, and produces results that can be viewed on web pages, paper, slides, or interactively on the screen. Standard types of plots may be done using *prefab* plot templates, or a user-developed *script* file may be supplied for greater flexibility and customization. **pl** may be executed from the command line or as a CGI program.

For complete online docs and downloads see <http://ploticus.sourceforge.net>

Where to find examples

See the various *prefab* examples. A large number of *script* examples are also available. Some usage examples are also shown below.

Command line arguments

Command line arguments may generally be given in any order. If there are arguments that you want to always have in effect, you can invoke them from a *config* file. Many settings can also be made dynamically from scripts via *proc settings* or *proc page*. Processing occurs in this order: first the *config* file is read; then command line args are processed (left to right); then *proc page* and/or *proc settings*. Later settings override earlier ones.

Basic command line options

-prefab *prefabname*

Produce a plot using a *prefab* plot template. *prefabname* identifies the template, eg. *cron* or *vbars*. Necessary parameters are supplied on the command line using the form *parm=value*.

scriptfile

-f *scriptfile*

names a *script* file that will be interpreted to produce results. Alternatively, **-stdin** may be used to indicate that script will be available on standard input.

variable=value

Declares the named *variable* and sets it to the given *value*. This is a convenient way to pass information to *prefabs* and *scripts*. Variable names are case-sensitive.

Example: CUTDATE=10-31-98

sets the variable CUTDATE to 10-31-98.

-o *outfile* | *stdout*

Specify a filename where the result will be written. No processing is applied to this name.. so the ending should be appropriate for the selected output format, eg. use `.png` for PNG files. If `-o stdout` is used, result will be sent to standard output. If **-o** is not specified, a default output filename will be used.

Example: `-o fp001.png`

-dir *dirname*

Set ploticus' working directory to *dirname*. If used, this argument should be specified leftmost on the command line, since it affects evaluation of other args.

Result format options

(Availability depends on your ploticus configuration/build)

-png PNG image

-gif pseudo-GIF image

-jpeg JPEG image

-svg or **-svgz** SVG graphic. See also SVG / XML options below.

-swf SWF (flash) result.

-wbmp WBMP image

-eps EPS (encapsulated PostScript)

-ps paginated PostScript to stdout

-x11 display on X11 screen

-drawdump *filename* produce no visible graphic; save a generic representation of the graphic result to a file. By using `-drawdump` and `-drawdumpa` you can easily overlay or combine results from separate pl runs. The drawdump file can be rendered later in any desired format, using this command: `pl -pre-fab draw dumpfile=filename` or by using `proc draw` commands. Drawdump capability is available in all builds. (2.30+)

-drawdumpa *filename* same as `-drawdump` but result is **appended** to file.

Clickable image maps and mouseover options

-csmmap

produce a client-side clickable imagemap to accompany a png, gif, or jpeg. These can be used for hyperlinks, and also for providing pop-up text labels that appear when the mouse passes over a region. By default, client-side map content is written to stdout.

-csmmapdemo

Same as **-csmmap** but all mapped regions are shown outlined in green, and a complete HTML chunk is produced which involves the output image name.

-mapfile *filename* | stdout | stderr

explicitly name the output file containing the map info. The name may also be set in `proc` page. If a name is not specified, client-side image map info will be written to stdout; For SVG this parameter is not needed, since image map info is embedded in the SVG file.

-map

produce a server-side clickable imagemap file to accompany a png, gif, jpeg, or SVG. **Note: server-side maps are deprecated.**

Result sizing options

-scale *sx[,sy]*

Scale the final result. If one value is given, the result is scaled by this amount in both x and y. If two values are given, scaling in x and scaling in y may be done independently. A scale value of less than 1.0 reduces the size; an scale value of greater than 1.0 enlarges. Scaling is done relative to the origin (0,0) which is at the lower left.

Example: `-scale 0.7`

-pagesize *width,height*

Sets the pre-crop size of the result image for GIF/PNG/JPEG, or sets the display window size when drawing to X11. On other output devices this option does nothing. *width* and *height* are in absolute units. 0,0 is the lower left corner. If `-pagesize` is not specified, the default size will be 8" x 8". Size is set before any drawing takes place and is unaffected by the `-scale` option.

When rendering PNG/GIF/JPEG images, this option determines amount of internal memory allocation for accommodating the image. The result can never be bigger than this size, and any drawing outside the bounds will not be visible. **To create PNG/GIF/JPEG images larger than 8" x 8", this option MUST be specified to set a bigger size.** Cropping options (below) can be used along with `-pagesize` as long as they result in a smaller rectangle than the `pagesize`; they take effect after all drawing has been completed.

-pagesize has no effect with EPS or paginated PostScript results (the PostScript BoundingBox will be determined by the extent of the graphic).

Example: `-pagesize 7,3`

-tightcrop

For image or EPS output, crop the result tightly to the extent of the design. Normally a small margin is allowed on all four sides. This option sometimes crops a bit too tight; if so try **-croprel**.

-crop *x1,y1,x2,y2*

Crop image or EPS result to the box specified by *x1,y1* and *x2,y2*, in absolute units.

Note that there may be no spaces in the coordinates specification. Cropping takes place after design is rendered and does not affect coordinate locations.

Example: `-crop 1.2,0.8,4.4,5.2`

-croprel *left,bottom,right,top*

Crop image or EPS result tightly to the extent of the design (like **-tightcrop**), but then adjust the cropping outward or inward on one or more sides. *left* is the amount to adjust the left side, in absolute units. Similarly for *bottom*, *right*, and *top*. Positive values always adjust outward from center; negative values adjust inward (tighter). There may be no spaces in the *left,bottom,right,top* specification. Cropping takes place after design is rendered and does not affect coordinate locations.

Example: `-croprel 0,-0.1,0,0.1`

-pixsize *width,height*

If specified, result PNG/GIF/JPG image will be created at exactly this width and height in pixels. Does not interact with scaling or cropping... user is responsible for ensuring that content fits appropriately into the specified size. User is also responsible for setting `-pagesize` appropriately for larger images. New in 2.40

Graphics environment options

-font *font*

sets the overall font to *font*. See `fonts` for more info.

-textsize *pointsize*

sets the overall default textsize to *pointsize*. All embedded size specifications will be rendered relative to this.

-linewidth *w*

sets the overall default linewidth to *w*. All embedded line width specifications will be rendered relative to this. See `linedetails(pli)` for more on line width.

-color *color*

sets the overall default text and line drawing color to *color*.

-backcolor *color*

sets the background color to *color*.

-cm

Use centimeters as your absolute units, instead of inches. On the command line this must appear to the left of any arguments dealing with absolute unit values, such as `-pagesize`. Centimeter absolute units can also be set via `proc` settings. If `cm` will always be the desired absolute units, the preferred way to achieve this is by using `units: cm` in a `ploticus` config file.

-inches

Use inches as your absolute units. This is the default.

-outlabel *label*

Set the label or title for the output. For X11 this sets the window title; for PostScript and SVG it sets the `%%Title` attribute.

Capacity setting options

These options (new with version 2.10) allow capacities to be raised for accomodation of very large data sets, or lowered to minimize memory usage. The defaults in this section are defined in `pl.h`.

-maxrows *nrows*

Set the capacity for data rows to *nrows*. Default *nrows* is 10,000. Ploticus will allocate one pointer for each row.

-maxfields *nfields*

Set the capacity for data fields to *nfields*. Default *nfields* is 200,000. Ploticus will allocate one pointer for each field.

-maxproclines *nlines*

Set the capacity for script lines for active procs to *nlines*. Default *nlines* is 5000. Active procs are the current proc, all `#saved` procs, and all `proc getdata` procs that contain embedded data. Ploticus will allocate one pointer for each line in each active proc.

-maxvector *ncells*

Set the capacity for the data plotting vector to *ncells*. Default *ncells* is 100,000. The data plotting vector is an array which holds plottable values for situations where the values must be sorted or pre-screened for bad values. Ploticus will allocate one `double` value for each cell.

-maxdrawpoints *n*

Use this if you need to render a polygon having more than 500 points in PNG/GIF/JPEG, X11, or SWF, or any continuous line having more than 500 points in SWF.

Note: raising the maximum number of categories may be done using `proc categories` from within the script.

-cpulimit #Include nbsp2 *s*

Set unix resource limit on cpu time to *s* seconds. Default is 30 seconds. New in 2.40

SVG / XML options:

-svg_tagparms *string*

This allows arbitrary `text` to be inserted into the opening `<svg>` tag.

Example: `-svg_tagparms 'height="10cm" width="15cm"'`

-omit_xml_declaration

By default the first line of the SVG result will be the XML declaration `<?xml . . >`. Use this option to suppress the XML declaration line if the SVG result is to be embedded into a larger XML document.

-xml_encoding *method*

Set the XML character encoding method. This encoding will be indicated in the XML declaration line. The default is `iso-8859-1` which provides Latin and Western European character sets. For Unicode fonts this should be set to `utf-8` (for more discussion see the Unicode section in fonts).

-tag

Causes a suitable HTML `<EMBED>` tag to be written to standard output.

-zlevel *n*

This may be used to set the compression level to *n* for SVGZ output (0 - 9 where 9 is highest level of compression and the default).

Interactive (workstation) use options

-winloc *x,y*

Control where on the screen the upper-left corner of the X11 display window will be placed. *x* and *y* are in pixels. Example: `-winloc 200 0`

-v *command*

-viewer *command*

After generating results in the specified format, execute *command* in order to view the results on your screen. The output file will automatically be included in the *command*. For example, if a GIF file is being generated you might use this to invoke the `xv` utility: `-viewer xv`. If

PostScript is being generated you could use something like this to invoke the ghostview utility: `-viewer "gv -magstep -1"`. The given command must be available on your system and locatable in your command search path. This option may not be used with `-o stdout`.

-noshell

If specified, ploticus is prohibited from issuing any shell commands. This is a security feature useful for example when running a script that was sent to you by an unknown party. New in 2.31

Paper orientation options

-landscape

For paginated postscript, set paper orientation to landscape (oblong).

-portrait

For paginated postscript, set paper orientation to portrait.

-posteroffset *x,y*

Allows production of large-size posters made up of multiple standard sheets of paper butted together. May be used only with paginated PostScript, and should be used in combination with the `-scale` and `-textsize` options. *x,y* is the point within your result (in absolute units) that is to be placed at the lower left corner of the page. For further discussion of this, see `posters`.

Development and debugging options

-debug

Debug mode. Causes diagnostic information to be written to the diagnostic stream (stderr by default, see `-diagfile` below). Highly recommended if you are experiencing difficulty. Best to use `-debug` as the first (leftmost) argument so that it can report on all arguments gotten. Another effect of debug mode is that any temporary files are not removed upon termination.

-ping

Write the ploticus name and version number to standard output and exit. versions 2.33+

-echo [*diag* | *stdout*]

Write ploticus script lines as they are executed. Lines are written to the diagnostic stream (standard error by default) or standard output. Lines are written after variables and most script directives, including flow-of-control directives, are evaluated.

-showbad

Identify unplottable data, showing the value, and its row and field.

-diagfile *filename* | *stderr* | *stdout*

All non-error messages and output will be written to this file (default is stderr).

-errmsgpre *tag*

Allows developer to set the first portion of all ploticus error messages to *tag* for purposes of presentation or identification.

-errfile *filename* | *stderr* | *stdout*

All error messages will be written to this file (default is stderr).

-help or **-?** or **-version**

Print version number, copyright info, web site address, etc.

Output file names

The output file may be specified on the command line using the **-o** option, or via Proc Page's `outfilename` attribute. If so, the result is written to a file of that name. `-o stdout` may also be used to send result to standard output.

Otherwise, if your script filename has a "recognized extension" (**.p**, **.pl**, **.plo**, **.pls**, **.htm** or **.html**), the base part of the script file name is used and **.png**, **.gif**, etc. is appended. If your script filename doesn't have a recognized extension, the generic name `out.*` will be used.

X11 output is always displayed on the screen, and paginated PostScript is written to standard output unless `-o` is used.

If page breaks (Proc Page) are encountered when rendering in any format other than paginated PostScript, special action is necessary since each page must go into a separate file. A Proc Page `outfilename` may be specified for each page; otherwise a `pn` prefix will be attached to the beginning of each page's output file name to indicate page *n*.

If a `clickmap` is being generated, the result file is named similarly to the above.

Usage examples

The following example uses the `scat` prefab:

```
pl -prefab scat -png datafile=results.dat x=2 y=3
```

The following examples assume that you have a script file called `lineplot1.p`.

```
pl -x lineplot1.p = view on X11 screen
pl -png lineplot1.p = create PNG image lineplot1.png
pl -gif lineplot1.p -o stdout = create GIF image on standard output
pl -gif lineplot1.p -viewer xv = produce GIF and view using xv (assuming xv
image viewer is available on your system).
```

```

pl -eps lineplot1.p = produce EPS file lineplot1.eps
pl -eps lineplot1.p -viewer gv = produce EPS and view using gv (that's ghostview,
assuming it is available on your system).
pl -eps lineplot1.p -o lineplot.eps = produce EPS into file lineplot.eps
pl -ps lineplot1.p | lp = produce paginated postscript and send to unix lp print
spooler.
pl -ps lineplot1.p -viewer gv = produce paginated postscript and view using ghost-
view.

```

Environment

PLOTICUS_CONFIG

The name of a ploticus configuration file, for setting default date notations, number notations, measurement units, etc.

PLOTICUS_PREFABS

The path name of a directory where ploticus will look for prefab scripts. The "factory" prefabs are located in the ploticus ./prefabs subdirectory.

LC_CTYPE, LC_COLLATE, LANG

Locale support. Thanks to Oleg Bartunov oleg@sai.msu.su for contributing this. **pl** must be built with -DLOCALE for this to work.

TDH_ERRMODE

Control the disposition of error messages. Allowable values: `stderr` which is the default, and `cgi` which causes error messages to be written to stdout with html formatting.

Bugs

Ploticus has some stated limitations (mostly related to capacities that you may run into if you're dealing with large data sets). To report problems or get help see the ploticus support page.

Author, Copyright, Licensing

The primary author is Stephen C. Grubb. Ploticus covered by the General Public License (GPL)... please see the ploticus copyright page for more info.

NAME

pmdesc – List name, version, and description of all installed perl modules and PODs

SYNOPSIS

```
pmdesc [-h]

pmdesc [-s] [-t ddd] [-v dd] [--] [dir [dir [dir [...]]]]

pmdesc [-s] [-d] [--] [dir [dir [dir [...]]]]
```

DESCRIPTION

Find name, version and description of all installed Perl modules and PODs. If no directories given, searches @INC. The first column of the output (see below) can be used as module name or FAQ-name for perldoc.

Some modules are split into a pm-file and an accompanying pod-file. The version number is always taken from the pm-file.

The description found will be cut down to a length of at most 150 characters (prevents slurping in big amount of faulty docs).

Output

The output looks like this:

```
:
:
IO::Socket          (1.28)  Object interface to socket communications
IO::Socket::INET    (1.27)  Object interface for AF_INET domain sockets
IO::Socket::UNIX    (1.21)  Object interface for AF_UNIX domain sockets
IO::Stty            (n/a)   <description not available>
IO::Tty             (1.02)  Low-level allocate a pseudo-Tty, import constants.
IO::Tty::Constant   (n/a)   Terminal Constants (autogenerated)
:
:
```

The three parts module name, version and description are separated by at least one blank.

OPTIONS

-h print help message; show search path

-s sort output (not under Windows)

-d csv output

-t ddd name column has width ddd (1–3 digits); default 52

-v dd version column has width dd (1–2 digits); default 16

REQUIREMENTS

ExtUtils::MakeMaker, File::Find, Getopt::Std

BUGS AND LIMITATIONS

The command line switch `-s` (sort) is not available under non-UNIX operating systems. An additional shell sort command can be used.

There are no known bugs in this module.

Please report problems to Fritz Mehner, mehner@fh-swf.de.

AUTHORS

Tom Christiansen, tchrist@perl.com (pmdesc)

Aristotle, <http://qs321.pair.com/~monkads/> (pmdesc2)

Fritz Mehner, mehner@fh-swf.de (pmdesc3.pl)

SEE ALSO

[edrcintro\(1\)](#), [csv\(3\)](#), [lspm\(1\)](#), [perlenv\(3\)](#), [perl_modules\(3\)](#)

NOTES

pmdesc is based on pmdesc2 (Aristotle, <http://qs321.pair.com/~monkads/>). pmdesc adds extensions and bugfixes.

pmdesc2 is based on pmdesc (Perl Cookbook, 1. Ed., recipe 12.19). pmdesc2 is at least one magnitude faster than pmdesc.

VERSION

1.2.3

NAME

pod2html – convert .pod files to .html files

SYNOPSIS

```
pod2html --help --htmldir=<name> --htmlroot=<URL>
        --infile=<name> --outfile=<name>
        --podpath=<name>:...:<name> --podroot=<name>
        --cachedir=<name> --flush --recurse --norecurse
        --quiet --noquiet --verbose --noverbose
        --index --noindex --backlink --nobacklink
        --header --noheader --poderrors --nopoderrors
        --css=<URL> --title=<name>
```

DESCRIPTION

Converts files from pod format (see `perlpod`) to HTML format.

ARGUMENTS

pod2html takes the following arguments:

help

 --help

Displays the usage message.

htmldir

 --htmldir=name

Sets the directory to which all cross references in the resulting HTML file will be relative. Not passing this causes all links to be absolute since this is the value that tells Pod::Html the root of the documentation tree.

Do not use this and `--htmlroot` in the same call to pod2html; they are mutually exclusive.

htmlroot

 --htmlroot=URL

Sets the base URL for the HTML files. When cross-references are made, the HTML root is prepended to the URL.

Do not use this if relative links are desired: use `--htmldir` instead.

Do not pass both this and `--htmldir` to pod2html; they are mutually exclusive.

infile

 --infile=name

Specify the pod file to convert. Input is taken from STDIN if no infile is specified.

outfile

 --outfile=name

Specify the HTML file to create. Output goes to STDOUT if no outfile is specified.

podroot

 --podroot=name

Specify the base directory for finding library pods.

podpath

 --podpath=name:...:name

Specify which subdirectories of the podroot contain pod files whose HTML converted forms can be linked-to in cross-references.

cachedir

--cachedir=name

Specify which directory is used for storing cache. Default directory is the current working directory.

flush

--flush

Flush the cache.

backlink

--backlink

Turn =head1 directives into links pointing to the top of the HTML file.

nobacklink

--nobacklink

Do not turn =head1 directives into links pointing to the top of the HTML file (default behaviour).

header

--header

Create header and footer blocks containing the text of the “NAME” section.

noheader

--noheader

Do not create header and footer blocks containing the text of the “NAME” section (default behaviour).

poderrors

--poderrors

Include a “POD ERRORS” section in the outfile if there were any POD errors in the infile (default behaviour).

nopoderrors

--nopoderrors

Do not include a “POD ERRORS” section in the outfile if there were any POD errors in the infile.

index

--index

Generate an index at the top of the HTML file (default behaviour).

noindex

--noindex

Do not generate an index at the top of the HTML file.

recurse

--recurse

Recurse into subdirectories specified in podpath (default behaviour).

norecurse

--norecurse

Do not recurse into subdirectories specified in podpath.

css

--css=URL

Specify the URL of cascading style sheet to link from resulting HTML file. Default is none style sheet.

title

--title=title

Specify the title of the resulting HTML file.

quiet

--quiet

Don't display mostly harmless warning messages.

noquiet

--noquiet

Display mostly harmless warning messages (default behaviour). But this is not the same as "verbose" mode.

verbose

--verbose

Display progress messages.

noverbose

--noverbose

Do not display progress messages (default behaviour).

NAME

portscan – scan for open ports on host from min to max

SYNOPSIS

edrc/lib/portscan [**-h**]

portscan *host* [*min* [*max*]]

AVAILABILITY

WA2L/edrc

DESCRIPTION

scan a target system for active ports.

It is possible to specify the minimum port where the scan should start and the maximum port number where the scan should stop.

Ports that are active are returned to **stdout**.

The port is scanned by connecting to the target system using the given port using a timeout of 1 second.

OPTIONS

-h print usage message.

host hostname.

min minimum port number.

If the minimum port number is not given, the default of 0 is used.

max maximum port number.

If the maximum port number is not given, the default of 65000 is used.

ENVIRONMENT

-

EXIT STATUS

| | |
|----------|---------------------------|
| 0 | no error. |
| 1 | cannot resolve host name. |
| 2 | cannot create socket. |
| 4 | usage message printed. |

FILES

-

EXAMPLES

-

SEE ALSO

edrcintro(1), **gethostbyname(1)**, **ping(8)**

NOTES

-

BUGS

sometimes open ports are not reported.

IPv6 is not supported yet.

AUTHOR

portscan was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

print_header – print a standard report header

SYNOPSIS

edrc/lib/print_header [**-h**]

print_header ["*report title*" [*indent* [*add_hostname*]]]

AVAILABILITY

WA2L/edrc

DESCRIPTION

print a standard report header to the terminal. The report header consists of the report title, the customer, the environment and the date of the report creation.

The customer and the environment part are resolved by **server_environment(3)** internally.

The output is limited to the current terminal width if the environment variable **\$PRINT_FIT2WIDTH** is not set to *False*.

OPTIONS

-h usage message.

"report title"
title of the report. The specified text is converted to upper case.

indent left indent of the output in characters. If not specified the output is not indented.

add_hostname
set to **True** to add a **Hostname:** ... entry after the **Environment:** ... line.

ENVIRONMENT

\$PRINT_FIT2WIDTH

If this environment variable is not set to *False*, the output is limited to the current width of the terminal window and rows extending the window width are marked with '>>'.

EXIT STATUS

0 no error.

4 usage displayed.

FILES

-

EXAMPLES

1) print a user account report to the terminal

This report is intended to be viewed on the terminal. All lines extending the terminal window width will be cut an marked with '>>' to show that there is hidden information.

```
#!/bin/sh
:
:
print_header "LOCAL USER ACCOUNTS"

{
    echo USERNAME:PASSWD:UID:GID:COMMENT:HOMEDIR:SHELL
    cat /etc/passwd
} | print_list ":"
:
:
```

The output of this example will look similar to:

```
Report:      LOCAL USER ACCOUNTS
Customer:    ACME
Environment: [PRODUCTION] ACME Corporation, Swit >>
Date:        Sun Jan 11 19:44:53 MET 2009

USERNAME     PASSWD  UID   GID   COMMENT  >>
-----
root         x       0     3     root     >>
bin          x       1     1     bin      >>
daemon      x       2     2     daemon   >>
adm          x       3     4     adm      >>
lp          x       4     7     lp        >>
sync        x       5     0     sync     >>
shutdown    x       6     0     shutdown >>
halt        x       7     0     halt     >>
(8)
```

2) create a user account report to be saved to a file

This report is intended to be saved to a file. This is why the environment variable **\$SPRINT_FIT2WIDTH** is set to *False* in this example.

```
#!/bin/sh
:
:
PRINT_FIT2WIDTH=False; export PRINT_FIT2WIDTH
print_header "LOCAL USER ACCOUNTS"

{
    echo USERNAME:PASSWD:UID:GID:COMMENT:HOMEDIR:SHELL
    cat /etc/passwd
} | print_list ":"
:
:
```

SEE ALSO

edrcintro(1), **csv(3)**, **csvcat(3)**, **print_list(3)**, **print_index(3)**, **select_columns(3)**

NOTES

The four commands **print_header(3)**, **select_columns(3)**, **print_header(3)** and **print_index(3)** provide the functionality to efficiently produce ASCII reports having an identical look.

BUGS

-

AUTHOR

print_header was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

print_index – print a standard column index

SYNOPSIS

edrc/lib/print_index [-h]

print_index ["*field separator*" [*indent* [*columns* [*fixwidth* [*nospace*]]]]]

AVAILABILITY

WA2L/edrc

DESCRIPTION

print a standard report column index to the terminal.

The output is limited to the current terminal width if the environment variable **\$PRINT_FIT2WIDTH** is not set to *False*.

OPTIONS

-h usage message.

"field separator"

field separator of the input data given via **stdin**. If not specified, the field separator defaults to the semicolon (;).

indent left indent of the output in characters. If not specified the output is not indented.

columns number of columns of the column index output. If not specified a default of 2 applies.

fixwidth set to **False** for dynamic description column with, else (**True**) all columns have the identical width.

nospace set to **True** to eliminate tailing spaces at index lines, else (**False**) all lines have the identical width filled with tailing spaces.

ENVIRONMENT

\$PRINT_FIT2WIDTH

If this environment variable is not set to *False*, the output is limited to the current width of the terminal window and rows extending the window width are marked with '>>'.

EXIT STATUS

| | |
|----------|------------------|
| 0 | no error. |
| 4 | usage displayed. |

FILES

-

EXAMPLES**1) print a column index to the terminal**

This report is intended to be viewed on the terminal. All lines extending the terminal window width will be cut and marked with '>>' to show that there is hidden information.

```
#!/bin/sh
:
:
cat<<EOM | print_index
ZIP;Postal Zip Code
CITY;Name of the City
STATE;State
CNT;Country Shortcut
COUNTRY; Country Full Name
EOM
:
:
```

Result of this script when the terminal window width is smaller than the output width:

COLUMN INDEX:

```
ZIP ..... Postal Zip Code      CNT ..... >>
CITY ..... Name of the City    COUNTRY .. >>
STATE ..... State
```

2) print a column index to be saved to a file

This report is intended to be saved to a file. This is why the environment variable **\$PRINT_FIT2WIDTH** is set to *False* in this example.

```
#!/bin/sh
:
:
PRINT_FIT2WIDTH=False; export PRINT_FIT2WIDTH

cat<<EOM | print_index
ZIP;Postal Zip Code
```

```
CITY;Name of the City
STATE;State
CNT;Country Shortcut
COUNTRY; Country Full Name
EOM
:
:
```

SEE ALSO

edrcintro(1), **print_header(3)**, **print_list(3)**, **select_columns(3)**

NOTES

The four commands **print_index(3)**, **select_columns(3)**, **print_index(3)** and **print_index(3)** provide the functionality to efficiently produce ASCII reports having an identical look.

BUGS

-

AUTHOR

print_index was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

print_list – format CSV data to a list with dynamic column widths

SYNOPSIS

edrc/lib/print_list [-h]

print_list ["*field_separator*" [*indent*]]

AVAILABILITY

WA2L/edrc

DESCRIPTION

the intention of this command is to print a list to a terminal in a good readable format. A CSV data provided via pipe from **stdin** is formatted and printed to **stdout**.

The first row is treated as header row. The width of all columns is dynamically adjusted to the row containing the longest column entry.

Text columns are aligned to the left, bare number columns are aligned to the right.

Furthermore the output is limited to the current terminal width if the environment variable **\$PRINT_FIT2WIDTH** is not set to *False*.

To select named columns from the CSV data prior to the formatting of the list with **print_list** use **select_columns(3)**.

OPTIONS

-h usage message.

"*field_separator*"
field separator. If not specified, the default field separator is the semicolon (;).

indent left indent of the output in characters. If not specified the output is not indented.

ENVIRONMENT

\$PRINT_FIT2WIDTH

If this environment variable is not set to *False*, the output is limited to the current width of the terminal window and rows extending the window width are marked with '>>'.

EXIT STATUS

| | |
|----------|------------------|
| 0 | no error. |
| 4 | usage displayed. |

FILES

-

EXAMPLES**1) print CSV data as formatted list**

The following CSV data received via pipe

```
cat<<EOM | print_list
ZIP;CITY;STATE;CNT;COUNTRY
93117;Goleta;CA;USA;United States of America
8222;Beringen;SH;CH;Switzerland
8005;Cape Town;WC;RSA;South Africa
EOM
```

results in the output:

| ZIP | CITY | STATE | CNT | COUNTRY |
|-------|-----------|-------|-----|--------------------------|
| ---- | ----- | ----- | --- | ----- |
| 93117 | Goleta | CA | USA | United States of America |
| 8222 | Beringen | SH | CH | Switzerland |
| 8005 | Cape Town | WC | RSA | South Africa |

(3)

2) print selected columns of CSV data as formatted list

The columns CNT, ZIP and CITY of the CSV data are selected using the **select_columns(3)** command and then formatted to a list using the **print_list** command

```
cat<<EOM | select_columns ";" "CNT;ZIP;CITY" | print_list
ZIP;CITY;STATE;CNT;COUNTRY
93117;Goleta;CA;USA;United States of America
8222;Beringen;SH;CH;Switzerland
8005;Cape Town;WC;RSA;South Africa
EOM
```

what will result in the output:

| CNT | ZIP | CITY |
|-----|-------|----------|
| --- | ----- | ----- |
| USA | 93117 | Goleta |
| CH | 8222 | Beringen |

print_list(3)

Library Commands

print_list(3)

RSA 8005 Cape Town
(3)

SEE ALSO

edrcintro(1), **csv(3)**, **csvcat(3)**, **print_header(3)**, **print_index(3)**, **select_columns(3)**

NOTES

The four commands **print_header(3)**, **select_columns(3)**, **print_list(3)** and **print_index(3)** provide the functionality to efficiently produce ASCII reports having an identical look.

BUGS

-

AUTHOR

print_list was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

version, msg – general program functions

SYNOPSIS

```
#define PROGNAME "mycommand"
#define PROGVERSION "1.0.07"
#define PROGAUTHOR "John Doe"

#include "program.h"

void version();

void msg(char *level, char *format, ...);
```

AVAILABILITY

WA2L/edrc

DESCRIPTION

program.h provides general program functions.

msg()

return a structured message to **stderr**.

Example:

```
msg("error", "cannot open file '%s' defined in line number '%d'\n", filename,
```

Output:

```
mycommand-ERROR: cannot open file 'config.cfg' defined in line number '16'
```

version()

print program version information.

The program name, version and author is printed from the **PROGVERSION**, **PROGNAME**, and **PROGAUTHOR** defines.

The output of the program name and version is printed **stdout**, the program author is printed to **stderr**.

Example:

```
version();
```

Output:

```
mycommand 1.0.07 John Doe
```

NAME

pscount – count operating systems processes

SYNOPSIS

edrc/lib/pscount [**-h**]

cat *ps_list* | **pscount**

pscount < *ps_list*

cat *ps_list* | **pscount** [**-l**] [**-d** *delimiter*] [**-i** *indent*] [**-f** *processfile*]

cat *ps_list* | **pscount** { **-s** | **-u** } [**-d** *delimiter*] [**-f** *processfile*]

pscount -p [**-d** *delimiter*] [**-f** *processfile*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

count processes and evaluate if the situation correlates to a defined situation as received thru **stdin**.

This command is intended to be used to check if the correct number of needed processes for an application are running on the system.

The format of the process count selection definition *ps_list* is:

MIN;*MAX*;*DESCRIPTION*;*USER*;*PROCESS_SELECTION*;

where

MIN Minimum number of processes that are expected (integer number). If there is no defined minimum, this field should be left empty. It is allowed to use spaces in the *MIN* field to align the numbers.

MAX Maximum number of processes that are expected (integer number). If there is no defined maximum, this field should be left empty. It is allowed to use spaces in the *MAX* field to align the numbers.

DESCRIPTION

Description of the selected processes.

USER

Username of the selected processes. This is a regular expression. If there is no defined user, this field can be left empty.

PROCESS_SELECTION

Process selection. This is a regular expression. When using the **pscount -p** command to get a first start for the *ps_list*, be aware, that there might be needed some more escaping of regular expression terms in addition to the ones given by the command output.

OPTIONS

- h** usage message.
- l** long output. Beside the **DESCRIPTION**, **MIN**, **MAX**, **CURRENT** and **STATE** columns, the **USER** and **PROCESS_SELECTION** columns are also printed.
- u** print processes not matched by any count selection. This is a verification function to help to check if all processes that relate to an application are selected in the process selection list.
- s** silent, no text output of counting result, only set the **EXIT STATUS**.
- p** print process list based on system. This output can be used to generate a process count selection definition or a *filename.kp* (known process) file.

The header line 'MIN;MAX;DESCRIPTION;USER;PROCESS_SELECTION;' can be kept in the **.kp* file, it does not influence the counting.

To print a nice formatted output of the 'known process' file, the command **pscount -p | csv list** can be used.
- d *deliminator*** record deliminator.
- i *indent*** left indent of output.
- f *processfile*** read the processes from a file instead directly from the system.

The format of the process file is the output created by the command **ps -eww -o user,command** on Linux and **ps -e -o user,command** on other operating systems.

ENVIRONMENT

-

EXIT STATUS

- 0** number of processes on the system are as defined.
- 1** number of processes on the system are different from the provided definition.

- 2 Operating system not supported. See **osid(3)** if you get this error.
- 4 usage printed.
- 5 program aborted.
- 11 a temporary directory could not be claimed or created in **/tmp**. Check the system temporary directory **/tmp** if you get this error, it is an indicator of system intrusion.

FILES

edrc/var/pscount/

base directory for the 'known process' files. The ***.kp** files are read when using the **pscount -p** command.

edrc/var/pscount/apps/<Application>.kp

in the **app** directory, application related ***.kp** files are saved.

edrc/var/pscount/os/<OSID>.kp

in the **os** directory, operating system related ***.kp** files are saved. The filename must be as returned by the **osid(3)** command.

edrc/var/pscount/template.kp

template ***.kp** file to be used for application or operating system 'known process' files. To efficiently create a 'known process' file of for a running system, use the **pscount -p > filename.kp** command and edit the *filename.kp* file.

EXAMPLES

1) count processes using the 'in here' mechanism (e.g. in a script)

```
cat << EOM | pscount
1; 1;Oracle Listener ;oracle;./tnslsnr LISTENER .+;
1;10;Oracle DB Writer;oracle;ora_dbw[0-9]_ACMEDB;
1; ;Oracle Connects ;oracle;oracleACMEDB .+;
EOM
```

| DESCRIPTION | MIN | MAX | CURRENT | STATE |
|------------------|-----|-----|---------|-------|
| ----- | --- | --- | ----- | ----- |
| Oracle Listener | 1 | 1 | 1 | OK |
| Oracle DB Writer | 1 | 10 | 2 | OK |
| Oracle Connects | 1 | | 0 | FAIL |
| *TOTAL* | 3 | 11 | 3 | FAIL |

(4)

2) count processes based on an input file

Process count definition list saved in a file:

```
cat ACME_DBs.kp
```

```
#
# ACME_DBs.kp - Process List for ACME Databases
#
# [00] 20.12.2012 CWa Initial Version
#
1; 1;Oracle Listener ;oracle;./tnslsnr LISTENER .+;
1;10;Oracle DB Writer;oracle;ora_dbw[0-9]_ACMEDB;
1; ;Oracle Connects ;oracle;oracleACMEDB .+;
```

Use the process count definition list thru a pipe:

```
cat ACME_DBs.kp | pscount
```

| DESCRIPTION | MIN | MAX | CURRENT | STATE |
|------------------|-----|-----|---------|-------|
| Oracle Listener | 1 | 1 | 1 | OK |
| Oracle DB Writer | 1 | 10 | 2 | OK |
| Oracle Connects | 1 | | 5 | OK |
| *TOTAL* | 3 | 11 | 8 | OK |

or use the process count definition list thru input redirection:

```
pscount -l < ACME_DBs.kp
```

| DESCRIPTION | MIN | MAX | CURRENT | STATE | USER | PROCESS_SELECTION |
|------------------|-----|-----|---------|-------|--------|----------------------|
| Oracle Listener | 1 | 1 | 1 | OK | oracle | ./tnslsnr LISTENER . |
| Oracle DB Writer | 1 | 10 | 2 | OK | oracle | ora_dbw[0-9]_ACMEDB |
| Oracle Connects | 1 | | 5 | OK | oracle | oracleACMEDB .+ |
| *TOTAL* | 3 | 11 | 8 | OK | | |

SEE ALSO
edrcintro(1), csv(3), osid(3), pslist(3)

NOTES
The **pscount** command uses the **pslist(3)** command internally to resolve the processes.

NAME

psjoin – concatenate PostScript files

SYNOPSIS

edrc/bin/psjoin [**-h**]

psjoin [**-a**] [**-s**] [**-p**] *files...*

AVAILABILITY

WA2L/edrc

DESCRIPTION

join concatenates several PostScript files and generate a single PostScript document. The output, concatenated PostScript document, will be written to the standard output.

The input PostScript files must comply with the DSC (Document Structuring Convention). **psjoin** can fail to work depends to the input PostScript file or combination of the input PostScript files.

OPTIONS

- h** usage message.
- a** Align first page of each documents to odd page, by inserting extra blank page after odd-paged documents - maybe useful when concatenating two-sided documents.
- s** Try to close unclosed save operators in the input files. This option may be useful when input PostScript files have save operators which doesn't have corresponding restore operators, and the joined PostScript file causes "limitcheck" PostScript error due to too deeply nested save operators.
- p** Force insert corresponding PostScript prolog/trailer codes into all pages. Normally, to reduce the size of the output file, **psjoin** try not to insert largest prolog/trailer codes repeatedly.

ENVIRONMENT

-

EXIT STATUS

0 no error.

2 unknown option.

FILES

-

EXAMPLES

NAME

pslist – list selected processes

SYNOPSIS

edrc/bin/pslist [**-h**]

pslist [*select_opts*] [**-l** | **-H**]

pslist [*select_opts*] [**-H**] [**-o** *output_format*]

select_opts ::= [**-u** *user*] [**-g** *group*] [**-p** *pid*] [**-P** *ppid*] [**-t** *tty*] [**-c** "*command*"]

AVAILABILITY

WA2L/edrc

DESCRIPTION

list selected processes in a cross operating system compatible format.

If the long (**-l**) or the output format option (**-o** *fmt*) is not used, only a list of the process-ids (**PID**) of the selected processes is printed. This might be useful when a certain set of processes have to be killed in a script.

All *select_opts* options provided are used to select the corresponding column(s) on the process table without the need of taking care, that also other column(s) might have the identical entry.

Therefore the command to list all PIDs of user *jdoue*:

```
ps -ef | egrep -v egrep |\
egrep -e '^jdoue[^\ ]+.*' |\
awk '{ print $3 }'
```

can be replaced by:

```
pslist -u jdoue
```

All selection option arguments (**-u**, **-g**, **-p**, **-P**, **-t**, **-c**) can also be regular expressions. If the selection argument contains spaces, it has to be quoted.

When no selection option is used, the whole process table is printed.

OPTIONS

-h usage message.

-H print the process table column headers depending on the output. By default the header is not printed. The header goes to **stderr**, while the process list output goes to **stdout**.

-l long list output. When this option is used header and the columns of the process table as explained below are printed.

Therefore the **-l** option is equal to the command call: **pslist -H -o user,group,pid,ppid,TTY,command**.

Columns:

USER effective user name. This will be the textual user ID if it can be obtained, the decimal representation otherwise.

GROUP effective group ID of the process. This will be the textual group ID if it can be obtained, the decimal representation otherwise.

PID process ID number of the process.

PPID parent process ID.

TTY controlling tty (terminal).

COMMAND

command with all its arguments as a string. Modifications to the arguments may be shown. The output in this column may contain spaces.

-u *username*
username (USER) of the process to be selected.

-g *groupname*
groupname (GROUP) of the process to be selected.

-p *process-id*
process-id (PID) to be selected.

-P *parent-process-id*
parent-process-id (PPID) to be selected.

-t *Tty* tty of the process (TT) to be selected.

-c "*command*"
command including arguments (COMMAND) of the process to be selected. The *command* has to be quoted, if the command selection contains spaces.

-o *output_format*
define the **pslist** output format. The *output_format* is a comma separated list of columns of the process table to be printed. The field names are: *user*, *group*, *pid*, *ppid*, *TTY*, *command*. The output is separated by one tabulator.

To produce a nice looking output, use **print_list(3)** to format the output of **pslist**:

```
pslist -l 2>&1 | print_list "\t"
```

or

```
pslist -H -o user,pid,ppid,command 2>&1 | \  
print_list "\t"
```

ENVIRONMENT

-

EXIT STATUS

4 usage printed

0 no error

FILES

-

EXAMPLES

-

SEE ALSO

edrcintro(1), **ps(3)**, **pscount(3)**, **pstree(1)**, **regexintro(4)**, **xpid(1)**

NOTES

On Sun Solaris, only the processes related to the global zone are selected, therefore the processes of running zones on a global zone are not selected when **pslist** is started on the global zone. On zones the processes of the zone are listed.

Parts of the process table columns description were extracted from the **ps(1)** man page for procps version 2.0.7, written by Michael K. Johnson <johnsonm@redhat.com> that is distributed with RedHat Linux 7.2.

BUGS

pslist was successfully tested on: HPUX 11.11, HPUX 11.31, RedHat Linux 7.2, Suse Linux, Solaris 10.

AUTHOR

pslist was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

ps2pdf – Convert PostScript to PDF using Ghostscript

SYNOPSIS

ps2pdf [options...] {input.[e]ps|-} [output.pdf|-]

AVAILABILITY

WA2L/edrc

DESCRIPTION

The **ps2pdf** command is a work-alike for nearly all the functionality (but not the user interface) of Adobe's Acrobat(TM) Distiller(TM) product: they convert PostScript files to Portable Document Format (PDF) files.

If the *output* filename is not specified, the output is placed in a file of the same name with a **'pdf'** extension in the current working directory. Either the *input* filename or the *output* filename can be **'-'** to request reading from **stdin** or writing to **stdout**, respectively, when used as a filter.

- **ps2pdf** per se currently produces PDF 1.4 output. However, this may change in the future. If you care about the compatibility level of the **output**, use the **-dCompatibilityLevel=1.x** switch in the command line.

There are some limitations in **ps2pdf**'s conversion. See the HTML documentation for more information. A large number of Adobe Distiller(TM) parameters which can be used to control the conversion are also documented there, including instructions for generating PDF/X and PDF/A documents.

OPTIONS

The **ps2pdf** command uses the same options as **gs(3)**.

EXAMPLES

Converting a *figure.ps* to *figure.pdf*:

```
ps2pdf figure.ps
```

A conversion with more specifics:

```
ps2pdf -dPDFSETTINGS=/prepress figure.ps proof.pdf
```

Converting as part of a pipe:

```
make_report.pl -t ps | ps2pdf -dCompatibilityLevel=1.3 - - | lpr
```

SEE ALSO

edrcintro(1), **gs(3)**, <https://ghostscript.readthedocs.io/en/latest/Use.html>, <https://ghostscript.readthedocs.io/en/latest/Use.html#convert-a-postscript-document-to-pdf>, <https://ghostscript.com/>

BUGS

See <http://bugs.ghostscript.com/> and the Usenet news group comp.lang.postscript.

VERSION

This document was last revised for Ghostscript version 10.00.

AUTHOR

Artifex Software, Inc. are the primary maintainers of Ghostscript. This manpage by George Ferguson.

This manpage of **ps2pdf** has been adapted from the original to reflect the integration into WA2L/edrc by Christian Walther. Send suggestions and bug reports regarding the integration to wa2l@users.sourceforge.net.

NAME

pstree – print a process tree

SYNOPSIS

edrc/bin/pstree [**-h**]

pstree [**-p** | **-r**] [*pid* | *processname*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

print a tree of processes and the dependent sub-processes. Beside the process-ids, the process command is printed.

If no starting process-id (*pid*) is specified, the process tree is started beginning by the root process-id, else the tree starts with the specified *pid*.

OPTIONS

-h usage message.

-p print a list of the process-ids participating on the selected process tree.

-r print a list of the process-ids participating on the selected process tree in reverse order. This output can be used to kill processes of a process tree from leaf-to-root.

pid process-id of the process from which the process tree should start.

processname
processname from where to start the process tree.

The processname is the first process-id returned by the **pslist -c "processname"** command. Therefore the *processname* is a regular expression.

ENVIRONMENT

-

EXIT STATUS

| | |
|-----------|---|
| 0 | no error. |
| 1 | error. |
| 2 | operating system not supported. See osid(3) if you get this error. |
| 4 | usage printed. |
| 5 | the pstree command was aborted (pressing Ctrl+C). |
| 11 | temporary directory could not be claimed in /tmp/ , check the system if this error occurs, it is a sign of system intrusion. |

NAME

psup – start edrc with a special Production Support configuration

SYNOPSIS

edrc/bin/psup [**-h** | **-V**]

psup [**-s**] [**-t**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

Short start of **edrc** with an other configuration which points to an own script tree. Internally **psup** calls **edrc -c edrc.psup.cfg -n PSUP_@ID@** .

psup stands for "Production SUPport".

The session name (as shown in the menu) is automatically set to **PSUP_<id>** . Where **<id>** is the process id of the started **edrc** instance if not already a session with the same name exists, if so the **<id>** is set to a random number.

If additional short starts are needed, create a symlink from the new short start command to **sat** (see section **EXAMPLES**).

OPTIONS

-h usage message.

-V print version and patch level of **edrc** For an explanation of the release numbering system see **edrcrevision(1)**.

-s silent startup. Startup without showing the EDRC banner.

-t no terminal initialization. Sometimes the terminal initialization causes unwanted behavior. To skip terminal initialization, invoke **edrc** with this option.

ENVIRONMENT

-

EXIT STATUS

see **edrc(1m)**.

FILES

etc/edrc.psup.cfg

configuration file of **psup**, see **edrc.cfg(4)** for more information.

Other files see section **FILES** in **edrc(1m)**.

EXAMPLES**1) create a new short start**

This creates a new short start command **new_shortstart** that will load the configuration file **edrc.new_shortstart.cfg**. The session name will automatically be set to **NEW_SHORTSTART_<id>** .

```
[ /root ]
[ root@rh7mzv7t001 ] [bash]: cd ~edrc/bin

[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ] [bash]: ln -s sat new_shortstart
```

SEE ALSO

sat(1), **edrc(1m)**, **edrc.cfg(4)**, **edrcintro(1)**, **edrcrevision(1)**

NOTES

-

BUGS

-

AUTHOR

psup was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net .

NAME

purgetemp – purge temporary directories created by maketemp

SYNOPSIS

edrc/lib/purgetemp [**-h**]

purgetemp [**-s** *scriptname*] [**-q**] **-d** *directory*

AVAILABILITY

WA2L/edrc

DESCRIPTION

purge (=remove) all temporary directories that have the state **IS_ACTIVE=False** starting at a given *directory* (as listed by **listtemp -d directory**) created by **maketemp**(3).

Directories not created by **maketemp** will not be removed by the **purgetemp** command.

Use the **listtemp**(3) command to list the state of temporary directories created by **maketemp**.

OPTIONS

-h usage message.

-s *scriptname*
 scriptname in message output of **purgetemp**.

-q quiet, no message output.

-d *directory*
 temporary base directory as specified in the **listtemp** command.

See section **EXAMPLES** for additional information.

ENVIRONMENT

-

EXIT STATUS

0 no error.

- 3 specified temporary base directory does not exist.
- 4 usage message listed.

FILES

<directory>/
temporary base directory to be purged.

<directory>/<tempdir>/maketemp.flagfile
flagfile containing the state information about the command that created the temporary directory. This file is created by the **maketemp**(3) command while creating the temporary directory and read by **purgetemp**(3) and **listtemp**(3).

EXAMPLES

1) purge tempdirs created in '/tmp':

```
[ /root ]
[ root@acme001 ][-sh]: maketemp -d /tmp/.example
/tmp/.example.3430.2Hpt0D/

[ /root ]
[ root@acme001 ][-sh]: purgetemp -d /tmp
```

SEE ALSO

edrcintro(1), **listtemp**(3), **maketemp**(3), **removetemp**(3)

NOTES

-

BUGS

if the tempdir is created in a temporary directory location where a regular file cleanup is configured, **purgetemp** will not be able to purge the directory specified in the **-d** option, due to the fact that the **.maketemp.flagfile** might be removed by the cleanup function.

Cleanup **crontab** entry that would cause the behaviour described:

```
#
# delete all files in /tmp which are older than one week
#
00 1 * * * find /tmp \( -mtime +7 -a -type f \) -exec /bin/rm {} \;
```

AUTHOR

purgetemp was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

pwcrypt – encrypt a password from stdin

SYNOPSIS

edrc/bin/pwcrypt

AVAILABILITY

WA2L/edrc

DESCRIPTION

encrypt a plain password.

The plain password can be entered interactively or can be passed via pipe or input redirection.

The crypted password can be used in **/etc/passwd** of SunOS, Solaris, HP-11 (untrusted), HP-11ia (untrusted) and Linux.

OPTIONS

-

ENVIRONMENT

-

EXIT STATUS

0 always.

NAME

pwsafe – query the password safe for a password

SYNOPSIS

edrc/lib/pwsafe [**-h**]

pwsafe [**-c** *config_file*] *user@system*

AVAILABILITY

WA2L/edrc

DESCRIPTION

The **pwsafe**(3) command provides the possibility to access the password safe maintained by the contributed **edrc** command **contrib.pwsafe**(1m) in read only mode from outside of an **edrc** session.

OPTIONS

-h print usage message.

-c *config_file*

edrc configuration file, see **edrc.cfg**(4) for more information.

This is to locate the password safe file within the related recovery tree.

user@system

the *user* on the related *system* or application to be queried.

ENVIRONMENT**\$PWSAFE_MASTERPASSWORD**

This environment variable must be set to the master password of the password safe to be able to query an encrypted password safe.

Be careful on how to handle the master password:

When writing a script accessing the **pwsafe** never supply the master password thru a command line option due to the fact that any user on the system would be able to see the password using the **ps -ef** command.

Therefore only use environment variables to pass the password around.

In addition the password shall not be saved in clear text.

EXIT STATUS

- | | |
|-----------|--|
| 0 | no error. |
| 1 | wrong master password. |
| 2 | operating system not supported. |
| 4 | usage message printed. |
| 5 | pwsafe aborted. |
| 6 | the given <i>config_file</i> does not exist in the edrc/etc/ directory. |
| 7 | the SCRIPTS_BASEDIR as defined in <i>config_file</i> does not exist. |
| 8 | permission denied to read password safe file. |
| 9 | CRYPT_MODE as defined for contrib.pwsafe(1m) is not supported on the system. |
| 11 | temporary directory could not be claimed or created in /var/tmp . Check the system temporary directory /var/tmp if you get this error, it is an indicator of system intrusion. |
| 99 | the CRYPT_MODE as defined for contrib.pwsafe(1m) is not implemented, yet. |

FILES

- pwsafe.dat**
password safe file in a recovery script tree referenced by the *config_file*.
- edrc/etc/contrib.edrc.pwsafe.cfg**
optional configuration file of the contributed command **contrib.pwsafe(1m)**.

EXAMPLES**1) using pwsafe in a script**

A simple script sniplet to show how to use the **pwsafe** usage:

```
#!/bin/ksh

:
:
PWSAFE_MASTERPASSWORD=enigma
export PWSAFE_MASTERPASSWORD

appadm_password=~edrc/lib/pwsafe appadmin@WEBAPP `
appsys_password=~edrc/lib/pwsafe system@acme007 `
```

:
:

NAME

pythonenv – print environment needed to start Python3 scripts

SYNOPSIS

edrc/lib/pythonenv [-n]

AVAILABILITY

WA2L/edrc

DESCRIPTION

print the environment used by **pythonenv** to access the Python3 packages/modules bundled with WA2L/edrc.

To set the environment prior to the execution of **python3**, invoke:

```
eval `pythonenv`
```

This command is **only** to be used to prepare the environment to execute Python3 scripts in "Recovery Script" trees.

When writing Python3 scripts for WA2L/edrc, do **not** use **pythonenv**, start the script thru the **.python_wrapper**. See **python_wrapper**(1) for information about integrating a Python3 script into WA2L/edrc.

OPTIONS

-n no **export** *VARIABLE* ... output.

ENVIRONMENT**\$PYTHONPATH**

this variable holds Python3 package/module locations additional to the standard applying to an installation. This variable will be expanded with the bundled Python3 module locations (in the Python3 virtual environment **venv**) when executing the **pythonenv** command.

\$VIRTUAL_ENV

path of the Python3 virtual environment (**venv**) for the related operating system id and Python3 version (.../**\$OSID**/*<major>.<minor>/*) bundled with WA2L/edrc.

\$PATH

command search path. This variable will be expanded with the path where the **python3** interpreter was found on the system when executing the **pythonenv** command. See also **python_wrapper**(1) for more information.

EXIT STATUS

0 always

FILES

edrc/etc/python_wrapper.cfg
configuration file for **.python_wrapper** and **pythonenv**.

edrc/lib/python/pym/

location of all bundled Python3 packages/modules. The related directory in **edrc/lib/python/pym/<OSID>/<major>.<minor>/lib/python<major>.<minor>/site-packages/** is pre-pended to the **\$PYTHONPATH** environment variable when executing **pythonenv**.

Where **<major>** is the major version number (e.g. 3) and **<minor>** is the minor Python3 version (e.g. 6).

EXAMPLES**1) Start a Python3 script from a recovery script**

To start a Python3 script that uses a bundled Python3 module from a recovery script, set the Python3 environment using the 'eval **'pythonenv'**' command in the recovery script and then call the **python3** interpreter.

Recovery script:

```
#!/bin/ksh
#
# 1:ascript - A Recovery Script
#
# [00] 08.02.2009 CWa Initial Version
#
#
test "$DEBUG" = True && set -x
:
:
eval `pythonenv`
python3 ./pythonscript
:
```

Python3 script:

```
#
# pythonscript - Python3 script using bundled complex module
#
# [00] 18.03.2009 CWa Initial Version
#
:
:
from complex import Complex
:
```

2) Start a Python3 script from a recovery script using the `_env` file mechanism

Create an `_env` file (using the `env edrc` command) and start the Python3 script from the recovery script.

`_env` file:

```
#
# _env - Environment settings for commands in /apps/eg
#
# [00] 18.03.2009 CWa Initial Version
#
#
test "$DEBUG" = True && set -x

eval `pythonenv`
:
```

Recovery script:

```
#!/bin/ksh
#
# 1:ascript - A Recovery Script
#
# [00] 08.02.2009 CWa Initial Version
#
#
test "$DEBUG" = True && set -x
:
:
python3 ./pythonscript
:
```

Python3 script:

```
#
# pythonscript - Python3 script using bundled complex module
#
# [00] 18.03.2009 CWa Initial Version
#
:
:
from complex import Complex
:
```

3) Write a recovery script in Python3

Create an `_env` file (using the `env edrc` command) and write the recovery script in Python3.

`_env` file:

```
#
# _env - Environment settings for commands in /apps/eg
```

```
#
# [00] 18.03.2009 CWa Initial Version
#
#
test "$DEBUG" = True && set -x

eval `pythonenv`
:
```

Python3 recovery script:

```
#!/usr/bin/env python3
#
# 1:ascrip - A Recovery Script
#
# [00] 08.02.2009 CWa Initial Version
#
:
:
from complex import Complex
:
```

Note the use of `#!/usr/bin/env python3` in the magic key to start the Python3 script. This ensures that the **python3** interpreter is found on the system, even when it is not installed in the default location you will normally specify. The path to the **python3** interpreter is added to the **\$PATH** using the **pythonenv** command.

4) Write a Python3 script outside of WA2L/edrc and profit from bundled Python3 modules

The startup method method below allows to start the **python3** interpreter from wherever it is installed and also enables to use all **python3** packages/modules bundled with WA2L/edrc using the **pythonenv** command to dynamically initialize the environment.

This method is similar to the use of the **.python_wrapper**, but the Python3 script can be placed somewhere of your liking outside of WA2L/edrc.

Set the permissions of the script to executable:

```
chmod +x pythonscript
```

Python3 script:

```
#!/bin/ksh
#
# pythonscript - Python3 script using bundled modules
#
# [00] 18.03.2009 CWa Initial Version
#

eval `~edrc/lib/pythonenv`

sed '1,/^exit \$\?/d' $0 | python3 - "$0" "$@"
exit $?
```

```
# python
#
import sys
from complex import Complex

sys.argv[0] = sys.argv.pop(1); __file__ = sys.argv[0]

def main():
    print("Hello World!\n");

    print("Arguments:", sys.argv[0:])

    x = Complex(2,3)
    y = Complex(4,5)
    print("x+y = {}".format(x+y))

    return(0)

if __name__ == "__main__": sys.exit(main())
```

5) Test the availability of a specific Python3 package/module

Set the needed **python3** environment:

```
[ / ]
[ root@acme007 ][*edrc*/bash]: eval `pythonenv`
```

Try to access the **python3** module:

```
[ / ]
[ root@acme007 ][*edrc*/bash]: python -c "import complex"
```

If an error message like

```
Traceback (most recent call last):
  File "<string>", line 1, in <module>
ModuleNotFoundError: No module named 'complex'
```

appears, the package/module cannot be found, if the package/module can be found there is no output.

6) List the available Python3 packages/modules

To list the installed Python3 packages, use the **pip3(1)** command.

To list the packages bundled in WA2L/edrc:

```
[ /opt/edrc/bin ]
[ root@acme007 ][*edrc*/bash]: pip list --local
```

To list all packages available (this includes the packages/modules bundled in WA2L/edrc):

```
[ /opt/edrc/bin ]  
[ root@acme007 ][*edrc*/bash]: pip list
```

7) Show detail information of an installed package

To list information about installed packages, the **pip3**(1) command is used.

The **pip show** [**--file**] *packagename* also displays the **Location** where the package is installed/read.

To show detail information of a package:

```
[ /opt/edrc/bin ]  
[ root@acme007 ][*edrc*/bash]: pip show complex
```

To show detail information and all installed files of a package:

```
[ /opt/edrc/bin ]  
[ root@acme007 ][*edrc*/bash]: pip show --file complex
```

NAME

python_wrapper – wrap Python3 scripts to ensure python3 startup

SYNOPSIS

edrc/bin/pythonscript -> **.python_wrapper**

edrc/lib/pythonscript -> **.python_wrapper**

AVAILABILITY

WA2L/edrc

DESCRIPTION

Wrap Python3 scripts to avoid using `#!/usr/bin/python3` or similar path names in the magic key. This enhances the portability of WA2L/edrc commands written in Python3 to systems where **python3** is not installed in the default install locations.

python3 has to be installed in `/usr/bin/`, `/bin/`, `/sbin/`, `/usr/local/bin/` or `/usr/contrib/bin/`.

Further **python3** locations can be configured in the optional config file **python_wrapper.cfg**.

The Python3 packages/modules bundled with WA2L/edrc that are installed in **lib/python/pym/<OS-Id>/<major>.<minor>/** are included in the Python3 path (**PYTHONPATH**) and the Python3 virtual environment **venv** (**VIRTUAL_ENV**).

To start a new command thru the **.python_wrapper**, follow the following steps:

- 1.) create a symlink to the new command in the **edrc/bin/** or **edrc/lib/** directory depending on your needs:

```
[ /opt/edrc/bin ]
[ root@acme001 ][*edrc*/bash]: ln -s .python_wrapper new_cmd
```

- 2.) install the Python3 script in the **edrc/lib/python/** directory:

```
[ /opt/edrc/lib/python ]
[ root@acme001 ][*edrc*/bash]: vi new_cmd

[ /opt/edrc/lib/python ]
[ root@acme001 ][*edrc*/bash]: chmod 644 new_cmd
```

OPTIONS

-

ENVIRONMENT

-

EXIT STATUS

- 101** shell (**python3**) not found. If **python3** is installed on the system and you get this error, add the **python3** location in the configuration file **python_wrapper.cfg**.
- 102** the Python3 script to be started that should be located in **lib/python/** does not exist.
- 103** user calling the command has no permission to access/execute the called *pythonscript*.
- 107** the **.python_wrapper** was called directly.

FILES

- etc/python_wrapper.cfg**
configuration file for the **.python_wrapper** command.
- lib/python/**
location of the wrapped Python3 scripts. This files should have the file permissions *644* to show, that those scripts should not be started directly.
- lib/python/pym/<OS-Id>/<python-revision>/**
location of the Python3 packages/modules bundled with WA2L/edrc.

NAME

python_wrapper.cfg – configuration file for .python_wrapper

SYNOPSIS

edrc/etc/python_wrapper.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **.python_wrapper** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**SEARCH_PATH**

Colon separated search path where to search for the **python3** interpreter.

Example: SEARCH_PATH="/usr/bin:/bin:/sbin:/usr/local/bin:/usr/contrib/bin"

Default: SEARCH_PATH="/usr/bin:/bin:/sbin:/usr/local/bin:/usr/contrib/bin"

NAME

rcmd – run command(s) on host(s)

SYNOPSIS

edrc/bin/rcmd [**-h**]

rcmd [**-n**][**-q**][**-r** [*num*]][**-t** *host_1,host_2,host_n*][**-c** *command*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

The **rcmd** command is used to run a command or a set of commands on a set of hosts. You can specify the command(s) on the command line, if you don't you are prompted for it.

The interactive query of hosts suggests as default the hosts as defined in the **EXEC_HOSTLIST** setting in the **rcmd.cfg** file. Furthermore it is possible to enter hostgroups (*@HOSTGROUP*), as known from the **hostlist** command. It is possible to specify multiple hostgroups or to mix hostgroups with hostnames. When using hostgroups the input default is expanded and the target prompt is repeated to give the user the opportunity to verify the target list and to correct it if needed.

All output as received from the commands started on the target hosts is printed to **stdout**, all **rcmd** state output and dialog is printed to **stderr** to enable the user to do further output processing of the received data, see also **-n** and **-q** options.

OPTIONS

-h usage message.

-n Do not indent the command output as received from the target host. This is useful if it is needed to do further output processing.

-q Quiet run, no state information is printed to **stderr**. To process the received output it is not imperative to use the **-q** option.

-r [*retries*]
number of retries to connect to the target host, if it was not possible to connect at the first try. This option can be used when using **rcmd** in unattended script runs. If *retries* is not set, the default as set in **CONNECTION_RETRIES** in the **rcmd.cfg** config file applies. If **-r** is not used in non-interactive script runs, this default applies, too. The interval of retries is eight seconds, if not specified differently in **RETRY_INTERVAL** in the **etc/rcmd.cfg** configuration file.

-t *hostlist* A comma separated list of target hosts. If the hostlist is not specified, an interactive query asks for it. The default hostlist for the interactive query is as defined in the **EXEC_HOSTLIST** setting in the **rcmd.cfg** config file.

See also **resolve_targetlist(3)** to see how to efficiently create a hostlist in scripts.

-c *command*

commands to be executed on the target nodes. If the commands are not specified on the command line a convenient interactive query allows to input the commands, even easy input editing is provided.

ENVIRONMENT

-

EXIT STATUS

- 0** no error.
- 2** operating system is not supported, yet. See **osid(3)** if you get this error.
- 4** usage printed.
- 5** the execution has been aborted using *Ctrl+C*.
- 6** the configuration file **rcmd.cfg** does not exist.
- 11** temporary directory could not be claimed or created in **/tmp**. Check the system temporary directory **/tmp** if you get this error, it is an indicator of system intrusion.

FILES

- etc/rcmd.cfg**
configuration file of **rcmd**, see **rcmd.cfg(4)** for more information.
- var/log/rcmd.log**
default logfile of **rcmd**.
- etc/exrc** settings for the **vi** / **vim** editor.

EXAMPLES

-

NAME

rcmd.cfg – configuration file for rcmd

SYNOPSIS

edrc/etc/rcmd.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **rcmd** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS

LOG Log output dir of **rcmd**. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation.

Example: LOG=/var/opt/edrc/log

Default: LOG=var/log

DIST_HOSTLIST

Space separated list of hosts. To this hosts the files specified on the command line will be distributed.

Example: EXEC_HOSTLIST="hostlist"

Default: –

START_USER

User that is allowed to start **rcmd**.

Example: START_USER=eroot

Default: START_USER=root

EXEC_USER

User used to connect to the target hosts. This user has to be allowed to switch to root on the target system using the correct security settings. See **edrcsetup**(1m) for more information.

Example: EXEC_USER=edrc

Default: EXEC_USER=edrc

EXEC_MODE

Comma separated list of modes used to connect to the target hosts. The supported modes are: *rtools* which result in the use of **rcp** and **rsh** or *OpenSSH* which results in the use of **scp** and **ssh** for distribution. If a comma separated list is provided, the connection initiation is made in the sequence specified. A pseudo distribution mode is *default* which results in the use of the **EXEC_MODE** specified in the configuration files **remote_shell.cfg** and **remote_copy.cfg**. It is not allowed to specify *default* as part of a comma separated list.

Example: EXEC_MODE=rtools,OpenSSH

Default: EXEC_MODE=rtools

EXEC_SHELL

This is the shell the entered commands will be executed on the host. The shell has to be Bourne Shell compatible if you turn **SET_PATH** to *True*.

Example: EXEC_SHELL=/bin/ksh

Default: EXEC_SHELL=/bin/sh

CONNECTION_RETRIES

Number of connection retries if the connection to the target host fails. This setting applies if **-r** without specifying a number of retries is used or if **rcmd** is called non-interactive.

Example: CONNECTION_RETRIES=5

Default: CONNECTION_RETRIES=2

RETRY_INTERVAL

Seconds between retry attempts.

Example: RETRY_INTERVAL=10

Default: RETRY_INTERVAL=8

SET_PATH

The shell has to be Bourne Shell compatible if you turn **SET_PATH** to *True*. If you set **SET_PATH** to *True*, the contents of the local \$PATH variable will be appended to the \$PATH variable on the remote system.

Example: SET_PATH=True

Default: SET_PATH=False

SET_UMASK

If set to *True* the umask on the remote system will be set as it is set on the local system.

Example: SET_UMASK=True

Default: SET_UMASK=False

SUMMARY

If set to *True* at the end of the remote command execution a state summary is printed. If set to *False* the summary is not printed.

Example: SUMMARY=True

Default: SUMMARY=False

SEE ALSO

NAME

rcomm – compare (comm) remote- or local file(s)

SYNOPSIS

edrc/bin/rcomm [**-h**]

rcomm [*options*] [[*user@*]*host*:]*file1* [[*user@*]*host*:]*file2*

rcomm [*options*] [*user@*]*host*:*file1*

rcomm [*options*] [[*user@*]*host*:]*file1* [*user@*]*host*:

rcomm [*options*] [[*user@*]*host*:] [[*user@*]*host*:]*file2*

options ::= [**-l** *localuser*] [*diff_options*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

compare (**comm**) remote- or local file(s).

When only specifying a remote file, it is compared with the related local file.

Example:

```
[ /opt/edrc/bin ]
[ root@acme-008 ] [*edrc*/bash]: rcomm acme-007:/etc/hosts
```

or

```
[ /opt/edrc/bin ]
[ root@acme-008 ] [*edrc*/bash]: rcomm acme-007: /etc/hosts
```

will compare the files **/etc/hosts** from the system acme-007 with the local **/etc/hosts** file on the acme-008 system.

The example above is therefore equal to:

```
[ /opt/edrc/bin ]
[ root@acme-008 ] [*edrc*/bash]: rcomm acme-007:/etc/hosts /etc/hosts
```

If the given file(s) are **gzipped** (**.gz**) or **bzip2ed** (**.bz2**, **.bz**), the related uncompressed content is compared.

OPTIONS

-h usage message.

[[user@]host:]file1
first remote- or local file.

[[user@]host:]file2
second remote- or local file.

When only specifying the first file, it is compared with the related local file.

-l localuser
use the local user *localuser* to initiate the connection. Default local user is **edrc**.
Use **-l \$USER** if you are not **root**.

comm_options
options of the **comm(1)** command.
See **comm(1)** for a description of the available **comm** options.

ENVIRONMENT

-

EXIT STATUS

0 no error.
1 error(s) while processing the given file(s) occurred.
4 usage printed.

FILES

-

EXAMPLES

-

SEE ALSO

edrcintro(1), **edrcsetup(1m)**, **comm(1)**, **diff(1)**, **rcat(1)**, **rdiff(1)**, **ssh-exec(1)**, **ssh-exec.cfg(4)**

NOTES

rcomm uses **rcat**(1) internally to get the remote- and local files.

BUGS

-

AUTHOR

rcomm was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

rdiff – show differences (diff) of remote- or local file(s)

SYNOPSIS

edrc/bin/rdiff [**-h**]

rdiff [*options*] [[*user@*]*host*:]*file1* [[*user@*]*host*:]*file2*

rdiff [*options*] [*user@*]*host*:*file1*

rdiff [*options*] [[*user@*]*host*:]*file1* [*user@*]*host*:

rdiff [*options*] [*user@*]*host*: [[*user@*]*host*:]*file2*

options ::= [**-l** *localuser*] [*diff_options*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

show differences (**diff**) of remote- or local file(s).

When not specifying a second remote file, it is compared with the related local file or vice versa.

Example:

```
[ /opt/edrc/bin ]
[ root@acme-008 ][*edrc*/bash]: rdiff acme-007:/etc/hosts
```

or

```
[ /opt/edrc/bin ]
[ root@acme-008 ][*edrc*/bash]: rdiff acme-007: /etc/hosts
```

will compare the files **/etc/hosts** from the system acme-007 with the local **/etc/hosts** file on the acme-008 system.

The example above is therefore equal to:

```
[ /opt/edrc/bin ]
[ root@acme-008 ][*edrc*/bash]: rdiff acme-007:/etc/hosts /etc/hosts
```

If the given file(s) are **gzipped** (**.gz**) or **bzip2ed** (**.bz2**, **.bz**), the related uncompressed content is compared.

OPTIONS

-h usage message.

[[user@]host:]file1
first remote- or local file.

[[user@]host:]file2
second remote- or local file.

When only specifying the first file, it is compared with the related local file.

-l localuser
use the local user *localuser* to initiate the connection.

diff_options
options of the **diff**(1) command.
See **diff**(1) for a description of the available **diff** options.

ENVIRONMENT

-

EXIT STATUS

0 no error.
1 error(s) while processing the given file(s) occurred.
4 usage printed.

FILES

-

EXAMPLES

-

SEE ALSO

NAME

regexintro – introduction to regular expression usage

SYNOPSIS

regexintro, regex, regexp

AVAILABILITY

WA2L/edrc

DESCRIPTION

In computing, regular expressions provide a concise and flexible means for identifying strings of text of interest, such as particular characters, words, or patterns of characters.

Regular expressions (abbreviated as *regex* or *regexp*, with plural forms *regexes*, *regexps*, or *regexen*) are written in a formal language that can be interpreted by a regular expression processor, a program that either serves as a parser generator or examines text and identifies parts that match the provided specification.

BASIC CONCEPTS

A regular expression, often called a pattern, is an expression that describes a set of strings. They are usually used to give a concise description of a set, without having to list all elements.

For example, the set containing the three strings *Handel*, *Händel*, and *Haendel* can be described by the pattern **H(ä|ae?)ndel** (or alternatively, it is said that the pattern matches each of the three strings).

In most formalisms, if there is any regex that matches a particular set then there is an infinite number of such expressions. Most formalisms provide the following operations to construct regular expressions:

Alternation

A vertical bar separates alternatives. For example, **gray|grey** can match *gray* or *grey*.

Grouping Parentheses are used to define the scope and precedence of the operators (among other uses). For example, **gray|grey** and **gr(a|e)y** are equivalent patterns which both describe the set of *gray* and *grey*.

Quantification

A quantifier after a token (such as a character) or group specifies how often that preceding element is allowed to occur. The most common quantifiers are **?**, *****, and **+**.

? The question mark indicates there is zero or one of the preceding element. For example, **colou?r** matches both *color* and *colour*.

***** The asterisk indicates there are zero or more of the preceding element. For example, **ab*c** matches *ac*, *abc*, *abbc*, *abbbc*, and so on.

- + The plus sign indicates that there is one or more of the preceding element. For example, **ab+c** matches **abc**, **abbc**, **abbbc**, and so on, but not *ac*.

These constructions can be combined to form arbitrarily complex expressions, much like one can construct arithmetical expressions from numbers and the operations **+**, **.** and *****. For example, **H(ae?[ä]ndel** and **H(a|ae|ä)ndel** are both valid patterns which match the same strings as the earlier example, **H(ä|ae?)ndel**.

The precise syntax for regular expressions varies among tools and with context; more detail is given in the Syntax section.

SYNTAX

POSIX BASIC REGULAR EXPRESSIONS

Traditional Unix regular expression syntax followed common conventions but often differed from tool to tool.

The IEEE POSIX Basic Regular Expressions (BRE) standard (released alongside an alternative flavor called Extended Regular Expressions or ERE) was designed mostly for backward compatibility with the traditional syntax but provided a common standard which has since been adopted as the default syntax of many Unix regular expression tools, though there is often some variation or additional features.

Many such tools also provide support for ERE syntax with command line arguments.

In the BRE syntax, most characters are treated as literals - they match only themselves (i.e., **a** matches *a*). The exceptions, listed below, are called meta characters or meta sequences.

- .** Matches any single character (many applications exclude newlines, and exactly which characters are considered newlines is flavor, character encoding, and platform specific, but it is safe to assume that the line feed character is included). Within POSIX bracket expressions, the dot character matches a literal dot. For example, **a.c** matches *abc*, etc., but **[a.c]** **matches only** *a*, *.*, or *c*.
- []** A bracket expression. Matches a single character that is contained within the brackets. For example, **[abc]** matches *a*, *b*, or *c*. **[a-z]** specifies a range which matches any lowercase letter from *a* to *z*. These forms can be mixed: **[abcx-z]** matches *a*, *b*, *c*, *x*, *y* and *z*, as does **[a-cx-z]**.

The **-** character is treated as a literal character if it is the last or the first character within the brackets, or if it is escaped with a backslash: **[abc-]**, **[-abc]** or **[a-bc]**.
- [^]** Matches a single character that is not contained within the brackets. For example, **[^abc]** matches any character other than *a*, *b* or *c*. **[^a-z]** matches any single character that is not a lowercase letter from *a* to *z*. As above, literal characters and ranges can be mixed.
- ^** Matches the starting position within the string. In line-based tools, it matches the starting position of any line.
- \$** Matches the ending position of the string or the position just before a string-ending newline. In line-based tools, it matches the ending position of any line.

- *** Matches the preceding element zero or more times. For example, **ab*c** matches *ac*, *abc*, *abbbc* etc. **[xyz]*** matches *x*, *y*, *z*, *zx*, *zyx*, *xyzy* and so on. **\(ab\)*** matches *ab*, *abab*, *ababab* and so on.
- \{m,n\}** Matches the preceding element at least *m* and not more than *n* times. For example, **a\{3,5\}** matches only *aaa*, *aaaa* and *aaaaa*. This is not found in a few, older instances of regular expressions. For compatibility reasons, this construct should be avoided.

POSIX EXTENDED REGULAR EXPRESSIONS

The meaning of meta characters escaped with a backslash is reversed for some characters in the POSIX Extended Regular Expression (ERE) syntax. With this syntax, a backslash causes the meta character to be treated as a literal character. Additionally, support is removed for `\n` back references and the following meta characters are added:

- ?** Matches the preceding element zero or one time. For example, **ba?** matches *b* or *ba*.
- +** Matches the preceding element one or more times. For example, **ba+** matches *ba*, *baa*, *baaa* and so on.
- |** The choice (aka alternation or set union) operator matches either the expression before or the expression after the operator. For example, **abc|def** matches *abc* or *def*.

POSIX CHARACTER CLASSES

Since many ranges of characters depend on the chosen locale setting (i.e., in some settings letters are organized as *abc...zABC...Z*, while in some others as *aAbBcC...zZ*), the POSIX standard defines some classes or categories of characters as shown in the following table. It is expected, that this constructs are less portable, then specifying expressions with the more basic constructs above. Therefore for compatibility reasons, it is recommended to avoid the following constructs.

- [:alnum:]** Alphanumeric characters.
- [:alpha:]** Alphabetic characters.
- [:blank:]** Space and tab.
- [:cntrl:]** Control characters.
- [:digit:]** Digits.
- [:graph:]** Visible characters.
- [:lower:]** Lowercase letters.
- [:print:]** Visible characters and spaces.

[punct:] Punctuation characters.

[space:] White-space characters.

[upper:] Uppercase letters.

[xdigit:] Hexadecimal digits.

POSIX character classes can only be used within bracket expressions. For example, **[[:upper:]ab]** matches the uppercase letters and lowercase *a* and *b*.

EXAMPLES

- 1) **.at** matches any three-character string ending with *at*, including *hat*, *cat* and *bat*.
- 2) **[hc]at** matches *hat* and *cat*.
- 3) **[^b]at** matches all strings matched by **.at** except *bat*.
- 4) **^[hc]at** matches *hat* and *cat*, but only at the beginning of the string or line.
- 5) **[hc]at\$** matches *hat* and *cat*, but only at the end of the string or line.
- 6) **[hc]+at** matches *hat*, *cat*, *hhat*, *chat*, *hcat*, *ccchat* and so on, but not *at*.
- 7) **[hc]*at** matches *hat*, *cat*, *hhat*, *chat*, *hcat*, *ccchat* and so on, and also *at*.
- 8) **[hc]?at** matches *hat*, *cat* and *at*.
- 9) **cat|dog** matches *cat* or *dog*.
- 10) **.*** matches any character.

NAME

remote_copy – start a remote copy

SYNOPSIS

edrc/lib/remote_copy [**-h**]

remote_copy [**-c** *cfg_file*] [**-m** *mode*[{*,mode*}]] [**-q**] [**-v**] [**-N**] [**-s** *username*] [**-l** *username*] *file_1*
[*file_2* ...] *dest*

remote_copy [**-c** *cfg_file*] **-f -m** *mode* [**-q**] [**-v**] [**-N**] [**-s** *username*] [**-l** *username*] *file_1* [*file_2* ...]
dest

AVAILABILITY

WA2L/edrc

DESCRIPTION

wrapper for remote copies.

This command enables you to write scripts independent of the current security policy of your systems.

Internally **remote_copy** uses **rcp** or **scp** dependent of the configuration settings.

Furthermore this command provides a caching mechanism which remembers successful connection modes to speed up future connections.

OPTIONS

-h usage message.

-c *cfg_file* config file (default=**edrc/etc/remote_copy.cfg**).

-m *mode* connection mode (default=**rtools**): **rtools**: rsh, rcp; **OpenSSH**: ssh, scp; **default**: default from config file.

-v verbose output.

-N do not **'su'** to the user given in **-s** *username* prior to invoking the connection.

-s *username* user to switch to on the local machine.

- f** force connection mode.
- l *username*** user to log in as on the remote machine.
- q** quiet, no error message output.
- file_n*** source file.
- dest*** destination file or directory in the form: [*user_name*@]*hostname:pathname/filename* or [*user_name*@]*hostname:pathname/dirname*

ENVIRONMENT

-

EXIT STATUS

- 0** no error.
- 2** operating system not supported.
- 3** remote system is not up.
- 4** usage displayed.
- 5** command aborted.
- 6** config file not found.
- 7** cannot log on to remote system.
- 1##** ## exit code of **rcp** or **scp** if not successful.

FILES

- edrc/etc/remote_copy.cfg**
configuration file.
- edrc/var/connection/security/**
connection security files (e.g. SSH keys).
- edrc/var/connection/cache/**
connection cache files.

EXAMPLES

NAME

`remote_shell` – start a remote shell

SYNOPSIS

`edrc/lib/remote_shell [-h]`

`remote_shell [-c cfg_file] [-m mode[{,mode}]] [-q] [-N] [-s username] [-l username] [-t] host [--] [command]`

`remote_shell [-c cfg_file] -f -m mode [-n] [-q] [-N] [-s username] [-l username] [-t] host [--] [command]`

AVAILABILITY

WA2L/edrc

DESCRIPTION

wrapper for remote shells.

This command enables you to write scripts independent of the current security policy of your systems.

Internally **remote_shell** uses **remsh**, **rsh** or **ssh** dependent of the configuration settings.

Furthermore this command provides a caching mechanism which remembers successful connection modes to speed up future connections.

OPTIONS

-h usage message.

-c *cfg_file* config file (default=**edrc/etc/remote_shell.cfg**).

-m *mode* connection mode (default=**rtools**): **rtools**: rsh, rcp; **OpenSSH**: ssh, scp; **default**: default from config file.

-n do not probe connection before executing the command.

-N do not 'su' to the user given in **-s** *username* prior to invoking the connection.

-s *username* user to switch to on the local machine.

-f force connection mode.

-l *username* user to log in as on the remote machine.

-q quiet, no error message output.

-t allocate a tty even if command is given.

host host to log on to.

-- mark end of **remote_shell** options.

command command to execute on the remote *host*.

ENVIRONMENT

-

EXIT STATUS

0 no error.

2 operating system not supported.

3 remote system is not up.

4 usage displayed.

5 command aborted.

6 config file not found.

7 cannot log on to remote system.

1## **##** exit code of **rsh** or **ssh** if not successful.

FILES

edrc/etc/remote_shell.cfg
configuration file.

edrc/var/connection/security/
connection security files (e.g. SSH keys).

edrc/var/connection/cache/
connection cache files.

EXAMPLES

-

SEE ALSO

NAME

removetemp – remove temporary directory created by maketemp

SYNOPSIS

edrc/lib/removetemp [**-h**]

removetemp [**-s** *scriptname*] [**-q**] **-d** *tempdir*

AVAILABILITY

WA2L/edrc

DESCRIPTION

remove a temporary directory created by **maketemp**(3).

Directories not created by **maketemp** will not be removed by the **removetemp** command.

Use the **listtemp**(3) command to list the state of temporary directories created by **maketemp**.

OPTIONS

-h usage message.

-s *scriptname*
scriptname in message output of **removetemp**.

-q quiet, no message output.

-d *tempdir* temporary directory as returned by the **maketemp** command.

See section **EXAMPLES** for additional information.

ENVIRONMENT

-

EXIT STATUS

0 no error.

1 cannot remove specified temporary directory.

- 2 directory not removed because it was not created using the **maketemp**(3) command.
- 3 specified temporary directory does not exist.
- 4 usage message listed.
- 5 cannot access the specified temporary directory.

FILES

<tempdir>/
temporary directory to be removed.

<tempdir>/maketemp.flagfile
flagfile containing the state information about the command that created the temporary directory. This file is created by the **maketemp**(3) command while creating the temporary directory and read by **removetemp**(3) and **listtemp**(3).

EXAMPLES

1) remove a tempdir created in '/tmp':

```
[ /root ]
[ root@acme001 ] [-sh]: maketemp -d /tmp/.example
/tmp/.example.3430.2Hpt0D/

[ /root ]
[ root@acme001 ] [-sh]: removetemp -d /tmp/.example.3430.2Hpt0D/
```

2) create/use/remove a tempdir in '/tmp' in a script:

```
#!/bin/sh

Scriptname=`basename $0`
Tmp=`maketemp -s $Scriptname -d /tmp/.$Scriptname` || exit 11

:
:

cat /etc/passwd | sort > ${Tmp}sorted_passwd

:
:

removetemp -q -d ${Tmp}
```

SEE ALSO

edrcintro(1), **listtemp(3)**, **maketemp(3)**, **purgetemp(3)**,

NOTES

-

BUGS

if the tempdir is created in a temporary directory location where a regular file cleanup is configured, **removetemp** will not be able to remove the directory specified in the **-d** option, due to the fact that the **.maketemp.flagfile** might be removed by the cleanup function.

Cleanup **crontab** entry that would cause the behaviour described:

```
#
# delete all files in /tmp which are older than one week
#
00 1 * * * find /tmp \( -mtime +7 -a -type f \) -exec /bin/rm {} \;
```

AUTHOR

removetemp was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

resolve_targetlist – produce contrib.doc OUTPUT-EXAMPLE output from logfile

SYNOPSIS

edrc/lib/resolve_targetlist [**-h**]

resolve_targetlist [**-l**] { *host* | **@GROUP** }

AVAILABILITY

WA2L/edrc

DESCRIPTION

resolve a targetlist which may consist of a list of hosts and hostgroups and return the resolved unique list of hosts.

OPTIONS

-h usage message.

-l the list is comma separated (instead of space separated).

host host name (list).

@GROUP group name (list).

ENVIRONMENT

-

EXIT STATUS

4 usage printed.

0 no error.

FILES

-

EXAMPLES

-

NAME

revision – print revision of a file examined from the file header

SYNOPSIS

edrc/bin/revision [*selection*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

Print revision of a selection of files in the current working directory examined from the file header.

This helps to get a quick overview of the revision and the last revision history entry of files located in a certain directory.

The file header must have the (very simple to remember) format:

[##] *DD.MM.YYYY INi Revision history text*

Binary files are not scanned for file header patterns.

OPTIONS

selection

selection as known from the **ls** command to select a subset of files from the current working directory.

EXAMPLES**1) Shellscript header**

```
#!/bin/sh
#
# busy - keep the line open
#
# [00] 28.02.2001 CWa   Initial Version
# [01] 02.03.2001 CWa   chg: comment text
#
```

2) Configuration file header

```
#
# /etc/hosts - internet host revisions
#
```

```
# [00] 28.02.2001 CWa    Initial Version
# [01] 08.08.2001 CWa    + timehost
#
#
127.0.0.1      localhost
192.168.75.1   rh7mzv7t001
102.168.75.9   timehost
```

3) Configuration file header

```
;
; /etc/samba/smb.conf - samba configuration file
;
; [00] 28.02.2001 CWa    Initial Version
; [01] 04.04.2001 CWa    chg: workgroup AGROUP -> MYGROUP
;
;
[global]
    workgroup = MYGROUP
    server string = %h
```

4) SQL script header

```
--
-- TopTen.sql - Reports lists DB statistics
--
-- [00] 31.1.2003 CBi    Initial
-- [01] 01.5.2003 CWa    fix: total_bytes -> total_kbytes
--
select
    a.tablespace_revision,
    a.bytes/1024 as total_kbytes,
```

5) Manpage file header

```
.\"
.\" revision.1 - manpage for revision
.\"
.\" [00] 30.11.2003 CWa Initial Version
.\" [01] 03.01.2003 CWa  ++
.\" [02] 05.01.2003 CWa  ++
.\"
```

NAME

rnano – Restricted mode for Nano's ANOther editor, an enhanced free Pico clone

SYNOPSIS

rnano [*OPTIONS*] [[*+LINE,COLUMN*] *FILE*]...

DESCRIPTION

This manual page briefly documents the **rnano** command.

nano is a small, free and friendly editor which aims to replace Pico, the default editor included in the non-free Pine package. Rather than just copying Pico's look and feel, **nano** also implements some missing (or disabled by default) features in Pico, such as "search and replace" and "go to line and column number".

rnano is a restricted version of **nano**, which only edits specific files and doesn't allow the user access to the filesystem or a command shell.

In restricted mode, **nano** will *not*:

- read or write to any file not specified on the command line;
- read any nanorc files;
- allow suspending;
- allow a file to be appended to, prepended to, or saved under a different name;
- use backup files or spell checking.

OPTIONS

+LINE,COLUMN

Places cursor at line number *LINE* and column number *COLUMN* (at least one of which must be specified) on startup, instead of the default of line 1, column 1.

-? Same as **-h** (**--help**).

-h (**--help**)

Show a summary of command line options and exit.

-V (**--version**)

Show the current version number and exit.

See the **nano(1)** manpage for the complete documentation of **nano**.

BUGS

Please send any comments or bug reports to **nano@nano-editor.org**.

The **nano** mailing list is available from **nano-devel@gnu.org**.

To subscribe, email to **nano-devel-request@gnu.org** with a subject of "subscribe".

HOMEPAGE

<http://www.nano-editor.org/>

AUTHOR

Chris Allegretta <chrisa@asty.org>, et al (see AUTHORS for details). This manual page was originally written by Thijs Kinkhorst <thijs@kinkhorst.com>, for the Debian system (but may be used by others).

NAME

role_option – resolve user role option

SYNOPSIS

edrc/bin/role_option [**-h**]

role_option [**-c** *cfg*] **-e** *environment* **-r** *role*[,*{role}*] **-o** *option*

role_option [**-c** *cfg*] **-A** [**-e** *environment*] [**-r** *role*[,*{role}*]] [**-o** *option*[,*{option}*]]

role_option [**-c** *cfg*] **-R** **-e** *environment*

AVAILABILITY

WA2L/edrc

DESCRIPTION

return the value of a certain option related to a role in an environment.

This function is used to support a role based user creation model based on role templates which can be defined in the relating configuration file **role_option.cfg**(4).

OPTIONS

-h usage message.

-e *environment*
server environment name.

-c *configfile*
configuration file (default=**/opt/edrc-DVLP/edrc/etc/role_option.cfg**).

-r *role* list of roles separated by comma.

-o *option* option name.

-R list all defined roles.

-A list all defined options.

ENVIRONMENT

-

EXIT STATUS

- | | |

NAME

role_option.cfg – role and option configuration for role_option

SYNOPSIS

edrc/etc/role_option.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the role/option definition for the **role_option** command.

FILEFORMAT

The fileformat is a list of definitions that have the format

ENVIRONMENT;ROLE;WEIGHT;CUMULATE;OPTION;VALUE;

Rows starting with a # are considered as comments. Empty lines are allowed, too.

OPTIONS*ENVIRONMENT*

Environment where the **ROLE** is valid.

The *ENVIRONMENT* name should be chosen as the environments defined in **edrc/etc/server_environment.cfg** respectively returned by the **server_environment** command.

ROLE

user role.

WEIGHT

The definition of the highest *WEIGHT* when multiple options with the identical *OPTION* name exist for the selected *ROLE*(es) is returned.

CUMULATE

if multiple options with the identical *OPTION* name exist for the selected *ROLE*(s) all defined *VALUE*(s) are cumulated (concatenated) in a comma separated list when this column is set to **T**.

When set to **F** the *VALUE* of the *OPTION* with the highest *WEIGHT* is returned.

OPTION

option name.

VALUE

value of the *OPTION*.

EXAMPLES

```
#
# role_option.cfg - config file for role_option
#
# [00] 16.06.2005 CWa Initial Version
#
#
#
# Format:
#
# <environment>;<role>;<weight>;<cumulate>;<option>;<value>;
#

NAME

rosid – evaluate the system’s operating system id of a remote system

SYNOPSIS

edrc/lib/rosid [**-h**]

rosid -t *hostname*

rosid [**-e** | **-l** *localuser*] **-u** *user@hostname*

rosid [**-e** | **-l** *localuser*] [**-u** *user*] **-t** *hostname*

AVAILABILITY

WA2L/edrc

DESCRIPTION

rosid generates an unique identifier for each combination of OS release (**uname -r**), OS version (**uname -s**) and machine architecture (**uname -m**) of a remote system.

The **rosid(3)** command does not probe the operating system and also does not resolve an existing **/etc/sfi/OSID** file on the remote system; else the operating system id resolution is identical to the **osid(3)** command.

See **osid(3)** for more information.

OPTIONS

-h print **osid** usage.

-e use **EDRC_USER** as defined in **etc/ssh-exec.cfg** (default=**edrc**) as local user.

-l *localuser*
use the local user *localuser* to initiate the connection. Default local user is **edrc**.

-u *user* remote user to connect on the target system. Default remote user is **root**.

-t *hostname*
target system *hostname* to execute the *commands*.

-u *user@hostname*
remote *user* to connect on the target system *hostname*.

EXIT STATUS

- | | |
|----------|--|
| 0 | the operating system id could be resolved. |
| 1 | the operating system id could not be resolved. In this case rosid returns <i>unknown</i> as OS-id. If you receive this return value you should check the configuration file edrc/etc/osid.dat or edrc/etc/osid.dat.WA2L if the entry for the current operating system is missing. If two releases on an operating system are sufficient similar, they should be mapped to the same OS-id. |
| 2 | cannot connect to the remote system. |
| 4 | usage listed. |
| 5 | command aborted. |

EXAMPLES

See **osid**(3).

SEE ALSO

osid(3), **osid.cfg**(4), **osid.dat**(4), **sysconfig**(1), **edrcintro**(1)

FILES

edrc/etc/osid.cfg

configuration file for **osid** and **rosid**. See **osid.cfg**(4) for more information.

edrc/etc/osid.dat

mapfile of **uname -rs** or **uname -rsm** to OS-id. See **osid.dat**(4) for more information.

NOTES

The WA2L/edrc package does not need to be installed on the remote system.

NAME

rsat – start sat on a remote system

SYNOPSIS

edrc/bin/rsat [**-h**]

rsat [**-c** *config_file*] [*sat_options*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

start **sat** on a remote system without the need to manually log in to the remote system first.

The list of hosts provided can be specified in the configuration file **etc/rsat.cfg**.

OPTIONS

-h usage message.

-c *config_file*
config file of **rsat**, located in **edrc/etc/**.

Default is: **etc/rsat.cfg**.

sat_options
all options of **sat(1)**.

ENVIRONMENT

-

EXIT STATUS

2 operating system not supported.

4 usage printed.

5 command aborted.

6 *config_file* not found.

FILES

-

EXAMPLES

NAME

rsat.cfg – configuration file for rsat

SYNOPSIS

edrc/etc/rsat.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **rsat** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**CONNECTION_USER**

User used to connect to the remote host if the user starting rsat is root.

Example: CONNECTION_USER=edrc

Default: CONNECTION_USER=edrc

EDRC_USER

The home of this user is considered as the root of the EDRC installation on remote systems.

Example: EDRC_USER=edrc

Default: EDRC_USER=edrc

REMOTE_PATH

General Path on remote systems.

Example: REMOTE_PATH=\$PATH

Default: REMOTE_PATH=\$PATH

TARGET_HOSTS Space separated list of hosts. This hosts will appear in the host selection list.

Example: TARGET_HOSTS="hostlist -g @ALL"

Default: TARGET_HOSTS="hostlist"

SEE ALSO

edrcintro(1), **rsat(1)**,

NAME

rssh – remote direct or interactive ssh connect

SYNOPSIS

edrc/bin/rssh [**-h**]

rssh [**-l**]

rssh-user@host [**-h**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

connect to a remote system using **ssh**(1).

When invoking the **rssh** command the remote user and the remote host is queried interactively, where the last chosen user- and host-name is provided as default input.

When a symlink to the **rssh** command in the format **rssh-user@host** is created, the newly created command variant will connect directly to the *host* with the *user* and the remote system will query for the password.

The main purpose for this is to create a pseudo user (without password) and add the command variant **rssh-user@host** to the shell field of the **/etc/passwd** field to allow to use a local system to be used as a direct terminal to a remote system, as for example:

/etc/passwd:

```
:
mars:x:1291:1291:mars login terminal:/tmp:/home/fred/bin/rssh-fred@mars
:
```

/etc/shadow:

```
:
mars::18715:0:99999:7:::
:
```

This would allow you to enter *mars* as login on the local system that will connect to the remote *host* with name *mars* where the login password of the *user* with name *fred* will be queried.

OPTIONS

-h usage message.

-l list past connections for selection.

ENVIRONMENT

-

EXIT STATUS

0 no error.

1 the **rssh** command has been aborted.

4 usage displayed.

FILES

\$HOME/.rssh
remember *user* and *host* of last **rssh** connection of the invoking user.

/etc/passwd
user base.

/etc/shadow
user passwords.

EXAMPLES

1) create a new rssh connect variant

This creates a new **rssh** command variant on host *earth* to directly connect to the host *mars* using the remote user-name *fred*.

```
[ /home/fred ]  
[ fred@earth ] [bash]: ln -s ~edrc/bin/rssh ~fred/bin/rssh-fred@mars
```

or:

```
[ /home/fred ]  
[ fred@earth ] [bash]: symlink ~edrc/bin/rssh ~fred/bin/rssh-fred@mars
```

NAME

rsync — a fast, versatile, remote (and local) file-copying tool

SYNOPSIS

Local: rsync [OPTION...] SRC... [DEST]

Access via remote shell:

Pull: rsync [OPTION...] [USER@]HOST:SRC... [DEST]

Push: rsync [OPTION...] SRC... [USER@]HOST:DEST

Access via rsync daemon:

Pull: rsync [OPTION...] [USER@]HOST::SRC... [DEST]

rsync [OPTION...] rsync://[USER@]HOST[:PORT]/SRC... [DEST]

Push: rsync [OPTION...] SRC... [USER@]HOST::DEST

rsync [OPTION...] SRC... rsync://[USER@]HOST[:PORT]/DEST

Usages with just one SRC arg and no DEST arg will list the source files instead of copying.

DESCRIPTION

Rsync is a fast and extraordinarily versatile file copying tool. It can copy locally, to/from another host over any remote shell, or to/from a remote rsync daemon. It offers a large number of options that control every aspect of its behavior and permit very flexible specification of the set of files to be copied. It is famous for its delta-transfer algorithm, which reduces the amount of data sent over the network by sending only the differences between the source files and the existing files in the destination. Rsync is widely used for back-ups and mirroring and as an improved copy command for everyday use.

Rsync finds files that need to be transferred using a “quick check” algorithm (by default) that looks for files that have changed in size or in last-modified time. Any changes in the other preserved attributes (as requested by options) are made on the destination file directly when the quick check indicates that the file’s data does not need to be updated.

Some of the additional features of rsync are:

- o support for copying links, devices, owners, groups, and permissions
- o exclude and exclude-from options similar to GNU tar
- o a CVS exclude mode for ignoring the same files that CVS would ignore
- o can use any transparent remote shell, including ssh or rsh
- o does not require super-user privileges
- o pipelining of file transfers to minimize latency costs
- o support for anonymous or authenticated rsync daemons (ideal for mirroring)

GENERAL

Rsync copies files either to or from a remote host, or locally on the current host (it does not support copying files between two remote hosts).

There are two different ways for rsync to contact a remote system: using a remote-shell program as the transport (such as ssh or rsh) or contacting an rsync daemon directly via TCP. The remote-shell transport is used whenever the source or destination path contains a single colon (:) separator after a host specification. Contacting an rsync daemon directly happens when the source or destination path contains a double colon (::) separator after a host specification, OR when an rsync:// URL is specified (see also the “USING RSYNC-DAEMON FEATURES VIA A REMOTE-SHELL CONNECTION” section for an exception to this latter rule).

As a special case, if a single source arg is specified without a destination, the files are listed in an output format similar to “ls -l”.

As expected, if neither the source or destination path specify a remote host, the copy occurs locally (see also the `--list-only` option).

SETUP

See the file README for installation instructions.

Once installed, you can use rsync to any machine that you can access via a remote shell (as well as some that you can access using the rsync daemon-mode protocol). For remote transfers, a modern rsync uses ssh for its communications, but it may have been configured to use a different remote shell by default, such as rsh or remsh.

You can also specify any remote shell you like, either by using the `-e` command line option, or by setting the RSYNC_RSH environment variable.

Note that rsync must be installed on both the source and destination machines.

USAGE

You use rsync in the same way you use rcp. You must specify a source and a destination, one of which may be remote.

Perhaps the best way to explain the syntax is with some examples:

```
rsync -t *.c foo:src/
```

This would transfer all files matching the pattern `*.c` from the current directory to the directory `src` on the machine `foo`. If any of the files already exist on the remote system then the rsync remote-update protocol is used to update the file by sending only the differences. See the tech report for details.

```
rsync -avz foo:src/bar /data/tmp
```

This would recursively transfer all files from the directory `src/bar` on the machine `foo` into the `/data/tmp/bar` directory on the local machine. The files are transferred in “archive” mode, which ensures that symbolic links, devices, attributes, permissions, ownerships, etc. are preserved in the transfer. Additionally, compression will be used to reduce the size of data portions of the transfer.

```
rsync -avz foo:src/bar/ /data/tmp
```

A trailing slash on the source changes this behavior to avoid creating an additional directory level at the destination. You can think of a trailing `/` on a source as meaning “copy the contents of this directory” as opposed to “copy the directory by name”, but in both cases the attributes of the containing directory are transferred to the containing directory on the destination. In other words, each of the following commands copies the files in the same way, including their setting of the attributes of `/dest/foo`:

```
rsync -av /src/foo /dest
rsync -av /src/foo/ /dest/foo
```

Note also that host and module references don’t require a trailing slash to copy the contents of the default directory. For example, both of these copy the remote directory’s contents into “`/dest`”:

```
rsync -av host: /dest
rsync -av host::module /dest
```

You can also use rsync in local-only mode, where both the source and destination don’t have a `‘:’` in the name. In this case it behaves like an improved copy command.

Finally, you can list all the (listable) modules available from a particular rsync daemon by leaving off the module name:

```
rsync somehost.mydomain.com::
```

And, if Service Location Protocol is available, the following will list the available rsync servers:

```
rsync rsync://
```

See the following section for even more usage details.

ADVANCED USAGE

The syntax for requesting multiple files from a remote host is done by specifying additional remote-host args in the same style as the first, or with the hostname omitted. For instance, all these work:

```
rsync -av host:file1 :file2 host:file{3,4} /dest/
rsync -av host::modname/file{1,2} host::modname/file3 /dest/
rsync -av host::modname/file1 ::modname/file{3,4}
```

Older versions of rsync required using quoted spaces in the SRC, like these examples:

```
rsync -av host:'dir1/file1 dir2/file2' /dest
rsync host::'modname/dir1/file1 modname/dir2/file2' /dest
```

This word-splitting still works (by default) in the latest rsync, but is not as easy to use as the first method.

If you need to transfer a filename that contains whitespace, you can either specify the **--protect-args (-s)** option, or you'll need to escape the whitespace in a way that the remote shell will understand. For instance:

```
rsync -av host:'file\ name\ with\ spaces' /dest
```

CONNECTING TO AN RSYNC DAEMON

It is also possible to use rsync without a remote shell as the transport. In this case you will directly connect to a remote rsync daemon, typically using TCP port 873. (This obviously requires the daemon to be running on the remote system, so refer to the **STARTING AN RSYNC DAEMON TO ACCEPT CONNECTIONS** section below for information on that.)

Using rsync in this way is the same as using it with a remote shell except that:

- o you either use a double colon :: instead of a single colon to separate the hostname from the path, or you use an rsync:// URL.
- o the first word of the “path” is actually a module name.
- o the remote daemon may print a message of the day when you connect.
- o if you specify no path name on the remote daemon then the list of accessible paths on the daemon will be shown.
- o if you specify no local destination then a listing of the specified files on the remote daemon is provided.
- o you must not specify the **--rsh (-e)** option.

An example that copies all the files in a remote module named “src”:

```
rsync -av host::src /dest
```

Some modules on the remote daemon may require authentication. If so, you will receive a password prompt when you connect. You can avoid the password prompt by setting the environment variable **RSYNC_PASSWORD** to the password you want to use or using the **--password-file** option. This may be useful when scripting rsync.

WARNING: On some systems environment variables are visible to all users. On those systems using **--password-file** is recommended.

You may establish the connection via a web proxy by setting the environment variable **RSYNC_PROXY** to

a hostname:port pair pointing to your web proxy. Note that your web proxy's configuration must support proxy connections to port 873.

You may also establish a daemon connection using a program as a proxy by setting the environment variable `RSYNC_CONNECT_PROG` to the commands you wish to run in place of making a direct socket connection. The string may contain the escape “%H” to represent the hostname specified in the `rsync` command (so use “%%” if you need a single “%” in your string). For example:

```
export RSYNC_CONNECT_PROG='ssh proxyhost nc %H 873'
rsync -av targethost1::module/src/ /dest/
rsync -av rsync:://targethost2/module/src/ /dest/
```

The command specified above uses `ssh` to run `nc` (netcat) on a proxyhost, which forwards all data to port 873 (the `rsync` daemon) on the targethost (%H).

USING RSYNC-DAEMON FEATURES VIA A REMOTE-SHELL CONNECTION

It is sometimes useful to use various features of an `rsync` daemon (such as named modules) without actually allowing any new socket connections into a system (other than what is already required to allow remote-shell access). `Rsync` supports connecting to a host using a remote shell and then spawning a single-use “daemon” server that expects to read its config file in the home dir of the remote user. This can be useful if you want to encrypt a daemon-style transfer's data, but since the daemon is started up fresh by the remote user, you may not be able to use features such as `chroot` or change the uid used by the daemon. (For another way to encrypt a daemon transfer, consider using `ssh` to tunnel a local port to a remote machine and configure a normal `rsync` daemon on that remote host to only allow connections from “localhost”.)

From the user's perspective, a daemon transfer via a remote-shell connection uses nearly the same command-line syntax as a normal `rsync-daemon` transfer, with the only exception being that you must explicitly set the remote shell program on the command-line with the `--rsh=COMMAND` option. (Setting the `RSYNC_RSH` in the environment will not turn on this functionality.) For example:

```
rsync -av --rsh=ssh host::module /dest
```

If you need to specify a different remote-shell user, keep in mind that the `user@` prefix in front of the host is specifying the `rsync-user` value (for a module that requires user-based authentication). This means that you must give the `-l user` option to `ssh` when specifying the remote-shell, as in this example that uses the short version of the `--rsh` option:

```
rsync -av -e "ssh -l ssh-user" rsync-user@host::module /dest
```

The “ssh-user” will be used at the `ssh` level; the “rsync-user” will be used to log-in to the “module”.

STARTING AN RSYNC DAEMON TO ACCEPT CONNECTIONS

In order to connect to an `rsync` daemon, the remote system needs to have a daemon already running (or it needs to have configured something like `inetd` to spawn an `rsync` daemon for incoming connections on a particular port). For full information on how to start a daemon that will handling incoming socket connections, see the **rsyncd.conf(5)** man page — that is the config file for the daemon, and it contains the full details for how to run the daemon (including stand-alone and `inetd` configurations).

If you're using one of the remote-shell transports for the transfer, there is no need to manually start an `rsync` daemon.

EXAMPLES

Here are some examples of how I use `rsync`.

To backup my wife's home directory, which consists of large MS Word files and mail folders, I use a cron job that runs

```
rsync -Cavz . arvidsjaur:backup
```

each night over a PPP connection to a duplicate directory on my machine “arvidsjaur”.

To synchronize my samba source trees I use the following Makefile targets:

```
get:
    rsync -avuzb --exclude '*' samba:samba/ .
put:
    rsync -Cavuzb . samba:samba/
sync: get put
```

this allows me to sync with a CVS directory at the other end of the connection. I then do CVS operations on the remote machine, which saves a lot of time as the remote CVS protocol isn't very efficient.

I mirror a directory between my “old” and “new” ftp sites with the command:

```
rsync -az -e ssh --delete ~ftp/pub/samba nimbus:~ftp/pub/tridge"
```

This is launched from cron every few hours.

OPTIONS SUMMARY

Here is a short summary of the options available in rsync. Please refer to the detailed description below for a complete description.

| | |
|---------------------|---|
| -v, --verbose | increase verbosity |
| -q, --quiet | suppress non-error messages |
| --no-motd | suppress daemon-mode MOTD (see caveat) |
| -c, --checksum | skip based on checksum, not mod-time & size |
| -a, --archive | archive mode; equals -rlptgoD (no -H, -A, -X) |
| --no-OPTION | turn off an implied OPTION (e.g. --no-D) |
| -r, --recursive | recurse into directories |
| -R, --relative | use relative path names |
| --no-implied-dirs | don't send implied dirs with --relative |
| -b, --backup | make backups (see --suffix & --backup-dir) |
| --backup-dir=DIR | make backups into hierarchy based in DIR |
| --suffix=SUFFIX | backup suffix (default ~ w/o --backup-dir) |
| -u, --update | skip files that are newer on the receiver |
| --inplace | update destination files in-place |
| --append | append data onto shorter files |
| --append-verify | --append w/old data in file checksum |
| -d, --dirs | transfer directories without recursing |
| -l, --links | copy symlinks as symlinks |
| -L, --copy-links | transform symlink into referent file/dir |
| --copy-unsafe-links | only "unsafe" symlinks are transformed |
| --safe-links | ignore symlinks that point outside the tree |
| -k, --copy-dirlinks | transform symlink to dir into referent dir |
| -K, --keep-dirlinks | treat symlinked dir on receiver as dir |
| -H, --hard-links | preserve hard links |
| -p, --perms | preserve permissions |
| -E, --executability | preserve executability |
| --chmod=CHMOD | affect file and/or directory permissions |
| -A, --acls | preserve ACLs (implies -p) |
| -X, --xattrs | preserve extended attributes |
| -o, --owner | preserve owner (super-user only) |
| -g, --group | preserve group |
| --devices | preserve device files (super-user only) |
| --specials | preserve special files |
| -D | same as --devices --specials |
| -t, --times | preserve modification times |

```

-O, --omit-dir-times    omit directories from --times
  --super               receiver attempts super-user activities
  --fake-super          store/recover privileged attrs using xattrs
-S, --sparse            handle sparse files efficiently
-n, --dry-run           perform a trial run with no changes made
-W, --whole-file        copy files whole (w/o delta-xfer algorithm)
-x, --one-file-system   don't cross filesystem boundaries
-B, --block-size=SIZE   force a fixed checksum block-size
-e, --rsh=COMMAND       specify the remote shell to use
  --rsync-path=PROGRAM  specify the rsync to run on remote machine
  --existing             skip creating new files on receiver
  --ignore-existing     skip updating files that exist on receiver
  --remove-source-files sender removes synchronized files (non-dir)
  --del                 an alias for --delete-during
  --delete              delete extraneous files from dest dirs
  --delete-before       receiver deletes before transfer (default)
  --delete-during       receiver deletes during xfer, not before
  --delete-delay        find deletions during, delete after
  --delete-after        receiver deletes after transfer, not before
  --delete-excluded     also delete excluded files from dest dirs
  --ignore-errors       delete even if there are I/O errors
  --force               force deletion of dirs even if not empty
  --max-delete=NUM      don't delete more than NUM files
  --max-size=SIZE       don't transfer any file larger than SIZE
  --min-size=SIZE       don't transfer any file smaller than SIZE
  --partial             keep partially transferred files
  --partial-dir=DIR     put a partially transferred file into DIR
  --delay-updates       put all updated files into place at end
-m, --prune-empty-dirs  prune empty directory chains from file-list
  --numeric-ids         don't map uid/gid values by user/group name
  --timeout=SECONDS     set I/O timeout in seconds
  --contimeout=SECONDS  set daemon connection timeout in seconds
-I, --ignore-times      don't skip files that match size and time
  --size-only           skip files that match in size
  --modify-window=NUM   compare mod-times with reduced accuracy
-T, --temp-dir=DIR      create temporary files in directory DIR
-y, --fuzzy             find similar file for basis if no dest file
  --compare-dest=DIR    also compare received files relative to DIR
  --copy-dest=DIR       ... and include copies of unchanged files
  --link-dest=DIR       hardlink to files in DIR when unchanged
-z, --compress          compress file data during the transfer
  --compress-level=NUM  explicitly set compression level
  --skip-compress=LIST  skip compressing files with suffix in LIST
-C, --cvs-exclude       auto-ignore files in the same way CVS does
-f, --filter=RULE       add a file-filtering RULE
-F                      same as --filter='dir-merge /rsync-filter'
                      repeated: --filter='- .rsync-filter'
  --exclude=PATTERN     exclude files matching PATTERN
  --exclude-from=FILE   read exclude patterns from FILE
  --include=PATTERN     don't exclude files matching PATTERN
  --include-from=FILE   read include patterns from FILE
  --files-from=FILE     read list of source-file names from FILE
-0, --from0             all *from/filter files are delimited by 0s
-s, --protect-args      no space-splitting; wildcard chars only

```

```

--address=ADDRESS    bind address for outgoing socket to daemon
--port=PORT          specify double-colon alternate port number
--sockopts=OPTIONS   specify custom TCP options
--blocking-io        use blocking I/O for the remote shell
--stats              give some file-transfer stats
-8, --8-bit-output    leave high-bit chars unescaped in output
-h, --human-readable  output numbers in a human-readable format
--progress           show progress during transfer
-P                  same as --partial --progress
-i, --itemize-changes output a change-summary for all updates
--out-format=FORMAT   output updates using the specified FORMAT
--log-file=FILE       log what we're doing to the specified FILE
--log-file-format=FMT log updates using the specified FMT
--password-file=FILE  read daemon-access password from FILE
--list-only           list the files instead of copying them
--bwlimit=KBPS        limit I/O bandwidth; KBytes per second
--write-batch=FILE    write a batched update to FILE
--only-write-batch=FILE like --write-batch but w/o updating dest
--read-batch=FILE     read a batched update from FILE
--protocol=NUM        force an older protocol version to be used
--iconv=CONVERT_SPEC request charset conversion of filenames
--checksum-seed=NUM   set block/file checksum seed (advanced)
-4, --ipv4            prefer IPv4
-6, --ipv6            prefer IPv6
--version            print version number
(-h) --help          show this help (see below for -h comment)

```

Rsync can also be run as a daemon, in which case the following options are accepted:

```

--daemon            run as an rsync daemon
--address=ADDRESS    bind to the specified address
--bwlimit=KBPS       limit I/O bandwidth; KBytes per second
--config=FILE        specify alternate rsyncd.conf file
--no-detach          do not detach from the parent
--port=PORT          listen on alternate port number
--log-file=FILE      override the "log file" setting
--log-file-format=FMT override the "log format" setting
--sockopts=OPTIONS   specify custom TCP options
-v, --verbose        increase verbosity
-4, --ipv4            prefer IPv4
-6, --ipv6            prefer IPv6
-h, --help           show this help (if used after --daemon)

```

OPTIONS

rsync uses the GNU long options package. Many of the command line options have two variants, one short and one long. These are shown below, separated by commas. Some options only have a long variant. The '=' for options that take a parameter is optional; whitespace can be used instead.

--help Print a short help page describing the options available in rsync and exit. For backward-compatibility with older versions of rsync, the help will also be output if you use the **-h** option without any other args.

--version
print the rsync version number and exit.

-v, --verbose

This option increases the amount of information you are given during the transfer. By default, rsync works silently. A single **-v** will give you information about what files are being transferred and a brief summary at the end. Two **-v** flags will give you information on what files are being skipped and slightly more information at the end. More than two **-v** flags should only be used if you are debugging rsync.

Note that the names of the transferred files that are output are done using a default **--out-format** of “%n%L”, which tells you just the name of the file and, if the item is a link, where it points. At the single **-v** level of verbosity, this does not mention when a file gets its attributes changed. If you ask for an itemized list of changed attributes (either **--itemize-changes** or adding “%i” to the **--out-format** setting), the output (on the client) increases to mention all items that are changed in any way. See the **--out-format** option for more details.

-q, --quiet

This option decreases the amount of information you are given during the transfer, notably suppressing information messages from the remote server. This flag is useful when invoking rsync from cron.

--no-motd

This option affects the information that is output by the client at the start of a daemon transfer. This suppresses the message-of-the-day (MOTD) text, but it also affects the list of modules that the daemon sends in response to the “rsync host:” request (due to a limitation in the rsync protocol), so omit this option if you want to request the list of modules from the daemon.

-I, --ignore-times

Normally rsync will skip any files that are already the same size and have the same modification timestamp. This option turns off this “quick check” behavior, causing all files to be updated.

--size-only

This modifies rsync’s “quick check” algorithm for finding files that need to be transferred, changing it from the default of transferring files with either a changed size or a changed last-modified time to just looking for files that have changed in size. This is useful when starting to use rsync after using another mirroring system which may not preserve timestamps exactly.

--modify-window

When comparing two timestamps, rsync treats the timestamps as being equal if they differ by no more than the modify-window value. This is normally 0 (for an exact match), but you may find it useful to set this to a larger value in some situations. In particular, when transferring to or from an MS Windows FAT filesystem (which represents times with a 2-second resolution), **--modify-window=1** is useful (allowing times to differ by up to 1 second).

-c, --checksum

This changes the way rsync checks if the files have been changed and are in need of a transfer. Without this option, rsync uses a “quick check” that (by default) checks if each file’s size and time of last modification match between the sender and receiver. This option changes this to compare a 128-bit MD4 checksum for each file that has a matching size. Generating the checksums means that both sides will expend a lot of disk I/O reading all the data in the files in the transfer (and this is prior to any reading that will be done to transfer changed files), so this can slow things down significantly.

The sending side generates its checksums while it is doing the file-system scan that builds the list of the available files. The receiver generates its checksums when it is scanning for changed files, and will checksum any file that has the same size as the corresponding sender’s file: files with either a changed size or a changed checksum are selected for transfer.

Note that rsync always verifies that each *transferred* file was correctly reconstructed on the receiving side by checking a whole-file checksum that is generated as the file is transferred, but that automatic after-the-transfer verification has nothing to do with this option’s before-the-transfer “Does this file need to be updated?” check.

-a, --archive

This is equivalent to **-rlptgoD**. It is a quick way of saying you want recursion and want to preserve almost everything (with **-H** being a notable omission). The only exception to the above equivalence is when **--files-from** is specified, in which case **-r** is not implied.

Note that **-a** **does not preserve hardlinks**, because finding multiply-linked files is expensive. You must separately specify **-H**.

--no-OPTION

You may turn off one or more implied options by prefixing the option name with “no-”. Not all options may be prefixed with a “no-”: only options that are implied by other options (e.g. **--no-D**, **--no-perms**) or have different defaults in various circumstances (e.g. **--no-whole-file**, **--no-blocking-io**, **--no-dirs**). You may specify either the short or the long option name after the “no-” prefix (e.g. **--no-R** is the same as **--no-relative**).

For example: if you want to use **-a** (**--archive**) but don’t want **-o** (**--owner**), instead of converting **-a** into **-rlptgD**, you could specify **-a --no-o** (or **-a --no-owner**).

The order of the options is important: if you specify **--no-r -a**, the **-r** option would end up being turned on, the opposite of **-a --no-r**. Note also that the side-effects of the **--files-from** option are NOT positional, as it affects the default state of several options and slightly changes the meaning of **-a** (see the **--files-from** option for more details).

-r, --recursive

This tells rsync to copy directories recursively. See also **--dirs (-d)**.

Beginning with rsync 3.0.0, the recursive algorithm used is now an incremental scan that uses much less memory than before and begins the transfer after the scanning of the first few directories have been completed. This incremental scan only affects our recursion algorithm, and does not change a non-recursive transfer. It is also only possible when both ends of the transfer are at least version 3.0.0.

Some options require rsync to know the full file list, so these options disable the incremental recursion mode. These include: **--delete-before**, **--delete-after**, **--prune-empty-dirs**, and **--delay-updates**. Because of this, the default delete mode when you specify **--delete** is now **--delete-during** when both ends of the connection are at least 3.0.0 (use **--del** or **--delete-during** to request this improved deletion mode explicitly). See also the **--delete-delay** option that is a better choice than using **--delete-after**.

Incremental recursion can be disabled using the **--no-inc-recursive** option or its shorter **--no-i-r** alias.

-R, --relative

Use relative paths. This means that the full path names specified on the command line are sent to the server rather than just the last parts of the filenames. This is particularly useful when you want to send several different directories at the same time. For example, if you used this command:

```
rsync -av /foo/bar/baz.c remote:/tmp/
```

... this would create a file named `baz.c` in `/tmp/` on the remote machine. If instead you used

```
rsync -avR /foo/bar/baz.c remote:/tmp/
```

then a file named `/tmp/foo/bar/baz.c` would be created on the remote machine, preserving its full path. These extra path elements are called “implied directories” (i.e. the “foo” and the “foo/bar” directories in the above example).

Beginning with rsync 3.0.0, rsync always sends these implied directories as real directories in the file list, even if a path element is really a symlink on the sending side. This prevents some really unexpected behaviors when copying the full path of a file that you didn’t realize had a symlink in its path. If you want to duplicate a server-side symlink, include both the symlink via its path, and

referent directory via its real path. If you're dealing with an older rsync on the sending side, you may need to use the **--no-implied-dirs** option.

It is also possible to limit the amount of path information that is sent as implied directories for each path you specify. With a modern rsync on the sending side (beginning with 2.6.7), you can insert a dot and a slash into the source path, like this:

```
rsync -avR /foo/./bar/baz.c remote:/tmp/
```

That would create /tmp/bar/baz.c on the remote machine. (Note that the dot must be followed by a slash, so "/foo/." would not be abbreviated.) (2) For older rsync versions, you would need to use a **chdir** to limit the source path. For example, when pushing files:

```
(cd /foo; rsync -avR bar/baz.c remote:/tmp/)
```

(Note that the parens put the two commands into a sub-shell, so that the "cd" command doesn't remain in effect for future commands.) If you're pulling files from an older rsync, use this idiom (but only for a non-daemon transfer):

```
rsync -avR --rsync-path="cd /foo; rsync" \
remote:bar/baz.c /tmp/
```

--no-implied-dirs

This option affects the default behavior of the **--relative** option. When it is specified, the attributes of the implied directories from the source names are not included in the transfer. This means that the corresponding path elements on the destination system are left unchanged if they exist, and any missing implied directories are created with default attributes. This even allows these implied path elements to have big differences, such as being a symlink to a directory on the receiving side.

For instance, if a command-line arg or a files-from entry told rsync to transfer the file "path/foo/file", the directories "path" and "path/foo" are implied when **--relative** is used. If "path/foo" is a symlink to "bar" on the destination system, the receiving rsync would ordinarily delete "path/foo", recreate it as a directory, and receive the file into the new directory. With **--no-implied-dirs**, the receiving rsync updates "path/foo/file" using the existing path elements, which means that the file ends up being created in "path/bar". Another way to accomplish this link preservation is to use the **--keep-dirlinks** option (which will also affect symlinks to directories in the rest of the transfer).

When pulling files from an rsync older than 3.0.0, you may need to use this option if the sending side has a symlink in the path you request and you wish the implied directories to be transferred as normal directories.

-b, --backup

With this option, preexisting destination files are renamed as each file is transferred or deleted. You can control where the backup file goes and what (if any) suffix gets appended using the **--backup-dir** and **--suffix** options.

Note that if you don't specify **--backup-dir**, (1) the **--omit-dir-times** option will be implied, and (2) if **--delete** is also in effect (without **--delete-excluded**), rsync will add a "protect" filter-rule for the backup suffix to the end of all your existing excludes (e.g. **-f "Pp *"**). This will prevent previously backed-up files from being deleted. Note that if you are supplying your own filter rules, you may need to manually insert your own exclude/protect rule somewhere higher up in the list so that it has a high enough priority to be effective (e.g., if your rules specify a trailing inclusion/exclusion of *****, the auto-added rule would never be reached).

--backup-dir=DIR

In combination with the **--backup** option, this tells rsync to store all backups in the specified directory on the receiving side. This can be used for incremental backups. You can additionally

specify a backup suffix using the **--suffix** option (otherwise the files backed up in the specified directory will keep their original filenames).

--suffix=SUFFIX

This option allows you to override the default backup suffix used with the **--backup (-b)** option. The default suffix is a ~ if no **--backup-dir** was specified, otherwise it is an empty string.

-u, --update

This forces rsync to skip any files which exist on the destination and have a modified time that is newer than the source file. (If an existing destination file has a modification time equal to the source file's, it will be updated if the sizes are different.)

Note that this does not affect the copying of symlinks or other special files. Also, a difference of file format between the sender and receiver is always considered to be important enough for an update, no matter what date is on the objects. In other words, if the source has a directory where the destination has a file, the transfer would occur regardless of the timestamps.

--inplace

This causes rsync not to create a new copy of the file and then move it into place. Instead rsync will overwrite the existing file, meaning that the rsync algorithm can't accomplish the full amount of network reduction it might be able to otherwise (since it does not yet try to sort data matches). One exception to this is if you combine the option with **--backup**, since rsync is smart enough to use the backup file as the basis file for the transfer.

This option is useful for transfer of large files with block-based changes or appended data, and also on systems that are disk bound, not network bound.

The option implies **--partial** (since an interrupted transfer does not delete the file), but conflicts with **--partial-dir** and **--delay-updates**. Prior to rsync 2.6.4 **--inplace** was also incompatible with **--compare-dest** and **--link-dest**.

WARNING: The file's data will be in an inconsistent state during the transfer (and possibly afterward if the transfer gets interrupted), so you should not use this option to update files that are in use. Also note that rsync will be unable to update a file in-place that is not writable by the receiving user.

--append

This causes rsync to update a file by appending data onto the end of the file, which presumes that the data that already exists on the receiving side is identical with the start of the file on the sending side. If a file needs to be transferred and its size on the receiver is the same or longer than the size on the sender, the file is skipped. This does not interfere with the updating of a file's non-content attributes (e.g. permissions, ownership, etc.) when the file does not need to be transferred, nor does it affect the updating of any non-regular files. Implies **--inplace**, but does not conflict with **--sparse** (since it is always extending a file's length).

--append-verify

This works just like the **--append** option, but the existing data on the receiving side is included in the full-file checksum verification step, which will cause a file to be resent if the final verification step fails (rsync uses a normal, non-appending **--inplace** transfer for the resend).

Note: prior to rsync 3.0.0, the **--append** option worked like **--append-verify**, so if you are interacting with an older rsync (or the transfer is using a protocol prior to 30), specifying either append option will initiate an **--append-verify** transfer.

-d, --dirs

Tell the sending side to include any directories that are encountered. Unlike **--recursive**, a directory's contents are not copied unless the directory name specified is "." or ends with a trailing slash (e.g. ".", "dir/.", "dir/", etc.). Without this option or the **--recursive** option, rsync will skip all directories it encounters (and output a message to that effect for each one). If you specify both **--dirs** and **--recursive**, **--recursive** takes precedence.

The **--dirs** option is implied by the **--files-from** option or the **--list-only** option (including an implied **--list-only** usage) if **--recursive** wasn't specified (so that directories are seen in the listing). Specify **--no-dirs** (or **--no-d**) if you want to turn this off.

There is also a backward-compatibility helper option, **--old-dirs** (or **--old-d**) that tells rsync to use a hack of "**-r --exclude='/*/*'**" to get an older rsync to list a single directory without recursing.

-l, --links

When symlinks are encountered, recreate the symlink on the destination.

-L, --copy-links

When symlinks are encountered, the item that they point to (the referent) is copied, rather than the symlink. In older versions of rsync, this option also had the side-effect of telling the receiving side to follow symlinks, such as symlinks to directories. In a modern rsync such as this one, you'll need to specify **--keep-dirlinks (-K)** to get this extra behavior. The only exception is when sending files to an rsync that is too old to understand **-K** — in that case, the **-L** option will still have the side-effect of **-K** on that older receiving rsync.

--copy-unsafe-links

This tells rsync to copy the referent of symbolic links that point outside the copied tree. Absolute symlinks are also treated like ordinary files, and so are any symlinks in the source path itself when **--relative** is used. This option has no additional effect if **--copy-links** was also specified.

--safe-links

This tells rsync to ignore any symbolic links which point outside the copied tree. All absolute symlinks are also ignored. Using this option in conjunction with **--relative** may give unexpected results.

-k, --copy-dirlinks

This option causes the sending side to treat a symlink to a directory as though it were a real directory. This is useful if you don't want symlinks to non-directories to be affected, as they would be using **--copy-links**.

Without this option, if the sending side has replaced a directory with a symlink to a directory, the receiving side will delete anything that is in the way of the new symlink, including a directory hierarchy (as long as **--force** or **--delete** is in effect).

See also **--keep-dirlinks** for an analogous option for the receiving side.

-K, --keep-dirlinks

This option causes the receiving side to treat a symlink to a directory as though it were a real directory, but only if it matches a real directory from the sender. Without this option, the receiver's symlink would be deleted and replaced with a real directory.

For example, suppose you transfer a directory "foo" that contains a file "file", but "foo" is a symlink to directory "bar" on the receiver. Without **--keep-dirlinks**, the receiver deletes symlink "foo", recreates it as a directory, and receives the file into the new directory. With **--keep-dirlinks**, the receiver keeps the symlink and "file" ends up in "bar".

One note of caution: if you use **--keep-dirlinks**, you must trust all the symlinks in the copy! If it is possible for an untrusted user to create their own symlink to any directory, the user could then (on a subsequent copy) replace the symlink with a real directory and affect the content of whatever directory the symlink references. For backup copies, you are better off using something like a bind mount instead of a symlink to modify your receiving hierarchy.

See also **--copy-dirlinks** for an analogous option for the sending side.

-H, --hard-links

This tells rsync to look for hard-linked files in the transfer and link together the corresponding files on the receiving side. Without this option, hard-linked files in the transfer are treated as though they were separate files.

When you are updating a non-empty destination, this option only ensures that files that are hard-linked together on the source are hard-linked together on the destination. It does NOT currently endeavor to break already existing hard links on the destination that do not exist between the source files. Note, however, that if one or more extra-linked files have content changes, they will become unlinked when updated (assuming you are not using the **---inplace** option).

Note that rsync can only detect hard links between files that are inside the transfer set. If rsync updates a file that has extra hard-link connections to files outside the transfer, that linkage will be broken. If you are tempted to use the **---inplace** option to avoid this breakage, be very careful that you know how your files are being updated so that you are certain that no unintended changes happen due to lingering hard links (and see the **---inplace** option for more caveats).

If incremental recursion is active (see **---recursive**), rsync may transfer a missing hard-linked file before it finds that another link for that contents exists elsewhere in the hierarchy. This does not affect the accuracy of the transfer, just its efficiency. One way to avoid this is to disable incremental recursion using the **---no-inc-recursive** option.

-p, ---perms

This option causes the receiving rsync to set the destination permissions to be the same as the source permissions. (See also the **---chmod** option for a way to modify what rsync considers to be the source permissions.)

When this option is *off*, permissions are set as follows:

- o Existing files (including updated files) retain their existing permissions, though the **---executability** option might change just the execute permission for the file.
- o New files get their “normal” permission bits set to the source file’s permissions masked with the receiving directory’s default permissions (either the receiving process’s umask, or the permissions specified via the destination directory’s default ACL), and their special permission bits disabled except in the case where a new directory inherits a setgid bit from its parent directory.

Thus, when **---perms** and **---executability** are both disabled, rsync’s behavior is the same as that of other file-copy utilities, such as **cp(1)** and **tar(1)**.

In summary: to give destination files (both old and new) the source permissions, use **---perms**. To give new files the destination-default permissions (while leaving existing files unchanged), make sure that the **---perms** option is off and use **---chmod=ugo=rwX** (which ensures that all non-masked bits get enabled). If you’d care to make this latter behavior easier to type, you could define a popt alias for it, such as putting this line in the file `~/popt` (the following defines the **-Z** option, and includes **---no-g** to use the default group of the destination dir):

```
rsync alias -Z --no-p --no-g --chmod=ugo=rwX
```

You could then use this new option in a command such as this one:

```
rsync -avZ src/ dest/
```

(Caveat: make sure that **-a** does not follow **-Z**, or it will re-enable the two “**---no-***” options mentioned above.)

The preservation of the destination’s setgid bit on newly-created directories when **---perms** is off was added in rsync 2.6.7. Older rsync versions erroneously preserved the three special permission bits for newly-created files when **---perms** was off, while overriding the destination’s setgid bit setting on a newly-created directory. Default ACL observance was added to the ACL patch for rsync 2.6.7, so older (or non-ACL-enabled) rsyncs use the umask even if default ACLs are present. (Keep in mind that it is the version of the receiving rsync that affects these behaviors.)

-E, --executability

This option causes rsync to preserve the executability (or non-executability) of regular files when **--perms** is not enabled. A regular file is considered to be executable if at least one 'x' is turned on in its permissions. When an existing destination file's executability differs from that of the corresponding source file, rsync modifies the destination file's permissions as follows:

- o To make a file non-executable, rsync turns off all its 'x' permissions.
- o To make a file executable, rsync turns on each 'x' permission that has a corresponding 'r' permission enabled.

If **--perms** is enabled, this option is ignored.

-A, --acls

This option causes rsync to update the destination ACLs to be the same as the source ACLs. The option also implies **--perms**.

The source and destination systems must have compatible ACL entries for this option to work properly. See the **--fake-super** option for a way to backup and restore ACLs that are not compatible.

-X, --xattrs

This option causes rsync to update the remote extended attributes to be the same as the local ones.

For systems that support extended-attribute namespaces, a copy being done by a super-user copies all namespaces except system.*. A normal user only copies the user.* namespace. To be able to backup and restore non-user namespaces as a normal user, see the **--fake-super** option.

--chmod

This option tells rsync to apply one or more comma-separated "chmod" strings to the permission of the files in the transfer. The resulting value is treated as though it was the permissions that the sending side supplied for the file, which means that this option can seem to have no effect on existing files if **--perms** is not enabled.

In addition to the normal parsing rules specified in the **chmod(1)** manpage, you can specify an item that should only apply to a directory by prefixing it with a 'D', or specify an item that should only apply to a file by prefixing it with a 'F'. For example:

```
--chmod=Dg+s,ug+w,Fo-w,+X
```

It is also legal to specify multiple **--chmod** options, as each additional option is just appended to the list of changes to make.

See the **--perms** and **--executability** options for how the resulting permission value can be applied to the files in the transfer.

-o, --owner

This option causes rsync to set the owner of the destination file to be the same as the source file, but only if the receiving rsync is being run as the super-user (see also the **--super** and **--fake-super** options). Without this option, the owner of new and/or transferred files are set to the invoking user on the receiving side.

The preservation of ownership will associate matching names by default, but may fall back to using the ID number in some circumstances (see also the **--numeric-ids** option for a full discussion).

-g, --group

This option causes rsync to set the group of the destination file to be the same as the source file. If the receiving program is not running as the super-user (or if **--no-super** was specified), only groups that the invoking user on the receiving side is a member of will be preserved. Without this option, the group is set to the default group of the invoking user on the receiving side.

The preservation of group information will associate matching names by default, but may fall back to using the ID number in some circumstances (see also the **--numeric-ids** option for a full discussion).

--devices

This option causes rsync to transfer character and block device files to the remote system to recreate these devices. This option has no effect if the receiving rsync is not run as the super-user (see also the **--super** and **--fake-super** options).

--specials

This option causes rsync to transfer special files such as named sockets and fifos.

-D The **-D** option is equivalent to **--devices --specials**.

-t, --times

This tells rsync to transfer modification times along with the files and update them on the remote system. Note that if this option is not used, the optimization that excludes files that have not been modified cannot be effective; in other words, a missing **-t** or **-a** will cause the next transfer to behave as if it used **-I**, causing all files to be updated (though the rsync algorithm will make the update fairly efficient if the files haven't actually changed, you're much better off using **-t**).

-O, --omit-dir-times

This tells rsync to omit directories when it is preserving modification times (see **--times**). If NFS is sharing the directories on the receiving side, it is a good idea to use **-O**. This option is inferred if you use **--backup** without **--backup-dir**.

--super

This tells the receiving side to attempt super-user activities even if the receiving rsync wasn't run by the super-user. These activities include: preserving users via the **--owner** option, preserving all groups (not just the current user's groups) via the **--groups** option, and copying devices via the **--devices** option. This is useful for systems that allow such activities without being the super-user, and also for ensuring that you will get errors if the receiving side isn't being running as the super-user. To turn off super-user activities, the super-user can use **--no-super**.

--fake-super

When this option is enabled, rsync simulates super-user activities by saving/restoring the privileged attributes via special extended attributes that are attached to each file (as needed). This includes the file's owner and group (if it is not the default), the file's device info (device & special files are created as empty text files), and any permission bits that we won't allow to be set on the real file (e.g. the real file gets u-s,g-s,o-t for safety) or that would limit the owner's access (since the real super-user can always access/change a file, the files we create can always be accessed/changed by the creating user). This option also handles ACLs (if **--acls** was specified) and non-user extended attributes (if **--xattrs** was specified).

This is a good way to backup data without using a super-user, and to store ACLs from incompatible systems.

The **--fake-super** option only affects the side where the option is used. To affect the remote side of a remote-shell connection, specify an rsync path:

```
rsync -av --rsync-path="rsync --fake-super" /src/ host:/dest/
```

Since there is only one "side" in a local copy, this option affects both the sending and receiving of files. You'll need to specify a copy using "localhost" if you need to avoid this, possibly using the "lsh" shell script (from the support directory) as a substitute for an actual remote shell (see **--rsh**).

This option is overridden by both **--super** and **--no-super**.

See also the "fake super" setting in the daemon's rsyncd.conf file.

-S, --sparse

Try to handle sparse files efficiently so they take up less space on the destination. Conflicts with **--inplace** because it's not possible to overwrite data in a sparse fashion.

NOTE: Don't use this option when the destination is a Solaris "tmpfs" filesystem. It doesn't seem to handle seeks over null regions correctly and ends up corrupting the files.

-n, --dry-run

This makes rsync perform a trial run that doesn't make any changes (and produces mostly the same output as a real run). It is most commonly used in combination with the **-v, --verbose** and/or **-i, --itemize-changes** options to see what an rsync command is going to do before one actually runs it.

The output of **--itemize-changes** is supposed to be exactly the same on a dry run and a subsequent real run (barring intentional trickery and system call failures); if it isn't, that's a bug. Other output is the same to the extent practical, but may differ in some areas. Notably, a dry run does not send the actual data for file transfers, so **--progress** has no effect, the "bytes sent", "bytes received", "literal data", and "matched data" statistics are too small, and the "speedup" value is equivalent to a run where no file transfers are needed.

-W, --whole-file

With this option the delta-transfer algorithm is not used and the whole file is sent as-is instead. The transfer may be faster if this option is used when the bandwidth between the source and destination machines is higher than the bandwidth to disk (especially when the "disk" is actually a networked filesystem). This is the default when both the source and destination are specified as local paths.

-x, --one-file-system

This tells rsync to avoid crossing a filesystem boundary when recursing. This does not limit the user's ability to specify items to copy from multiple filesystems, just rsync's recursion through the hierarchy of each directory that the user specified, and also the analogous recursion on the receiving side during deletion. Also keep in mind that rsync treats a "bind" mount to the same device as being on the same filesystem.

If this option is repeated, rsync omits all mount-point directories from the copy. Otherwise, it includes an empty directory at each mount-point it encounters (using the attributes of the mounted directory because those of the underlying mount-point directory are inaccessible).

If rsync has been told to collapse symlinks (via **--copy-links** or **--copy-unsafe-links**), a symlink to a directory on another device is treated like a mount-point. Symlinks to non-directories are unaffected by this option.

--existing, --ignore-non-existing

This tells rsync to skip creating files (including directories) that do not exist yet on the destination. If this option is combined with the **--ignore-existing** option, no files will be updated (which can be useful if all you want to do is delete extraneous files).

--ignore-existing

This tells rsync to skip updating files that already exist on the destination (this does *not* ignore existing directories, or nothing would get done). See also **--existing**.

This option can be useful for those doing backups using the **--link-dest** option when they need to continue a backup run that got interrupted. Since a **--link-dest** run is copied into a new directory hierarchy (when it is used properly), using **--ignore-existing** will ensure that the already-handled files don't get tweaked (which avoids a change in permissions on the hard-linked files). This does mean that this option is only looking at the existing files in the destination hierarchy itself.

--remove-source-files

This tells rsync to remove from the sending side the files (meaning non-directories) that are a part of the transfer and have been successfully duplicated on the receiving side.

--delete

This tells rsync to delete extraneous files from the receiving side (ones that aren't on the sending side), but only for the directories that are being synchronized. You must have asked rsync to send the whole directory (e.g. "dir" or "dir/") without using a wildcard for the directory's contents (e.g. "dir/*") since the wildcard is expanded by the shell and rsync thus gets a request to transfer individual files, not the files' parent directory. Files that are excluded from transfer are also excluded from being deleted unless you use the **--delete-excluded** option or mark the rules as only matching on the sending side (see the include/exclude modifiers in the FILTER RULES section).

Prior to rsync 2.6.7, this option would have no effect unless **--recursive** was enabled. Beginning with 2.6.7, deletions will also occur when **--dirs (-d)** is enabled, but only for directories whose contents are being copied.

This option can be dangerous if used incorrectly! It is a very good idea to first try a run using the **--dry-run** option (**-n**) to see what files are going to be deleted.

If the sending side detects any I/O errors, then the deletion of any files at the destination will be automatically disabled. This is to prevent temporary filesystem failures (such as NFS errors) on the sending side causing a massive deletion of files on the destination. You can override this with the **--ignore-errors** option.

The **--delete** option may be combined with one of the **--delete-WHEN** options without conflict, as well as **--delete-excluded**. However, if none of the **--delete-WHEN** options are specified, rsync will choose the **--delete-during** algorithm when talking to an rsync 3.0.0 or newer, and the **--delete-before** algorithm when talking to an older rsync. See also **--delete-delay** and **--delete-after**.

--delete-before

Request that the file-deletions on the receiving side be done before the transfer starts. See **--delete** (which is implied) for more details on file-deletion.

Deleting before the transfer is helpful if the filesystem is tight for space and removing extraneous files would help to make the transfer possible. However, it does introduce a delay before the start of the transfer, and this delay might cause the transfer to timeout (if **--timeout** was specified). It also forces rsync to use the old, non-incremental recursion algorithm that requires rsync to scan all the files in the transfer into memory at once (see **--recursive**).

--delete-during, --del

Request that the file-deletions on the receiving side be done incrementally as the transfer happens. This is a faster method than choosing the before- or after-transfer algorithm, but it is only supported beginning with rsync version 2.6.4. See **--delete** (which is implied) for more details on file-deletion.

--delete-delay

Request that the file-deletions on the receiving side be computed during the transfer, and then removed after the transfer completes. If the number of removed files overflows an internal buffer, a temporary file will be created on the receiving side to hold the names (it is removed while open, so you shouldn't see it during the transfer). If the creation of the temporary file fails, rsync will try to fall back to using **--delete-after** (which it cannot do if **--recursive** is doing an incremental scan).

--delete-after

Request that the file-deletions on the receiving side be done after the transfer has completed. This is useful if you are sending new per-directory merge files as a part of the transfer and you want their exclusions to take effect for the delete phase of the current transfer. It also forces rsync to use the old, non-incremental recursion algorithm that requires rsync to scan all the files in the transfer into memory at once (see **--recursive**). See **--delete** (which is implied) for more details on file-deletion.

--delete-excluded

In addition to deleting the files on the receiving side that are not on the sending side, this tells rsync to also delete any files on the receiving side that are excluded (see **--exclude**). See the FILTER RULES section for a way to make individual exclusions behave this way on the receiver, and for a way to protect files from **--delete-excluded**. See **--delete** (which is implied) for more details on file-deletion.

--ignore-errors

Tells **--delete** to go ahead and delete files even when there are I/O errors.

--force

This option tells rsync to delete a non-empty directory when it is to be replaced by a non-directory. This is only relevant if deletions are not active (see **--delete** for details).

Note for older rsync versions: **--force** used to still be required when using **--delete-after**, and it used to be non-functional unless the **--recursive** option was also enabled.

--max-delete=NUM

This tells rsync not to delete more than NUM files or directories. If that limit is exceeded, a warning is output and rsync exits with an error code of 25 (new for 3.0.0).

Also new for version 3.0.0, you may specify **--max-delete=0** to be warned about any extraneous files in the destination without removing any of them. Older clients interpreted this as “unlimited”, so if you don’t know what version the client is, you can use the less obvious **--max-delete=-1** as a backward-compatible way to specify that no deletions be allowed (though older versions didn’t warn when the limit was exceeded).

--max-size=SIZE

This tells rsync to avoid transferring any file that is larger than the specified SIZE. The SIZE value can be suffixed with a string to indicate a size multiplier, and may be a fractional value (e.g. **--max-size=1.5m**).

The suffixes are as follows: “K” (or “KiB”) is a kibibyte (1024), “M” (or “MiB”) is a mebibyte (1024*1024), and “G” (or “GiB”) is a gibibyte (1024*1024*1024). If you want the multiplier to be 1000 instead of 1024, use “KB”, “MB”, or “GB”. (Note: lower-case is also accepted for all values.) Finally, if the suffix ends in either “+1” or “-1”, the value will be offset by one byte in the indicated direction.

Examples: **--max-size=1.5mb-1** is 1499999 bytes, and **--max-size=2g+1** is 2147483649 bytes.

--min-size=SIZE

This tells rsync to avoid transferring any file that is smaller than the specified SIZE, which can help in not transferring small, junk files. See the **--max-size** option for a description of SIZE.

-B, --block-size=BLOCKSIZE

This forces the block size used in the rsync algorithm to a fixed value. It is normally selected based on the size of each file being updated. See the technical report for details.

-e, --rsh=COMMAND

This option allows you to choose an alternative remote shell program to use for communication between the local and remote copies of rsync. Typically, rsync is configured to use ssh by default, but you may prefer to use rsh on a local network.

If this option is used with **[user@]host::module/path**, then the remote shell *COMMAND* will be used to run an rsync daemon on the remote host, and all data will be transmitted through that remote shell connection, rather than through a direct socket connection to a running rsync daemon on the remote host. See the section “USING RSYNC-DAEMON FEATURES VIA A REMOTE-SHELL CONNECTION” above.

Command-line arguments are permitted in *COMMAND* provided that *COMMAND* is presented to rsync as a single argument. You must use spaces (not tabs or other whitespace) to separate the command and args from each other, and you can use single- and/or double-quotes to preserve

spaces in an argument (but not backslashes). Note that doubling a single-quote inside a single-quoted string gives you a single-quote; likewise for double-quotes (though you need to pay attention to which quotes your shell is parsing and which quotes rsync is parsing). Some examples:

```
-e 'ssh -p 2234'
-e 'ssh -o "ProxyCommand nohup ssh firewall nc -w1 %h %p"'
```

(Note that ssh users can alternately customize site-specific connect options in their .ssh/config file.)

You can also choose the remote shell program using the RSYNC_RSH environment variable, which accepts the same range of values as **-e**.

See also the **--blocking-io** option which is affected by this option.

--rsync-path=PROGRAM

Use this to specify what program is to be run on the remote machine to start-up rsync. Often used when rsync is not in the default remote-shell's path (e.g. **--rsync-path=/usr/local/bin/rsync**). Note that PROGRAM is run with the help of a shell, so it can be any program, script, or command sequence you'd care to run, so long as it does not corrupt the standard-in & standard-out that rsync is using to communicate.

One tricky example is to set a different default directory on the remote machine for use with the **--relative** option. For instance:

```
rsync -avR --rsync-path="cd /a/b && rsync" host:c/d /e/
```

-C, --cvs-exclude

This is a useful shorthand for excluding a broad range of files that you often don't want to transfer between systems. It uses a similar algorithm to CVS to determine if a file should be ignored.

The exclude list is initialized to exclude the following items (these initial items are marked as perishable — see the FILTER RULES section):

```
RCS SCCS CVS CVS.adm RCSLOG cvslog.* tags TAGS .make.state
.nse_depinfo *~ #* .* ,* _$* *$ *.old *.bak *.BAK *.orig
*.rej .del-* *.a *.olb *.o *.obj *.so *.exe *.Z *.elc *.ln
core .svn/ .git/ .bzr/
```

then, files listed in a \$HOME/.cvsignore are added to the list and any files listed in the CVSIGNORE environment variable (all cvsignore names are delimited by whitespace).

Finally, any file is ignored if it is in the same directory as a .cvsignore file and matches one of the patterns listed therein. Unlike rsync's filter/exclude files, these patterns are split on whitespace. See the **cvs(1)** manual for more information.

If you're combining **-C** with your own **--filter** rules, you should note that these CVS excludes are appended at the end of your own rules, regardless of where the **-C** was placed on the command-line. This makes them a lower priority than any rules you specified explicitly. If you want to control where these CVS excludes get inserted into your filter rules, you should omit the **-C** as a command-line option and use a combination of **--filter=:C** and **--filter=-C** (either on your command-line or by putting the ":C" and "-C" rules into a filter file with your other rules). The first option turns on the per-directory scanning for the .cvsignore file. The second option does a one-time import of the CVS excludes mentioned above.

-f, --filter=RULE

This option allows you to add rules to selectively exclude certain files from the list of files to be transferred. This is most useful in combination with a recursive transfer.

You may use as many **--filter** options on the command line as you like to build up the list of files to exclude. If the filter contains whitespace, be sure to quote it so that the shell gives the rule to rsync as a single argument. The text below also mentions that you can use an underscore to replace the space that separates a rule from its arg.

See the FILTER RULES section for detailed information on this option.

- F** The **-F** option is a shorthand for adding two **--filter** rules to your command. The first time it is used is a shorthand for this rule:

```
--filter='dir-merge /.rsync-filter'
```

This tells rsync to look for per-directory .rsync-filter files that have been sprinkled through the hierarchy and use their rules to filter the files in the transfer. If **-F** is repeated, it is a shorthand for this rule:

```
--filter='exclude .rsync-filter'
```

This filters out the .rsync-filter files themselves from the transfer.

See the FILTER RULES section for detailed information on how these options work.

--exclude=PATTERN

This option is a simplified form of the **--filter** option that defaults to an exclude rule and does not allow the full rule-parsing syntax of normal filter rules.

See the FILTER RULES section for detailed information on this option.

--exclude-from=FILE

This option is related to the **--exclude** option, but it specifies a FILE that contains exclude patterns (one per line). Blank lines in the file and lines starting with ';' or '#' are ignored. If FILE is -, the list will be read from standard input.

--include=PATTERN

This option is a simplified form of the **--filter** option that defaults to an include rule and does not allow the full rule-parsing syntax of normal filter rules.

See the FILTER RULES section for detailed information on this option.

--include-from=FILE

This option is related to the **--include** option, but it specifies a FILE that contains include patterns (one per line). Blank lines in the file and lines starting with ';' or '#' are ignored. If FILE is -, the list will be read from standard input.

--files-from=FILE

Using this option allows you to specify the exact list of files to transfer (as read from the specified FILE or - for standard input). It also tweaks the default behavior of rsync to make transferring just the specified files and directories easier:

- o The **--relative** (**-R**) option is implied, which preserves the path information that is specified for each item in the file (use **--no-relative** or **--no-R** if you want to turn that off).
- o The **--dirs** (**-d**) option is implied, which will create directories specified in the list on the destination rather than noisily skipping them (use **--no-dirs** or **--no-d** if you want to turn that off).
- o The **--archive** (**-a**) option's behavior does not imply **--recursive** (**-r**), so specify it explicitly, if you want it.
- o These side-effects change the default state of rsync, so the position of the **--files-from** option on the command-line has no bearing on how other options are parsed (e.g. **-a** works the same before or after **--files-from**, as does **--no-R** and all other options).

The filenames that are read from the FILE are all relative to the source dir — any leading slashes are removed and no “..” references are allowed to go higher than the source dir. For example, take this command:

```
rsync -a --files-from=/tmp/foo /usr remote:/backup
```

If /tmp/foo contains the string “bin” (or even “/bin”), the /usr/bin directory will be created as /backup/bin on the remote host. If it contains “bin/” (note the trailing slash), the immediate contents of the directory would also be sent (without needing to be explicitly mentioned in the file — this began in version 2.6.4). In both cases, if the **-r** option was enabled, that dir’s entire hierarchy would also be transferred (keep in mind that **-r** needs to be specified explicitly with **--files-from**, since it is not implied by **-a**). Also note that the effect of the (enabled by default) **--relative** option is to duplicate only the path info that is read from the file — it does not force the duplication of the source-spec path (/usr in this case).

In addition, the **--files-from** file can be read from the remote host instead of the local host if you specify a “host:” in front of the file (the host must match one end of the transfer). As a short-cut, you can specify just a prefix of “:” to mean “use the remote end of the transfer”. For example:

```
rsync -a --files-from=:/path/file-list src:/ /tmp/copy
```

This would copy all the files specified in the /path/file-list file that was located on the remote “src” host.

-0, --from0

This tells rsync that the rules/filenames it reads from a file are terminated by a null ('\0') character, not a NL, CR, or CR+LF. This affects **--exclude-from**, **--include-from**, **--files-from**, and any merged files specified in a **--filter** rule. It does not affect **--cvs-exclude** (since all names read from a .cvsignore file are split on whitespace).

If the **--iconv** and **--protect-args** options are specified and the **--files-from** filenames are being sent from one host to another, the filenames will be translated from the sending host’s charset to the receiving host’s charset.

-s, --protect-args

This option sends all filenames and some options to the remote rsync without allowing the remote shell to interpret them. This means that spaces are not split in names, and any non-wildcard special characters are not translated (such as ~, \$, :, &, etc.). Wildcards are expanded on the remote host by rsync (instead of the shell doing it).

If you use this option with **--iconv**, the args will also be translated from the local to the remote character-set. The translation happens before wild-cards are expanded. See also the **--files-from** option.

-T, --temp-dir=DIR

This option instructs rsync to use DIR as a scratch directory when creating temporary copies of the files transferred on the receiving side. The default behavior is to create each temporary file in the same directory as the associated destination file.

This option is most often used when the receiving disk partition does not have enough free space to hold a copy of the largest file in the transfer. In this case (i.e. when the scratch directory is on a different disk partition), rsync will not be able to rename each received temporary file over the top of the associated destination file, but instead must copy it into place. Rsync does this by copying the file over the top of the destination file, which means that the destination file will contain truncated data during this copy. If this were not done this way (even if the destination file were first removed, the data locally copied to a temporary file in the destination directory, and then renamed into place) it would be possible for the old file to continue taking up disk space (if someone had it open), and thus there might not be enough room to fit the new version on the disk at the same time.

If you are using this option for reasons other than a shortage of disk space, you may wish to combine it with the **--delay-updates** option, which will ensure that all copied files get put into subdirectories in the destination hierarchy, awaiting the end of the transfer. If you don't have enough room to duplicate all the arriving files on the destination partition, another way to tell rsync that you aren't overly concerned about disk space is to use the **--partial-dir** option with a relative path; because this tells rsync that it is OK to stash off a copy of a single file in a subdir in the destination hierarchy, rsync will use the partial-dir as a staging area to bring over the copied file, and then rename it into place from there. (Specifying a **--partial-dir** with an absolute path does not have this side-effect.)

-y, --fuzzy

This option tells rsync that it should look for a basis file for any destination file that is missing. The current algorithm looks in the same directory as the destination file for either a file that has an identical size and modified-time, or a similarly-named file. If found, rsync uses the fuzzy basis file to try to speed up the transfer.

Note that the use of the **--delete** option might get rid of any potential fuzzy-match files, so either use **--delete-after** or specify some filename exclusions if you need to prevent this.

--compare=dest=DIR

This option instructs rsync to use *DIR* on the destination machine as an additional hierarchy to compare destination files against doing transfers (if the files are missing in the destination directory). If a file is found in *DIR* that is identical to the sender's file, the file will NOT be transferred to the destination directory. This is useful for creating a sparse backup of just files that have changed from an earlier backup.

Beginning in version 2.6.4, multiple **--compare=dest** directories may be provided, which will cause rsync to search the list in the order specified for an exact match. If a match is found that differs only in attributes, a local copy is made and the attributes updated. If a match is not found, a basis file from one of the *DIRs* will be selected to try to speed up the transfer.

If *DIR* is a relative path, it is relative to the destination directory. See also **--copy=dest** and **--link=dest**.

--copy=dest=DIR

This option behaves like **--compare=dest**, but rsync will also copy unchanged files found in *DIR* to the destination directory using a local copy. This is useful for doing transfers to a new destination while leaving existing files intact, and then doing a flash-cutover when all files have been successfully transferred.

Multiple **--copy=dest** directories may be provided, which will cause rsync to search the list in the order specified for an unchanged file. If a match is not found, a basis file from one of the *DIRs* will be selected to try to speed up the transfer.

If *DIR* is a relative path, it is relative to the destination directory. See also **--compare=dest** and **--link=dest**.

--link=dest=DIR

This option behaves like **--copy=dest**, but unchanged files are hard linked from *DIR* to the destination directory. The files must be identical in all preserved attributes (e.g. permissions, possibly ownership) in order for the files to be linked together. An example:

```
rsync -av --link=dest=$PWD/prior_dir host:src_dir/ new_dir/
```

Beginning in version 2.6.4, multiple **--link=dest** directories may be provided, which will cause rsync to search the list in the order specified for an exact match. If a match is found that differs only in attributes, a local copy is made and the attributes updated. If a match is not found, a basis file from one of the *DIRs* will be selected to try to speed up the transfer.

This option works best when copying into an empty destination hierarchy, as rsync treats existing files as definitive (so it never looks in the link=dest dirs when a destination file already exists), and

as malleable (so it might change the attributes of a destination file, which affects all the hard-linked versions).

Note that if you combine this option with **--ignore-times**, rsync will not link any files together because it only links identical files together as a substitute for transferring the file, never as an additional check after the file is updated.

If *DIR* is a relative path, it is relative to the destination directory. See also **--compare-dest** and **--copy-dest**.

Note that rsync versions prior to 2.6.1 had a bug that could prevent **--link-dest** from working properly for a non-super-user when **-o** was specified (or implied by **-a**). You can work-around this bug by avoiding the **-o** option when sending to an old rsync.

-z, --compress

With this option, rsync compresses the file data as it is sent to the destination machine, which reduces the amount of data being transmitted — something that is useful over a slow connection.

Note that this option typically achieves better compression ratios than can be achieved by using a compressing remote shell or a compressing transport because it takes advantage of the implicit information in the matching data blocks that are not explicitly sent over the connection.

See the **--skip-compress** option for the default list of file suffixes that will not be compressed.

--compress-level=NUM

Explicitly set the compression level to use (see **--compress**) instead of letting it default. If NUM is non-zero, the **--compress** option is implied.

--skip-compress=LIST

Override the list of file suffixes that will not be compressed. The **LIST** should be one or more file suffixes (without the dot) separated by slashes (/).

You may specify an empty string to indicate that no file should be skipped.

Simple character-class matching is supported: each must consist of a list of letters inside the square brackets (e.g. no special classes, such as “[:alpha:]”, are supported).

The characters asterisk (*) and question-mark (?) have no special meaning.

Here’s an example that specifies 6 suffixes to skip (since 1 of the 5 rules matches 2 suffixes):

```
--skip-compress=gz/jpg/mp[34]/7z/bz2
```

The default list of suffixes that will not be compressed is this (several of these are newly added for 3.0.0):

```
gz/zip/z/rpm/deb/iso/bz2/t[gb]z/7z/mp[34]/mov/avi/ogg/jpg/jpeg
```

This list will be replaced by your **--skip-compress** list in all but one situation: a copy from a daemon rsync will add your skipped suffixes to its list of non-compressing files (and its list may be configured to a different default).

--numeric-ids

With this option rsync will transfer numeric group and user IDs rather than using user and group names and mapping them at both ends.

By default rsync will use the username and groupname to determine what ownership to give files. The special uid 0 and the special group 0 are never mapped via user/group names even if the **--numeric-ids** option is not specified.

If a user or group has no name on the source system or it has no match on the destination system, then the numeric ID from the source system is used instead. See also the comments on the “use chroot” setting in the rsyncd.conf manpage for information on how the chroot setting affects rsync’s ability to look up the names of the users and groups and what you can do about it.

--timeout=TIMEOUT

This option allows you to set a maximum I/O timeout in seconds. If no data is transferred for the specified time then rsync will exit. The default is 0, which means no timeout.

--contimeout

This option allows you to set the amount of time that rsync will wait for its connection to an rsync daemon to succeed. If the timeout is reached, rsync exits with an error.

--address

By default rsync will bind to the wildcard address when connecting to an rsync daemon. The **--address** option allows you to specify a specific IP address (or hostname) to bind to. See also this option in the **--daemon** mode section.

--port=PORT

This specifies an alternate TCP port number to use rather than the default of 873. This is only needed if you are using the double-colon (::) syntax to connect with an rsync daemon (since the URL syntax has a way to specify the port as a part of the URL). See also this option in the **--daemon** mode section.

--sockopts

This option can provide endless fun for people who like to tune their systems to the utmost degree. You can set all sorts of socket options which may make transfers faster (or slower!). Read the man page for the `setsockopt()` system call for details on some of the options you may be able to set. By default no special socket options are set. This only affects direct socket connections to a remote rsync daemon. This option also exists in the **--daemon** mode section.

--blocking-io

This tells rsync to use blocking I/O when launching a remote shell transport. If the remote shell is either rsh or remsh, rsync defaults to using blocking I/O, otherwise it defaults to using non-blocking I/O. (Note that ssh prefers non-blocking I/O.)

-i, --itemize-changes

Requests a simple itemized list of the changes that are being made to each file, including attribute changes. This is exactly the same as specifying **--out-format='%i %n%L'**. If you repeat the option, unchanged files will also be output, but only if the receiving rsync is at least version 2.6.7 (you can use **-vv** with older versions of rsync, but that also turns on the output of other verbose messages).

The “%i” escape has a cryptic output that is 11 letters long. The general format is like the string **YXcstpoguax**, where **Y** is replaced by the type of update being done, **X** is replaced by the file-type, and the other letters represent attributes that may be output if they are being modified.

The update types that replace the **Y** are as follows:

- o A < means that a file is being transferred to the remote host (sent).
- o A > means that a file is being transferred to the local host (received).
- o A **c** means that a local change/creation is occurring for the item (such as the creation of a directory or the changing of a symlink, etc.).
- o A **h** means that the item is a hard link to another item (requires **--hard-links**).
- o A **.** means that the item is not being updated (though it might have attributes that are being modified).
- o A ***** means that the rest of the itemized-output area contains a message (e.g. “deleting”).

The file-types that replace the **X** are: **f** for a file, a **d** for a directory, an **L** for a symlink, a **D** for a device, and a **S** for a special file (e.g. named sockets and fifos).

The other letters in the string above are the actual letters that will be output if the associated attribute for the item is being updated or a “.” for no change. Three exceptions to this are: (1) a

newly created item replaces each letter with a “+”, (2) an identical item replaces the dots with spaces, and (3) an unknown attribute replaces each letter with a “?” (this can happen when talking to an older rsync).

The attribute that is associated with each letter is as follows:

- o A **c** means either that a regular file has a different checksum (requires **--checksum**) or that a symlink, device, or special file has a changed value. Note that if you are sending files to an rsync prior to 3.0.1, this change flag will be present only for checksum-differing regular files.
- o A **s** means the size of a regular file is different and will be updated by the file transfer.
- o A **t** means the modification time is different and is being updated to the sender’s value (requires **--times**). An alternate value of **T** means that the modification time will be set to the transfer time, which happens when a file/symlink/device is updated without **--times** and when a symlink is changed and the receiver can’t set its time. (Note: when using an rsync 3.0.0 client, you might see the **s** flag combined with **t** instead of the proper **T** flag for this time-setting failure.)
- o A **p** means the permissions are different and are being updated to the sender’s value (requires **--perms**).
- o An **o** means the owner is different and is being updated to the sender’s value (requires **--owner** and super-user privileges).
- o A **g** means the group is different and is being updated to the sender’s value (requires **--group** and the authority to set the group).
- o The **u** slot is reserved for future use.
- o The **a** means that the ACL information changed.
- o The **x** means that the extended attribute information changed.

One other output is possible: when deleting files, the “%i” will output the string “*deleting” for each item that is being removed (assuming that you are talking to a recent enough rsync that it logs deletions instead of outputting them as a verbose message).

--out-format=FORMAT

This allows you to specify exactly what the rsync client outputs to the user on a per-update basis. The format is a text string containing embedded single-character escape sequences prefixed with a percent (%) character. For a list of the possible escape characters, see the “log format” setting in the `rsyncd.conf` manpage.

Specifying this option will mention each file, dir, etc. that gets updated in a significant way (a transferred file, a recreated symlink/device, or a touched directory). In addition, if the `itemize-changes` escape (%i) is included in the string, the logging of names increases to mention any item that is changed in any way (as long as the receiving side is at least 2.6.4). See the **--itemize-changes** option for a description of the output of “%i”.

The **--verbose** option implies a format of “%n%L”, but you can use **--out-format** without **--verbose** if you like, or you can override the format of its per-file output using this option.

Rsync will output the out-format string prior to a file’s transfer unless one of the transfer-statistic escapes is requested, in which case the logging is done at the end of the file’s transfer. When this late logging is in effect and **--progress** is also specified, rsync will also output the name of the file being transferred prior to its progress information (followed, of course, by the out-format output).

--log-file=FILE

This option causes rsync to log what it is doing to a file. This is similar to the logging that a daemon does, but can be requested for the client side and/or the server side of a non-daemon transfer.

If specified as a client option, transfer logging will be enabled with a default format of “%i%n%L”. See the **--log-file-format** option if you wish to override this.

Here’s a example command that requests the remote side to log what is happening:

```
rsync -av --rsync-path="rsync --log-file=/tmp/rlog" src/ dest/
```

This is very useful if you need to debug why a connection is closing unexpectedly.

--log-file-format=FORMAT

This allows you to specify exactly what per-update logging is put into the file specified by the **--log-file** option (which must also be specified for this option to have any effect). If you specify an empty string, updated files will not be mentioned in the log file. For a list of the possible escape characters, see the “log format” setting in the rsyncd.conf manpage.

--stats This tells rsync to print a verbose set of statistics on the file transfer, allowing you to tell how effective the rsync algorithm is for your data.

The current statistics are as follows:

- o **Number of files** is the count of all “files” (in the generic sense), which includes directories, symlinks, etc.
- o **Number of files transferred** is the count of normal files that were updated via the rsync algorithm, which does not include created dirs, symlinks, etc.
- o **Total file size** is the total sum of all file sizes in the transfer. This does not count any size for directories or special files, but does include the size of symlinks.
- o **Total transferred file size** is the total sum of all files sizes for just the transferred files.
- o **Literal data** is how much unmatched file-update data we had to send to the receiver for it to recreate the updated files.
- o **Matched data** is how much data the receiver got locally when recreating the updated files.
- o **File list size** is how big the file-list data was when the sender sent it to the receiver. This is smaller than the in-memory size for the file list due to some compressing of duplicated data when rsync sends the list.
- o **File list generation time** is the number of seconds that the sender spent creating the file list. This requires a modern rsync on the sending side for this to be present.
- o **File list transfer time** is the number of seconds that the sender spent sending the file list to the receiver.
- o **Total bytes sent** is the count of all the bytes that rsync sent from the client side to the server side.
- o **Total bytes received** is the count of all non-message bytes that rsync received by the client side from the server side. “Non-message” bytes means that we don’t count the bytes for a verbose message that the server sent to us, which makes the stats more consistent.

-8, --8-bit-output

This tells rsync to leave all high-bit characters unescaped in the output instead of trying to test them to see if they’re valid in the current locale and escaping the invalid ones. All control characters (but never tabs) are always escaped, regardless of this option’s setting.

The escape idiom that started in 2.6.7 is to output a literal backslash (\) and a hash (#), followed by exactly 3 octal digits. For example, a newline would output as “\#012”. A literal backslash that is in a filename is not escaped unless it is followed by a hash and 3 digits (0–9).

-h, --human-readable

Output numbers in a more human-readable format. This makes big numbers output using larger units, with a K, M, or G suffix. If this option was specified once, these units are K (1000), M (1000*1000), and G (1000*1000*1000); if the option is repeated, the units are powers of 1024 instead of 1000.

--partial

By default, rsync will delete any partially transferred file if the transfer is interrupted. In some circumstances it is more desirable to keep partially transferred files. Using the **--partial** option tells rsync to keep the partial file which should make a subsequent transfer of the rest of the file much faster.

--partial-dir=DIR

A better way to keep partial files than the **--partial** option is to specify a *DIR* that will be used to hold the partial data (instead of writing it out to the destination file). On the next transfer, rsync will use a file found in this dir as data to speed up the resumption of the transfer and then delete it after it has served its purpose.

Note that if **--whole-file** is specified (or implied), any partial-dir file that is found for a file that is being updated will simply be removed (since rsync is sending files without using the delta transfer algorithm).

Rsync will create the *DIR* if it is missing (just the last dir — not the whole path). This makes it easy to use a relative path (such as “**--partial-dir=.rsync-partial**”) to have rsync create the partial-directory in the destination file’s directory when needed, and then remove it again when the partial file is deleted.

If the partial-dir value is not an absolute path, rsync will add an exclude rule at the end of all your existing excludes. This will prevent the sending of any partial-dir files that may exist on the sending side, and will also prevent the untimely deletion of partial-dir items on the receiving side. An example: the above **--partial-dir** option would add the equivalent of “**-f ’-p .rsync-partial/**” at the end of any other filter rules.

If you are supplying your own exclude rules, you may need to add your own exclude/hide/protect rule for the partial-dir because (1) the auto-added rule may be ineffective at the end of your other rules, or (2) you may wish to override rsync’s exclude choice. For instance, if you want to make rsync clean-up any left-over partial-dirs that may be lying around, you should specify **--delete-after** and add a “risk” filter rule, e.g. **-f ’R .rsync-partial/**. (Avoid using **--delete-before** or **--delete-during** unless you don’t need rsync to use any of the left-over partial-dir data during the current run.)

IMPORTANT: the **--partial-dir** should not be writable by other users or it is a security risk. E.g. AVOID “/tmp”.

You can also set the partial-dir value the `RSYNC_PARTIAL_DIR` environment variable. Setting this in the environment does not force **--partial** to be enabled, but rather it affects where partial files go when **--partial** is specified. For instance, instead of using **--partial-dir=.rsync-tmp** along with **--progress**, you could set `RSYNC_PARTIAL_DIR=.rsync-tmp` in your environment and then just use the **-P** option to turn on the use of the `.rsync-tmp` dir for partial transfers. The only times that the **--partial** option does not look for this environment value are (1) when **--inplace** was specified (since **--inplace** conflicts with **--partial-dir**), and (2) when **--delay-updates** was specified (see below).

For the purposes of the daemon-config’s “refuse options” setting, **--partial-dir** does *not* imply **--partial**. This is so that a refusal of the **--partial** option can be used to disallow the overwriting of destination files with a partial transfer, while still allowing the safer idiom provided by **--partial-dir**.

--delay-updates

This option puts the temporary file from each updated file into a holding directory until the end of the transfer, at which time all the files are renamed into place in rapid succession. This attempts to make the updating of the files a little more atomic. By default the files are placed into a directory named “`~tmp`” in each file’s destination directory, but if you’ve specified the **--partial-dir** option, that directory will be used instead. See the comments in the **--partial-dir** section for a discussion of how this “`~tmp`” dir will be excluded from the transfer, and what you can do if you want rsync to cleanup old “`~tmp`” dirs that might be lying around. Conflicts with **--inplace** and **--append**.

This option uses more memory on the receiving side (one bit per file transferred) and also requires enough free disk space on the receiving side to hold an additional copy of all the updated files. Note also that you should not use an absolute path to **--partial-dir** unless (1) there is no chance of any of the files in the transfer having the same name (since all the updated files will be put into a single directory if the path is absolute) and (2) there are no mount points in the hierarchy (since the delayed updates will fail if they can’t be renamed into place).

See also the “atomic-rsync” perl script in the “support” subdir for an update algorithm that is even more atomic (it uses **--link-dest** and a parallel hierarchy of files).

-m, --prune-empty-dirs

This option tells the receiving rsync to get rid of empty directories from the file-list, including nested directories that have no non-directory children. This is useful for avoiding the creation of a bunch of useless directories when the sending rsync is recursively scanning a hierarchy of files using include/exclude/filter rules.

Because the file-list is actually being pruned, this option also affects what directories get deleted when a delete is active. However, keep in mind that excluded files and directories can prevent existing items from being deleted (because an exclude hides source files and protects destination files).

You can prevent the pruning of certain empty directories from the file-list by using a global “protect” filter. For instance, this option would ensure that the directory “emptydir” was kept in the file-list:

```
--filter 'protect emptydir/'
```

Here’s an example that copies all .pdf files in a hierarchy, only creating the necessary destination directories to hold the .pdf files, and ensures that any superfluous files and directories in the destination are removed (note the hide filter of non-directories being used instead of an exclude):

```
rsync -avm --del --include='*.pdf' -f 'hide,! */' src/ dest
```

If you didn’t want to remove superfluous destination files, the more time-honored options of “**--include='*/'** **--exclude='*'**” would work fine in place of the hide-filter (if that is more natural to you).

--progress

This option tells rsync to print information showing the progress of the transfer. This gives a bored user something to watch. Implies **--verbose** if it wasn’t already specified.

While rsync is transferring a regular file, it updates a progress line that looks like this:

```
782448 63% 110.64kB/s 0:00:04
```

In this example, the receiver has reconstructed 782448 bytes or 63% of the sender’s file, which is being reconstructed at a rate of 110.64 kilobytes per second, and the transfer will finish in 4 seconds if the current rate is maintained until the end.

These statistics can be misleading if the delta transfer algorithm is in use. For example, if the sender's file consists of the basis file followed by additional data, the reported rate will probably drop dramatically when the receiver gets to the literal data, and the transfer will probably take much longer to finish than the receiver estimated as it was finishing the matched part of the file.

When the file transfer finishes, rsync replaces the progress line with a summary line that looks like this:

```
1238099 100% 146.38kB/s 0:00:08 (xfer#5, to-check=169/396)
```

In this example, the file was 1238099 bytes long in total, the average rate of transfer for the whole file was 146.38 kilobytes per second over the 8 seconds that it took to complete, it was the 5th transfer of a regular file during the current rsync session, and there are 169 more files for the receiver to check (to see if they are up-to-date or not) remaining out of the 396 total files in the file-list.

-P The **-P** option is equivalent to **--partial --progress**. Its purpose is to make it much easier to specify these two options for a long transfer that may be interrupted.

--password=file

This option allows you to provide a password in a file for accessing an rsync daemon. The file must not be world readable. It should contain just the password as a single line.

This option does not supply a password to a remote shell transport such as ssh; to learn how to do that, consult the remote shell's documentation. When accessing an rsync daemon using a remote shell as the transport, this option only comes into effect after the remote shell finishes its authentication (i.e. if you have also specified a password in the daemon's config file).

--list-only

This option will cause the source files to be listed instead of transferred. This option is inferred if there is a single source arg and no destination specified, so its main uses are: (1) to turn a copy command that includes a destination arg into a file-listing command, or (2) to be able to specify more than one source arg (note: be sure to include the destination). Caution: keep in mind that a source arg with a wild-card is expanded by the shell into multiple args, so it is never safe to try to list such an arg without using this option. For example:

```
rsync -av --list-only foo* dest/
```

Compatibility note: when requesting a remote listing of files from an rsync that is version 2.6.3 or older, you may encounter an error if you ask for a non-recursive listing. This is because a file listing implies the **--dirs** option w/o **--recursive**, and older rsyncs don't have that option. To avoid this problem, either specify the **--no-dirs** option (if you don't need to expand a directory's content), or turn on recursion and exclude the content of subdirectories: **-r --exclude='/*/*'**.

--bwlimit=KBPS

This option allows you to specify a maximum transfer rate in kilobytes per second. This option is most effective when using rsync with large files (several megabytes and up). Due to the nature of rsync transfers, blocks of data are sent, then if rsync determines the transfer was too fast, it will wait before sending the next data block. The result is an average transfer rate equaling the specified limit. A value of zero specifies no limit.

--write-batch=FILE

Record a file that can later be applied to another identical destination with **--read-batch**. See the "BATCH MODE" section for details, and also the **--only-write-batch** option.

--only-write-batch=FILE

Works like **--write-batch**, except that no updates are made on the destination system when creating the batch. This lets you transport the changes to the destination system via some other means and then apply the changes via **--read-batch**.

Note that you can feel free to write the batch directly to some portable media: if this media fills to capacity before the end of the transfer, you can just apply that partial transfer to the destination and repeat the whole process to get the rest of the changes (as long as you don't mind a partially updated destination system while the multi-update cycle is happening).

Also note that you only save bandwidth when pushing changes to a remote system because this allows the batched data to be diverted from the sender into the batch file without having to flow over the wire to the receiver (when pulling, the sender is remote, and thus can't write the batch).

--read=batch=FILE

Apply all of the changes stored in FILE, a file previously generated by **--write=batch**. If FILE is -, the batch data will be read from standard input. See the "BATCH MODE" section for details.

--protocol=NUM

Force an older protocol version to be used. This is useful for creating a batch file that is compatible with an older version of rsync. For instance, if rsync 2.6.4 is being used with the **--write=batch** option, but rsync 2.6.3 is what will be used to run the **--read=batch** option, you should use "**--protocol=28**" when creating the batch file to force the older protocol version to be used in the batch file (assuming you can't upgrade the rsync on the reading system).

--iconv=CONVERT_SPEC

Rsync can convert filenames between character sets using this option. Using a CONVERT_SPEC of "." tells rsync to look up the default character-set via the locale setting. Alternately, you can fully specify what conversion to do by giving a local and a remote charset separated by a comma in the order **--iconv=LOCAL,REMOTE**, e.g. **--iconv=utf8,iso88591**. This order ensures that the option will stay the same whether you're pushing or pulling files. Finally, you can specify either **--no-iconv** or a CONVERT_SPEC of "-" to turn off any conversion. The default setting of this option is site-specific, and can also be affected via the RSYNC_ICONV environment variable.

For a list of what charset names your local iconv library supports, you can run "iconv --list".

If you specify the **--protect-args** option (**-s**), rsync will translate the filenames you specify on the command-line that are being sent to the remote host. See also the **--files-from** option.

Note that rsync does not do any conversion of names in filter files (including include/exclude files). It is up to you to ensure that you're specifying matching rules that can match on both sides of the transfer. For instance, you can specify extra include/exclude rules if there are filename differences on the two sides that need to be accounted for.

When you pass an **--iconv** option to an rsync daemon that allows it, the daemon uses the charset specified in its "charset" configuration parameter regardless of the remote charset you actually pass. Thus, you may feel free to specify just the local charset for a daemon transfer (e.g. **--iconv=utf8**).

-4, --ipv4 or -6, --ipv6

Tells rsync to prefer IPv4/IPv6 when creating sockets. This only affects sockets that rsync has direct control over, such as the outgoing socket when directly contacting an rsync daemon. See also these options in the **--daemon** mode section.

If rsync was compiled without support for IPv6, the **--ipv6** option will have no effect. The **--version** output will tell you if this is the case.

--checksum-seed=NUM

Set the MD4 checksum seed to the integer NUM. This 4 byte checksum seed is included in each block and file MD4 checksum calculation. By default the checksum seed is generated by the server and defaults to the current `time()`. This option is used to set a specific checksum seed, which is useful for applications that want repeatable block and file checksums, or in the case where the user wants a more random checksum seed. Note that setting NUM to 0 causes rsync to use the default of `time()` for checksum seed.

DAEMON OPTIONS

The options allowed when starting an rsync daemon are as follows:

--daemon

This tells rsync that it is to run as a daemon. The daemon you start running may be accessed using an rsync client using the **host::module** or **rsync://host/module/** syntax.

If standard input is a socket then rsync will assume that it is being run via inetd, otherwise it will detach from the current terminal and become a background daemon. The daemon will read the config file (rsyncd.conf) on each connect made by a client and respond to requests accordingly. See the **rsyncd.conf(5)** man page for more details.

--address

By default rsync will bind to the wildcard address when run as a daemon with the **--daemon** option. The **--address** option allows you to specify a specific IP address (or hostname) to bind to. This makes virtual hosting possible in conjunction with the **--config** option. See also the “address” global option in the rsyncd.conf manpage.

--bwlimit=KBPS

This option allows you to specify a maximum transfer rate in kilobytes per second for the data the daemon sends. The client can still specify a smaller **--bwlimit** value, but their requested value will be rounded down if they try to exceed it. See the client version of this option (above) for some extra details.

--config=FILE

This specifies an alternate config file than the default. This is only relevant when **--daemon** is specified. The default is /etc/rsyncd.conf unless the daemon is running over a remote shell program and the remote user is not the super-user; in that case the default is rsyncd.conf in the current directory (typically \$HOME).

--no-detach

When running as a daemon, this option instructs rsync to not detach itself and become a background process. This option is required when running as a service on Cygwin, and may also be useful when rsync is supervised by a program such as **daemontools** or AIX’s **System Resource Controller**. **--no-detach** is also recommended when rsync is run under a debugger. This option has no effect if rsync is run from inetd or sshd.

--port=PORT

This specifies an alternate TCP port number for the daemon to listen on rather than the default of 873. See also the “port” global option in the rsyncd.conf manpage.

--log-file=FILE

This option tells the rsync daemon to use the given log-file name instead of using the “log file” setting in the config file.

--log-file-format=FORMAT

This option tells the rsync daemon to use the given FORMAT string instead of using the “log format” setting in the config file. It also enables “transfer logging” unless the string is empty, in which case transfer logging is turned off.

--sockopts

This overrides the **socket options** setting in the rsyncd.conf file and has the same syntax.

-v, --verbose

This option increases the amount of information the daemon logs during its startup phase. After the client connects, the daemon’s verbosity level will be controlled by the options that the client used and the “max verbosity” setting in the module’s config section.

-4, --ipv4 or -6, --ipv6

Tells rsync to prefer IPv4/IPv6 when creating the incoming sockets that the rsync daemon will use to listen for connections. One of these options may be required in older versions of Linux to work around an IPv6 bug in the kernel (if you see an “address already in use” error when nothing else is

using the port, try specifying **--ipv6** or **--ipv4** when starting the daemon).

If rsync was compiled without support for IPv6, the **--ipv6** option will have no effect. The **--version** output will tell you if this is the case.

-h, --help

When specified after **--daemon**, print a short help page describing the options available for starting an rsync daemon.

FILTER RULES

The filter rules allow for flexible selection of which files to transfer (include) and which files to skip (exclude). The rules either directly specify include/exclude patterns or they specify a way to acquire more include/exclude patterns (e.g. to read them from a file).

As the list of files/directories to transfer is built, rsync checks each name to be transferred against the list of include/exclude patterns in turn, and the first matching pattern is acted on: if it is an exclude pattern, then that file is skipped; if it is an include pattern then that filename is not skipped; if no matching pattern is found, then the filename is not skipped.

Rsync builds an ordered list of filter rules as specified on the command-line. Filter rules have the following syntax:

```
RULE [PATTERN_OR_FILENAME]
RULE, MODIFIERS [PATTERN_OR_FILENAME]
```

You have your choice of using either short or long RULE names, as described below. If you use a short-named rule, the ‘,’ separating the RULE from the MODIFIERS is optional. The PATTERN or FILENAME that follows (when present) must come after either a single space or an underscore (_). Here are the available rule prefixes:

- exclude, -** specifies an exclude pattern.
- include, +** specifies an include pattern.
- merge, .** specifies a merge-file to read for more rules.
- dir-merge, :** specifies a per-directory merge-file.
- hide, H** specifies a pattern for hiding files from the transfer.
- show, S** files that match the pattern are not hidden.
- protect, P** specifies a pattern for protecting files from deletion.
- risk, R** files that match the pattern are not protected.
- clear, !** clears the current include/exclude list (takes no arg)

When rules are being read from a file, empty lines are ignored, as are comment lines that start with a “#”.

Note that the **--include/--exclude** command-line options do not allow the full range of rule parsing as described above — they only allow the specification of include/exclude patterns plus a “!” token to clear the list (and the normal comment parsing when rules are read from a file). If a pattern does not begin with “- ” (dash, space) or “+ ” (plus, space), then the rule will be interpreted as if “+ ” (for an include option) or “- ” (for an exclude option) were prefixed to the string. A **--filter** option, on the other hand, must always contain either a short or long rule name at the start of the rule.

Note also that the **--filter**, **--include**, and **--exclude** options take one rule/pattern each. To add multiple ones, you can repeat the options on the command-line, use the merge-file syntax of the **--filter** option, or the **--include-from/--exclude-from** options.

INCLUDE/EXCLUDE PATTERN RULES

You can include and exclude files by specifying patterns using the “+”, “-”, etc. filter rules (as introduced in the FILTER RULES section above). The include/exclude rules each specify a pattern that is matched against the names of the files that are going to be transferred. These patterns can take several forms:

- o if the pattern starts with a / then it is anchored to a particular spot in the hierarchy of files, otherwise it is matched against the end of the pathname. This is similar to a leading ^ in regular expressions. Thus “/foo” would match a name of “foo” at either the “root of the transfer” (for a global rule) or in the merge-file’s directory (for a per-directory rule). An unqualified “foo” would match a name of “foo” anywhere in the tree because the algorithm is applied recursively from the top down; it behaves as if each path component gets a turn at being the end of the filename. Even the unanchored “sub/foo” would match at any point in the hierarchy where a “foo” was found within a directory named “sub”. See the section on ANCHORING INCLUDE/EXCLUDE PATTERNS for a full discussion of how to specify a pattern that matches at the root of the transfer.
- o if the pattern ends with a / then it will only match a directory, not a regular file, symlink, or device.
- o rsync chooses between doing a simple string match and wildcard matching by checking if the pattern contains one of these three wildcard characters: ‘*’, ‘?’, and ‘[’.
- o a ‘*’ matches any non-empty path component (it stops at slashes).
- o use ‘***’ to match anything, including slashes.
- o a ‘?’ matches any character except a slash (/).
- o a ‘[’ introduces a character class, such as [a–z] or [[:alpha:]].
- o in a wildcard pattern, a backslash can be used to escape a wildcard character, but it is matched literally when no wildcards are present.
- o if the pattern contains a / (not counting a trailing /) or a “***”, then it is matched against the full pathname, including any leading directories. If the pattern doesn’t contain a / or a “***”, then it is matched only against the final component of the filename. (Remember that the algorithm is applied recursively so “full filename” can actually be any portion of a path from the starting directory on down.)
- o a trailing “dir_name/***” will match both the directory (as if “dir_name/” had been specified) and everything in the directory (as if “dir_name/***” had been specified). This behavior was added in version 2.6.7.

Note that, when using the **—recursive** (**–r**) option (which is implied by **–a**), every subcomponent of every path is visited from the top down, so include/exclude patterns get applied recursively to each subcomponent’s full name (e.g. to include “/foo/bar/baz” the subcomponents “/foo” and “/foo/bar” must not be excluded). The exclude patterns actually short-circuit the directory traversal stage when rsync finds the files to send. If a pattern excludes a particular parent directory, it can render a deeper include pattern ineffectual because rsync did not descend through that excluded section of the hierarchy. This is particularly important when using a trailing ‘*’ rule. For instance, this won’t work:

```
+ /some/path/this-file-will-not-be-found
+ /file-is-included
- *
```

This fails because the parent directory “some” is excluded by the ‘*’ rule, so rsync never visits any of the files in the “some” or “some/path” directories. One solution is to ask for all directories in the hierarchy to be included by using a single rule: “+ */” (put it somewhere before the “– *” rule), and perhaps use the **—prune-empty-dirs** option. Another solution is to add specific include rules for all the parent dirs that need to be visited. For instance, this set of rules works fine:

```
+ /some/
+ /some/path/
+ /some/path/this-file-is-found
+ /file-also-included
- *
```

Here are some examples of exclude/include matching:

- o “- *.o” would exclude all names matching *.o
- o “- /foo” would exclude a file (or directory) named foo in the transfer-root directory
- o “- foo/” would exclude any directory named foo
- o “- /foo/*/bar” would exclude any file named bar which is at two levels below a directory named foo in the transfer-root directory
- o “- /foo/**/bar” would exclude any file named bar two or more levels below a directory named foo in the transfer-root directory
- o The combination of “+ */”, “+ *.c”, and “- *” would include all directories and C source files but nothing else (see also the **--prune-empty-dirs** option)
- o The combination of “+ foo/”, “+ foo/bar.c”, and “- *” would include only the foo directory and foo/bar.c (the foo directory must be explicitly included or it would be excluded by the “-”)

MERGE-FILE FILTER RULES

You can merge whole files into your filter rules by specifying either a merge (.) or a dir-merge (:) filter rule (as introduced in the FILTER RULES section above).

There are two kinds of merged files — single-instance (‘.’) and per-directory (‘:’). A single-instance merge file is read one time, and its rules are incorporated into the filter list in the place of the “.” rule. For per-directory merge files, rsync will scan every directory that it traverses for the named file, merging its contents when the file exists into the current list of inherited rules. These per-directory rule files must be created on the sending side because it is the sending side that is being scanned for the available files to transfer. These rule files may also need to be transferred to the receiving side if you want them to affect what files don’t get deleted (see PER-DIRECTORY RULES AND DELETE below).

Some examples:

```
merge /etc/rsync/default.rules
. /etc/rsync/default.rules
dir-merge .per-dir-filter
dir-merge,n- .non-inherited-per-dir-excludes
:n- .non-inherited-per-dir-excludes
```

The following modifiers are accepted after a merge or dir-merge rule:

- o A **-** specifies that the file should consist of only exclude patterns, with no other rule-parsing except for in-file comments.
- o A **+** specifies that the file should consist of only include patterns, with no other rule-parsing except for in-file comments.
- o A **C** is a way to specify that the file should be read in a CVS-compatible manner. This turns on ‘n’, ‘w’, and ‘-’, but also allows the list-clearing token (!) to be specified. If no filename is provided, “cvsignore” is assumed.
- o A **e** will exclude the merge-file name from the transfer; e.g. “dir-merge,e.rules” is like “dir-merge.rules” and “- .rules”.
- o An **n** specifies that the rules are not inherited by subdirectories.
- o A **w** specifies that the rules are word-split on whitespace instead of the normal line-splitting. This also turns off comments. Note: the space that separates the prefix from the rule is treated specially, so “- foo + bar” is parsed as two rules (assuming that prefix-parsing wasn’t also disabled).
- o You may also specify any of the modifiers for the “+” or “-” rules (below) in order to have the rules that are read in from the file default to having that modifier set. For instance, “merge,-/.excl” would treat the contents of .excl as absolute-path excludes, while “dir-merge,s.filt” and

“:sC” would each make all their per-directory rules apply only on the sending side.

The following modifiers are accepted after a “+” or “-”:

- o A **/** specifies that the include/exclude rule should be matched against the absolute pathname of the current item. For example, “-/ /etc/passwd” would exclude the passwd file any time the transfer was sending files from the “/etc” directory, and “-/ subdir/foo” would always exclude “foo” when it is in a dir named “subdir”, even if “foo” is at the root of the current transfer.
- o A **!** specifies that the include/exclude should take effect if the pattern fails to match. For instance, “-! */” would exclude all non-directories.
- o A **C** is used to indicate that all the global CVS-exclude rules should be inserted as excludes in place of the “-C”. No arg should follow.
- o An **s** is used to indicate that the rule applies to the sending side. When a rule affects the sending side, it prevents files from being transferred. The default is for a rule to affect both sides unless **--delete-excluded** was specified, in which case default rules become sender-side only. See also the hide (H) and show (S) rules, which are an alternate way to specify sending-side includes/excludes.
- o An **r** is used to indicate that the rule applies to the receiving side. When a rule affects the receiving side, it prevents files from being deleted. See the **s** modifier for more info. See also the protect (P) and risk (R) rules, which are an alternate way to specify receiver-side includes/excludes.
- o A **p** indicates that a rule is perishable, meaning that it is ignored in directories that are being deleted. For instance, the **-C** option’s default rules that exclude things like “CVS” and “*.o” are marked as perishable, and will not prevent a directory that was removed on the source from being deleted on the destination.

Per-directory rules are inherited in all subdirectories of the directory where the merge-file was found unless the ‘n’ modifier was used. Each subdirectory’s rules are prefixed to the inherited per-directory rules from its parents, which gives the newest rules a higher priority than the inherited rules. The entire set of dir-merge rules are grouped together in the spot where the merge-file was specified, so it is possible to override dir-merge rules via a rule that got specified earlier in the list of global rules. When the list-clearing rule (“!”) is read from a per-directory file, it only clears the inherited rules for the current merge file.

Another way to prevent a single rule from a dir-merge file from being inherited is to anchor it with a leading slash. Anchored rules in a per-directory merge-file are relative to the merge-file’s directory, so a pattern “/foo” would only match the file “foo” in the directory where the dir-merge filter file was found.

Here’s an example filter file which you’d specify via **--filter=". file"**:

```
merge /home/user/.global-filter
- *.gz
dir-merge .rules
+ *.[ch]
- *.o
```

This will merge the contents of the /home/user/.global-filter file at the start of the list and also turns the “.rules” filename into a per-directory filter file. All rules read in prior to the start of the directory scan follow the global anchoring rules (i.e. a leading slash matches at the root of the transfer).

If a per-directory merge-file is specified with a path that is a parent directory of the first transfer directory, rsync will scan all the parent dirs from that starting point to the transfer directory for the indicated per-directory file. For instance, here is a common filter (see **-F**):

```
--filter=' : /.rsync-filter'
```

That rule tells rsync to scan for the file `.rsync-filter` in all directories from the root down through the parent directory of the transfer prior to the start of the normal directory scan of the file in the directories that are sent as a part of the transfer. (Note: for an rsync daemon, the root is always the same as the module's "path".)

Some examples of this pre-scanning for per-directory files:

```
rsync -avF /src/path/ /dest/dir
rsync -av --filter=': ../../.rsync-filter' /src/path/ /dest/dir
rsync -av --filter=': .rsync-filter' /src/path/ /dest/dir
```

The first two commands above will look for `.rsync-filter` in `/` and `/src` before the normal scan begins looking for the file in `/src/path` and its subdirectories. The last command avoids the parent-dir scan and only looks for the `.rsync-filter` files in each directory that is a part of the transfer.

If you want to include the contents of a `.cvsignore` in your patterns, you should use the rule `:C`, which creates a dir-merge of the `.cvsignore` file, but parsed in a CVS-compatible manner. You can use this to affect where the **--cvs-exclude (-C)** option's inclusion of the per-directory `.cvsignore` file gets placed into your rules by putting the `:C` wherever you like in your filter rules. Without this, rsync would add the dir-merge rule for the `.cvsignore` file at the end of all your other rules (giving it a lower priority than your command-line rules). For example:

```
cat <<EOT | rsync -avC --filter='.' -' a/ b
+ foo.o
:C
- *.old
EOT
rsync -avC --include=foo.o -f :C --exclude='*.old' a/ b
```

Both of the above rsync commands are identical. Each one will merge all the per-directory `.cvsignore` rules in the middle of the list rather than at the end. This allows their dir-specific rules to supersede the rules that follow the `:C` instead of being subservient to all your rules. To affect the other CVS exclude rules (i.e. the default list of exclusions, the contents of `$HOME/.cvsignore`, and the value of `$CVSIGNORE`) you should omit the `-C` command-line option and instead insert a `-C` rule into your filter rules; e.g. **--filter=-C**.

LIST-CLEARING FILTER RULE

You can clear the current include/exclude list by using the `!` filter rule (as introduced in the FILTER RULES section above). The "current" list is either the global list of rules (if the rule is encountered while parsing the filter options) or a set of per-directory rules (which are inherited in their own sub-list, so a sub-directory can use this to clear out the parent's rules).

ANCHORING INCLUDE/EXCLUDE PATTERNS

As mentioned earlier, global include/exclude patterns are anchored at the "root of the transfer" (as opposed to per-directory patterns, which are anchored at the merge-file's directory). If you think of the transfer as a subtree of names that are being sent from sender to receiver, the transfer-root is where the tree starts to be duplicated in the destination directory. This root governs where patterns that start with a `/` match.

Because the matching is relative to the transfer-root, changing the trailing slash on a source path or changing your use of the **--relative** option affects the path you need to use in your matching (in addition to changing how much of the file tree is duplicated on the destination host). The following examples demonstrate this.

Let's say that we want to match two source files, one with an absolute path of `/home/me/foo/bar`, and one with a path of `/home/you/bar/baz`. Here is how the various command choices differ for a 2-source transfer:

```
Example cmd: rsync -a /home/me /home/you /dest
+/- pattern: /me/foo/bar
+/- pattern: /you/bar/baz
```

Target file: /dest/me/foo/bar
 Target file: /dest/you/bar/baz

Example cmd: `rsync -a /home/me/ /home/you/ /dest`
 +/- pattern: /foo/bar (note missing “me”)
 +/- pattern: /bar/baz (note missing “you”)
 Target file: /dest/foo/bar
 Target file: /dest/bar/baz

Example cmd: `rsync -a --relative /home/me/ /home/you /dest`
 +/- pattern: /home/me/foo/bar (note full path)
 +/- pattern: /home/you/bar/baz (ditto)
 Target file: /dest/home/me/foo/bar
 Target file: /dest/home/you/bar/baz

Example cmd: `cd /home; rsync -a --relative me/foo you/ /dest`
 +/- pattern: /me/foo/bar (starts at specified path)
 +/- pattern: /you/bar/baz (ditto)
 Target file: /dest/me/foo/bar
 Target file: /dest/you/bar/baz

The easiest way to see what name you should filter is to just look at the output when using **--verbose** and put a / in front of the name (use the **--dry-run** option if you’re not yet ready to copy any files).

PER-DIRECTORY RULES AND DELETE

Without a delete option, per-directory rules are only relevant on the sending side, so you can feel free to exclude the merge files themselves without affecting the transfer. To make this easy, the ‘e’ modifier adds this exclude for you, as seen in these two equivalent commands:

```
rsync -av --filter=': .excl' --exclude=.excl host:src/dir /dest
rsync -av --filter=':e .excl' host:src/dir /dest
```

However, if you want to do a delete on the receiving side AND you want some files to be excluded from being deleted, you’ll need to be sure that the receiving side knows what files to exclude. The easiest way is to include the per-directory merge files in the transfer and use **--delete-after**, because this ensures that the receiving side gets all the same exclude rules as the sending side before it tries to delete anything:

```
rsync -avF --delete-after host:src/dir /dest
```

However, if the merge files are not a part of the transfer, you’ll need to either specify some global exclude rules (i.e. specified on the command line), or you’ll need to maintain your own per-directory merge files on the receiving side. An example of the first is this (assume that the remote .rules files exclude themselves):

```
rsync -av --filter=': .rules' --filter='./my/extra.rules'
--delete host:src/dir /dest
```

In the above example the extra.rules file can affect both sides of the transfer, but (on the sending side) the rules are subservient to the rules merged from the .rules files because they were specified after the per-directory merge rule.

In one final example, the remote side is excluding the .rsync-filter files from the transfer, but we want to use our own .rsync-filter files to control what gets deleted on the receiving side. To do this we must specifically exclude the per-directory merge files (so that they don’t get deleted) and then put rules into the local files to control what else should not get deleted. Like one of these commands:

```
rsync -av --filter=':e /rsync-filter' --delete \
  host:src/dir /dest
rsync -avFF --delete host:src/dir /dest
```

BATCH MODE

Batch mode can be used to apply the same set of updates to many identical systems. Suppose one has a tree which is replicated on a number of hosts. Now suppose some changes have been made to this source tree and those changes need to be propagated to the other hosts. In order to do this using batch mode, rsync is run with the write-batch option to apply the changes made to the source tree to one of the destination trees. The write-batch option causes the rsync client to store in a “batch file” all the information needed to repeat this operation against other, identical destination trees.

To apply the recorded changes to another destination tree, run rsync with the read-batch option, specifying the name of the same batch file, and the destination tree. Rsync updates the destination tree using the information stored in the batch file.

For convenience, one additional file is created when the write-batch option is used. This file’s name is created by appending “.sh” to the batch filename. The .sh file contains a command-line suitable for updating a destination tree using that batch file. It can be executed using a Bourne (or Bourne-like) shell, optionally passing in an alternate destination tree pathname which is then used instead of the original path. This is useful when the destination tree path differs from the original destination tree path.

Generating the batch file once saves having to perform the file status, checksum, and data block generation more than once when updating multiple destination trees. Multicast transport protocols can be used to transfer the batch update files in parallel to many hosts at once, instead of sending the same data to every host individually.

Examples:

```
$ rsync --write-batch=foo -a host:/source/dir/ /adest/dir/
$ scp foo* remote:
$ ssh remote ./foo.sh /bdest/dir/

$ rsync --write-batch=foo -a /source/dir/ /adest/dir/
$ ssh remote rsync --read-batch=- -a /bdest/dir/ <foo
```

In these examples, rsync is used to update /adest/dir/ from /source/dir/ and the information to repeat this operation is stored in “foo” and “foo.sh”. The host “remote” is then updated with the batched data going into the directory /bdest/dir. The differences between the two examples reveals some of the flexibility you have in how you deal with batches:

- o The first example shows that the initial copy doesn’t have to be local — you can push or pull data to/from a remote host using either the remote-shell syntax or rsync daemon syntax, as desired.
- o The first example uses the created “foo.sh” file to get the right rsync options when running the read-batch command on the remote host.
- o The second example reads the batch data via standard input so that the batch file doesn’t need to be copied to the remote machine first. This example avoids the foo.sh script because it needed to use a modified **--read-batch** option, but you could edit the script file if you wished to make use of it (just be sure that no other option is trying to use standard input, such as the **--exclude-from=-** option).

Caveats:

The read-batch option expects the destination tree that it is updating to be identical to the destination tree that was used to create the batch update fileset. When a difference between the destination trees is encountered the update might be discarded with a warning (if the file appears to be up-to-date already) or the file-

update may be attempted and then, if the file fails to verify, the update discarded with an error. This means that it should be safe to re-run a read-batch operation if the command got interrupted. If you wish to force the batched-update to always be attempted regardless of the file's size and date, use the **-I** option (when reading the batch). If an error occurs, the destination tree will probably be in a partially updated state. In that case, rsync can be used in its regular (non-batch) mode of operation to fix up the destination tree.

The rsync version used on all destinations must be at least as new as the one used to generate the batch file. Rsync will die with an error if the protocol version in the batch file is too new for the batch-reading rsync to handle. See also the **--protocol** option for a way to have the creating rsync generate a batch file that an older rsync can understand. (Note that batch files changed format in version 2.6.3, so mixing versions older than that with newer versions will not work.)

When reading a batch file, rsync will force the value of certain options to match the data in the batch file if you didn't set them to the same as the batch-writing command. Other options can (and should) be changed. For instance **--write-batch** changes to **--read-batch**, **--files-from** is dropped, and the **--filter/--include/--exclude** options are not needed unless one of the **--delete** options is specified.

The code that creates the BATCH.sh file transforms any filter/include/exclude options into a single list that is appended as a "here" document to the shell script file. An advanced user can use this to modify the exclude list if a change in what gets deleted by **--delete** is desired. A normal user can ignore this detail and just use the shell script as an easy way to run the appropriate **--read-batch** command for the batched data.

The original batch mode in rsync was based on "rsync+", but the latest version uses a new implementation.

SYMBOLIC LINKS

Three basic behaviors are possible when rsync encounters a symbolic link in the source directory.

By default, symbolic links are not transferred at all. A message "skipping non-regular" file is emitted for any symlinks that exist.

If **--links** is specified, then symlinks are recreated with the same target on the destination. Note that **--archive** implies **--links**.

If **--copy-links** is specified, then symlinks are "collapsed" by copying their referent, rather than the symlink.

rsync also distinguishes "safe" and "unsafe" symbolic links. An example where this might be used is a web site mirror that wishes ensure the rsync module they copy does not include symbolic links to **/etc/passwd** in the public section of the site. Using **--copy-unsafe-links** will cause any links to be copied as the file they point to on the destination. Using **--safe-links** will cause unsafe links to be omitted altogether. (Note that you must specify **--links** for **--safe-links** to have any effect.)

Symbolic links are considered unsafe if they are absolute symlinks (start with **/**), empty, or if they contain enough **".."** components to ascend from the directory being copied.

Here's a summary of how the symlink options are interpreted. The list is in order of precedence, so if your combination of options isn't mentioned, use the first line that is a complete subset of your options:

--copy-links

Turn all symlinks into normal files (leaving no symlinks for any other options to affect).

--links --copy-unsafe-links

Turn all unsafe symlinks into files and duplicate all safe symlinks.

--copy-unsafe-links

Turn all unsafe symlinks into files, noisily skip all safe symlinks.

--links --safe-links

Duplicate safe symlinks and skip unsafe ones.

--links

Duplicate all symlinks.

DIAGNOSTICS

rsync occasionally produces error messages that may seem a little cryptic. The one that seems to cause the most confusion is “protocol version mismatch — is your shell clean?”.

This message is usually caused by your startup scripts or remote shell facility producing unwanted garbage on the stream that rsync is using for its transport. The way to diagnose this problem is to run your remote shell like this:

```
ssh remotehost /bin/true > out.dat
```

then look at out.dat. If everything is working correctly then out.dat should be a zero length file. If you are getting the above error from rsync then you will probably find that out.dat contains some text or data. Look at the contents and try to work out what is producing it. The most common cause is incorrectly configured shell startup scripts (such as .cshrc or .profile) that contain output statements for non-interactive logins.

If you are having trouble debugging filter patterns, then try specifying the **-vv** option. At this level of verbosity rsync will show why each individual file is included or excluded.

EXIT VALUES

- | | |
|-----------|--|
| 0 | Success |
| 1 | Syntax or usage error |
| 2 | Protocol incompatibility |
| 3 | Errors selecting input/output files, dirs |

ENVIRONMENT VARIABLES

CVSIGNORE

The CVSIGNORE environment variable supplements any ignore patterns in .cvsignore files. See the **--cvs-exclude** option for more details.

RSYNC_ICONV

Specify a default **--iconv** setting using this environment variable.

RSYNC_RSH

The RSYNC_RSH environment variable allows you to override the default shell used as the transport for rsync. Command line options are permitted after the command name, just as in the **-e** option.

RSYNC_PROXY

The RSYNC_PROXY environment variable allows you to redirect your rsync client to use a web proxy when connecting to a rsync daemon. You should set RSYNC_PROXY to a hostname:port pair.

RSYNC_PASSWORD

Setting RSYNC_PASSWORD to the required password allows you to run authenticated rsync connections to an rsync daemon without user intervention. Note that this does not supply a password to a remote shell transport such as ssh; to learn how to do that, consult the remote shell's documentation.

USER or LOGNAME

The USER or LOGNAME environment variables are used to determine the default username sent to an rsync daemon. If neither is set, the username defaults to "nobody".

HOME

The HOME environment variable is used to find the user's default .cvsignore file.

FILES

/etc/rsyncd.conf or rsyncd.conf

SEE ALSO

rsyncd.conf(5)

BUGS

times are transferred as *nix time_t values

When transferring to FAT filesystems rsync may re-sync unmodified files. See the comments on the **--modify-window** option.

file permissions, devices, etc. are transferred as native numerical values

see also the comments on the **--delete** option

Please report bugs! See the web site at <http://rsync.samba.org/>

VERSION

This man page is current for version 3.0.2 of rsync.

INTERNAL OPTIONS

The options **--server** and **--sender** are used internally by rsync, and should never be typed by a user under normal circumstances. Some awareness of these options may be needed in certain scenarios, such as when setting up a login that can only run an rsync command. For instance, the support directory of the rsync distribution has an example script named rrsync (for restricted rsync) that can be used with a restricted ssh login.

CREDITS

rsync is distributed under the GNU public license. See the file COPYING for details.

A WEB site is available at <http://rsync.samba.org/>. The site includes an FAQ-O-Matic which may cover questions unanswered by this manual page.

The primary ftp site for rsync is <ftp://rsync.samba.org/pub/rsync>.

We would be delighted to hear from you if you like this program. Please contact the mailing-list at rsync@lists.samba.org.

This program uses the excellent zlib compression library written by Jean-loup Gailly and Mark Adler.

THANKS

Especial thanks go out to: John Van Essen, Matt McCutchen, Wesley W. Terpstra, David Dykstra, Jos Backus, Sebastian Krahmer, Martin Pool, and our gone-but-not-forgotten compadre, J.W. Schultz.

Thanks also to Richard Brent, Brendan Mackay, Bill Waite, Stephen Rothwell and David Bell. I've probably missed some people, my apologies if I have.

AUTHOR

rsync was originally written by Andrew Tridgell and Paul Mackerras. Many people have later contributed to it. It is currently maintained by Wayne Davison.

Mailing lists for support and development are available at <http://lists.samba.org>

NAME

rsyncd.conf — configuration file for rsync in daemon mode

SYNOPSIS

rsyncd.conf

DESCRIPTION

The rsyncd.conf file is the runtime configuration file for rsync when run as an rsync daemon.

The rsyncd.conf file controls authentication, access, logging and available modules.

FILE FORMAT

The file consists of modules and parameters. A module begins with the name of the module in square brackets and continues until the next module begins. Modules contain parameters of the form “name = value”.

The file is line-based — that is, each newline-terminated line represents either a comment, a module name or a parameter.

Only the first equals sign in a parameter is significant. Whitespace before or after the first equals sign is discarded. Leading, trailing and internal whitespace in module and parameter names is irrelevant. Leading and trailing whitespace in a parameter value is discarded. Internal whitespace within a parameter value is retained verbatim.

Any line beginning with a hash (#) is ignored, as are lines containing only whitespace.

Any line ending in a \ is “continued” on the next line in the customary UNIX fashion.

The values following the equals sign in parameters are all either a string (no quotes needed) or a boolean, which may be given as yes/no, 0/1 or true/false. Case is not significant in boolean values, but is preserved in string values.

LAUNCHING THE RSYNC DAEMON

The rsync daemon is launched by specifying the **--daemon** option to rsync.

The daemon must run with root privileges if you wish to use chroot, to bind to a port numbered under 1024 (as is the default 873), or to set file ownership. Otherwise, it must just have permission to read and write the appropriate data, log, and lock files.

You can launch it either via inetd, as a stand-alone daemon, or from an rsync client via a remote shell. If run as a stand-alone daemon then just run the command “**rsync --daemon**” from a suitable startup script.

When run via inetd you should add a line like this to /etc/services:

```
rsync      873/tcp
```

and a single line something like this to /etc/inetd.conf:

```
rsync  stream tcp  nowait root  /usr/bin/rsync rsyncd --daemon
```

Replace “/usr/bin/rsync” with the path to where you have rsync installed on your system. You will then need to send inetd a HUP signal to tell it to reread its config file.

Note that you should **not** send the rsync daemon a HUP signal to force it to reread the `rsyncd.conf` file. The file is re-read on each client connection.

GLOBAL OPTIONS

The first parameters in the file (before a [module] header) are the global parameters.

You may also include any module parameters in the global part of the config file in which case the supplied value will override the default for that parameter.

motd file

The “motd file” option allows you to specify a “message of the day” to display to clients on each connect. This usually contains site information and any legal notices. The default is no motd file.

pid file The “pid file” option tells the rsync daemon to write its process ID to that file. If the file already exists, the rsync daemon will abort rather than overwrite the file.

port You can override the default port the daemon will listen on by specifying this value (defaults to 873). This is ignored if the daemon is being run by inetd, and is superseded by the **--port** command-line option.

address

You can override the default IP address the daemon will listen on by specifying this value. This is ignored if the daemon is being run by inetd, and is superseded by the **--address** command-line option.

socket options

This option can provide endless fun for people who like to tune their systems to the utmost degree. You can set all sorts of socket options which may make transfers faster (or slower!). Read the man page for the `setsockopt()` system call for details on some of the options you may be able to set. By default no special socket options are set. These settings are superseded by the **--sockopts** command-line option.

slp refresh

This option is used to determine how long service advertisements are valid (measured in seconds), and is only applicable if you have Service Location Protocol support compiled in. If this option is not set or is set to zero, then service advertisements never time out. If this is set to less than 120 seconds, then 120 seconds is used. If it is set to more than 65535, then 65535 is used (which is a limitation of SLP). Using 3600 (one hour) is a good number if you tend to change your configuration.

MODULE OPTIONS

After the global options you should define a number of modules, each module exports a directory tree as a symbolic name. Modules are exported by specifying a module name in square brackets [module] followed by the options for that module. The module name cannot contain a slash or a closing square bracket. If the name contains whitespace, each internal sequence of whitespace will be changed into a single space, while leading or trailing whitespace will be discarded.

comment

The “comment” option specifies a description string that is displayed next to the module name when clients obtain a list of available modules. The default is no comment.

path The “path” option specifies the directory in the daemon’s filesystem to make available in this module. You must specify this option for each module in `rsyncd.conf`.

use chroot

If “use chroot” is true, the rsync daemon will chroot to the “path” before starting the file transfer with the client. This has the advantage of extra protection against possible implementation security holes, but it has the disadvantages of requiring super-user privileges, of not being able to follow symbolic links that are either absolute or outside of the new root path, and of complicating the preservation of users and groups by name (see below).

As an additional safety feature, you can specify a dot-dir in the module’s “path” to indicate the point where the chroot should occur. This allows rsync to run in a chroot with a non-“/” path for the top of the transfer hierarchy. Doing this guards against unintended library loading (since those absolute paths will not be inside the transfer hierarchy unless you have used an unwise pathname), and lets you setup libraries for the chroot that are outside of the transfer. For example, specifying “/var/rsync/.module1” will chroot to the “/var/rsync” directory and set the inside-chroot path to “/module1”. If you had omitted the dot-dir, the chroot would have used the whole path, and the inside-chroot path would have been “/”.

When “use chroot” is false or the inside-chroot path is not “/”, rsync will: (1) munge symlinks by default for security reasons (see “munge symlinks” for a way to turn this off, but only if you trust your users), (2) substitute leading slashes in absolute paths with the module’s path (so that options

such as **—backup-dir**, **—compare-dest**, etc. interpret an absolute path as rooted in the module’s “path” dir), and (3) trim “..” path elements from args if rsync believes they would escape the module hierarchy. The default for “use chroot” is true, and is the safer choice (especially if the module is not read-only).

When this option is enabled, rsync will not attempt to map users and groups by name (by default), but instead copy IDs as though **—numeric-ids** had been specified. In order to enable name-mapping, rsync needs to be able to use the standard library functions for looking up names and IDs (i.e. `getpwuid()`, `getgrgid()`, `getpwnam()`, and `getgrnam()`). This means the rsync process in the chroot hierarchy will need to have access to the resources used by these library functions (traditionally `/etc/passwd` and `/etc/group`, but perhaps additional dynamic libraries as well).

If you copy the necessary resources into the module’s chroot area, you should protect them through your OS’s normal user/group or ACL settings (to prevent the rsync module’s user from being able to change them), and then hide them from the user’s view via “exclude” (see how in the discussion of that option). At that point it will be safe to enable the mapping of users and groups by name using the “numeric ids” daemon option (see below).

Note also that you are free to setup custom user/group information in the chroot area that is different from your normal system. For example, you could abbreviate the list of users and groups.

numeric ids

Enabling the “numeric ids” option disables the mapping of users and groups by name for the current daemon module. This prevents the daemon from trying to load any user/group-related files or libraries. Enabling this option makes the transfer behave as if the client had passed the **—numeric-ids** command-line option. By default, this parameter is enabled for chroot modules and disabled for non-chroot modules.

A chroot-enabled module should not have this option enabled unless you’ve taken steps to ensure that the module has the necessary resources it needs to translate names, and that it is not possible for a user to change those resources.

munge symlinks

The “munge symlinks” option tells rsync to modify all incoming symlinks in a way that makes them unusable but recoverable (see below). This should help protect your files from user trickery when your daemon module is writable. The default is disabled when “use chroot” is on and the inside-chroot path is “/”, otherwise it is enabled.

If you disable this option on a daemon that is not read-only, there are tricks that a user can play with uploaded symlinks to access daemon-excluded items (if your module has any), and, if “use chroot” is off, rsync can even be tricked into showing or changing data that is outside the module’s path (as access-permissions allow).

The way rsync disables the use of symlinks is to prefix each one with the string “/rsyncd-munged/”. This prevents the links from being used as long as that directory does not exist. When this option is enabled, rsync will refuse to run if that path is a directory or a symlink to a directory. When using the “munge symlinks” option in a chroot area that has an inside-chroot path of “/”, you should add “/rsyncd-munged/” to the exclude setting for the module so that a user can’t try to create it.

Note: rsync makes no attempt to verify that any pre-existing symlinks in the hierarchy are as safe as you want them to be. If you setup an rsync daemon on a new area or locally add symlinks, you can manually protect your symlinks from being abused by prefixing “/rsyncd-munged/” to the start of every symlink’s value. There is a perl script in the support directory of the source code named “munge-symlinks” that can be used to add or remove this prefix from your symlinks.

When this option is disabled on a writable module and “use chroot” is off (or the inside-chroot path is not “/”), incoming symlinks will be modified to drop a leading slash and to remove “..” path elements that rsync believes will allow a symlink to escape the module’s hierarchy. There are

tricky ways to work around this, though, so you had better trust your users if you choose this combination of options.

charset

This specifies the name of the character set in which the module's filenames are stored. If the client uses an **--iconv** option, the daemon will use the value of the "charset" parameter regardless of the character set the client actually passed. This allows the daemon to support charset conversion in a chroot module without extra files in the chroot area, and also ensures that name-translation is done in a consistent manner. If the "charset" parameter is not set, the **--iconv** option is refused, just as if "iconv" had been specified via "refuse options".

If you wish to force users to always use **--iconv** for a particular module, add "no-iconv" to the "refuse options" parameter. Keep in mind that this will restrict access to your module to very new rsync clients.

max connections

The "max connections" option allows you to specify the maximum number of simultaneous connections you will allow. Any clients connecting when the maximum has been reached will receive a message telling them to try later. The default is 0, which means no limit. A negative value disables the module. See also the "lock file" option.

log file When the "log file" option is set to a non-empty string, the rsync daemon will log messages to the indicated file rather than using syslog. This is particularly useful on systems (such as AIX) where `syslog()` doesn't work for chrooted programs. The file is opened before `chroot()` is called, allowing it to be placed outside the transfer. If this value is set on a per-module basis instead of globally, the global log will still contain any authorization failures or config-file error messages.

If the daemon fails to open to specified file, it will fall back to using syslog and output an error about the failure. (Note that the failure to open the specified log file used to be a fatal error.)

syslog facility

The "syslog facility" option allows you to specify the syslog facility name to use when logging messages from the rsync daemon. You may use any standard syslog facility name which is defined on your system. Common names are auth, authpriv, cron, daemon, ftp, kern, lpr, mail, news, security, syslog, user, uucp, local0, local1, local2, local3, local4, local5, local6 and local7. The default is daemon. This setting has no effect if the "log file" setting is a non-empty string (either set in the per-modules settings, or inherited from the global settings).

max verbosity

The "max verbosity" option allows you to control the maximum amount of verbose information that you'll allow the daemon to generate (since the information goes into the log file). The default is 1, which allows the client to request one level of verbosity.

lock file

The "lock file" option specifies the file to use to support the "max connections" option. The rsync daemon uses record locking on this file to ensure that the max connections limit is not exceeded for the modules sharing the lock file. The default is `/var/run/rsyncd.lock`.

read only

The "read only" option determines whether clients will be able to upload files or not. If "read only" is true then any attempted uploads will fail. If "read only" is false then uploads will be possible if file permissions on the daemon side allow them. The default is for all modules to be read only.

write only

The "write only" option determines whether clients will be able to download files or not. If "write only" is true then any attempted downloads will fail. If "write only" is false then downloads will be possible if file permissions on the daemon side allow them. The default is for this option to be disabled.

- list** The “list” option determines if this module should be listed when the client asks for a listing of available modules. By setting this to false you can create hidden modules. The default is for modules to be listable.
- uid** The “uid” option specifies the user name or user ID that file transfers to and from that module should take place as when the daemon was run as root. In combination with the “gid” option this determines what file permissions are available. The default is uid -2, which is normally the user “nobody”.
- gid** The “gid” option specifies the group name or group ID that file transfers to and from that module should take place as when the daemon was run as root. This complements the “uid” option. The default is gid -2, which is normally the group “nobody”.

fake super

Setting “fake super = yes” for a module causes the daemon side to behave as if the **—fake-user** command-line option had been specified. This allows the full attributes of a file to be stored without having to have the daemon actually running as root.

- filter** The daemon has its own filter chain that determines what files it will let the client access. This chain is not sent to the client and is independent of any filters the client may have specified. Files excluded by the daemon filter chain (**daemon-excluded** files) are treated as non-existent if the client tries to pull them, are skipped with an error message if the client tries to push them (triggering exit code 23), and are never deleted from the module. You can use daemon filters to prevent clients from downloading or tampering with private administrative files, such as files you may add to support uid/gid name translations.

The daemon filter chain is built from the “filter”, “include from”, “include”, “exclude from”, and “exclude” parameters, in that order of priority. Anchored patterns are anchored at the root of the module. To prevent access to an entire subtree, for example, “/secret”, you *must* exclude everything in the subtree; the easiest way to do this is with a triple-star pattern like “/secret/**”.

The “filter” parameter takes a space-separated list of daemon filter rules, though it is smart enough to know not to split a token at an internal space in a rule (e.g. “- /foo — /bar” is parsed as two rules). You may specify one or more merge-file rules using the normal syntax. Only one “filter” parameter can apply to a given module in the config file, so put all the rules you want in a single parameter. Note that per-directory merge-file rules do not provide as much protection as global rules, but they can be used to make **—delete** work better during a client download operation if the per-dir merge files are included in the transfer and the client requests that they be used.

exclude

The “exclude” parameter takes a space-separated list of daemon exclude patterns. As with the client **—exclude** option, patterns can be qualified with “- ” or “+ ” to explicitly indicate exclude/include. Only one “exclude” parameter can apply to a given module. See the “filter” parameter for a description of how excluded files affect the daemon.

include

Use an “include” to override the effects of the “exclude” parameter. Only one “include” parameter can apply to a given module. See the “filter” parameter for a description of how excluded files affect the daemon.

exclude from

The “exclude from” parameter specifies the name of a file on the daemon that contains daemon exclude patterns, one per line. Only one “exclude from” parameter can apply to a given module; if you have multiple exclude-from files, you can specify them as a merge file in the “filter” parameter. See the “filter” parameter for a description of how excluded files affect the daemon.

include from

Analogue of “exclude from” for a file of daemon include patterns. Only one “include from” parameter can apply to a given module. See the “filter” parameter for a description of how excluded files affect the daemon.

incoming chmod

This option allows you to specify a set of comma-separated chmod strings that will affect the permissions of all incoming files (files that are being received by the daemon). These changes happen after all other permission calculations, and this will even override destination-default and/or existing permissions when the client does not specify **--perms**. See the description of the **--chmod** rsync option and the **chmod(1)** manpage for information on the format of this string.

outgoing chmod

This option allows you to specify a set of comma-separated chmod strings that will affect the permissions of all outgoing files (files that are being sent out from the daemon). These changes happen first, making the sent permissions appear to be different than those stored in the filesystem itself. For instance, you could disable group write permissions on the server while having it appear to be on to the clients. See the description of the **--chmod** rsync option and the **chmod(1)** manpage for information on the format of this string.

auth users

The “auth users” option specifies a comma and space-separated list of usernames that will be allowed to connect to this module. The usernames do not need to exist on the local system. The usernames may also contain shell wildcard characters. If “auth users” is set then the client will be challenged to supply a username and password to connect to the module. A challenge response authentication protocol is used for this exchange. The plain text usernames and passwords are stored in the file specified by the “secrets file” option. The default is for all users to be able to connect without a password (this is called “anonymous rsync”).

See also the “CONNECTING TO AN RSYNC DAEMON OVER A REMOTE SHELL PROGRAM” section in **rsync(1)** for information on how handle an rsyncd.conf–level username that differs from the remote-shell-level username when using a remote shell to connect to an rsync daemon.

secrets file

The “secrets file” option specifies the name of a file that contains the username:password pairs used for authenticating this module. This file is only consulted if the “auth users” option is specified. The file is line based and contains username:password pairs separated by a single colon. Any line starting with a hash (#) is considered a comment and is skipped. The passwords can contain any characters but be warned that many operating systems limit the length of passwords that can be typed at the client end, so you may find that passwords longer than 8 characters don’t work.

There is no default for the “secrets file” option, you must choose a name (such as `/etc/rsyncd.secrets`). The file must normally not be readable by “other”; see “strict modes”.

strict modes

The “strict modes” option determines whether or not the permissions on the secrets file will be checked. If “strict modes” is true, then the secrets file must not be readable by any user ID other than the one that the rsync daemon is running under. If “strict modes” is false, the check is not performed. The default is true. This option was added to accommodate rsync running on the Windows operating system.

hosts allow

The “hosts allow” option allows you to specify a list of patterns that are matched against a connecting clients hostname and IP address. If none of the patterns match then the connection is rejected.

Each pattern can be in one of five forms:

- o a dotted decimal IPv4 address of the form a.b.c.d, or an IPv6 address of the form a:b:c::d:e:f. In this case the incoming machine’s IP address must match exactly.
- o an address/mask in the form ipaddr/n where ipaddr is the IP address and n is the number of one bits in the netmask. All IP addresses which match the masked IP address will be

allowed in.

- o an address/mask in the form `ipaddr/maskaddr` where `ipaddr` is the IP address and `maskaddr` is the netmask in dotted decimal notation for IPv4, or similar for IPv6, e.g. `ffff:ffff:ffff:ffff::` instead of `/64`. All IP addresses which match the masked IP address will be allowed in.
- o a hostname. The hostname as determined by a reverse lookup will be matched (case insensitive) against the pattern. Only an exact match is allowed in.
- o a hostname pattern using wildcards. These are matched using the same rules as normal unix filename matching. If the pattern matches then the client is allowed in.

Note IPv6 link-local addresses can have a scope in the address specification:

```
fe80::1%link1
fe80::%link1/64
fe80::%link1/ffff:ffff:ffff:ffff::
```

You can also combine “hosts allow” with a separate “hosts deny” option. If both options are specified then the “hosts allow” option is checked first and a match results in the client being able to connect. The “hosts deny” option is then checked and a match means that the host is rejected. If the host does not match either the “hosts allow” or the “hosts deny” patterns then it is allowed to connect.

The default is no “hosts allow” option, which means all hosts can connect.

hosts deny

The “hosts deny” option allows you to specify a list of patterns that are matched against a connecting clients hostname and IP address. If the pattern matches then the connection is rejected. See the “hosts allow” option for more information.

The default is no “hosts deny” option, which means all hosts can connect.

ignore errors

The “ignore errors” option tells rsync to ignore I/O errors on the daemon when deciding whether to run the delete phase of the transfer. Normally rsync skips the **—delete** step if any I/O errors have occurred in order to prevent disastrous deletion due to a temporary resource shortage or other I/O error. In some cases this test is counter productive so you can use this option to turn off this behavior.

ignore nonreadable

This tells the rsync daemon to completely ignore files that are not readable by the user. This is useful for public archives that may have some non-readable files among the directories, and the sysadmin doesn’t want those files to be seen at all.

transfer logging

The “transfer logging” option enables per-file logging of downloads and uploads in a format somewhat similar to that used by ftp daemons. The daemon always logs the transfer at the end, so if a transfer is aborted, no mention will be made in the log file.

If you want to customize the log lines, see the “log format” option.

log format

The “log format” option allows you to specify the format used for logging file transfers when transfer logging is enabled. The format is a text string containing embedded single-character escape sequences prefixed with a percent (%) character. An optional numeric field width may also be specified between the percent and the escape letter (e.g. “**%-50n %8l %07p**”).

The default log format is “**%o %h [%a] %m (%u) %f %l**”, and a “**%t [%p]**” is always prefixed when using the “log file” option. (A perl script that will summarize this default log format is

included in the rsync source code distribution in the “support” subdirectory: rsyncstats.)

The single-character escapes that are understood are as follows:

- o %a the remote IP address
- o %b the number of bytes actually transferred
- o %B the permission bits of the file (e.g. rwxrwxrwt)
- o %c the checksum bytes received for this file (only when sending)
- o %f the filename (long form on sender; no trailing “/”)
- o %G the gid of the file (decimal) or “DEFAULT”
- o %h the remote host name
- o %i an itemized list of what is being updated
- o %l the length of the file in bytes
- o %L the string “ -> SYMLINK”, “ => HARDLINK”, or “” (where **SYMLINK** or **HARDLINK** is a filename)
- o %m the module name
- o %M the last-modified time of the file
- o %n the filename (short form; trailing “/” on dir)
- o %o the operation, which is “send”, “recv”, or “del.” (the latter includes the trailing period)
- o %p the process ID of this rsync session
- o %P the module path
- o %t the current date time
- o %u the authenticated username or an empty string
- o %U the uid of the file (decimal)

For a list of what the characters mean that are output by “%i”, see the **--itemize-changes** option in the rsync manpage.

Note that some of the logged output changes when talking with older rsync versions. For instance, deleted files were only output as verbose messages prior to rsync 2.6.4.

timeout

The “timeout” option allows you to override the clients choice for I/O timeout for this module. Using this option you can ensure that rsync won’t wait on a dead client forever. The timeout is specified in seconds. A value of zero means no timeout and is the default. A good choice for anonymous rsync daemons may be 600 (giving a 10 minute timeout).

refuse options

The “refuse options” option allows you to specify a space-separated list of rsync command line options that will be refused by your rsync daemon. You may specify the full option name, its one-letter abbreviation, or a wild-card string that matches multiple options. For example, this would refuse **--checksum** (**-c**) and all the various delete options:

```
refuse options = c delete
```

The reason the above refuses all delete options is that the options imply **--delete**, and implied options are refused just like explicit options. As an additional safety feature, the refusal of “delete” also refuses **remove-source-files** when the daemon is the sender; if you want the latter without the former, instead refuse “delete-*” — that refuses all the delete modes without affecting

--remove-source-files.

When an option is refused, the daemon prints an error message and exits. To prevent all compression when serving files, you can use “dont compress = *” (see below) instead of “refuse options = compress” to avoid returning an error to a client that requests compression.

dont compress

The “dont compress” option allows you to select filenames based on wildcard patterns that should not be compressed when pulling files from the daemon (no analogous option exists to govern the pushing of files to a daemon). Compression is expensive in terms of CPU usage, so it is usually good to not try to compress files that won’t compress well, such as already compressed files.

The “dont compress” option takes a space-separated list of case-insensitive wildcard patterns. Any source filename matching one of the patterns will not be compressed during transfer.

See the **--skip-compress** option in the **rsync(1)** manpage for the list of file suffixes that are not compressed by default. Specifying a value for the “dont compress” option changes the default when the daemon is the sender.

pre-xfer exec, post-xfer exec

You may specify a command to be run before and/or after the transfer. If the **pre-xfer exec** command fails, the transfer is aborted before it begins.

The following environment variables will be set, though some are specific to the pre-xfer or the post-xfer environment:

- o **RSYNC_MODULE_NAME**: The name of the module being accessed.
- o **RSYNC_MODULE_PATH**: The path configured for the module.
- o **RSYNC_HOST_ADDR**: The accessing host’s IP address.
- o **RSYNC_HOST_NAME**: The accessing host’s name.
- o **RSYNC_USER_NAME**: The accessing user’s name (empty if no user).
- o **RSYNC_PID**: A unique number for this transfer.
- o **RSYNC_REQUEST**: (pre-xfer only) The module/path info specified by the user (note that the user can specify multiple source files, so the request can be something like “mod/path1 mod/path2”, etc.).
- o **RSYNC_ARG#**: (pre-xfer only) The pre-request arguments are set in these numbered values. **RSYNC_ARG0** is always “rsyncd”, and the last value contains a single period.
- o **RSYNC_EXIT_STATUS**: (post-xfer only) the server side’s exit value. This will be 0 for a successful run, a positive value for an error that the server generated, or a -1 if rsync failed to exit properly. Note that an error that occurs on the client side does not currently get sent to the server side, so this is not the final exit status for the whole transfer.
- o **RSYNC_RAW_STATUS**: (post-xfer only) the raw exit value from `waitpid()`.

Even though the commands can be associated with a particular module, they are run using the permissions of the user that started the daemon (not the module’s uid/gid setting) without any chroot restrictions.

AUTHENTICATION STRENGTH

The authentication protocol used in rsync is a 128 bit MD4 based challenge response system. This is fairly weak protection, though (with at least one brute-force hash-finding algorithm publicly available), so if you want really top-quality security, then I recommend that you run rsync over ssh. (Yes, a future version of rsync will switch over to a stronger hashing method.)

Also note that the rsync daemon protocol does not currently provide any encryption of the data that is transferred over the connection. Only authentication is provided. Use ssh as the transport if you want encryption.

Future versions of rsync may support SSL for better authentication and encryption, but that is still being investigated.

EXAMPLES

A simple rsyncd.conf file that allow anonymous rsync to a ftp area at `/home/ftp` would be:

```
[ftp]
  path = /home/ftp
  comment = ftp export area
```

A more sophisticated example would be:

```
uid = nobody
gid = nobody
use chroot = yes
max connections = 4
syslog facility = local5
pid file = /var/run/rsyncd.pid
slp refresh = 3600
```

```
[ftp]
  path = /var/ftp/.pub
  comment = whole ftp area (approx 6.1 GB)
```

```
[smbaftp]
  path = /var/ftp/.pub/samba
  comment = Samba ftp area (approx 300 MB)
```

```
[rsyncftp]
  path = /var/ftp/.pub/rsync
  comment = rsync ftp area (approx 6 MB)
```

```
[sambawww]
  path = /public_html/samba
  comment = Samba WWW pages (approx 240 MB)
```

```
[cvs]
  path = /data/cvs
  comment = CVS repository (requires authentication)
  auth users = tridge, susan
  secrets file = /etc/rsyncd.secrets
```

The `/etc/rsyncd.secrets` file would look something like this:

```
tridge:mypass
susan:herpass
```

FILES

`/etc/rsyncd.conf` or `rsyncd.conf`

DIAGNOSTICS**BUGS**

Please report bugs! The rsync bug tracking system is online at <http://rsync.samba.org/>

VERSION

This man page is current for version 3.0.2 of rsync.

CREDITS

rsync is distributed under the GNU public license. See the file COPYING for details.

The primary ftp site for rsync is <ftp://rsync.samba.org/pub/rsync>.

A WEB site is available at <http://rsync.samba.org/>

We would be delighted to hear from you if you like this program.

This program uses the zlib compression library written by Jean-loup Gailly and Mark Adler.

THANKS

Thanks to Warren Stanley for his original idea and patch for the rsync daemon. Thanks to Karsten Thygesen for his many suggestions and documentation!

AUTHOR

rsync was written by Andrew Tridgell and Paul Mackerras. Many people have later contributed to it.

Mailing lists for support and development are available at <http://lists.samba.org>

NAME

sat – start edrc with a special System Administration configuration

SYNOPSIS

edrc/bin/sat [**-h** | **-V**]

sat [**-s**] [**-t**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

Short start of **edrc** with an other configuration which points to an own script tree. Internally **sat** calls **edrc -c edrc.sat.cfg -n SAT_@ID@** .

sat stands for "System Administration Tool".

The session name (as shown in the menu) is automatically set to **SAT_<id>** . Where **<id>** is the process id of the started **edrc** instance if not already a session with the same name exists, if so the **<id>** is set to a random number.

If additional short starts are needed, create a symlink from the new short start command to **sat** (see section **EXAMPLES**).

OPTIONS

- h** usage message.
- V** print version and patch level of **edrc**. For an explanation of the release numbering system see **edrcrevision(1)**.
- s** silent startup. Startup without showing the EDRC banner.
- t** no terminal initialization. Sometimes the terminal initialization causes unwanted behavior. To skip terminal initialization, invoke **edrc** with this option.

ENVIRONMENT

-

EXIT STATUS

see **edrc(1m)**.

FILES

etc/edrc.sat.cfg

configuration file of **sat**, see **edrc.cfg(4)** for more information.

Other files see section **FILES** in **edrc(1m)**.

EXAMPLES**1) create a new short start**

This creates a new short start command **new_shortstart** that will load the configuration file **edrc.new_shortstart.cfg**. The session name will automatically be set to **NEW_SHORTSTART_<id>** .

```
[ /root ]
[ root@rh7mzv7t001 ] [bash]: cd ~edrc/bin

[ /opt/edrc/bin ]
[ root@acme007 ] [bash]: ln -s sat new_shortstart
```

or:

```
[ /opt/edrc/bin ]
[ root@acme007 ] [bash]: symlink sat ~edrc/bin/new_shortstart
```

NAME

sav – Make Backup Copy

SYNOPSIS

edrc/bin/sav -h

sav [**-q**] *file*...

sav [**-q**] { **-d** | **-D** *subdir* } *file*...

AVAILABILITY

WA2L/edrc

DESCRIPTION

The **sav** utility is used by **mkuser** (for example) to make a backup copy of one or more files. Without options, the backup file will be named **file.\$TODAY** and stored in the same directory as the original. With a **-d** or **-D** *subdir* option, the backup file will be stored in a subdirectory.

Saves of files located in special operating system configuration or state directories are always done into a **.\$TODAY/** directory to ensure proper system functionality. See section **FILES** for a complete list of those directories.

OPTIONS

-q Quiet mode, does not give any warnings to standard output.

-d For each *file*, copy it to **.\$TODAY/file**, where TODAY is today's date in the form YYYYMMDD. If the directory does not exist, it is created.

-D *subdir* For each file, *file* copy it to **subdir.\$TODAY/file**, where TODAY is today's date in the form YYYYMMDD. If the directory does not exist, it is created. (This option is used by **mkuser**.)

ENVIRONMENT

\$TZ timezone setting.

EXIT STATUS

0 no error

4 usage displayed

8 could not create subdir or command interrupted

FILES

Files located in the following operating system configuration or state directories are always saved into the **.\$TODAY/** directory as if **sav** would be invoked using the **-d** option:

/etc/*.d/, /etc/*/*.d/, /etc/*/*/*.d, /etc/default/

as links to the rc scripts in **/etc/init.d** and configuration of rc scripts, as seen on HPUX, Linux and Solaris.

/sbin/*.d/ as links to the rc scripts in **/etc/init.d**, as seen on HPUX.

/var/spool/at/

defined at jobs, as seen on Linux.

/var/spool/cron/atjobs/

defined at jobs, as seen on HPUX and Solaris.

/var/spool/cron/

defined crontabs, as seen on Linux.

/var/spool/cron/crontabs/

defined crontabs, as seen on HPUX and Solaris.

***/man/man*/, */man/*/*man*/**

manual pages directories.

/lib/sypoll/protocols/

protocol plugins of **sypoll(1)**.

EXAMPLES

NAME

schedule.dat – schedule definition for lots

SYNOPSIS

edrc/var/lots/objects/schedule.dat
VARDIR/objects/schedule.dat

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the scheduling definition for the **lots** command.

FILEFORMAT

The fileformat is a list of definitions that have the format

DATALIST ; DESCRIPTION ; HOSTNAME ; RETENTION ; COMPRESSION ; SCHEDULE ;

Rows starting with a **#** are considered as comments. Empty lines are allowed, too.

OPTIONS*DATALIST*

name of the data list as defined in the **datalist.dat** file. For each scheduled *DATALIST* in the **schedule.dat** file at least a *DATALIST* in the **datalist.dat** file must exist.

DESCRIPTION

description of the schedule.

Be aware that this should be a meaningful description due to the fact that this data is saved for a long time and people having done the definition might have moved on before the data might be needed for restore.

HOSTNAME

hostname where the schedule should be active.

RETENTION

number of days the data is locked for. If multiple schedules match for a certain day, the schedule having the highest retention will be executed.

If the defined *RETENTION* is outside the **RETENTION_MIN** and **RETENTION_MAX** range as defined in the **lots.cfg** file, the effective *RETENTION* is adjusted accordingly.

COMPRESSION

compression mode:

NONE

no compression.

GZIP

use **gzip** to compress the data. The command executed is: **gzip -cv --fast**.

COMPRESS

use **compress** to compress the data. The command executed is: **compress -cv**.

ZIP

use **zip** to compress the data. The command executed is: **zip**.

BZIP2

use **bzip2** to compress the data. The command executed is: **bzip2 -cv --fast**.

SCHEDULE

schedule definitions. This is a space separated list of schedule definitions of the format explained below. A schedule can consist on any combination of the following entries:

DD.

day of the month. This schedule will match each month on the day specified. Therefore the schedule **28.** will match each month at the 28th.

DD.MM.

specify day and month. This schedule will match each day of the month every year. Therefore the schedule **04.07.** will match on the July 4th every year.

DD.MM.YYYY

precise date specification. This schedule will only match on the precise date. Therefore the schedule **28.01.1986** will only match on the January 28th 1986. It is allowed to specify the schedule entry **00.00.0000** to mark a prepared but not really planned schedule.

WDay

short English weekday name: **Mon Tue Wed Thu Fri Sat Sun**. This schedule will only match on the weekday specified. Therefore the schedule **Fri** will match every Friday.

EXAMPLES

```
#
# var/lots/objects/schedule.dat - schedule and retention information
#
# [00] 30.09.2009 CWa Initial Version
#
# LEVEL          RETENTION          BACKUP (= DB export)    => SAVE_SCHEDULIN
```

```

# -----
# Silver      5 Months => 150 days  Sunday                => Mon
# Gold        2 Years  => 730 days  last day of the month => 01.
# Platinum    4 Years  => 1460 days last day of the quarter => 01.04. 01.07.
#
#
#DATALIST      ;DESCRIPTION                ;HOSTNAME      ;RETENTION    ;COMPRESSION   ;

NAME

screen – screen manager with VT100/ANSI terminal emulation

SYNOPSIS

```
screen [ -options ] [ cmd [ args ] ]  
screen -r [[pid.]tty[.host]]  
screen -r sessionowner/[[pid.]tty[.host]]
```

DESCRIPTION

Screen is a full-screen window manager that multiplexes a physical terminal between several processes (typically interactive shells). Each virtual terminal provides the functions of a DEC VT100 terminal and, in addition, several control functions from the ISO 6429 (ECMA 48, ANSI X3.64) and ISO 2022 standards (e.g. insert/delete line and support for multiple character sets). There is a scrollback history buffer for each virtual terminal and a copy-and-paste mechanism that allows moving text regions between windows.

When *screen* is called, it creates a single window with a shell in it (or the specified command) and then gets out of your way so that you can use the program as you normally would. Then, at any time, you can create new (full-screen) windows with other programs in them (including more shells), kill existing windows, view a list of windows, turn output logging on and off, copy-and-paste text between windows, view the scrollback history, switch between windows in whatever manner you wish, etc. All windows run their programs completely independent of each other. Programs continue to run when their window is currently not visible and even when the whole *screen* session is detached from the user's terminal. When a program terminates, *screen* (per default) kills the window that contained it. If this window was in the foreground, the display switches to the previous window; if none are left, *screen* exits.

Everything you type is sent to the program running in the current window. The only exception to this is the one keystroke that is used to initiate a command to the window manager. By default, each command begins with a control-a (abbreviated C-a from now on), and is followed by one other keystroke. The command character and all the key bindings can be fully customized to be anything you like, though they are always two characters in length.

Screen does not understand the prefix “C-” to mean control. Please use the caret notation (“^A” instead of “C-a”) as arguments to e.g. the *escape* command or the *-e* option. *Screen* will also print out control characters in caret notation.

The standard way to create a new window is to type “C-a c”. This creates a new window running a shell and switches to that window immediately, regardless of the state of the process running in the current window. Similarly, you can create a new window with a custom command in it by first binding the command to a keystroke (in your *.screenrc* file or at the “C-a :” command line) and then using it just like the “C-a c” command. In addition, new windows can be created by running a command like:

```
screen emacs prog.c
```

from a shell prompt within a previously created window. This will not run another copy of *screen*, but will instead supply the command name and its arguments to the window manager (specified in the \$STY environment variable) who will use it to create the new window. The above example would start the emacs editor (editing prog.c) and switch to its window.

If “/etc/utmp” is writable by *screen*, an appropriate record will be written to this file for each window, and removed when the window is terminated. This is useful for working with “talk”, “script”, “shutdown”, “rsend”, “sccs” and other similar programs that use the utmp file to determine who you are. As long as *screen* is active on your terminal, the terminal's own record is removed from the utmp file. See also “C-a L”.

GETTING STARTED

Before you begin to use *screen* you'll need to make sure you have correctly selected your terminal type, just as you would for any other termcap/terminfo program. (You can do this by using *tset* for example.)

If you're impatient and want to get started without doing a lot more reading, you should remember this one command: "C-a ?". Typing these two characters will display a list of the available *screen* commands and their bindings. Each keystroke is discussed in the section "DEFAULT KEY BINDINGS". The manual section "CUSTOMIZATION" deals with the contents of your *.screenrc*.

If your terminal is a "true" auto-margin terminal (it doesn't allow the last position on the screen to be updated without scrolling the screen) consider using a version of your terminal's termcap that has automatic margins turned *off*. This will ensure an accurate and optimal update of the screen in all circumstances. Most terminals nowadays have "magic" margins (automatic margins plus usable last column). This is the VT100 style type and perfectly suited for *screen*. If all you've got is a "true" auto-margin terminal *screen* will be content to use it, but updating a character put into the last position on the screen may not be possible until the screen scrolls or the character is moved into a safe position in some other way. This delay can be shortened by using a terminal with insert-character capability.

COMMAND-LINE OPTIONS

Screen has the following command-line options:

- a** include *all* capabilities (with some minor exceptions) in each window's termcap, even if *screen* must redraw parts of the display in order to implement a function.
- A** Adapt the sizes of all windows to the size of the current terminal. By default, *screen* tries to restore its old window sizes when attaching to resizable terminals (those with "WS" in its description, e.g. *suncmd* or some *xterm*).
- c file**
override the default configuration file from "\$HOME/.screenrc" to *file*.
- d|-D [pid.tty.host]**
does not start *screen*, but detaches the elsewhere running *screen* session. It has the same effect as typing "C-a d" from *screen*'s controlling terminal. **-D** is the equivalent to the power detach key. If no session can be detached, this option is ignored. In combination with the **-r/-R** option more powerful effects can be achieved:
- d -r** Reattach a session and if necessary detach it first.
- d -R** Reattach a session and if necessary detach or even create it first.
- d -RR** Reattach a session and if necessary detach or create it. Use the first session if more than one session is available.
- D -r** Reattach a session. If necessary detach and logout remotely first.
- D -R** Attach here and now. In detail this means: If a session is running, then reattach. If necessary detach and logout remotely first. If it was not running create it and notify the user. This is the author's favorite.
- D -RR**
Attach here and now. Whatever that means, just do it.

Note: It is always a good idea to check the status of your sessions by means of "screen -list".

- e xy**
specifies the command character to be *x* and the character generating a literal command character to *y* (when typed after the command character). The default is "C-a" and 'a', which can be specified as "-e^Aa". When creating a *screen* session, this option sets the default command character. In a multi-user session all users added will start off with this command character. But when attaching to an already running session, this option changes only the command character of the attaching user. This

option is equivalent to either the commands “defescape” or “escape” respectively.

-f, -fn, and -fa

turns flow-control on, off, or “automatic switching mode”. This can also be defined through the “defflow” .screenrc command.

-h *num*

Specifies the history scrollback buffer to be *num* lines high.

-i

will cause the interrupt key (usually C-c) to interrupt the display immediately when flow-control is on. See the “defflow” .screenrc command for details. The use of this option is discouraged.

-l and -ln

turns login mode on or off (for /etc/utmp updating). This can also be defined through the “deflogin” .screenrc command.

-ls and -list

does not start *screen*, but prints a list of *pid.tty.host* strings identifying your *screen* sessions. Sessions marked ‘detached’ can be resumed with “screen -r”. Those marked ‘attached’ are running and have a controlling terminal. If the session runs in multiuser mode, it is marked ‘multi’. Sessions marked as ‘unreachable’ either live on a different host or are ‘dead’. An unreachable session is considered dead, when its name matches either the name of the local host, or the specified parameter, if any. See the **-r** flag for a description how to construct matches. Sessions marked as ‘dead’ should be thoroughly checked and removed. Ask your system administrator if you are not sure. Remove sessions with the **-wipe** option.

-L

tells *screen* to turn on automatic output logging for the windows.

-m

causes *screen* to ignore the \$STY environment variable. With “screen -m” creation of a new session is enforced, regardless whether *screen* is called from within another *screen* session or not. This flag has a special meaning in connection with the ‘-d’ option:

-d -m

Start *screen* in “detached” mode. This creates a new session but doesn’t attach to it. This is useful for system startup scripts.

-D -m

This also starts *screen* in “detached” mode, but doesn’t fork a new process. The command exits if the session terminates.

-O

selects a more optimal output mode for your terminal rather than true VT100 emulation (only affects auto-margin terminals without ‘LP’). This can also be set in your .screenrc by specifying ‘OP’ in a “termcap” command.

-p *number_or_name*

Preselect a window. This is useful when you want to reattach to a specific window or you want to send a command via the “-X” option to a specific window. As with *screen*’s select command, “-” selects the blank window. As a special case for reattach, “=” brings up the windowlist on the blank window.

-q

Suppress printing of error messages. In combination with “-ls” the exit value is as follows: 9 indicates a directory without sessions. 10 indicates a directory with running but not attachable sessions. 11 (or more) indicates 1 (or more) usable sessions. In combination with “-r” the exit value is as follows: 10 indicates that there is no session to resume. 12 (or more) indicates that there are 2 (or more) sessions to resume and you should specify which one to choose. In all other cases “-q” has no effect.

-r [*pid.tty.host*]

-r *sessionowner*/[*pid.tty.host*]

resumes a detached *screen* session. No other options (except combinations with **-d/-D**) may be specified, though an optional prefix of [*pid.tty.host*] may be needed to distinguish between multiple detached *screen* sessions. The second form is used to connect to another user’s *screen* session which runs in multiuser mode. This indicates that *screen* should look for sessions in another user’s directory. This requires setuid-root.

- R** attempts to resume the first detached *screen* session it finds. If successful, all other command-line options are ignored. If no detached session exists, starts a new session using the specified options, just as if **-R** had not been specified. The option is set by default if *screen* is run as a login-shell (actually *screen* uses “-xRR” in that case). For combinations with the **-d/-D** option see there.
- s** sets the default shell to the program specified, instead of the value in the environment variable \$SHELL (or “/bin/sh” if not defined). This can also be defined through the “shell” *.screenrc* command.
- S sessionname**
When creating a new session, this option can be used to specify a meaningful name for the session. This name identifies the session for “screen -list” and “screen -r” actions. It substitutes the default [tty.host] suffix.
- t name**
sets the title (a.k.a.) for the default shell or specified program. See also the “shelltitle” *.screenrc* command.
- U** Run *screen* in UTF-8 mode. This option tells *screen* that your terminal sends and understands UTF-8 encoded characters. It also sets the default encoding for new windows to ‘utf8’.
- v** Print version number.
- wipe [match]**
does the same as “screen -ls”, but removes destroyed sessions instead of marking them as ‘dead’. An unreachable session is considered dead, when its name matches either the name of the local host, or the explicitly given parameter, if any. See the **-r** flag for a description how to construct matches.
- x** Attach to a not detached *screen* session. (Multi display mode).
- X** Send the specified command to a running *screen* session. You can use the **-d** or **-r** option to tell *screen* to look only for attached or detached *screen* sessions. Note that this command doesn’t work if the session is password protected.

DEFAULT KEY BINDINGS

As mentioned, each *screen* command consists of a “C-a” followed by one other character. For your convenience, all commands that are bound to lower-case letters are also bound to their control character counterparts (with the exception of “C-a a”; see below), thus, “C-a c” as well as “C-a C-c” can be used to create a window. See section “CUSTOMIZATION” for a description of the command.

The following table shows the default key bindings:

| | | |
|----------------|-----------------|--|
| C-a ’ | (select) | Prompt for a window name or number to switch to. |
| C-a " | (windowlist -b) | Present a list of all windows for selection. |
| C-a 0 | (select 0) | |
| ... | ... | |
| C-a 9 | (select 9) | |
| C-a - | (select -) | Switch to window number 0 – 9, or to the blank window. |
| C-a tab | (focus) | Switch the input focus to the next region. |
| C-a C-a | (other) | Toggle to the window displayed previously. Note that this binding defaults to the command character typed twice, unless overridden. For instance, if you use the option “-e x”, this command becomes “]]”. |
| C-a a | (meta) | Send the command character (C-a) to window. See <i>escape</i> command. |
| C-a A | (title) | Allow the user to enter a name for the current window. |
| C-a b | | |

| | | |
|----------------------|--------------|--|
| C-a C-b | (break) | Send a break to window. |
| C-a B | (pow_break) | Reopen the terminal line and send a break. |
| C-a c | | |
| C-a C-c | (screen) | Create a new window with a shell and switch to that window. |
| C-a C | (clear) | Clear the screen. |
| C-a d | | |
| C-a C-d | (detach) | Detach <i>screen</i> from this terminal. |
| C-a D D | (pow_detach) | Detach and logout. |
| C-a f | | |
| C-a C-f | (flow) | Toggle flow <i>on</i> , <i>off</i> or <i>auto</i> . |
| C-a F | (fit) | Resize the window to the current region size. |
| C-a C-g | (vbell) | Toggles <i>screen</i> 's visual bell mode. |
| C-a h | (hardcopy) | Write a hardcopy of the current window to the file “hardcopy. <i>n</i> ”. |
| C-a H | (log) | Begins/ends logging of the current window to the file “screenlog. <i>n</i> ”. |
| C-a i | | |
| C-a C-i | (info) | Show info about this window. |
| C-a k | | |
| C-a C-k | (kill) | Destroy current window. |
| C-a l | | |
| C-a C-l | (redisplay) | Fully refresh current window. |
| C-a L | (login) | Toggle this windows login slot. Available only if <i>screen</i> is configured to update the utmp database. |
| C-a m | | |
| C-a C-m | (lastmsg) | Repeat the last message displayed in the message line. |
| C-a M | (monitor) | Toggles monitoring of the current window. |
| C-a space | | |
| C-a n | | |
| C-a C-n | (next) | Switch to the next window. |
| C-a N | (number) | Show the number (and title) of the current window. |
| C-a backspace | | |
| C-a h | | |
| C-a p | | |
| C-a C-p | (prev) | Switch to the previous window (opposite of C-a n). |
| C-a q | | |
| C-a C-q | (xon) | Send a control-q to the current window. |
| C-a Q | (only) | Delete all regions but the current one. |
| C-a r | | |
| C-a C-r | (wrap) | Toggle the current window's line-wrap setting (turn the current window's automatic margins on and off). |
| C-a s | | |
| C-a C-s | (xoff) | Send a control-s to the current window. |
| C-a S | (split) | Split the current region into two new ones. |
| C-a t | | |

| | | |
|-----------------|---------------|--|
| C-a C-t | (time) | Show system information. |
| C-a v | (version) | Display the version and compilation date. |
| C-a C-v | (digraph) | Enter digraph. |
| C-a w | | |
| C-a C-w | (windows) | Show a list of window. |
| C-a W | (width) | Toggle 80/132 columns. |
| C-a x | | |
| C-a C-x | (lockscreen) | Lock this terminal. |
| C-a X | (remove) | Kill the current region. |
| C-a z | | |
| C-a C-z | (suspend) | Suspend <i>screen</i> . Your system must support BSD-style job-control. |
| C-a Z | (reset) | Reset the virtual terminal to its “power-on” values. |
| C-a . | (dumftermcap) | Write out a “.termcap” file. |
| C-a ? | (help) | Show key bindings. |
| C-a C-\ | (quit) | Kill all windows and terminate <i>screen</i> . |
| C-a : | (colon) | Enter command line mode. |
| C-a [| | |
| C-a C-[| | |
| C-a esc | (copy) | Enter copy/scrollback mode. |
| C-a] | (paste .) | Write the contents of the paste buffer to the stdin queue of the current window. |
| C-a { | | |
| C-a } | (history) | Copy and paste a previous (command) line. |
| C-a > | (writebuf) | Write paste buffer to a file. |
| C-a < | (readbuf) | Reads the screen-exchange file into the paste buffer. |
| C-a = | (removebuf) | Removes the file used by C-a < and C-a > . |
| C-a , | (license) | Shows where <i>screen</i> comes from, where it went to and why you can use it. |
| C-a _ | (silence) | Start/stop monitoring the current window for inactivity. |
| C-a * | (displays) | Show a listing of all currently attached displays. |

CUSTOMIZATION

The “socket directory” defaults either to \$HOME/.screen or simply to /tmp/screens or preferably to /usr/local/screens chosen at compile-time. If *screen* is installed setuid-root, then the administrator should compile *screen* with an adequate (not NFS mounted) socket directory. If *screen* is not running setuid-root, the user can specify any mode 700 directory in the environment variable \$SCREENDIR.

When *screen* is invoked, it executes initialization commands from the files “/etc/screenrc” and “.screenrc” in the user’s home directory. These are the “programmer’s defaults” that can be overridden in the following ways: for the global screenrc file *screen* searches for the environment variable \$SYSSCREENRC (this override feature may be disabled at compile-time). The user specific screenrc file is searched in \$SCREENRC, then \$HOME/.screenrc. The command line option **-c** takes precedence over the above user screenrc files.

Commands in these files are used to set options, bind functions to keys, and to automatically establish one or more windows at the beginning of your *screen* session. Commands are listed one per line, with empty lines being ignored. A command’s arguments are separated by tabs or spaces, and may be surrounded by

single or double quotes. A '#' turns the rest of the line into a comment, except in quotes. Unintelligible lines are warned about and ignored. Commands may contain references to environment variables. The syntax is the shell-like "\$VAR " or "\${VAR} ". Note that this causes incompatibility with previous *screen* versions, as now the '\$'-character has to be protected with '\' if no variable substitution shall be performed. A string in single-quotes is also protected from variable substitution.

Two configuration files are shipped as examples with your *screen* distribution: "etc/screenrc" and "etc/etc-screenrc". They contain a number of useful examples for various commands.

Customization can also be done 'on-line'. To enter the command mode type 'C-a :'. Note that commands starting with "def" change default values, while others change current settings.

The following commands are available:

acladd *usernames* [*crypted-pw*]

addacl *usernames*

Enable users to fully access this *screen* session. *Usernames* can be one user or a comma separated list of users. This command enables to attach to the *screen* session and performs the equivalent of 'aclchg *usernames* +rwx "#?"'. executed. To add a user with restricted access, use the 'aclchg' command below. If an optional second parameter is supplied, it should be a crypted password for the named user(s). 'Addacl' is a synonym to 'acladd'. Multi user mode only.

aclchg *usernames* *permbits* *list*

chacl *usernames* *permbits* *list*

Change permissions for a comma separated list of users. Permission bits are represented as 'r', 'w' and 'x'. Prefixing '+' grants the permission, '-' removes it. The third parameter is a comma separated list of commands and/or windows (specified either by number or title). The special list '#' refers to all windows, '?' to all commands. if *usernames* consists of a single '*', all known users are affected. A command can be executed when the user has the 'x' bit for it. The user can type input to a window when he has its 'w' bit set and no other user obtains a writelock for this window. Other bits are currently ignored. To withdraw the writelock from another user in window 2: 'aclchg *username* -w+w 2'. To allow read-only access to the session: 'aclchg *username* -w "#?". As soon as a user's name is known to *screen* he can attach to the session and (per default) has full permissions for all command and windows. Execution permission for the acl commands, 'at' and others should also be removed or the user may be able to regain write permission. Rights of the special username **nobody** cannot be changed (see the "su" command). 'Chacl' is a synonym to 'aclchg'. Multi user mode only.

acldel *username*

Remove a user from *screen*'s access control list. If currently attached, all the user's displays are detached from the session. He cannot attach again. Multi user mode only.

aclgrp *username* [*groupname*]

Creates groups of users that share common access rights. The name of the group is the username of the group leader. Each member of the group inherits the permissions that are granted to the group leader. That means, if a user fails an access check, another check is made for the group leader. A user is removed from all groups the special value "none" is used for *groupname*. If the second parameter is omitted all groups the user is in are listed.

aclumask [[*users*]+*bits* [[*users*]-*bits*]

umask [[*users*]+*bits* [[*users*]-*bits*]

This specifies the access other users have to windows that will be created by the caller of the command. *Users* may be no, one or a comma separated list of known usernames. If no users are specified, a list of all currently known users is assumed. *Bits* is any combination of access control bits allowed defined with the "aclchg" command. The special username "?" predefines the access that not yet known users will be

granted to any window initially. The special username “??” predefines the access that not yet known users are granted to any command. Rights of the special username **nobody** cannot be changed (see the “su” command). ‘Umask’ is a synonym to ‘aclumask’.

activity *message*

When any activity occurs in a background window that is being monitored, *screen* displays a notification in the message line. The notification message can be re-defined by means of the “activity” command. Each occurrence of ‘%’ in *message* is replaced by the number of the window in which activity has occurred, and each occurrence of ‘^G’ is replaced by the definition for bell in your termcap (usually an audible bell). The default message is

’Activity in window %n’

Note that monitoring is off for all windows by default, but can be altered by use of the “monitor” command (C-a M).

allpartial on|off

If set to on, only the current cursor line is refreshed on window change. This affects all windows and is useful for slow terminal lines. The previous setting of full/partial refresh for each window is restored with “allpartial off”. This is a global flag that immediately takes effect on all windows overriding the “partial” settings. It does not change the default redraw behavior of newly created windows.

altscreen on|off

If set to on, “alternate screen” support is enabled in virtual terminals, just like in xterm. Initial setting is ‘off’.

at [*identifier*][#|*|%] *command* [*args* ...]

Execute a command at other displays or windows as if it had been entered there. “At” changes the context (the ‘current window’ or ‘current display’ setting) of the command. If the first parameter describes a non-unique context, the command will be executed multiple times. If the first parameter is of the form ‘*identifier**’ then *identifier* is matched against user names. The command is executed once for each display of the selected user(s). If the first parameter is of the form ‘*identifier*%’ *identifier* is matched against displays. Displays are named after the ttys they attach. The prefix ‘/dev/’ or ‘/dev/tty’ may be omitted from the identifier. If *identifier* has a ‘#’ or nothing appended it is matched against window numbers and titles. Omitting an identifier in front of the ‘#’, ‘*’ or ‘%’-character selects all users, displays or windows because a prefix-match is performed. Note that on the affected display(s) a short message will describe what happened. Permission is checked for initiator of the “at” command, not for the owners of the affected display(s). Note that the ‘#’ character works as a comment introducer when it is preceded by whitespace. This can be escaped by prefixing a ‘\’. Permission is checked for the initiator of the “at” command, not for the owners of the affected display(s).

Caveat: When matching against windows, the command is executed at least once per window. Commands that change the internal arrangement of windows (like “other”) may be called again. In shared windows the command will be repeated for each attached display. Beware, when issuing toggle commands like “login”! Some commands (e.g. “process”) require that a display is associated with the target windows. These commands may not work correctly under “at” looping over windows.

attrcolor *attrib* [*attribute/color-modifier*]

This command can be used to highlight attributes by changing the color of the text. If the attribute *attrib* is in use, the specified attribute/color modifier is also applied. If no modifier is given, the current one is deleted. See the “STRING ESCAPES” chapter for the syntax of the modifier. Screen understands two pseudo-attributes, “i” stands for high-intensity foreground color and “I” for high-intensity background color.

Examples:

```
attrcolor b "R"
```

Change the color to bright red if bold text is to be printed.

```
attrcolor u "-u b"
```

Use blue text instead of underline.

```
attrcolor b ".I"
```

Use bright colors for bold text. Most terminal emulators do this already.

```
attrcolor i "+b"
```

Make bright colored text also bold.

autodetach on|off

Sets whether *screen* will automatically detach upon hangup, which saves all your running programs until they are resumed with a **screen -r** command. When turned off, a hangup signal will terminate *screen* and all the processes it contains. Autodetach is on by default.

autonuke on|off

Sets whether a clear screen sequence should nuke all the output that has not been written to the terminal. See also “obuflimit”.

backtick *id lifespan autorefresh cmd args...*

backtick *id*

Program the backtick command with the numerical id *id*. The output of such a command is used for substitution of the “%” string escape. The specified *lifespan* is the number of seconds the output is considered valid. After this time, the command is run again if a corresponding string escape is encountered. The *autorefresh* parameter triggers an automatic refresh for caption and hardstatus strings after the specified number of seconds. Only the last line of output is used for substitution.

If both the *lifespan* and the *autorefresh* parameters are zero, the backtick program is expected to stay in the background and generate output once in a while. In this case, the command is executed right away and *screen* stores the last line of output. If a new line gets printed *screen* will automatically refresh the hardstatus or the captions.

The second form of the command deletes the backtick command with the numerical id *id*.

bce [on|off]

Change background-color-erase setting. If “bce” is set to on, all characters cleared by an erase/insert/scroll/clear operation will be displayed in the current background color. Otherwise the default background color is used.

bell_msg [message]

When a bell character is sent to a background window, *screen* displays a notification in the message line. The notification message can be re-defined by this command. Each occurrence of ‘%’ in *message* is replaced by the number of the window to which a bell has been sent, and each occurrence of ‘^G’ is replaced by the definition for bell in your termcap (usually an audible bell). The default message is

```
'Bell in window %n'
```

An empty message can be supplied to the “bell_msg” command to suppress output of a message line (bell_msg ""). Without parameter, the current message is shown.

bind [-c *class*] *key* [*command* [*args*]]

Bind a command to a key. By default, most of the commands provided by *screen* are bound to one or more keys as indicated in the “DEFAULT KEY BINDINGS” section, e. g. the command to create a new window is bound to “C-c” and “c”. The “bind” command can be used to redefine the key bindings and to define new bindings. The *key* argument is either a single character, a two-character sequence of the form “^x” (meaning “C-x”), a backslash followed by an octal number (specifying the ASCII code of the character), or a backslash followed by a second character, such as “\^” or “\\”. The argument can also be quoted, if you like. If no further argument is given, any previously established binding for this key is removed. The *command* argument can be any command listed in this section.

If a command class is specified via the “-c” option, the key is bound for the specified class. Use the “command” command to activate a class. Command classes can be used to create multiple command keys or multi-character bindings.

Some examples:

```
bind ' ' windows
bind ^k
bind k
bind K kill
bind ^f screen telnet foobar
bind \033 screen -ln -t root -h 1000 9 su
```

would bind the space key to the command that displays a list of windows (so that the command usually invoked by “C-a C-w” would also be available as “C-a space”). The next three lines remove the default kill binding from “C-a C-k” and “C-a k”. “C-a K” is then bound to the kill command. Then it binds “C-f” to the command “create a window with a TELNET connection to foobar”, and bind “escape” to the command that creates an non-login window with a.k.a. “root” in slot #9, with a superuser shell and a scrollbar buffer of 1000 lines.

```
bind -c demo1 0 select 10
bind -c demo1 1 select 11
bind -c demo1 2 select 12
bindkey ""B" command -c demo1
```

makes “C-b 0” select window 10, “C-b 1” window 11, etc.

```
bind -c demo2 0 select 10
bind -c demo2 1 select 11
bind -c demo2 2 select 12
bind - command -c demo2
```

makes “C-a - 0” select window 10, “C-a - 1” window 11, etc.

bindkey [-d] [-m] [-a] [[-k|-t] *string* [*cmd* *args*]]

This command manages screen’s input translation tables. Every entry in one of the tables tells screen how to react if a certain sequence of characters is encountered. There are three tables: one that should contain actions programmed by the user, one for the default actions used for terminal emulation and one for screen’s copy mode to do cursor movement. See section “INPUT TRANSLATION” for a list of default key bindings.

If the **-d** option is given, bindkey modifies the default table, **-m** changes the copy mode table and with neither option the user table is selected. The argument *string* is the sequence of characters to which an action is bound. This can either be a fixed string or a termcap keyboard capability name (selectable with the **-k** option).

Some keys on a VT100 terminal can send a different string if application mode is turned on (e.g the cursor keys). Such keys have two entries in the translation table. You can select the application mode entry by specifying the **-a** option.

The **-t** option tells screen not to do inter-character timing. One cannot turn off the timing if a termcap

capability is used.

Cmd can be any of screen's commands with an arbitrary number of *args*. If *cmd* is omitted the key-binding is removed from the table.

Here are some examples of keyboard bindings:

```
bindkey -d
```

Show all of the default key bindings. The application mode entries are marked with [A].

```
bindkey -k k1 select 1
```

Make the "F1" key switch to window one.

```
bindkey -t foo stuff barfoo
```

Make "foo" an abbreviation of the word "barfoo". Timeout is disabled so that users can type slowly.

```
bindkey "\024" mapdefault
```

This key-binding makes “^T” an escape character for key-bindings. If you did the above “stuff barfoo” binding, you can enter the word “foo” by typing “^Tfoo”. If you want to insert a “^T” you have to press the key twice (i.e. escape the escape binding).

```
bindkey -k F1 command
```

Make the F11 (not F1!) key an alternative screen escape (besides ^A).

break [*duration*]

Send a break signal for *duration**0.25 seconds to this window. For non-Posix systems the time interval may be rounded up to full seconds. Most useful if a character device is attached to the window rather than a shell process (See also chapter “WINDOW TYPES”). The maximum duration of a break signal is limited to 15 seconds.

blanker

Activate the screen blanker. First the screen is cleared. If no blanker program is defined, the cursor is turned off, otherwise, the program is started and its output is written to the screen. The screen blanker is killed with the first keypress, the read key is discarded.

This command is normally used together with the “idle” command.

blankerprg [*program args*]

Defines a blanker program. Disables the blanker program if no arguments are given.

breaktype [*tcsendbreak*|*TIOCSBRK*|*TCSBRK*]

Choose one of the available methods of generating a break signal for terminal devices. This command should affect the current window only. But it still behaves identical to “defbreaktype”. This will be changed in the future. Calling “breaktype” with no parameter displays the break method for the current window.

bufferfile [*exchange-file*]

Change the filename used for reading and writing with the paste buffer. If the optional argument to the “bufferfile” command is omitted, the default setting (“/tmp/screen-exchange”) is reactivated. The following example will paste the system's password file into the *screen* window (using the paste buffer, where a copy remains):

```
C-a : bufferfile /etc/passwd
C-a < C-a ]
C-a : bufferfile
```

c1 [**on|off**]

Change c1 code processing. “C1 on” tells screen to treat the input characters between 128 and 159 as control functions. Such an 8-bit code is normally the same as ESC followed by the corresponding 7-bit code. The default setting is to process c1 codes and can be changed with the “defc1” command. Users with fonts that have usable characters in the c1 positions may want to turn this off.

caption always|splitonly [*string*]**caption string** [*string*]

This command controls the display of the window captions. Normally a caption is only used if more than one window is shown on the display (split screen mode). But if the type is set to **always** screen shows a caption even if only one window is displayed. The default is **splitonly**.

The second form changes the text used for the caption. You can use all escapes from the “STRING ESCAPES” chapter. Screen uses a default of ‘%3n %t’.

You can mix both forms by providing a string as an additional argument.

charset *set*

Change the current character set slot designation and charset mapping. The first four character of *set* are treated as charset designators while the fifth and sixth character must be in range ‘0’ to ‘3’ and set the GL/GR charset mapping. On every position a ‘.’ may be used to indicate that the corresponding charset/mapping should not be changed (*set* is padded to six characters internally by appending ‘.’ chars). New windows have “BBBB02” as default charset, unless a “encoding” command is active.

The current setting can be viewed with the “info” command.

chdir [*directory*]

Change the *current directory* of *screen* to the specified directory or, if called without an argument, to your home directory (the value of the environment variable \$HOME). All windows that are created by means of the “screen” command from within “.screenrc” or by means of “C-a : screen ...” or “C-a c” use this as their default directory. Without a chdir command, this would be the directory from which *screen* was invoked. Hardcopy and log files are always written to the *window*’s default directory, *not* the current directory of the process running in the window. You can use this command multiple times in your .screenrc to start various windows in different default directories, but the last chdir value will affect all the windows you create interactively.

clear

Clears the current window and saves its image to the scrollbar buffer.

colon [*prefix*]

Allows you to enter “.screenrc” command lines. Useful for on-the-fly modification of key bindings, specific window creation and changing settings. Note that the “set” keyword no longer exists! Usually commands affect the current window rather than default settings for future windows. Change defaults with commands starting with ‘def...’.

If you consider this as the ‘Ex command mode’ of *screen*, you may regard “C-a esc” (copy mode) as its ‘Vi command mode’.

command [**-c** *class*]

This command has the same effect as typing the screen escape character (^A). It is probably only useful for key bindings. If the “-c” option is given, select the specified command class. See also “bind” and “bind-key”.

compacthist [on|off]

This tells screen whether to suppress trailing blank lines when scrolling up text into the history buffer.

console [on|off]

Grabs or un-grabs the machines console output to a window. *Note:* Only the owner of `/dev/console` can grab the console output. This command is only available if the machine supports the ioctl `TIOCCONS`.

copy

Enter copy/scrollback mode. This allows you to copy text from the current window and its history into the paste buffer. In this mode a vi-like ‘full screen editor’ is active:

Movement keys:

- h, j, k, l** move the cursor line by line or column by column.
- 0, ^** and **\$** move to the leftmost column, to the first or last non-whitespace character on the line.
- H, M** and **L** move the cursor to the leftmost column of the top, center or bottom line of the window.
- +** and **-** positions one line up and down.
- G** moves to the specified absolute line (default: end of buffer).
- |** moves to the specified absolute column.
- w, b, e** move the cursor word by word.
- B, E** move the cursor WORD by WORD (as in vi).
- C-u** and **C-d** scroll the display up/down by the specified amount of lines while preserving the cursor position. (Default: half screen-full).
- C-b** and **C-f** scroll the display up/down a full screen.
- g** moves to the beginning of the buffer.
- %** jumps to the specified percentage of the buffer.

Note:

Emacs style movement keys can be customized by a `.screenrc` command. (E.g. `markkeys "h=^B:l=^F:$=^E"`) There is no simple method for a full emacs-style keymap, as this involves multi-character codes.

Marking:

The copy range is specified by setting two marks. The text between these marks will be highlighted. Press

- space** to set the first or second mark respectively.
- Y** and **y** used to mark one whole line or to mark from start of line.
- W** marks exactly one word.

Repeat count:

Any of these commands can be prefixed with a repeat count number by pressing digits

- 0..9** which is taken as a repeat count.
- Example: “`C-a C-[H 10 j 5 Y`” will copy lines 11 to 15 into the paste buffer.

Searching:

- /** Vi-like search forward.
- ?** Vi-like search backward.
- C-a s** Emacs style incremental search forward.
- C-r** Emacs style reverse i-search.

Specials:

There are however some keys that act differently than in *vi*. *Vi* does not allow one to yank rectangular blocks of text, but *screen* does. Press

- c** or **C** to set the left or right margin respectively. If no repeat count is given, both default to the current cursor position.

Example: Try this on a rather full text screen: “`C-a [M 20 l SPACE c 10 l 5 j C SPACE`”.

This moves one to the middle line of the screen, moves in 20 columns left, marks the beginning of the

paste buffer, sets the left column, moves 5 columns down, sets the right column, and then marks the end of the paste buffer. Now try:

```
“C-a [ M 20 l SPACE 10 l 5 j SPACE”
```

and notice the difference in the amount of text copied.

J joins lines. It toggles between 4 modes: lines separated by a newline character (012), lines glued seamless, lines separated by a single whitespace and comma separated lines. Note that you can prepend the newline character with a carriage return character, by issuing a “crlf on”.

v is for all the *vi* users with “:set numbers” – it toggles the left margin between column 9 and 1. Press **a** before the final space key to toggle in append mode. Thus the contents of the paste buffer will not be overwritten, but is appended to.

A toggles in append mode and sets a (second) mark.

> sets the (second) mark and writes the contents of the paste buffer to the screen-exchange file (/tmp/screen-exchange per default) once copy-mode is finished.

This example demonstrates how to dump the whole scrollback buffer to that file: “C-A [g SPACE G \$ >”.

C-g gives information about the current line and column.

x exchanges the first mark and the current cursor position. You can use this to adjust an already placed mark.

@ does nothing. Does not even exit copy mode.

All keys not described here exit copy mode.

copy_reg [*key*]

No longer exists, use “readreg” instead.

crlf [on|off]

This affects the copying of text regions with the ‘C-a [’ command. If it is set to ‘on’, lines will be separated by the two character sequence ‘CR’ - ‘LF’. Otherwise (default) only ‘LF’ is used. When no parameter is given, the state is toggled.

debug on|off

Turns runtime debugging on or off. If *screen* has been compiled with option -DDEBUG debugging available and is turned on per default. Note that this command only affects debugging output from the main “SCREEN” process correctly. Debug output from attacher processes can only be turned off once and forever.

defc1 on|off

Same as the **c1** command except that the default setting for new windows is changed. Initial setting is ‘on’.

defautonuke on|off

Same as the **autonuke** command except that the default setting for new displays is changed. Initial setting is ‘off’. Note that you can use the special ‘AN’ terminal capability if you want to have a dependency on the terminal type.

defbce on|off

Same as the **bce** command except that the default setting for new windows is changed. Initial setting is ‘off’.

defbreaktype [*tcsendbreak*|*TIOCSBRK*|*TCSBRK*]

Choose one of the available methods of generating a break signal for terminal devices. The preferred methods are *tcsendbreak* and *TIOCSBRK*. The third, *TCSBRK*, blocks the complete *screen* session for the duration of the break, but it may be the only way to generate long breaks. *Tcsendbreak* and *TIOCSBRK* may or

may not produce long breaks with spikes (e.g. 4 per second). This is not only system dependant, this also differs between serial board drivers. Calling “defbreaktype” with no parameter displays the current setting.

defcharset [*set*]

Like the **charset** command except that the default setting for new windows is changed. Shows current default if called without argument.

defescape *xy*

Set the default command characters. This is equivalent to the “escape” except that it is useful multiuser sessions only. In a multiuser session “escape” changes the command character of the calling user, where “defescape” changes the default command characters for users that will be added later.

defflow on|off|auto [**interrupt**]

Same as the **flow** command except that the default setting for new windows is changed. Initial setting is ‘auto’. Specifying “defflow auto interrupt” is the same as the command-line options **-fa** and **-i**.

defgr on|off

Same as the **gr** command except that the default setting for new windows is changed. Initial setting is ‘off’.

defhstatus [*status*]

The hardstatus line that all new windows will get is set to *status*. This command is useful to make the hardstatus of every window display the window number or title or the like. *Status* may contain the same directives as in the window messages, but the directive escape character is ‘^E’ (octal 005) instead of ‘%’. This was done to make a misinterpretation of program generated hardstatus lines impossible. If the parameter *status* is omitted, the current default string is displayed. Per default the hardstatus line of new windows is empty.

defencoding *enc*

Same as the **encoding** command except that the default setting for new windows is changed. Initial setting is the encoding taken from the terminal.

deflog on|off

Same as the **log** command except that the default setting for new windows is changed. Initial setting is ‘off’.

deflogin on|off

Same as the **login** command except that the default setting for new windows is changed. This is initialized with ‘on’ as distributed (see config.h.in).

defmode *mode*

The mode of each newly allocated pseudo-tty is set to *mode*. *Mode* is an octal number. When no “defmode” command is given, mode 0622 is used.

defmonitor on|off

Same as the **monitor** command except that the default setting for new windows is changed. Initial setting is ‘off’.

defnonblock on|off*numsecs*

Same as the **nonblock** command except that the default setting for displays is changed. Initial setting is 'off'.

defobuflimit *limit*

Same as the **obuflimit** command except that the default setting for new displays is changed. Initial setting is 256 bytes. Note that you can use the special 'OL' terminal capability if you want to have a dependency on the terminal type.

defscrollback *num*

Same as the **scrollback** command except that the default setting for new windows is changed. Initial setting is 100.

defshell *command*

Synonym to the **shell** command. See there.

defsilence on|off

Same as the **silence** command except that the default setting for new windows is changed. Initial setting is 'off'.

defslowpaste *msec*

Same as the **slowpaste** command except that the default setting for new windows is changed. Initial setting is 0 milliseconds, meaning 'off'.

defutf8 on|off

Same as the **utf8** command except that the default setting for new windows is changed. Initial setting is 'on' if screen was started with "-U", otherwise 'off'.

defwrap on|off

Same as the **wrap** command except that the default setting for new windows is changed. Initially line-wrap is on and can be toggled with the "wrap" command ("C-a r") or by means of "C-a : wrap on|off".

defwritelock on|off|auto

Same as the **writelock** command except that the default setting for new windows is changed. Initially write-locks will off.

defzombie [*keys*]

Synonym to the **zombie** command. Both currently change the default. See there.

detach [-h]

Detach the *screen* session (disconnect it from the terminal and put it into the background). This returns you to the shell where you invoked *screen*. A detached *screen* can be resumed by invoking *screen* with the **-r** option (see also section "COMMAND-LINE OPTIONS"). The **-h** option tells screen to immediately close the connection to the terminal ("hangup").

dinfo

Show what screen thinks about your terminal. Useful if you want to know why features like color or the alternate charset don't work.

displays

Shows a tabular listing of all currently connected user front-ends (displays). This is most useful for multi-user sessions.

digraph [*preset*]

This command prompts the user for a digraph sequence. The next two characters typed are looked up in a builtin table and the resulting character is inserted in the input stream. For example, if the user enters 'a', an a-umlaut will be inserted. If the first character entered is a 0 (zero), *screen* will treat the following characters (up to three) as an octal number instead. The optional argument *preset* is treated as user input, thus one can create an "umlaut" key. For example the command "bindkey ^K digraph ''" enables the user to generate an a-umlaut by typing CTRL-K a.

dumftermcap

Write the termcap entry for the virtual terminal optimized for the currently active window to the file ".termcap" in the user's "\$HOME/.screen" directory (or wherever *screen* stores its sockets. See the "FILES" section below). This termcap entry is identical to the value of the environment variable \$TERMCAP that is set up by *screen* for each window. For terminfo based systems you will need to run a converter like *cap-toinfo* and then compile the entry with *tic*.

echo [-n] *message*

The echo command may be used to annoy *screen* users with a 'message of the day'. Typically installed in a global /etc/screenrc. The option "-n" may be used to suppress the line feed. See also "sleep". Echo is also useful for online checking of environment variables.

encoding *enc* [*enc*]

Tell *screen* how to interpret the input/output. The first argument sets the encoding of the current window. Each window can emulate a different encoding. The optional second parameter overwrites the encoding of the connected terminal. It should never be needed as *screen* uses the locale setting to detect the encoding. There is also a way to select a terminal encoding depending on the terminal type by using the "KJ" termcap entry.

Supported encodings are eucJP, SJIS, eucKR, eucCN, Big5, GBK, KOI8-R, CP1251, UTF-8, ISO8859-2, ISO8859-3, ISO8859-4, ISO8859-5, ISO8859-6, ISO8859-7, ISO8859-8, ISO8859-9, ISO8859-10, ISO8859-15, jis.

See also "defencoding", which changes the default setting of a new window.

escape *xy*

Set the command character to *x* and the character generating a literal command character (by triggering the "meta" command) to *y* (similar to the -e option). Each argument is either a single character, a two-character sequence of the form "^x" (meaning "C-x"), a backslash followed by an octal number (specifying the ASCII code of the character), or a backslash followed by a second character, such as "\^" or "\\\". The default is "^Aa".

eval *command1* [*command2* ...]

Parses and executes each argument as separate command.

exec [[*fdpat*] *newcommand* [*args* ...]]

Run a unix subprocess (specified by an executable path *newcommand* and its optional arguments) in the current window. The flow of data between newcommands stdin/stdout/stderr, the process originally started in the window (let us call it "application-process") and *screen* itself (window) is controlled by the

filedescriptor pattern *fdpat*. This pattern is basically a three character sequence representing *stdin*, *stdout* and *stderr* of *newcommand*. A dot (.) connects the file descriptor to *screen*. An exclamation mark (!) causes the file descriptor to be connected to the application-process. A colon (:) combines both. User input will go to *newcommand* unless *newcommand* receives the application-process' output (*fdpats* first character is '!' or ':' or a pipe symbol (|) is added (as a fourth character) to the end of *fdpat*.

Invoking 'exec' without arguments shows name and arguments of the currently running subprocess in this window. Only one subprocess a time can be running in each window.

When a subprocess is running the 'kill' command will affect it instead of the windows process.

Refer to the postscript file 'doc/fdpat.ps' for a confusing illustration of all 21 possible combinations. Each drawing shows the digits 2,1,0 representing the three file descriptors of *newcommand*. The box marked 'W' is the usual *pty* that has the application-process on its slave side. The box marked 'P' is the secondary *pty* that now has *screen* at its master side.

Abbreviations:

Whitespace between the word 'exec' and *fdpat* and the command can be omitted. Trailing dots and a *fdpat* consisting only of dots can be omitted. A simple '|' is synonymous for the pattern '!.|'; the word *exec* can be omitted here and can always be replaced by '!'.

Examples:

```
exec ... /bin/sh
exec /bin/sh
!/bin/sh
```

Creates another shell in the same window, while the original shell is still running. Output of both shells is displayed and user input is sent to the new */bin/sh*.

```
exec !.. stty 19200
exec ! stty 19200
!!stty 19200
```

Set the speed of the window's *tty*. If your *stty* command operates on *stdout*, then add another '!'.

```
exec !..| less
|less
```

This adds a pager to the window output. The special character '|' is needed to give the user control over the pager although it gets its input from the window's process. This works, because *less* listens on *stderr* (a behavior that *screen* would not expect without the '|') when its *stdin* is not a *tty*. *Less* versions newer than 177 fail miserably here; good old *pg* still works.

```
!:sed -n s/. *Error.*\007/p
```

Sends window output to both, the user and the *sed* command. The *sed* inserts an additional bell character (oct. 007) to the window output seen by *screen*. This will cause "Bell in window x" messages, whenever the string "Error" appears in the window.

fit

Change the window size to the size of the current region. This command is needed because *screen* doesn't adapt the window size automatically if the window is displayed more than once.

flow [on|off|auto]

Sets the flow-control mode for this window. Without parameters it cycles the current window's flow-control setting from "automatic" to "on" to "off". See the discussion on "FLOW-CONTROL" later on in this document for full details and note, that this is subject to change in future releases. Default is set by 'def-flow'.

focus [**up**|**down**|**top**|**bottom**]

Move the input focus to the next region. This is done in a cyclic way so that the top region is selected after the bottom one. If no subcommand is given it defaults to 'down'. 'up' cycles in the opposite order, 'top' and 'bottom' go to the top and bottom region respectively. Useful bindings are (j and k as in vi)

```
bind j focus down
bind k focus up
bind t focus top
bind b focus bottom
```

gr [**on**|**off**]

Turn GR charset switching on/off. Whenever screen sees an input character with the 8th bit set, it will use the charset stored in the GR slot and print the character with the 8th bit stripped. The default (see also "defgr") is not to process GR switching because otherwise the ISO88591 charset would not work.

hardcopy [**-h**] [*file*]

Writes out the currently displayed image to the file *file*, or, if no filename is specified, to *hardcopy.n* in the default directory, where *n* is the number of the current window. This either appends or overwrites the file if it exists. See below. If the option **-h** is specified, dump also the contents of the scrollbar buffer.

hardcopy_append **on**|**off**

If set to "on", *screen* will append to the "hardcopy.n" files created by the command "C-a h", otherwise these files are overwritten each time. Default is 'off'.

hardcopydir *directory*

Defines a directory where hardcopy files will be placed. If unset, hardcopies are dumped in *screen*'s current working directory.

hardstatus [**on**|**off**]**hardstatus** [**always**]*lastline*|*message*|*ignore* [*string*]**hardstatus string** [*string*]

This command configures the use and emulation of the terminal's hardstatus line. The first form toggles whether *screen* will use the hardware status line to display messages. If the flag is set to 'off', these messages are overlaid in reverse video mode at the display line. The default setting is 'on'.

The second form tells *screen* what to do if the terminal doesn't have a hardstatus line (i.e. the termcap/terminfo capabilities "hs", "ts", "fs" and "ds" are not set). If the type "lastline" is used, *screen* will reserve the last line of the display for the hardstatus. "message" uses *screen*'s message mechanism and "ignore" tells *screen* never to display the hardstatus. If you prepend the word "always" to the type (e.g., "alwayslastline"), *screen* will use the type even if the terminal supports a hardstatus.

The third form specifies the contents of the hardstatus line. '%h' is used as default string, i.e. the stored hardstatus of the current window (settable via "ESC]0;<string>^G" or "ESC_<string>ESC\\") is displayed. You can customize this to any string you like including the escapes from the "STRING ESCAPES" chapter. If you leave out the argument *string*, the current string is displayed.

You can mix the second and third form by providing the string as additional argument.

height [**-w**|**-d**] [*lines* [*cols*]]

Set the display height to a specified number of lines. When no argument is given it toggles between 24 and 42 lines display. You can also specify a width if you want to change both values. The **-w** option tells screen to leave the display size unchanged and just set the window size, **-d** vice versa.

help [-c *class*]

Not really a online help, but displays a help *screen* showing you all the key bindings. The first pages list all the internal commands followed by their current bindings. Subsequent pages will display the custom commands, one command per key. Press space when you're done reading each page, or return to exit early. All other characters are ignored. If the "-c" option is given, display all bound commands for the specified command class. See also "DEFAULT KEY BINDINGS" section.

history

Usually users work with a shell that allows easy access to previous commands. For example *cs*h has the command "!!" to repeat the last command executed. *Screen* allows you to have a primitive way of re-calling "the command that started ...": You just type the first letter of that command, then hit 'C-a {' and *screen* tries to find a previous line that matches with the 'prompt character' to the left of the cursor. This line is pasted into this window's input queue. Thus you have a crude command history (made up by the visible window and its scrollbar buffer).

hstatus *status*

Change the window's hardstatus line to the string *status*.

idle [*timeout* [*cmd args*]]

Sets a command that is run after the specified number of seconds inactivity is reached. This command will normally be the "blinker" command to create a screen blanker, but it can be any screen command. If no command is specified, only the timeout is set. A timeout of zero (or the special timeout **off**) disables the timer. If no arguments are given, the current settings are displayed.

ignorecase [**on**|**off**]

Tell screen to ignore the case of characters in searches. Default is 'off'.

info

Uses the message line to display some information about the current window: the cursor position in the form "(column,row)" starting with "(1,1)", the terminal width and height plus the size of the scrollbar buffer in lines, like in "(80,24)+50", the current state of window XON/XOFF flow control is shown like this (See also section FLOW CONTROL):

```
+flow  automatic flow control, currently on.
-flow  automatic flow control, currently off.
+(+)flow flow control enabled. Agrees with automatic control.
-(-)flow flow control disabled. Disagrees with automatic control.
+(-)flow flow control enabled. Disagrees with automatic control.
-(-)flow flow control disabled. Agrees with automatic control.
```

The current line wrap setting ('+wrap' indicates enabled, '-wrap' not) is also shown. The flags 'ins', 'org', 'app', 'log', 'mon' or 'nored' are displayed when the window is in insert mode, origin mode, application-keypad mode, has output logging, activity monitoring or partial redraw enabled.

The currently active character set (*G0*, *G1*, *G2*, or *G3*) and in square brackets the terminal character sets that are currently designated as *G0* through *G3* is shown. If the window is in UTF-8 mode, the string "UTF-8" is shown instead.

Additional modes depending on the type of the window are displayed at the end of the status line (See also chapter "WINDOW TYPES").

If the state machine of the terminal emulator is in a non-default state, the info line is started with a string identifying the current state.

For system information use the “time” command.

ins_reg [*key*]

No longer exists, use “paste” instead.

kill

Kill current window.

If there is an ‘exec’ command running then it is killed. Otherwise the process (shell) running in the window receives a HANGUP condition, the window structure is removed and *screen* (your display) switches to another window. When the last window is destroyed, *screen* exits. After a kill *screen* switches to the previously displayed window.

Note: *Emacs* users should keep this command in mind, when killing a line. It is recommended not to use “C-a” as the *screen* escape key or to rebind kill to “C-a K”.

lastmsg

Redisplay the last contents of the message/status line. Useful if you’re typing when a message appears, because the message goes away when you press a key (unless your terminal has a hardware status line). Refer to the commands “msgwait” and “msgminwait” for fine tuning.

license

Display the disclaimer page. This is done whenever *screen* is started without options, which should be often enough. See also the “startup_message” command.

lockscreen

Lock this display. Call a screenlock program (/local/bin/lck or /usr/bin/lock or a builtin if no other is available). Screen does not accept any command keys until this program terminates. Meanwhile processes in the windows may continue, as the windows are in the ‘detached’ state. The screenlock program may be changed through the environment variable \$LOCKPRG (which must be set in the shell from which *screen* is started) and is executed with the user’s uid and gid.

Warning: When you leave other shells unlocked and you have no password set on *screen*, the lock is void: One could easily re-attach from an unlocked shell. This feature should rather be called ‘lockterminal’.

log [on|off]

Start/stop writing output of the current window to a file “screenlog.*n*” in the window’s default directory, where *n* is the number of the current window. This filename can be changed with the ‘logfile’ command. If no parameter is given, the state of logging is toggled. The session log is appended to the previous contents of the file if it already exists. The current contents and the contents of the scrollback history are not included in the session log. Default is ‘off’.

logfile *filename***logfile flush** *secs*

Defines the name the logfiles will get. The default is “screenlog.%*n*”. The second form changes the number of seconds *screen* will wait before flushing the logfile buffer to the file-system. The default value is 10 seconds.

login [on|off]

Adds or removes the entry in the utmp database file for the current window. This controls if the window is ‘logged in’. When no parameter is given, the login state of the window is toggled. Additionally to that toggle, it is convenient having a ‘log in’ and a ‘log out’ key. E. g. ‘bind I login on’ and ‘bind O login off’ will map these keys to be C-a I and C-a O. The default setting (in config.h.in) should be “on” for a *screen* that runs under suid-root. Use the “deflogin” command to change the default login state for new windows.

Both commands are only present when *screen* has been compiled with utmp support.

logtstamp [on|off]

logtstamp after [secs]

logtstamp string [string]

This command controls logfile time-stamp mechanism of *screen*. If time-stamps are turned “on”, *screen* adds a string containing the current time to the logfile after two minutes of inactivity. When output continues and more than another two minutes have passed, a second time-stamp is added to document the restart of the output. You can change this timeout with the second form of the command. The third form is used for customizing the time-stamp string (‘-- %n:%t -- time-stamp -- %M/%d/%y %c:%s --\n’ by default).

mapdefault

Tell *screen* that the next input character should only be looked up in the default bindkey table. See also “bindkey”.

mapnotnext

Like mapdefault, but don’t even look in the default bindkey table.

maptimeout [timo]

Set the inter-character timer for input sequence detection to a timeout of *timo* ms. The default timeout is 300ms. Maptimeout with no arguments shows the current setting. See also “bindkey”.

markkeys string

This is a method of changing the keymap used for copy/history mode. The string is made up of *old-char=newchar* pairs which are separated by ‘:’. Example: The string “B=^B:F=^F” will change the keys ‘C-b’ and ‘C-f’ to the vi style binding (scroll up/down fill page). This happens to be the default binding for ‘B’ and ‘F’. The command “markkeys h=^B:l=^F:\$=^E” would set the mode for an emacs-style binding. If your terminal sends characters, that cause you to abort copy mode, then this command may help by binding these characters to do nothing. The no-op character is ‘@’ and is used like this: “markkeys @=L=H” if you do not want to use the ‘H’ or ‘L’ commands any longer. As shown in this example, multiple keys can be assigned to one function in a single statement.

maxwin num

Set the maximum window number *screen* will create. Doesn’t affect already existing windows. The number may only be decreased.

meta

Insert the command character (C-a) in the current window’s input stream.

monitor [on|off]

Toggles activity monitoring of windows. When monitoring is turned on and an affected window is switched into the background, you will receive the activity notification message in the status line at the first sign of output and the window will also be marked with an ‘@’ in the window-status display. Monitoring is initially off for all windows.

msgminwait sec

Defines the time *screen* delays a new message when one message is currently displayed. The default is 1 second.

msgwait *sec*

Defines the time a message is displayed if *screen* is not disturbed by other activity. The default is 5 seconds.

multiuser *on|off*

Switch between singleuser and multiuser mode. Standard *screen* operation is singleuser. In multiuser mode the commands ‘acladd’, ‘aclchg’, ‘aclgrp’ and ‘acldel’ can be used to enable (and disable) other users accessing this *screen* session.

nethack *on|off*

Changes the kind of error messages used by *screen*. When you are familiar with the game “nethack”, you may enjoy the nethack-style messages which will often blur the facts a little, but are much funnier to read. Anyway, standard messages often tend to be unclear as well.

This option is only available if *screen* was compiled with the NETHACK flag defined. The default setting is then determined by the presence of the environment variable \$NETHACKOPTIONS.

next

Switch to the next window. This command can be used repeatedly to cycle through the list of windows.

nonblock [*on|off|numsecs*]

Tell *screen* how to deal with user interfaces (displays) that cease to accept output. This can happen if a user presses ^S or a TCP/modem connection gets cut but no hangup is received. If nonblock is **off** (this is the default) *screen* waits until the display restarts to accept the output. If nonblock is **on**, *screen* waits until the timeout is reached (**on** is treated as 1s). If the display still doesn’t receive characters, *screen* will consider it “blocked” and stop sending characters to it. If at some time it restarts to accept characters, *screen* will unblock the display and redisplay the updated window contents.

number [*n*]

Change the current windows number. If the given number *n* is already used by another window, both windows exchange their numbers. If no argument is specified, the current window number (and title) is shown.

obuflimit [*limit*]

If the output buffer contains more bytes than the specified limit, no more data will be read from the windows. The default value is 256. If you have a fast display (like *xterm*), you can set it to some higher value. If no argument is specified, the current setting is displayed.

only

Kill all regions but the current one.

other

Switch to the window displayed previously. If this window does no longer exist, *other* has the same effect as *next*.

partial *on|off*

Defines whether the display should be refreshed (as with *redisplay*) after switching to the current window. This command only affects the current window. To immediately affect all windows use the *allpartial* command. Default is ‘off’, of course. This default is fixed, as there is currently no *defpartial* command.

password [*encrypted_pw*]

Present a crypted password in your “.screenrc” file and *screen* will ask for it, whenever someone attempts to resume a detached. This is useful if you have privileged programs running under *screen* and you want to

protect your session from reattach attempts by another user masquerading as your uid (i.e. any superuser.) If no crypted password is specified, *screen* prompts twice for typing a password and places its encryption in the paste buffer. Default is 'none', this disables password checking.

paste [*registers* [*dest_reg*]]

Write the (concatenated) contents of the specified registers to the stdin queue of the current window. The register '.' is treated as the paste buffer. If no parameter is given the user is prompted for a single register to paste. The paste buffer can be filled with the *copy*, *history* and *readbuf* commands. Other registers can be filled with the *register*, *readreg* and *paste* commands. If *paste* is called with a second argument, the contents of the specified registers is pasted into the named destination register rather than the window. If '.' is used as the second argument, the displays paste buffer is the destination. Note, that "paste" uses a wide variety of resources: Whenever a second argument is specified no current window is needed. When the source specification only contains registers (not the paste buffer) then there need not be a current display (terminal attached), as the registers are a global resource. The paste buffer exists once for every user.

pastefont [*on|off*]

Tell *screen* to include font information in the paste buffer. The default is not to do so. This command is especially useful for multi character fonts like kanji.

pow_break

Reopen the window's terminal line and send a break condition. See 'break'.

pow_detach

Power detach. Mainly the same as *detach*, but also sends a HANGUP signal to the parent process of *screen*. CAUTION: This will result in a logout, when *screen* was started from your login shell.

pow_detach_msg [*message*]

The *message* specified here is output whenever a 'Power detach' was performed. It may be used as a replacement for a logout message or to reset baud rate, etc. Without parameter, the current message is shown.

prev

Switch to the window with the next lower number. This command can be used repeatedly to cycle through the list of windows.

printcmd [*cmd*]

If *cmd* is not an empty string, *screen* will not use the terminal capabilities "po/pf" if it detects an ansi print sequence ESC [5 i, but pipe the output into *cmd*. This should normally be a command like "lpr" or "'cat > /tmp/scrprint'". **printcmd** without a command displays the current setting. The ansi sequence ESC \ ends printing and closes the pipe.

Warning: Be careful with this command! If other user have write access to your terminal, they will be able to fire off print commands.

process [*key*]

Stuff the contents of the specified register into *screen*'s input queue. If no argument is given you are prompted for a register name. The text is parsed as if it had been typed in from the user's keyboard. This command can be used to bind multiple actions to a single key.

quit

Kill all windows and terminate *screen*. Note that on VT100-style terminals the keys C-4 and C-\ are identical. This makes the default bindings dangerous: Be careful not to type C-a C-4 when selecting window no. 4. Use the empty bind command (as in “bind ``\””) to remove a key binding.

readbuf [-e *encoding*] [*filename*]

Reads the contents of the specified file into the paste buffer. You can tell screen the encoding of the file via the -e option. If no file is specified, the screen-exchange filename is used. See also “bufferfile” command.

readreg [-e *encoding*] [*register* [*filename*]]

Does one of two things, dependent on number of arguments: with zero or one arguments it duplicates the paste buffer contents into the register specified or entered at the prompt. With two arguments it reads the contents of the named file into the register, just as *readbuf* reads the screen-exchange file into the paste buffer. You can tell screen the encoding of the file via the -e option. The following example will paste the system’s password file into the *screen* window (using register p, where a copy remains):

```
C-a : readreg p /etc/passwd
C-a : paste p
```

redisplay

Redisplay the current window. Needed to get a full redisplay when in partial redraw mode.

register [-e *encoding*] *key string*

Save the specified *string* to the register *key*. The encoding of the string can be specified via the -e option. See also the “paste” command.

remove

Kill the current region. This is a no-op if there is only one region.

removebuf

Unlinks the screen-exchange file used by the commands “writebuf” and “readbuf”.

reset

Reset the virtual terminal to its “power-on” values. Useful when strange settings (like scroll regions or graphics character set) are left over from an application.

resize

Resize the current region. The space will be removed from or added to the region below or if there’s not enough space from the region above.

```
resize +N    increase current region height by N
resize -N    decrease current region height by N
resize N     set current region height to N
resize =     make all windows equally high
resize max   maximize current region height
resize min   minimize current region height
```

screen [-opts] [*n*] [*cmd* [*args*]]

Establish a new window. The flow-control options (-f, -fn and -fa), title (a.k.a.) option (-t), login options (-l and -ln), terminal type option (-T <term>), the all-capability-flag (-a) and scrollbar option (-h

`<num>`) may be specified with each command. The option **(-M)** turns monitoring on for this window. The option **(-L)** turns output logging on for this window. If an optional number *n* in the range 0..9 is given, the window number *n* is assigned to the newly created window (or, if this number is already in-use, the next available number). If a command is specified after “screen”, this command (with the given arguments) is started in the window; otherwise, a shell is created. Thus, if your “.screenrc” contains the lines

```
# example for .screenrc:
screen 1
screen -fn -t foobar -L 2 telnet foobar
```

screen creates a shell window (in window #1) and a window with a TELNET connection to the machine foobar (with no flow-control using the title “foobar” in window #2) and will write a logfile (“screenlog.2”) of the telnet session. Note, that unlike previous versions of *screen* no additional default window is created when “screen” commands are included in your “.screenrc” file. When the initialization is completed, *screen* switches to the last window specified in your .screenrc file or, if none, opens a default window #0. *Screen* has built in some functionality of “cu” and “telnet”. See also chapter “WINDOW TYPES”.

scrollback *num*

Set the size of the scrollbar buffer for the current windows to *num* lines. The default scrollbar is 100 lines. See also the “defscrollback” command and use “C-a i” to view the current setting.

select [*WindowID*]

Switch to the window identified by *WindowID*. This can be a prefix of a window title (alphanumeric window name) or a window number. The parameter is optional and if omitted, you get prompted for an identifier. When a new window is established, the first available number is assigned to this window. Thus, the first window can be activated by “select 0”. The number of windows is limited at compile-time by the MAXWIN configuration parameter. There are two special WindowIDs, “-” selects the internal blank window and “.” selects the current window. The latter is useful if used with screen’s “-X” option.

sessionname [*name*]

Rename the current session. Note, that for “screen -list” the name shows up with the process-id prepended. If the argument “name” is omitted, the name of this session is displayed. Caution: The \$STY environment variables still reflects the old name. This may result in confusion. The default is constructed from the tty and host names.

setenv [*var* [*string*]]

Set the environment variable *var* to value *string*. If only *var* is specified, the user will be prompted to enter a value. If no parameters are specified, the user will be prompted for both variable and value. The environment is inherited by all subsequently forked shells.

setsid [**on**|**off**]

Normally screen uses different sessions and process groups for the windows. If setsid is turned *off*, this is not done anymore and all windows will be in the same process group as the screen backend process. This also breaks job-control, so be careful. The default is *on*, of course. This command is probably useful only in rare circumstances.

shell *command*

Set the command to be used to create a new shell. This overrides the value of the environment variable \$SHELL. This is useful if you’d like to run a tty-enhancer which is expecting to execute the program specified in \$SHELL. If the command begins with a ‘-’ character, the shell will be started as a login-shell.

shelltitle *title*

Set the title for all shells created during startup or by the C-A C-c command. For details about what a title is, see the discussion entitled “TITLES (naming windows)”.

silence [**on|off**]*sec*

Toggles silence monitoring of windows. When silence is turned on and an affected window is switched into the background, you will receive the silence notification message in the status line after a specified period of inactivity (silence). The default timeout can be changed with the ‘silencewait’ command or by specifying a number of seconds instead of ‘on’ or ‘off’. Silence is initially off for all windows.

silencewait *sec*

Define the time that all windows monitored for silence should wait before displaying a message. Default 30 seconds.

sleep *num*

This command will pause the execution of a .screenrc file for *num* seconds. Keyboard activity will end the sleep. It may be used to give users a chance to read the messages output by “echo”.

slowpaste *msec*

Define the speed at which text is inserted into the current window by the paste ("C-a J") command. If the slowpaste value is nonzero text is written character by character. *screen* will make a pause of *msec* milliseconds after each single character write to allow the application to process its input. Only use slowpaste if your underlying system exposes flow control problems while pasting large amounts of text.

source *file*

Read and execute commands from file *file*. Source commands may be nested to a maximum recursion level of ten. If file is not an absolute path and screen is already processing a source command, the parent directory of the running source command file is used to search for the new command file before screen’s current directory.

Note that termcap/terminfo/termcapinfo commands only work at startup and reattach time, so they must be reached via the default screenrc files to have an effect.

sorendition [*attr* [*color*]]

Change the way *screen* does highlighting for text marking and printing messages. See the “STRING ESCAPES” chapter for the syntax of the modifiers. The default is currently “=s dd” (standout, default colors).

split

Split the current region into two new ones. All regions on the display are resized to make room for the new region. The blank window is displayed on the new region. Use the “remove” or the “only” command to delete regions.

startup_message **on|off**

Select whether you want to see the copyright notice during startup. Default is ‘on’, as you probably noticed.

stuff *string*

Stuff the string *string* in the input buffer of the current window. This is like the “paste” command but with much less overhead. You cannot paste large buffers with the “stuff” command. It is most useful for key

bindings. See also “bindkey”.

su [username [password [password2]]

Substitute the user of a display. The command prompts for all parameters that are omitted. If passwords are specified as parameters, they have to be specified un-crypted. The first password is matched against the systems passwd database, the second password is matched against the *screen* password as set with the commands “acladd” or “password”. “Su” may be useful for the *screen* administrator to test multiuser setups. When the identification fails, the user has access to the commands available for user **nobody**. These are “detach”, “license”, “version”, “help” and “displays”.

suspend

Suspend *screen*. The windows are in the ‘detached’ state, while *screen* is suspended. This feature relies on the shell being able to do job control.

term *term*

In each window’s environment *screen* opens, the \$TERM variable is set to “screen” by default. But when no description for “screen” is installed in the local termcap or terminfo data base, you set \$TERM to – say – “vt100”. This won’t do much harm, as *screen* is VT100/ANSI compatible. The use of the “term” command is discouraged for non-default purpose. That is, one may want to specify special \$TERM settings (e.g. vt100) for the next “screen rlogin othermachine” command. Use the command “screen -T vt100 rlogin othermachine” rather than setting and resetting the default.

termcap *term terminal-tweaks [window-tweaks]*

terminfo *term terminal-tweaks [window-tweaks]*

termcapinfo *term terminal-tweaks [window-tweaks]*

Use this command to modify your terminal’s termcap entry without going through all the hassles involved in creating a custom termcap entry. Plus, you can optionally customize the termcap generated for the windows. You have to place these commands in one of the screenrc startup files, as they are meaningless once the terminal emulator is booted.

If your system works uses the terminfo database rather than termcap, *screen* will understand the ‘terminfo’ command, which has the same effects as the ‘termcap’ command. Two separate commands are provided, as there are subtle syntactic differences, e.g. when parameter interpolation (using ‘%’) is required. Note that termcap names of the capabilities have to be used with the ‘terminfo’ command.

In many cases, where the arguments are valid in both terminfo and termcap syntax, you can use the command ‘termcapinfo’, which is just a shorthand for a pair of ‘termcap’ and ‘terminfo’ commands with identical arguments.

The first argument specifies which terminal(s) should be affected by this definition. You can specify multiple terminal names by separating them with ‘|’s. Use ‘*’ to match all terminals and ‘vt*’ to match all terminals that begin with “vt”.

Each *tweak* argument contains one or more termcap defines (separated by ‘:’s) to be inserted at the start of the appropriate termcap entry, enhancing it or overriding existing values. The first tweak modifies your terminal’s termcap, and contains definitions that your terminal uses to perform certain functions. Specify a null string to leave this unchanged (e. g. ”). The second (optional) tweak modifies all the window termcaps, and should contain definitions that *screen* understands (see the “VIRTUAL TERMINAL” section).

Some examples:

```
termcap xterm* LP:hs@
```

Informs *screen* that all terminals that begin with ‘xterm’ have firm auto-margins that allow the last position on the screen to be updated (LP), but they don’t really have a status line (no ‘hs’ – append ‘@’ to turn entries off). Note that we assume ‘LP’ for all terminal names that start with “vt”, but only if you don’t specify a termcap command for that terminal.

```
termcap vt* LP
termcap vt102|vt220 Z0=\E[?3h;Z1=\E[?3l
```

Specifies the firm-margined ‘LP’ capability for all terminals that begin with ‘vt’, and the second line will also add the escape-sequences to switch into (Z0) and back out of (Z1) 132-character-per-line mode if this is a VT102 or VT220. (You must specify Z0 and Z1 in your termcap to use the width-changing commands.)

```
termcap vt100 "" l0=PF1:l1=PF2:l2=PF3:l3=PF4
```

This leaves your vt100 termcap alone and adds the function key labels to each window’s termcap entry.

```
termcap h19|z19 am@:im=\E@:ei=\EO dc=\E[P
```

Takes a h19 or z19 termcap and turns off auto-margins (am@) and enables the insert mode (im) and end-insert (ei) capabilities (the ‘@’ in the ‘im’ string is after the ‘=’, so it is part of the string). Having the ‘im’ and ‘ei’ definitions put into your terminal’s termcap will cause *screen* to automatically advertise the character-insert capability in each window’s termcap. Each window will also get the delete-character capability (dc) added to its termcap, which *screen* will translate into a line-update for the terminal (we’re pretending it doesn’t support character deletion).

If you would like to fully specify each window’s termcap entry, you should instead set the \$SCREENCAP variable prior to running *screen*. See the discussion on the “VIRTUAL TERMINAL” in this manual, and the termcap(5) man page for more information on termcap definitions.

time [*string*]

Uses the message line to display the time of day, the host name, and the load averages over 1, 5, and 15 minutes (if this is available on your system). For window specific information use “info”.

If a string is specified, it changes the format of the time report like it is described in the “STRING ESCAPES” chapter. Screen uses a default of “%c:%s %M %d %H%? %l%?”.

title [*windowtitle*]

Set the name of the current window to *windowtitle*. If no name is specified, *screen* prompts for one. This command was known as ‘aka’ in previous releases.

unsetenv *var*

Unset an environment variable.

utf8 [**on**|**off** [**on**|**off**]]

Change the encoding used in the current window. If utf8 is enabled, the strings sent to the window will be UTF-8 encoded and vice versa. Omitting the parameter toggles the setting. If a second parameter is given, the display’s encoding is also changed (this should rather be done with screen’s “-U” option). See also “defutf8”, which changes the default setting of a new window.

vbell [**on**|**off**]

Sets the visual bell setting for this window. Omitting the parameter toggles the setting. If vbell is switched on, but your terminal does not support a visual bell, a ‘vbell-message’ is displayed in the status line when the bell character (^G) is received. Visual bell support of a terminal is defined by the termcap variable ‘vb’ (terminfo: ‘flash’).

Per default, vbell is off, thus the audible bell is used. See also ‘bell_msg’.

vbell_msg [*message*]

Sets the visual bell message. *message* is printed to the status line if the window receives a bell character (^G), vbell is set to “on”, but the terminal does not support a visual bell. The default message is “Wuff, Wuff!!!”. Without parameter, the current message is shown.

vbellwait *sec*

Define a delay in seconds after each display of *screen*'s visual bell message. The default is 1 second.

verbose [**on**|**off**]

If verbose is switched on, the command name is echoed, whenever a window is created (or resurrected from zombie state). Default is off. Without parameter, the current setting is shown.

version

Print the current version and the compile date in the status line.

wall *message*

Write a message to all displays. The message will appear in the terminal's status line.

width [**-w**|-**d**] [*cols* [*lines*]]

Toggle the window width between 80 and 132 columns or set it to *cols* columns if an argument is specified. This requires a capable terminal and the termcap entries "Z0" and "Z1". See the "termcap" command for more information. You can also specify a new height if you want to change both values. The **-w** option tells screen to leave the display size unchanged and just set the window size, **-d** vice versa.

windowlist [**-b**] [**-m**]**windowlist string** [*string*]**windowlist title** [*title*]

Display all windows in a table for visual window selection. The desired window can be selected via the standard movement keys (see the "copy" command) and activated via the return key. If the **-b** option is given, screen will switch to the blank window before presenting the list, so that the current window is also selectable. The **-m** option changes the order of the windows, instead of sorting by window numbers screen uses its internal most-recently-used list.

The table format can be changed with the **string** and **title** option, the title is displayed as table heading, while the lines are made by using the string setting. The default setting is "Num Name%=Flags" for the title and "%3n %t%=%f" for the lines. See the "STRING ESCAPES" chapter for more codes (e.g. color settings).

windows

Uses the message line to display a list of all the windows. Each window is listed by number with the name of process that has been started in the window (or its title); the current window is marked with a '*'; the previous window is marked with a '-'; all the windows that are "logged in" are marked with a '\$'; a background window that has received a bell is marked with a '!'; a background window that is being monitored and has had activity occur is marked with an '@'; a window which has output logging turned on is marked with '(L)'; windows occupied by other users are marked with '&'; windows in the zombie state are marked with 'Z'. If this list is too long to fit on the terminal's status line only the portion around the current window is displayed.

wrap [**on**|**off**]

Sets the line-wrap setting for the current window. When line-wrap is on, the second consecutive printable character output at the last column of a line will wrap to the start of the following line. As an added feature, backspace (^H) will also wrap through the left margin to the previous line. Default is 'on'.

writebuf [-e *encoding*] [*filename*]

Writes the contents of the paste buffer to the specified file, or the public accessible screen-exchange file if no filename is given. This is thought of as a primitive means of communication between *screen* users on the same host. If an encoding is specified the paste buffer is recoded on the fly to match the encoding. The filename can be set with the *bufferfile* command and defaults to “/tmp/screen-exchange”.

writelock [on|off|auto]

In addition to access control lists, not all users may be able to write to the same window at once. Per default, writelock is in ‘auto’ mode and grants exclusive input permission to the user who is the first to switch to the particular window. When he leaves the window, other users may obtain the writelock (automatically). The writelock of the current window is disabled by the command “writelock off”. If the user issues the command “writelock on” he keeps the exclusive write permission while switching to other windows.

xoff**xon**

Insert a CTRL-s / CTRL-q character to the stdin queue of the current window.

zmodem [off|auto|catch|pass]**zmodem sendcmd** [*string*]**zmodem recvcmd** [*string*]

Define zmodem support for screen. Screen understands two different modes when it detects a zmodem request: “pass” and “catch”. If the mode is set to “pass”, screen will relay all data to the attacher until the end of the transmission is reached. In “catch” mode screen acts as a zmodem endpoint and starts the corresponding rz/sz commands. If the mode is set to “auto”, screen will use “catch” if the window is a tty (e.g. a serial line), otherwise it will use “pass”.

You can define the templates screen uses in “catch” mode via the second and the third form.

Note also that this is an experimental feature.

zombie [*keys*]**defzombie** [*keys*]

Per default *screen* windows are removed from the window list as soon as the windows process (e.g. shell) exits. When a string of two keys is specified to the zombie command, ‘dead’ windows will remain in the list. The **kill** command may be used to remove such a window. Pressing the first key in the dead window has the same effect. When pressing the second key, *screen* will attempt to resurrect the window. The process that was initially running in the window will be launched again. Calling **zombie** without parameters will clear the zombie setting, thus making windows disappear when their process exits.

As the zombie-setting is manipulated globally for all windows, this command should only be called **defzombie**. Until we need this as a per window setting, the commands **zombie** and **defzombie** are synonymous.

THE MESSAGE LINE

Screen displays informational messages and other diagnostics in a *message line*. While this line is distributed to appear at the bottom of the screen, it can be defined to appear at the top of the screen during compilation. If your terminal has a status line defined in its termcap, *screen* will use this for displaying its messages, otherwise a line of the current screen will be temporarily overwritten and output will be momentarily interrupted. The message line is automatically removed after a few seconds delay, but it can also be removed early (on terminals without a status line) by beginning to type.

The message line facility can be used by an application running in the current window by means of the ANSI *Privacy message* control sequence. For instance, from within the shell, try something like:

```
echo ^<esc>^Hello world from window '$WINDOW' <esc>\\
```

where '`<esc>`' is an *escape*, '^' is a literal up-arrow, and '\\ turns into a single backslash.

WINDOW TYPES

Screen provides three different window types. New windows are created with *screen*'s **screen** command (see also the entry in chapter "CUSTOMIZATION"). The first parameter to the **screen** command defines which type of window is created. The different window types are all special cases of the normal type. They have been added in order to allow *screen* to be used efficiently as a console multiplexer with 100 or more windows.

- The normal window contains a shell (default, if no parameter is given) or any other system command that could be executed from a shell (e.g. **slogin**, etc...)
- If a tty (character special device) name (e.g. `"/dev/ttya"`) is specified as the first parameter, then the window is directly connected to this device. This window type is similar to `"screen cu -l /dev/ttya"`. Read and write access is required on the device node, an exclusive open is attempted on the node to mark the connection line as busy. An optional parameter is allowed consisting of a comma separated list of flags in the notation used by `stty(1)`:

`<baud_rate>`

Usually 300, 1200, 9600 or 19200. This affects transmission as well as receive speed.

`cs8` or `cs7`

Specify the transmission of eight (or seven) bits per byte.

`ixon` or `-ixon`

Enables (or disables) software flow-control (CTRL-S/CTRL-Q) for sending data.

`ixoff` or `-ixon`

Enables (or disables) software flow-control for receiving data.

`istrip` or `-istrip`

Clear (or keep) the eight bit in each received byte.

You may want to specify as many of these options as applicable. Unspecified options cause the terminal driver to make up the parameter values of the connection. These values are system dependant and may be in defaults or values saved from a previous connection.

For tty windows, the **info** command shows some of the modem control lines in the status line. These may include 'RTS', 'CTS', 'DTR', 'DSR', 'CD' and more. This depends on the available `ioctl()`'s and system header files as well as the on the physical capabilities of the serial board. Signals that are logical low (inactive) have their name preceded by an exclamation mark (!), otherwise the signal is logical high (active). Signals not supported by the hardware but available to the `ioctl()` interface are usually shown low.

When the CLOCAL status bit is true, the whole set of modem signals is placed inside curly braces ({ and }). When the CRTSCTS or TIOCSOFTCAR bit is set, the signals 'CTS' or 'CD' are shown in parenthesis, respectively.

For tty windows, the command **break** causes the Data transmission line (TxD) to go low for a specified period of time. This is expected to be interpreted as break signal on the other side. No data is sent and no modem control line is changed when a **break** is issued.

- If the first parameter is `"/telnet"`, the second parameter is expected to be a host name, and an optional third parameter may specify a TCP port number (default decimal 23). Screen will connect to a server listening on the remote host and use the telnet protocol to communicate with that server. For telnet windows, the command **info** shows details about the connection in square brackets ([and]) at the end of the status line.

- b BINARY. The connection is in binary mode.
- e ECHO. Local echo is disabled.
- c SGA. The connection is in 'character mode' (default: 'line mode').
- t TTYPE. The terminal type has been requested by the remote host. Screen sends the name "screen" unless instructed otherwise (see also the command 'term').
- w NAWS. The remote site is notified about window size changes.
- f LFLOW. The remote host will send flow control information. (Ignored at the moment.)

Additional flags for debugging are x, t and n (XDISPLOC, TSPEED and NEWENV).

For telnet windows, the command **break** sends the telnet code IAC BREAK (decimal 243) to the remote host.

This window type is only available if *screen* was compiled with the BUILTIN_TELNET option defined.

STRING ESCAPES

Screen provides an escape mechanism to insert information like the current time into messages or file names. The escape character is '%' with one exception: inside of a window's hardstatus '^%' ('^E') is used instead.

Here is the full list of supported escapes:

- % the escape character itself
- a either 'am' or 'pm'
- A either 'AM' or 'PM'
- c current time HH:MM in 24h format
- C current time HH:MM in 12h format
- d day number
- D weekday name
- f flags of the window
- F sets %? to true if the window has the focus
- h hardstatus of the window
- H hostname of the system
- l current load of the system
- m month number
- M month name
- n window number
- s seconds
- t window title
- u all other users on this window
- w all window numbers and names. With '-' qualifier: up to the current window; with '+' qualifier: starting with the window after the current one.
- W all window numbers and names except the current one

| | |
|---|---|
| y | last two digits of the year number |
| Y | full year number |
| ? | the part to the next '%?' is displayed only if a '%' escape inside the part expands to a non-empty string |
| : | else part of '%?' |
| = | pad the string to the display's width (like TeX's hfill). If a number is specified, pad to the percentage of the window's width. A '0' qualifier tells screen to treat the number as absolute position. You can specify to pad relative to the last absolute pad position by adding a '+' qualifier or to pad relative to the right margin by using '-'. The padding truncates the string if the specified position lies before the current position. Add the 'L' qualifier to change this. |
| < | same as '%=' but just do truncation, do not fill with spaces |
| > | mark the current text position for the next truncation. When screen needs to do truncation, it tries to do it in a way that the marked position gets moved to the specified percentage of the output area. (The area starts from the last absolute pad position and ends with the position specified by the truncation operator.) The 'L' qualifier tells screen to mark the truncated parts with '...'. |
| { | attribute/color modifier string terminated by the next "}" |
| ` | Substitute with the output of a 'backtick' command. The length qualifier is misused to identify one of the commands. |

The 'c' and 'C' escape may be qualified with a '0' to make *screen* use zero instead of space as fill character. The '0' qualifier also makes the '=' escape use absolute positions. The 'n' and '=' escapes understand a length qualifier (e.g. '%3n'), 'D' and 'M' can be prefixed with 'L' to generate long names, 'w' and 'W' also show the window flags if 'L' is given.

An attribute/color modifier is used to change the attributes or the color settings. Its format is "[attribute modifier] [color description]". The attribute modifier must be prefixed by a change type indicator if it can be confused with a color description. The following change types are known:

| | |
|---|--|
| + | add the specified set to the current attributes |
| - | remove the set from the current attributes |
| ! | invert the set in the current attributes |
| = | change the current attributes to the specified set |

The attribute set can either be specified as a hexadecimal number or a combination of the following letters:

| | |
|---|-----------|
| d | dim |
| u | underline |
| b | bold |
| r | reverse |
| s | standout |
| B | blinking |

Colors are coded either as a hexadecimal number or two letters specifying the desired background and foreground color (in that order). The following colors are known:

| | |
|---|---------|
| k | black |
| r | red |
| g | green |
| y | yellow |
| b | blue |
| m | magenta |
| c | cyan |
| w | white |

d default color
 . leave color unchanged

The capitalized versions of the letter specify bright colors. You can also use the pseudo-color 'i' to set just the brightness and leave the color unchanged.

A one digit/letter color description is treated as foreground or background color dependant on the current attributes: if reverse mode is set, the background color is changed instead of the foreground color. If you don't like this, prefix the color with a ".". If you want the same behaviour for two-letter color descriptions, also prefix them with a ".".

As a special case, "%{-}" restores the attributes and colors that were set before the last change was made (i.e. pops one level of the color-change stack).

Examples:

"G" set color to bright green
 "+b r" use bold red
 "= yd" clear all attributes, write in default color on yellow background.

%-Lw%{= BW}%50>%n%f* %t%{-}%+Lw%<

The available windows centered at the current window and truncated to the available width. The current window is displayed white on blue. This can be used with "hardstatus alwayslastline".

%?%F%{.R.}%?%3n %t%? [%h]%?

The window number and title and the window's hardstatus, if one is set. Also use a red background if this is the active focus. Useful for "caption string".

FLOW-CONTROL

Each window has a flow-control setting that determines how *screen* deals with the XON and XOFF characters (and perhaps the interrupt character). When flow-control is turned off, *screen* ignores the XON and XOFF characters, which allows the user to send them to the current program by simply typing them (useful for the *emacs* editor, for instance). The trade-off is that it will take longer for output from a "normal" program to pause in response to an XOFF. With flow-control turned on, XON and XOFF characters are used to immediately pause the output of the current window. You can still send these characters to the current program, but you must use the appropriate two-character *screen* commands (typically "C-a q" (xon) and "C-a s" (xoff)). The xon/xoff commands are also useful for typing C-s and C-q past a terminal that intercepts these characters.

Each window has an initial flow-control value set with either the `-f` option or the "defflow" .screenrc command. Per default the windows are set to automatic flow-switching. It can then be toggled between the three states 'fixed on', 'fixed off' and 'automatic' interactively with the "flow" command bound to "C-a f".

The automatic flow-switching mode deals with flow control using the TIOCPKT mode (like "rlogin" does). If the tty driver does not support TIOCPKT, *screen* tries to find out the right mode based on the current setting of the application keypad – when it is enabled, flow-control is turned off and visa versa. Of course, you can still manipulate flow-control manually when needed.

If you're running with flow-control enabled and find that pressing the interrupt key (usually C-c) does not interrupt the display until another 6-8 lines have scrolled by, try running *screen* with the "interrupt" option (add the "interrupt" flag to the "flow" command in your .screenrc, or use the `-i` command-line option). This causes the output that *screen* has accumulated from the interrupted program to be flushed. One disadvantage is that the virtual terminal's memory contains the non-flushed version of the output, which in rare cases can cause minor inaccuracies in the output. For example, if you switch screens and return, or update the screen with "C-a l" you would see the version of the output you would have gotten without "interrupt" being on. Also, you might need to turn off flow-control (or use auto-flow mode to turn it off automatically) when running a program that expects you to type the interrupt character as input, as it is possible to interrupt the output of the virtual terminal to your physical terminal when flow-control is enabled. If this happens, a simple refresh of the screen with "C-a l" will restore it. Give each mode a try, and use whichever mode you find more comfortable.

TITLES (naming windows)

You can customize each window's name in the window display (viewed with the "windows" command (C-a w)) by setting it with one of the title commands. Normally the name displayed is the actual command name of the program created in the window. However, it is sometimes useful to distinguish various programs of the same name or to change the name on-the-fly to reflect the current state of the window.

The default name for all shell windows can be set with the "shelltitle" command in the .screenrc file, while all other windows are created with a "screen" command and thus can have their name set with the `-t` option. Interactively, there is the title-string escape-sequence (`<esc>kname<esc>\`) and the "title" command (C-a A). The former can be output from an application to control the window's name under software control, and the latter will prompt for a name when typed. You can also bind pre-defined names to keys with the "title" command to set things quickly without prompting.

Finally, *screen* has a shell-specific heuristic that is enabled by setting the window's name to "*search|name*" and arranging to have a null title escape-sequence output as a part of your prompt. The *search* portion specifies an end-of-prompt search string, while the *name* portion specifies the default shell name for the window. If the *name* ends in a ':' *screen* will add what it believes to be the current command running in the window to the end of the window's shell name (e. g. "*name:cmd*"). Otherwise the current command name supersedes the shell name while it is running.

Here's how it works: you must modify your shell prompt to output a null title-escape-sequence (`<esc>k<esc>\`) as a part of your prompt. The last part of your prompt must be the same as the string you specified for the *search* portion of the title. Once this is set up, *screen* will use the title-escape-sequence to clear the previous command name and get ready for the next command. Then, when a newline is received from the shell, a search is made for the end of the prompt. If found, it will grab the first word after the matched string and use it as the command name. If the command name begins with either '!', '%', or '^' *screen* will use the first word on the following line (if found) in preference to the just-found name. This helps csh users get better command names when using job control or history recall commands.

Here's some .screenrc examples:

```
screen -t top 2 nice top
```

Adding this line to your .screenrc would start a nice-d version of the "top" command in window 2 named "top" rather than "nice".

```
shelltitle '> |csh'
screen 1
```

These commands would start a shell with the given shelltitle. The title specified is an auto-title that would expect the prompt and the typed command to look something like the following:

```
/usr/joe/src/dir> trn
```

(it looks after the '>' for the command name). The window status would show the name "trn" while the command was running, and revert to "csh" upon completion.

```
bind R screen -t '% |root:' su
```

Having this command in your .screenrc would bind the key sequence "C-a R" to the "su" command and give it an auto-title name of "root:". For this auto-title to work, the screen could look something like this:

```
% !em
emacs file.c
```

Here the user typed the csh history command "!em" which ran the previously entered "emacs" command. The window status would show "root:emacs" during the execution of the command, and revert to simply "root:" at its completion.

```
bind o title
bind E title ""
```

```
bind u title (unknown)
```

The first binding doesn't have any arguments, so it would prompt you for a title. when you type "C-a o". The second binding would clear an auto-title's current setting (C-a E). The third binding would set the current window's title to "(unknown)" (C-a u).

One thing to keep in mind when adding a null title-escape-sequence to your prompt is that some shells (like the *csh*) count all the non-control characters as part of the prompt's length. If these invisible characters aren't a multiple of 8 then backspacing over a tab will result in an incorrect display. One way to get around this is to use a prompt like this:

```
set prompt='^[0000m^[k^[\'% '
```

The escape-sequence "<esc>[0000m" not only normalizes the character attributes, but all the zeros round the length of the invisible characters up to 8. Bash users will probably want to echo the escape sequence in the PROMPT_COMMAND:

```
PROMPT_COMMAND='echo -n -e "\033k\033\134"'
```

(I used "134" to output a '\ because of a bug in bash v1.04).

THE VIRTUAL TERMINAL

Each window in a *screen* session emulates a VT100 terminal, with some extra functions added. The VT100 emulator is hard-coded, no other terminal types can be emulated.

Usually *screen* tries to emulate as much of the VT100/ANSI standard as possible. But if your terminal lacks certain capabilities, the emulation may not be complete. In these cases *screen* has to tell the applications that some of the features are missing. This is no problem on machines using *termcap*, because *screen* can use the \$TERMCAP variable to customize the standard *screen* *termcap*.

But if you do a rlogin on another machine or your machine supports only *terminfo* this method fails. Because of this, *screen* offers a way to deal with these cases. Here is how it works:

When *screen* tries to figure out a terminal name for itself, it first looks for an entry named "screen.<term>", where <term> is the contents of your \$TERM variable. If no such entry exists, *screen* tries "screen" (or "screen-w" if the terminal is wide (132 cols or more)). If even this entry cannot be found, "vt100" is used as a substitute.

The idea is that if you have a terminal which doesn't support an important feature (e.g. delete char or clear to EOS) you can build a new *termcap*/*terminfo* entry for *screen* (named "screen.<dumbterm>") in which this capability has been disabled. If this entry is installed on your machines you are able to do a rlogin and still keep the correct *termcap*/*terminfo* entry. The terminal name is put in the \$TERM variable of all new windows. *Screen* also sets the \$TERMCAP variable reflecting the capabilities of the virtual terminal emulated. Notice that, however, on machines using the *terminfo* database this variable has no effect. Furthermore, the variable \$WINDOW is set to the window number of each window.

The actual set of capabilities supported by the virtual terminal depends on the capabilities supported by the physical terminal. If, for instance, the physical terminal does not support underscore mode, *screen* does not put the 'us' and 'ue' capabilities into the window's \$TERMCAP variable, accordingly. However, a minimum number of capabilities must be supported by a terminal in order to run *screen*; namely scrolling, clear screen, and direct cursor addressing (in addition, *screen* does not run on hardcopy terminals or on terminals that over-strike).

Also, you can customize the \$TERMCAP value used by *screen* by using the "termcap" .screenrc command, or by defining the variable \$SCREENCAP prior to startup. When the latter is defined, its value will be copied verbatim into each window's \$TERMCAP variable. This can either be the full terminal definition, or a filename where the terminal "screen" (and/or "screen-w") is defined.

Note that *screen* honors the "terminfo" .screenrc command if the system uses the *terminfo* database rather than *termcap*.

When the boolean ‘G0’ capability is present in the termcap entry for the terminal on which *screen* has been called, the terminal emulation of *screen* supports multiple character sets. This allows an application to make use of, for instance, the VT100 graphics character set or national character sets. The following control functions from ISO 2022 are supported: *lock shift G0 (SI)*, *lock shift G1 (SO)*, *lock shift G2*, *lock shift G3*, *single shift G2*, and *single shift G3*. When a virtual terminal is created or reset, the ASCII character set is designated as *G0* through *G3*. When the ‘G0’ capability is present, *screen* evaluates the capabilities ‘S0’, ‘E0’, and ‘C0’ if present. ‘S0’ is the sequence the terminal uses to enable and start the graphics character set rather than *SI*. ‘E0’ is the corresponding replacement for *SO*. ‘C0’ gives a character by character translation string that is used during semi-graphics mode. This string is built like the ‘acsc’ terminfo capability.

When the ‘po’ and ‘pf’ capabilities are present in the terminal’s termcap entry, applications running in a *screen* window can send output to the printer port of the terminal. This allows a user to have an application in one window sending output to a printer connected to the terminal, while all other windows are still active (the printer port is enabled and disabled again for each chunk of output). As a side-effect, programs running in different windows can send output to the printer simultaneously. Data sent to the printer is not displayed in the window. The *info* command displays a line starting ‘PRIN’ while the printer is active.

Screen maintains a hardstatus line for every window. If a window gets selected, the display’s hardstatus will be updated to match the window’s hardstatus line. If the display has no hardstatus the line will be displayed as a standard *screen* message. The hardstatus line can be changed with the ANSI Application Program Command (APC): “ESC_<string>ESC\”. As a convenience for xterm users the sequence “ESC]0..2;<string>^G” is also accepted.

Some capabilities are only put into the \$TERMCAP variable of the virtual terminal if they can be efficiently implemented by the physical terminal. For instance, ‘dl’ (delete line) is only put into the \$TERMCAP variable if the terminal supports either delete line itself or scrolling regions. Note that this may provoke confusion, when the session is reattached on a different terminal, as the value of \$TERMCAP cannot be modified by parent processes.

The “alternate screen” capability is not enabled by default. Set the **altscreen** .screenrc command to enable it.

The following is a list of control sequences recognized by *screen*. “(V)” and “(A)” indicate VT100-specific and ANSI- or ISO-specific functions, respectively.

| | | |
|-----------------|-----|----------------------------------|
| ESC E | | Next Line |
| ESC D | | Index |
| ESC M | | Reverse Index |
| ESC H | | Horizontal Tab Set |
| ESC Z | | Send VT100 Identification String |
| ESC 7 | (V) | Save Cursor and Attributes |
| ESC 8 | (V) | Restore Cursor and Attributes |
| ESC [s | (A) | Save Cursor and Attributes |
| ESC [u | (A) | Restore Cursor and Attributes |
| ESC c | | Reset to Initial State |
| ESC g | | Visual Bell |
| ESC Pn p | | Cursor Visibility (97801) |
| Pn = 6 | | Invisible |
| 7 | | Visible |
| ESC = | (V) | Application Keypad Mode |
| ESC > | (V) | Numeric Keypad Mode |

| | |
|----------------------------|---|
| ESC # 8 | (V) Fill Screen with E's |
| ESC \ | (A) String Terminator |
| ESC ^ | (A) Privacy Message String (Message Line) |
| ESC ! | Global Message String (Message Line) |
| ESC k | A. k. a. Definition String |
| ESC P | (A) Device Control String. Outputs a string directly to the host terminal without interpretation. |
| ESC _ | (A) Application Program Command (Hardstatus) |
| ESC] 0 ; string ^G | (A) Operating System Command (Hardstatus, xterm title hack) |
| ESC] 83 ; cmd ^G | (A) Execute screen command. This only works if multi-user support is compiled into screen. The pseudo-user “:window:” is used to check the access control list. Use “addacl :window: -rwx #?” to create a user with no rights and allow only the needed commands. |
| Control-N | (A) Lock Shift G1 (SO) |
| Control-O | (A) Lock Shift G0 (SI) |
| ESC n | (A) Lock Shift G2 |
| ESC o | (A) Lock Shift G3 |
| ESC N | (A) Single Shift G2 |
| ESC O | (A) Single Shift G3 |
| ESC (Pcs | (A) Designate character set as G0 |
| ESC) Pcs | (A) Designate character set as G1 |
| ESC * Pcs | (A) Designate character set as G2 |
| ESC + Pcs | (A) Designate character set as G3 |
| ESC [Pn ; Pn H | Direct Cursor Addressing |
| ESC [Pn ; Pn f | same as above |
| ESC [Pn J | Erase in Display |
| Pn = None or 0 | From Cursor to End of Screen |
| 1 | From Beginning of Screen to Cursor |
| 2 | Entire Screen |
| ESC [Pn K | Erase in Line |
| Pn = None or 0 | From Cursor to End of Line |
| 1 | From Beginning of Line to Cursor |
| 2 | Entire Line |
| ESC [Pn X | Erase character |
| ESC [Pn A | Cursor Up |
| ESC [Pn B | Cursor Down |
| ESC [Pn C | Cursor Right |
| ESC [Pn D | Cursor Left |
| ESC [Pn E | Cursor next line |

| | | |
|----------------------------|-----|---|
| ESC [Pn F | | Cursor previous line |
| ESC [Pn G | | Cursor horizontal position |
| ESC [Pn ‘ | | same as above |
| ESC [Pn d | | Cursor vertical position |
| ESC [Ps ;...; Ps m | | Select Graphic Rendition |
| Ps = None or 0 | | Default Rendition |
| 1 | | Bold |
| 2 | (A) | Faint |
| 3 | (A) | <i>Standout</i> Mode (ANSI: Italicized) |
| 4 | | Underlined |
| 5 | | Blinking |
| 7 | | Negative Image |
| 22 | (A) | Normal Intensity |
| 23 | (A) | <i>Standout</i> Mode off (ANSI: Italicized off) |
| 24 | (A) | Not Underlined |
| 25 | (A) | Not Blinking |
| 27 | (A) | Positive Image |
| 30 | (A) | Foreground Black |
| 31 | (A) | Foreground Red |
| 32 | (A) | Foreground Green |
| 33 | (A) | Foreground Yellow |
| 34 | (A) | Foreground Blue |
| 35 | (A) | Foreground Magenta |
| 36 | (A) | Foreground Cyan |
| 37 | (A) | Foreground White |
| 39 | (A) | Foreground Default |
| 40 | (A) | Background Black |
| ... | | |
| 49 | (A) | Background Default |
| ESC [Pn g | | Tab Clear |
| Pn = None or 0 | | Clear Tab at Current Position |
| 3 | | Clear All Tabs |
| ESC [Pn ; Pn r | (V) | Set Scrolling Region |
| ESC [Pn I | (A) | Horizontal Tab |
| ESC [Pn Z | (A) | Backward Tab |
| ESC [Pn L | (A) | Insert Line |
| ESC [Pn M | (A) | Delete Line |
| ESC [Pn @ | (A) | Insert Character |

| | | |
|----------------------------|-----|--|
| ESC [Pn P | (A) | Delete Character |
| ESC [Pn S | | Scroll Scrolling Region Up |
| ESC [Pn T | | Scroll Scrolling Region Down |
| ESC [Pn ^ | | same as above |
| ESC [Ps ;...; Ps h | | Set Mode |
| ESC [Ps ;...; Ps l | | Reset Mode |
| Ps = 4 | (A) | Insert Mode |
| 20 | (A) | <i>Automatic Linefeed</i> Mode |
| 34 | | Normal Cursor Visibility |
| ?1 | (V) | Application Cursor Keys |
| ?3 | (V) | Change Terminal Width to 132 columns |
| ?5 | (V) | Reverse Video |
| ?6 | (V) | <i>Origin</i> Mode |
| ?7 | (V) | <i>Wrap</i> Mode |
| ?9 | | X10 mouse tracking |
| ?25 | (V) | Visible Cursor |
| ?47 | | Alternate Screen (old xterm code) |
| ?1000 | (V) | VT200 mouse tracking |
| ?1047 | | Alternate Screen (new xterm code) |
| ?1049 | | Alternate Screen (new xterm code) |
| ESC [5 i | (A) | Start relay to printer (ANSI Media Copy) |
| ESC [4 i | (A) | Stop relay to printer (ANSI Media Copy) |
| ESC [8 ; Ph ; Pw t | | Resize the window to 'Ph' lines and 'Pw' columns (SunView special) |
| ESC [c | | Send VT100 Identification String |
| ESC [x | | Send Terminal Parameter Report |
| ESC [> c | | Send VT220 Secondary Device Attributes String |
| ESC [6 n | | Send Cursor Position Report |

INPUT TRANSLATION

In order to do a full VT100 emulation *screen* has to detect that a sequence of characters in the input stream was generated by a keypress on the user's keyboard and insert the VT100 style escape sequence. *Screen* has a very flexible way of doing this by making it possible to map arbitrary commands on arbitrary sequences of characters. For standard VT100 emulation the command will always insert a string in the input buffer of the window (see also command **stuff** in the command table). Because the sequences generated by a keypress can change after a reattach from a different terminal type, it is possible to bind commands to the termcap name of the keys. *Screen* will insert the correct binding after each reattach. See the **bindkey** command for further details on the syntax and examples.

Here is the table of the default key bindings. (A) means that the command is executed if the keyboard is switched into application mode.

| Key name | Termcap name | Command |
|-----------|--------------|--------------|
| Cursor up | ku | stuff \033[A |

| | | | |
|-----------------|----|----------------|-----|
| | | stuff \033OA | (A) |
| Cursor down | kd | stuff \033[B | |
| | | stuff \033OB | (A) |
| Cursor right | kr | stuff \033[C | |
| | | stuff \033OC | (A) |
| Cursor left | kl | stuff \033[D | |
| | | stuff \033OD | (A) |
| Function key 0 | k0 | stuff \033[10~ | |

SPECIAL TERMINAL CAPABILITIES

The following table describes all terminal capabilities that are recognized by *screen* and are not in the *termcap(5)* manual. You can place these capabilities in your *termcap* entries (in */etc/termcap*) or use them with the commands *'termcap'*, *'terminfo'* and *'termcapinfo'* in your *screenrc* files. It is often not possible to place these capabilities in the *terminfo* database.

| | | |
|-----------|--------|--|
| LP | (bool) | Terminal has VT100 style margins ('magic margins'). Note that this capability is obsolete because <i>screen</i> uses the standard 'xn' instead. |
| Z0 | (str) | Change width to 132 columns. |
| Z1 | (str) | Change width to 80 columns. |
| WS | (str) | Resize display. This capability has the desired width and height as arguments. <i>SunView(tm)</i> example: '\E[8;%d;%dt'. |
| NF | (bool) | Terminal doesn't need flow control. Send ^S and ^Q direct to the application. Same as 'flow off'. The opposite of this capability is 'nx'. |
| G0 | (bool) | Terminal can deal with ISO 2022 font selection sequences. |
| S0 | (str) | Switch charset 'G0' to the specified charset. Default is '\E(%.'. |
| E0 | (str) | Switch charset 'G0' back to standard charset. Default is '\E(B'. |
| C0 | (str) | Use the string as a conversion table for font '0'. See the 'ac' capability for more details. |
| CS | (str) | Switch cursor-keys to application mode. |
| CE | (str) | Switch cursor-keys back to normal mode. |
| AN | (bool) | Turn on autonuke. See the 'autonuke' command for more details. |
| OL | (num) | Set the output buffer limit. See the 'obuflimit' command for more details. |
| KJ | (str) | Set the encoding of the terminal. See the 'encoding' command for valid encodings. |
| AF | (str) | Change character foreground color in an ANSI conform way. This capability will almost always be set to '\E[3%dm' ('\E[3%p1%dm' on <i>terminfo</i> machines). |
| AB | (str) | Same as 'AF', but change background color. |
| AX | (bool) | Does understand ANSI set default fg/bg color (\E[39m / \E[49m). |
| XC | (str) | Describe a translation of characters to strings depending on the current font. More details follow in the next section. |
| XT | (bool) | Terminal understands special xterm sequences (OSC, mouse tracking). |
| C8 | (bool) | Terminal needs bold to display high-intensity colors (e.g. Eterm). |
| TF | (bool) | Add missing capabilities to the <i>termcap/info</i> entry. (Set by default). |

CHARACTER TRANSLATION

Screen has a powerful mechanism to translate characters to arbitrary strings depending on the current font and terminal type. Use this feature if you want to work with a common standard character set (say

ISO8851-latin1) even on terminals that scatter the more unusual characters over several national language font pages.

Syntax:

```
XC=<charset-mapping>{,<charset-mapping>}
<charset-mapping> := <designator><template>{,<mapping>}
<mapping> := <char-to-be-mapped><template-arg>
```

The things in braces may be repeated any number of times.

A *<charset-mapping>* tells *screen* how to map characters in font *<designator>* ('B': Ascii, 'A': UK, 'K': german, etc.) to strings. Every *<mapping>* describes to what string a single character will be translated. A template mechanism is used, as most of the time the codes have a lot in common (for example strings to switch to and from another charset). Each occurrence of '%' in *<template>* gets substituted with the *<template-arg>* specified together with the character. If your strings are not similar at all, then use '%' as a template and place the full string in *<template-arg>*. A quoting mechanism was added to make it possible to use a real '%'. The '\ ' character quotes the special characters '\', '\%', and '\,'.

Here is an example:

```
termcap hp700 'XC=B\E(K%\E(B,\304[\326\\,\334]'
```

This tells *screen* how to translate ISOlatin1 (charset 'B') upper case umlaut characters on a hp700 terminal that has a german charset. '\304' gets translated to '\E(K\E(B' and so on. Note that this line gets parsed *three* times before the internal lookup table is built, therefore a lot of quoting is needed to create a single '\ '.

Another extension was added to allow more emulation: If a mapping translates the unquoted '%' char, it will be sent to the terminal whenever *screen* switches to the corresponding *<designator>*. In this special case the template is assumed to be just '%' because the charset switch sequence and the character mappings normally haven't much in common.

This example shows one use of the extension:

```
termcap xterm 'XC=K%,%\E(B,[\304,\\326,]\334'
```

Here, a part of the german ('K') charset is emulated on an xterm. If *screen* has to change to the 'K' charset, '\E(B' will be sent to the terminal, i.e. the ASCII charset is used instead. The template is just '%', so the mapping is straightforward: '[' to '\304', '\ ' to '\326', and ']' to '\334'.

ENVIRONMENT

| | |
|----------------|--|
| COLUMNS | Number of columns on the terminal (overrides termcap entry). |
| HOME | Directory in which to look for .screenrc. |
| LINES | Number of lines on the terminal (overrides termcap entry). |
| LOCKPRG | Screen lock program. |
| NETHACKOPTIONS | Turns on nethack option. |
| PATH | Used for locating programs to run. |
| SCREENCAP | For customizing a terminal's TERMCAP value. |
| SCREENDIR | Alternate socket directory. |
| SCREENRC | Alternate user screenrc file. |
| SHELL | Default shell program for opening windows (default "/bin/sh"). |
| STY | Alternate socket name. |

SYSSCREENRC

Alternate system screenrc file.

TERM

Terminal name.

TERMCAP

Terminal description.

WINDOW

Window number of a window (at creation time).

FILES

.../screen-4.?.?/etc/screenrc

.../screen-4.?.?/etc/etcscreenrc

Examples in the *screen* distribution package for private and global initialization files.**\$SYSSCREENRC**

/etc/screenrc

screen initialization commands**\$SCREENRC**

\$HOME/.screenrc

Read in after /etc/screenrc

\$SCREENDIR/S-<login>

/local/screens/S-<login>

Socket directories (default)

/usr/tmp/screens/S-<login>

Alternate socket directories.

<socket directory>/termcap

Written by the "termcap" output function

/usr/tmp/screens/screen-exchange

or

/tmp/screen-exchange

screen 'interprocess communication buffer'

hardcopy.[0-9]

Screen images created by the hardcopy function

screenlog.[0-9]

Output log files created by the log function

/usr/lib/terminfo/?/*

or

/etc/termcap

Terminal capability databases

/etc/utmp

Login records

\$LOCKPRG

Program that locks a terminal.

VERSION

This is version 4.0.2. Its roots are a merge of a custom version 2.3PR7 by Wayne Davison and several enhancements to Oliver Laumann's version 2.0. Note that all versions numbered 2.x are copyright by Oliver Laumann.

AVAILABILITY

The latest official release of *screen* available via anonymous ftp from gnudist.gnu.org, nic.funet.fi or any other *GNU* distribution site. The home site of *screen* is ftp.uni-erlangen.de, in the directory pub/utilities/screen. The subdirectory 'private' contains the latest beta testing release. If you want to help, send a note to screen@uni-erlangen.de.

BUGS

- 'dm' (delete mode) and 'xs' are not handled correctly (they are ignored). 'xn' is treated as a magic-margin indicator.
- *Screen* has no clue about double-high or double-wide characters. But this is the only area where *vttest* is allowed to fail.
- It is not possible to change the environment variable \$TERMCAP when reattaching under a different terminal type.
- The support of terminfo based systems is very limited. Adding extra capabilities to \$TERMCAP may not have any effects.
- *Screen* does not make use of hardware tabs.
- *Screen* must be installed as set-uid with owner root on most systems in order to be able to correctly change the owner of the tty device file for each window. Special permission may also be required to write the file "/etc/utmp".

- Entries in “/etc/utmp” are not removed when *screen* is killed with SIGKILL. This will cause some programs (like “w” or “rwho”) to advertise that a user is logged on who really isn’t.
- *Screen* may give a strange warning when your tty has no utmp entry.
- When the modem line was hung up, *screen* may not automatically detach (or quit) unless the device driver is configured to send a HANGUP signal. To detach a *screen* session use the -D or -d command line option.
- If a password is set, the command line options -d and -D still detach a session without asking.
- Both “breaktype” and “defbreaktype” change the break generating method used by all terminal devices. The first should change a window specific setting, where the latter should change only the default for new windows.
- When attaching to a multiuser session, the user’s .screenrc file is not sourced. Each user’s personal settings have to be included in the .screenrc file from which the session is booted, or have to be changed manually.
- A weird imagination is most useful to gain full advantage of all the features.
- Send bug-reports, fixes, enhancements, t-shirts, money, beer & pizza to **screen@uni-erlangen.de**.

NAME

scriptextract – extract scripts distributed with the edrc distribute command

SYNOPSIS

edrc/lib/edrc/scriptextract [**-h** | **-V**]

edrc/lib/edrc/scriptextract -m { **full** | **differential** } **-c** *config_file*

AVAILABILITY

WA2L/edrc

DESCRIPTION

extract scripts distributed with the **distribute** EDRC command.

For a detail description of the distribution mechanism, see manpage of the **edrc(1m)** command.

OPTIONS

-h this usage message.

-V print scriptextract version.

-m *mode* install mode.

-c *config_file*
 configuration file.

ENVIRONMENT

-

EXIT STATUS

- | | |
|----------|---------------------------------------|
| 0 | no error. |
| 1 | command started using the wrong user. |
| 2 | operating system not supported. |
| 3 | command version printed. |

- 5** command aborted.
- 6** configuration file *config_file* not found.

FILES

edrc/var/repl/rec.config_file.full.cpio.gz

distribution file containing the received script files for a full distribution.

edrc/var/repl/rec.config_file.diff.cpio.gz

distribution file containing the received script files for a differential distribution.

edrc/var/lock/scriptextract.scriptextract.lock

lock file to ensure that only one instance of the **scriptextract** command is running.

EXAMPLES

-

SEE ALSO

edrcintro(1), **edrc**(1m)

NOTES

-

BUGS

-

AUTHOR

scriptextract was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

scriptgrep – grep underlying recovery scripts for a pattern

SYNOPSIS

edrc/bin/scriptgrep [-l] *pattern*

AVAILABILITY

WA2L/edrc

DESCRIPTION

grep all recovery scripts for a pattern. Files in **.sav** directories and files not following the name convention ***.*** are excluded from the search.

OPTIONS

-l list only names of files containing matches.

pattern regular expression pattern to be searched for in underlying recovery scripts. See **regexintro(4)** for more information about regular expressions.

ENVIRONMENT

-

EXIT STATUS

4 no pattern defined, usage displayed.

X exit code of **grep(1)**.

FILES

-

EXAMPLES

-

NAME

scriptheadersync – sync recovery script file header information to actual filename

SYNOPSIS

edrc/bin/scriptheadersync [**-h**]

scriptheadersync **-print** | **-execute**

AVAILABILITY

WA2L/edrc

DESCRIPTION

synchronize the header entries in recovery scripts with the actual filename of the script.

scriptheadersync starts in the current working directory and searches all underlying directories for environment files (*_env*) and recovery scripts matching the filename convention: *<menupoint>:<scriptname>*.

This command is useful if after cloning a menu and the scriptnames were renamed using the **lsmv**(1) or copied using the **lscp**(1) command.

OPTIONS

-h usage message.

-print print the intended changes to the script headers.

-execute apply the synchronization changes to the script headers.

ENVIRONMENT

-

EXIT STATUS

0 no error.

2 operating system not supported yet, see **osid**(3) if you get this error.

4 usage printed.

FILES

- .sav** directories where file saves are stored in recovery script trees. Those directories are excluded from header synchronization.
- _env** environment file.

EXAMPLES

-

SEE ALSO

edrcintro(1)

NOTES

-

NAME

scriptmenupath – return recovery script menu path

SYNOPSIS

edrc/lib/scriptmenupath [**-h**]

scriptmenupath [**-d**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

return recovery script menu path with menu point when called from a recovery script or **_env** file in the form 'menu -> submenu -> subsubmenu -> menupoint'.

OPTIONS

-h usage message.

-d print the menu path without menu point in the form 'menu -> submenu -> subsubmenu'.

ENVIRONMENT

-

EXIT STATUS

0 always

1 the **scriptmenupath** command has been called from outside of an **edrc** session.

4 usage printed.

FILES

_env environment file where **scriptmenupath** is started. See **edrc(1m)** for more information.

<recovery script>

recovery script that is started, when a menupoint is called.

EXAMPLES

-

SEE ALSO

edrcintro(1), **scripttitle(3)**

NOTES

-

BUGS

-

AUTHOR

scriptmenupath was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net .

NAME

scriptrevision – revision (version) of a script- or text-file

SYNOPSIS

edrc/lib/scriptrevision *file*

AVAILABILITY

WA2L/edrc

DESCRIPTION

print the revision number of a (script)file following the [##] revision notation as also resolved by **revision(1)**.

OPTIONS

file file to resolve the version number from.

ENVIRONMENT

-

EXIT STATUS

0 no error.

1 given file does not exist or cannot be read.

FILES

-

EXAMPLES

-

SEE ALSO

edrcintro(1), apprevision(3), revision(1)

NOTES

NAME

scriptsequence – check if scripts are called in ascending order

SYNOPSIS

edrc/lib/scriptsequence [-h]

scriptsequence [-a inform | -a query | -a cancel | -a init]

AVAILABILITY

WA2L/edrc

DESCRIPTION

check if recovery scripts are called in ascending sequence. If not a message is printed or the script is aborted. **scriptsequence** must be called from a recovery script or **_env** file to give the user more awareness if the sequence is broken.

The **scriptsequence** command reads the **contrib.doc**(1m) tag **# R: text** to check if it is allowed to rerun a recovery script without a message/query.

If *text* in **# R: text** is set to **YES**, **JA**, **OUI** or **SI** and the related recovery script is started again, no message is printed or no query is performed.

OPTIONS

-a inform if the script is started out of ascending sequence or if a script is started again and no **# R: YES** is found in the recovery script documentation, print an information WARNING message, but start the recovery script nevertheless.

-a query if the script is started out of ascending sequence or if a script is started again and no **# R: YES** is found in the recovery script documentation, query the user if the script should be started or canceled.

-a cancel if the script is started out of ascending sequence or if a script is started again and no **# R: YES** is found in the recovery script documentation, cancel the recovery script start.

-a init force the **scriptsequence** command to re-read the script tree on next start.

Normally this is not necessary, but if recovery scripts were added/deleted the **scriptsequence** needs to re-read the script tree.

When the current **edrc** session is exited and a new session is started, it is also not needed to invoke **scripttree -a init**.

ENVIRONMENT

-

EXIT STATUS

- | | |
|----------|--|
| 0 | no abnormality discovered. |
| 1 | scriptsequence is started from outside of a recovery script tree. |
| 2 | the script is started out of ascending sequence or the a script is started again and no # R: YES is found in the recovery script documentation and either -a cancel was invoked or the query to start/cancel the recovery script was answered to cancel. |
| 4 | usage displayed. |

FILES

_env environment file where **scriptsequence** is started. See **edrc(1m)** for more information.

<recovery script>

recovery script that is started, when a menupoint is called.

edrc/var/log/scriptsequence.log

log file of **scriptsequence**.

EXAMPLES

1. Usage example (query to abort or not):

```
scriptsequence || exit
```

2. Usage example (inform only):

```
scriptsequence -a inform || exit
```

NAME

scripttitle – print recovery script title and duration

SYNOPSIS

edrc/lib/scripttitle [**-h**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

print recovery script title (menupoint, description and duration as defined in **doc** tag) when called from a recovery script or **_env** file to give the user more awareness which menu point is started.

OPTIONS

-h usage message.

ENVIRONMENT

-

EXIT STATUS

| | |
|----------|--|
| 0 | always |
| 1 | the scripttitle command has been called from outside of an edrc session. |
| 4 | usage printed. |

FILES

_env environment file where **scripttitle** is started. See **edrc(1m)** for more information.

<recovery script>

recovery script that is started, when a menupoint is called.

EXAMPLES

-

SEE ALSO

edrcintro(1), **contrib.doc(1m)**

NOTES

-

BUGS

-

AUTHOR

scripttitle was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

seconds – print seconds since Epoch for a given date and time

SYNOPSIS

edrc/lib/seconds [**-h**]

seconds *MM/DD/YYYY hh:mm:ss*

AVAILABILITY

WA2L/edrc

DESCRIPTION

Calculate seconds since the Epoch for a given date and time.

seconds is the inverse function of the **timer** command.

In conjunction with the **timer** command, the **seconds** command can be used to do some date and time calculation.

Use **timer** to evaluate the seconds since the Epoch for the current moment.

OPTIONS

-h usage message.

YYYY-MM-DD hh:mm:ss

date and time in format "Year-Month-Day Hour:Minute:Second".

ENVIRONMENT

-

EXIT STATUS

0 no error.

4 usage displayed.

FILES

-

EXAMPLES

- 1) print seconds since Epoch for Sun Mar 18 23:47:05 CET 2007

```
[ /home/mzv7t0 ]
[ mzv7t0@rh7mzv7t001 ][ksh]: seconds 2007-03-18 23:47:05

1174258025
```

- 2) print date for 1174258025 since the Epoch

```
[ /home/mzv7t0 ]
[ mzv7t0@rh7mzv7t001 ][ksh]: timer 1174258025

2007-03-18 23:47:05
```

- 3) print seconds since the Epoch of current point in time

```
[ /home/mzv7t0 ]
[ mzv7t0@rh7mzv7t001 ][ksh]: timer

1174258402
```

- 4) print the date and time when a 72 hour countdown that started at February 1st 2007 at 12:00:00 will end.

```
[ /home/mzv7t0 ]
[ mzv7t0@rh7mzv7t001 ][ksh]: begin='seconds 2007-02-01 12:00:00'

[ /home/mzv7t0 ]
[ mzv7t0@rh7mzv7t001 ][ksh]: end='expr $begin + 72 \* 60 \* 60'

[ /home/mzv7t0 ]
[ mzv7t0@rh7mzv7t001 ][ksh]: timer $end

2007-02-04 12:00:00
```

- 5) same as example 4, but in an one-line statement.

```
[ /home/mzv7t0 ]
[ mzv7t0@rh7mzv7t001 ][ksh]: \
timer `expr \`seconds 2007-02-01 12:00:00\` + 72 \* 60 \* 60`

2007-02-04 12:00:00
```

seconds(3)

Library Commands

seconds(3)

SEE ALSO

NAME

sed1line – useful one-line scripts for sed

SYNOPSIS

sed [*OPTION*]... *{script-only-if-no-other-script}* [*input-file*]...

AVAILABILITY

WA2L/edrc

DESCRIPTION**INTRODUCTION:**

```
-----
USEFUL ONE-LINE SCRIPTS FOR SED (Unix stream editor)          Dec. 29, 2005
Compiled by Eric Pement - pement[at]northpark[dot]edu          version 5.5
```

Latest version of this file (in English) is usually at:
<http://sed.sourceforge.net/sed1line.txt>
<http://www.pement.org/sed/sed1line.txt>

This file will also available in other languages:

```
Chinese      - http://sed.sourceforge.net/sed1line_zh-CN.html
Czech        - http://sed.sourceforge.net/sed1line_cz.html
Dutch        - http://sed.sourceforge.net/sed1line_nl.html
French       - http://sed.sourceforge.net/sed1line_fr.html
German       - http://sed.sourceforge.net/sed1line_de.html
Italian      - (pending)
Portuguese   - http://sed.sourceforge.net/sed1line_pt-BR.html
Spanish      - (pending)
```

FILE SPACING:

```
# double space a file
sed G
```

```
# double space a file which already has blank lines in it. Output file
# should contain no more than one blank line between lines of text.
sed '/^$/d;G'
```

```
# triple space a file
sed 'G;G'
```

```
# undo double-spacing (assumes even-numbered lines are always blank)
sed 'n;d'
```

```
# insert a blank line above every line which matches "regex"
sed '/regex/{x;p;x;}'
```

```
# insert a blank line below every line which matches "regex"
```

```
sed '/regex/G'
```

```
# insert a blank line above and below every line which matches "regex"
sed '/regex/{x;p;x;G;}'
```

NUMBERING:

```
# number each line of a file (simple left alignment). Using a tab (see
# note on '\t' at end of file) instead of space will preserve margins.
sed = filename | sed 'N;s/\n/\t/'
```

```
# number each line of a file (number on left, right-aligned)
sed = filename | sed 'N; s/^/      /; s/ *\(.\\{6,\\}\)\n/\1  /'
```

```
# number each line of file, but only print numbers if line is not blank
sed '/./=' filename | sed '/./N; s/\n/ /'
```

```
# count lines (emulates "wc -l")
sed -n '$='
```

TEXT CONVERSION AND SUBSTITUTION:

```
# IN UNIX ENVIRONMENT: convert DOS newlines (CR/LF) to Unix format.
sed 's/.$//' # assumes that all lines end with CR/LF
sed 's/^M$//' # in bash/tcsh, press Ctrl-V then Ctrl-M
sed 's/\x0D$//' # works on ssed, gsed 3.02.80 or higher
```

```
# IN UNIX ENVIRONMENT: convert Unix newlines (LF) to DOS format.
sed "s/$/'\`echo -e \\r\'/" # command line under ksh
sed 's/$/'"/`echo \\r`/'" # command line under bash
sed "s/$/'\`echo \\r\'/" # command line under zsh
sed 's/$/\r/' # gsed 3.02.80 or higher
```

```
# IN DOS ENVIRONMENT: convert Unix newlines (LF) to DOS format.
sed "s/$/" # method 1
sed -n p # method 2
```

```
# IN DOS ENVIRONMENT: convert DOS newlines (CR/LF) to Unix format.
# Can only be done with UnxUtils sed, version 4.0.7 or higher. The
# UnxUtils version can be identified by the custom "--text" switch
# which appears when you use the "--help" switch. Otherwise, changing
# DOS newlines to Unix newlines cannot be done with sed in a DOS
# environment. Use "tr" instead.
```

```
sed "s/\r/" infile >outfile # UnxUtils sed v4.0.7 or higher
tr -d \r <infile >outfile # GNU tr version 1.22 or higher
```

```
# delete leading whitespace (spaces, tabs) from front of each line
# aligns all text flush left
sed 's/^[ \t]*//'
```

```
# delete trailing whitespace (spaces, tabs) from end of each line
sed 's/[ \t]*$//'
```

```
# delete BOTH leading and trailing whitespace from each line
sed 's/^[ \t]*//;s/[ \t]*$//'
```

```

# insert 5 blank spaces at beginning of each line (make page offset)
sed 's/^/     /'

# align all text flush right on a 79-column width
sed -e :a -e 's/^\{1,78\}$ / & /;ta' # set at 78 plus 1 space

# center all text in the middle of 79-column width. In method 1,
# spaces at the beginning of the line are significant, and trailing
# spaces are appended at the end of the line. In method 2, spaces at
# the beginning of the line are discarded in centering the line, and
# no trailing spaces appear at the end of lines.
sed -e :a -e 's/^\{1,77\}$ / & /;ta' # method 1
sed -e :a -e 's/^\{1,77\}$ / & /;ta' -e 's/\( *\)\1/\1/' # method 2

# substitute (find and replace) "foo" with "bar" on each line
sed 's/foo/bar/' # replaces only 1st instance in a line
sed 's/foo/bar/4' # replaces only 4th instance in a line
sed 's/foo/bar/g' # replaces ALL instances in a line
sed 's/\(.*\)foo\(.*foo\)\/\1bar\2/' # replace the next-to-last case
sed 's/\(.*\)foo\/\1bar/' # replace only the last case

# substitute "foo" with "bar" ONLY for lines which contain "baz"
sed '/baz/s/foo/bar/g'

# substitute "foo" with "bar" EXCEPT for lines which contain "baz"
sed '/baz/!s/foo/bar/g'

# change "scarlet" or "ruby" or "puce" to "red"
sed 's/scarlet/red/g;s/ruby/red/g;s/puce/red/g' # most sed's
gsed 's/scarlet|ruby|puce/red/g' # GNU sed only

# reverse order of lines (emulates "tac")
# bug/feature in HHsed v1.5 causes blank lines to be deleted
sed '1!G;h;$!d' # method 1
sed -n '1!G;h;$p' # method 2

# reverse each character on the line (emulates "rev")
sed '/\n/!G;s/\(.\)\(.*\n\)\/&\2\1/;/D;s./'

# join pairs of lines side-by-side (like "paste")
sed '$!N;s/\n/ /'

# if a line ends with a backslash, append the next line to it
sed -e :a -e '/\$/N; s/\n\n//; ta'

# if a line begins with an equal sign, append it to the previous line
# and replace the "=" with a single space
sed -e :a -e '$!N;s/\n=/ /;ta' -e 'P;D'

# add commas to numeric strings, changing "1234567" to "1,234,567"
gsed ':a;s/\B[0-9]\{3\}\>/,/;ta' # GNU sed
sed -e :a -e 's/\([0-9]\{3\}\)/\1,2/;ta' # other sed's

# add commas to numbers with decimal points and minus signs (GNU sed)

```

```
gsed -r ':a;s/(\|[\^0-9.]) ([0-9]+) ([0-9]{3})/\1\2,\3/g;ta'
```

add a blank line every 5 lines (after lines 5, 10, 15, 20, etc.)

```
gsed '0~5G' # GNU sed only
sed 'n;n;n;n;G;' # other seds
```

SELECTIVE PRINTING OF CERTAIN LINES:

```
# print first 10 lines of file (emulates behavior of "head")
sed 10q

# print first line of file (emulates "head -1")
sed q

# print the last 10 lines of a file (emulates "tail")
sed -e :a -e '$q;N;11,$D;ba'
```

print the last 2 lines of a file (emulates "tail -2")

```
sed '$!N;$!D'
```

print the last line of a file (emulates "tail -1")

```
sed '$!d' # method 1
sed -n '$p' # method 2
```

print the next-to-the-last line of a file

```
sed -e '${h;d;}' -e x # for 1-line files, print blank line
sed -e '1{$q;}' -e '${h;d;}' -e x # for 1-line files, print the line
sed -e '1{$d;}' -e '${h;d;}' -e x # for 1-line files, print nothing
```

print only lines which match regular expression (emulates "grep")

```
sed -n '/regexp/p' # method 1
sed '/regexp/d' # method 2
```

print only lines which do NOT match regexp (emulates "grep -v")

```
sed -n '/regexp/!p' # method 1, corresponds to above
sed '/regexp/d' # method 2, simpler syntax
```

print the line immediately before a regexp, but not the line
containing the regexp

```
sed -n '/regexp/{g;1!p;};h'
```

print the line immediately after a regexp, but not the line
containing the regexp

```
sed -n '/regexp/{n;p;}'
```

print 1 line of context before and after regexp, with line number
indicating where the regexp occurred (similar to "grep -A1 -B1")

```
sed -n -e '/regexp/{=;x;1!p;g;$!N;p;D;}' -e h
```

grep for AAA and BBB and CCC (in any order)

```
sed '/AAA/!d; /BBB/!d; /CCC/!d'
```

grep for AAA and BBB and CCC (in that order)

```
sed '/AAA.*BBB.*CCC/!d'
```

```

# grep for AAA or BBB or CCC (emulates "egrep")
sed -e '/AAA/b' -e '/BBB/b' -e '/CCC/b' -e d      # most sed's
gsed '/AAA\|BBB\|CCC/!d'                        # GNU sed only

# print paragraph if it contains AAA (blank lines separate paragraphs)
# HHsed v1.5 must insert a 'G;' after 'x;' in the next 3 scripts below
sed -e '/./{H;$!d;} -e 'x;/AAA/!d;'

# print paragraph if it contains AAA and BBB and CCC (in any order)
sed -e '/./{H;$!d;} -e 'x;/AAA/!d;/BBB/!d;/CCC/!d'

# print paragraph if it contains AAA or BBB or CCC
sed -e '/./{H;$!d;} -e 'x;/AAA/b' -e '/BBB/b' -e '/CCC/b' -e d
gsed '/./{H;$!d;};x;/AAA\|BBB\|CCC/b;d'          # GNU sed only

# print only lines of 65 characters or longer
sed -n '/^.\{65\}/p'

# print only lines of less than 65 characters
sed -n '/^.\{65\}/!p'          # method 1, corresponds to above
sed '/^.\{65\}/d'             # method 2, simpler syntax

# print section of file from regular expression to end of file
sed -n '/regexp/, $p'

# print section of file based on line numbers (lines 8-12, inclusive)
sed -n '8,12p'                # method 1
sed '8,12!d'                  # method 2

# print line number 52
sed -n '52p'                  # method 1
sed '52!d'                    # method 2
sed '52q;d'                   # method 3, efficient on large files

# beginning at line 3, print every 7th line
gsed -n '3~7p'                # GNU sed only
sed -n '3,$ {p;n;n;n;n;n;n;} ' # other sed's

# print section of file between two regular expressions (inclusive)
sed -n '/Iowa/,/Montana/p'     # case sensitive

```

SELECTIVE DELETION OF CERTAIN LINES:

```

# print all of file EXCEPT section between 2 regular expressions
sed '/Iowa/,/Montana/d'

# delete duplicate, consecutive lines from a file (emulates "uniq").
# First line in a set of duplicate lines is kept, rest are deleted.
sed '$!N; /\^(.*)\n\1$/!P; D'

# delete duplicate, nonconsecutive lines from a file. Beware not to
# overflow the buffer size of the hold space, or else use GNU sed.
sed -n 'G; s/\n/&&; /\^(.*)\n\1$/d; s/\n//; h; P'

# delete all lines except duplicate lines (emulates "uniq -d").

```

```

sed '$!N; s/^\(.*\)\\n\\1$/\\1/; t; D'

# delete the first 10 lines of a file
sed '1,10d'

# delete the last line of a file
sed '$d'

# delete the last 2 lines of a file
sed 'N;$!P;$!D;$d'

# delete the last 10 lines of a file
sed -e :a -e '$d;N;2,10ba' -e 'P;D'      # method 1
sed -n -e :a -e '1,10!{P;N;D;};N;ba'    # method 2

# delete every 8th line
gsed '0~8d'                             # GNU sed only
sed 'n;n;n;n;n;n;n;d;'                  # other seds

# delete lines matching pattern
sed '/pattern/d'

# delete ALL blank lines from a file (same as "grep '.' ")
sed '/^$/d'                             # method 1
sed '/./!d'                             # method 2

# delete all CONSECUTIVE blank lines from file except the first; also
# deletes all blank lines from top and end of file (emulates "cat -s")
sed '/./,/^$/!d'                        # method 1, allows 0 blanks at top, 1 at EOF
sed '/^$/N;/\\n$/D'                     # method 2, allows 1 blank at top, 0 at EOF

# delete all CONSECUTIVE blank lines from file except the first 2:
sed '/^$/N;/\\n$/N;///D'

# delete all leading blank lines at top of file
sed '/./,$!d'

# delete all trailing blank lines at end of file
sed -e :a -e '/^\\n*${$d;N;ba' -e '}'     # works on all seds
sed -e :a -e '/^\\n*$/N;/\\n$/ba'         # ditto, except for gsed 3.02.*

# delete the last line of each paragraph
sed -n '/^$/{p;h;};/./{x;/./p;}'

```

SPECIAL APPLICATIONS:

```

# remove nroff overstrikes (char, backspace) from man pages. The 'echo'
# command may need an -e switch if you use Unix System V or bash shell.
sed "s/.'echo \\b'//g"                  # double quotes required for Unix environment
sed 's/.'^H//g'                         # in bash/tcsh, press Ctrl-V and then Ctrl-H
sed 's/.'x08//g'                        # hex expression for sed 1.5, GNU sed, ssed

# get Usenet/e-mail message header
sed '/^$/q'                             # deletes everything after first blank line

```

```

# get Usenet/e-mail message body
sed '1,/^$/d'          # deletes everything up to first blank line

# get Subject header, but remove initial "Subject: " portion
sed '/^Subject: *!/d; s///;q'

# get return address header
sed '/^Reply-To:/q; /^From:/h; ./d;q;q'

# parse out the address proper. Pulls out the e-mail address by itself
# from the 1-line return address header (see preceding script)
sed 's/ *(.*)//; s/>.*//; s/.*[[:<]] *//'

# add a leading angle bracket and space to each line (quote a message)
sed 's/^/> //'

# delete leading angle bracket & space from each line (unquote a message)
sed 's/^> //'

# remove most HTML tags (accommodates multiple-line tags)
sed -e :a -e 's/<[^>]*>//g;/</N//ba'

# extract multi-part uuencoded binaries, removing extraneous header
# info, so that only the uuencoded portion remains. Files passed to
# sed must be passed in the proper order. Version 1 can be entered
# from the command line; version 2 can be made into an executable
# Unix shell script. (Modified from a script by Rahul Dhesi.)
sed '/^end/,/^begin/d' file1 file2 ... fileX | uuencode      # vers. 1
sed '/^end/,/^begin/d' "$@" | uuencode                      # vers. 2

# sort paragraphs of file alphabetically. Paragraphs are separated by blank
# lines. GNU sed uses \v for vertical tab, or any unique char will do.
sed '/./{H;d};x;s/\n/{NL}=/g' file | sort | sed '1s/{NL}=//;s/{NL}=/\n/g'
gsed '/./{H;d};x;y/\n/\v/' file | sort | sed '1s/\v//;y/\v/\n/'

# zip up each .TXT file individually, deleting the source file and
# setting the name of each .ZIP file to the basename of the .TXT file
# (under DOS: the "dir /b" switch returns bare filenames in all caps).
echo @echo off >zipup.bat
dir /b *.txt | sed "s/^\(.*\)\.TXT/pkzip -mo \1 \1.TXT/" >>zipup.bat

```

TYPICAL USE:

Sed takes one or more editing commands and applies all of them, in sequence, to each line of input. After all the commands have been applied to the first input line, that line is output and a second input line is taken for processing, and the cycle repeats. The preceding examples assume that input comes from the standard input device (i.e., the console, normally this will be piped input). One or more filenames can be appended to the command line if the input does not come from stdin. Output is sent to stdout (the screen). Thus:

```

cat filename | sed '10q'      # uses piped input
sed '10q' filename           # same effect, avoids a useless "cat"
sed '10q' filename > newfile # redirects output to disk

```

For additional syntax instructions, including the way to apply editing commands from a disk file instead of the command line, consult "sed & awk, 2nd Edition," by Dale Dougherty and Arnold Robbins (O'Reilly, 1997; <http://www.ora.com>), "UNIX Text Processing," by Dale Dougherty and Tim O'Reilly (Hayden Books, 1987) or the tutorials by Mike Arst distributed in U-SEDIT2.ZIP (many sites). To fully exploit the power of sed, one must understand "regular expressions." For this, see "Mastering Regular Expressions" by Jeffrey Friedl (O'Reilly, 1997). The manual ("man") pages on Unix systems may be helpful (try "man sed", "man regexp", or the subsection on regular expressions in "man ed"), but man pages are notoriously difficult. They are not written to teach sed use or regexps to first-time users, but as a reference text for those already acquainted with these tools.

QUOTING SYNTAX:

The preceding examples use single quotes ('...') instead of double quotes ("...") to enclose editing commands, since sed is typically used on a Unix platform. Single quotes prevent the Unix shell from interpreting the dollar sign (\$) and backquotes (`...`), which are expanded by the shell if they are enclosed in double quotes. Users of the "csh" shell and derivatives will also need to quote the exclamation mark (!) with the backslash (i.e., \!) to properly run the examples listed above, even within single quotes. Versions of sed written for DOS invariably require double quotes ("...") instead of single quotes to enclose editing commands.

USE OF '\t' IN SED SCRIPTS: For clarity in documentation, we have used the expression '\t' to indicate a tab character (0x09) in the scripts. However, most versions of sed do not recognize the '\t' abbreviation, so when typing these scripts from the command line, you should press the TAB key instead. '\t' is supported as a regular expression metacharacter in awk, perl, and HHsed, sedmod, and GNU sed v3.02.80.

VERSIONS OF SED:

Versions of sed do differ, and some slight syntax variation is to be expected. In particular, most do not support the use of labels (:name) or branch instructions (b,t) within editing commands, except at the end of those commands. We have used the syntax which will be portable to most users of sed, even though the popular GNU versions of sed allow a more succinct syntax. When the reader sees a fairly long command such as this:

```
sed -e '/AAA/b' -e '/BBB/b' -e '/CCC/b' -e d
```

it is heartening to know that GNU sed will let you reduce it to:

```
sed '/AAA/b;/BBB/b;/CCC/b;d'      # or even
sed '/AAA\|BBB\|CCC/b;d'
```

In addition, remember that while many versions of sed accept a command like "/one/ s/RE1/RE2/", some do NOT allow "/one/! s/RE1/RE2/", which contains space before the 's'. Omit the space when typing the command.

OPTIMIZING FOR SPEED:

If execution speed needs to be increased (due to large input files or slow processors or hard disks), substitution will be executed more quickly if the "find" expression is specified before giving the "s/.../.../" instruction. Thus:

```
sed 's/foo/bar/g' filename      # standard replace command
sed '/foo/ s/foo/bar/g' filename # executes more quickly
sed '/foo/ s//bar/g' filename   # shorthand sed syntax
```

On line selection or deletion in which you only need to output lines from the first part of the file, a "quit" command (q) in the script will drastically reduce processing time for large files. Thus:

```
sed -n '45,50p' filename      # print line nos. 45-50 of a file
sed -n '51q;45,50p' filename  # same, but executes much faster
```

CONTRIBUTIONS:

If you have any additional scripts to contribute or if you find errors in this document, please send e-mail to the compiler. Indicate the version of sed you used, the operating system it was compiled for, and the nature of the problem. To qualify as a one-liner, the command line must be 65 characters or less. Various scripts in this file have been written or contributed by:

```
Al Aab                # founder of "seders" list
Edgar Allen           # various
Yiorgos Adamopoulos  # various
Dale Dougherty       # author of "sed & awk"
Carlos Duarte         # author of "do it with sed"
Eric Pement          # author of this document
Ken Pizzini           # author of GNU sed v3.02
S.G. Ravenhall       # great de-html script
Greg Ubben           # many contributions & much help
```

NAME

select_columns – select named columns from CSV stream

SYNOPSIS

edrc/lib/select_columns -h

select_columns "*field_separator*" "*column_list*"

AVAILABILITY

WA2L/edrc

DESCRIPTION

filter to select named columns that are separated by a field separator from **stdin** and print the selected columns to **stdout**. The first row of the data stream must contain the row header. Columns that do not exist, are printed as empty columns.

OPTIONS

-h usage message.

"*field_separator*"
field separator.

"*column_list*"
separated list of columns to be printed from the CSV stream from **stdin**.

ENVIRONMENT

-

EXIT STATUS

0 no error.

4 usage displayed.

FILES

-

EXAMPLES**1) select certain columns form CSV data**

The following CSV data received via pipe

```
cat<<EOM | select_columns ";" "CNT;ZIP;CITY"
ZIP;CITY;STATE;CNT;COUNTRY
93117;Goleta;CA;USA;United States of America
8222;Beringen;SH;CH;Switzerland
8005;Cape Town;WC;RSA;South Africa
EOM
```

results in the output:

```
CNT;ZIP;CITY;
USA;93117;Goleta;
CH;8222;Beringen;
RSA;8222;Cape Town;
```

2) print selected columns of CSV data as formatted list

The columns CNT, ZIP and CITY of the CSV data are selected using the **select_columns** command and then formatted to a list using the **print_list(3)** command

```
cat<<EOM | select_columns ";" "CNT;ZIP;CITY" | print_list
ZIP;CITY;STATE;CNT;COUNTRY
93117;Goleta;CA;USA;United States of America
8222;Beringen;SH;CH;Switzerland
8005;Cape Town;WC;RSA;South Africa
EOM
```

what will result in the output:

```
CNT  ZIP    CITY
---  -
USA  93117   Goleta
CH   8222    Beringen
RSA  8005    Cape Town
(3)
```

SEE ALSO

edrcintro(1), **csv(3)**, **csvcat(3)**, **print_header(3)**, **print_index(3)**, **print_list(3)**

NOTES

The four commands **print_header(3)**, **print_list(3)**, **select_columns(3)** and **print_index(3)** provide the functionality to efficiently produce ASCII reports having an identical look.

NAME

`server_environment` – print server environment

SYNOPSIS

`edrc/lib/server_environment [-h | -l]`

server_environment

`server_environment [-d | -C | -R][-s servername]`

AVAILABILITY

WA2L/edrc

DESCRIPTION

Return a name for the environment of the server where running the command.

In the configuration file `edrc/etc/server_environment.cfg` it can be defined which server relates to what environment. The **server_environment** command can be used to develop scripts which act specific on different environments without hardcoding hostnames into the scripts.

When the server environment cannot be resolved, **unknown** is returned.

OPTIONS

return the name of the server environment where logged on.

-h usage message.

-d print the description of the server environment.

-C print customer name of the server environment.

-R print the whole info record in a **SERVER_ENVIRONMENT_<FIELD>='Value'** syntax that can be used to set variables in a script.

-l list all configured server environments.

-s *servername*

server to be resolved. For common usage it is not needed to specify the *servername* on the command line. This option can be used to verify configuration file definitions.

ENVIRONMENT

-

EXIT STATUS

- 0** no error.
- 1** information could not be resolved. In this case **unknown** is returned.
- 2** Operating system not supported. See **osid (3)** if you get this error.
- 4** usage printed.
- 6** configuration file **edrc/etc/server_environment.cfg** does not exist.

FILES

- edrc/etc/server_environment.cfg**
configuration file of **server_environment**. This file contains all server environment definitions.
- edrc/var/cache/server_environment/**
resolution cache of the **server_environment** command.
- edrc/var/cache/server_environment/meta**
meta data for the resolution cache. This file is used to check if the cache data is still valid.
- edrc/var/cache/server_environment/data**
this file contains the cache data, the resolved **CUSTOMER**, **NAME** and **DESCRIPTION** settings for the system where **server_environment** has been executed.
- edrc/var/samples/hostlist/**
configuration examples for **hostlist(3)** and **server_environment(3)**.

EXAMPLES

1) script cut out

In this script server environment dependent variable initialization is implemented using the **server_environment** command:

```
#!/bin/sh
:
:
:

case `server_environment` in
    TEST)
```

```

        Max_load=100
        Mail_to=fred.developer@acme.com
        ;;
    PREPRODUCTION)
        Max_load=200
        Mail_to=barney.verifier@acme.com
        ;;
    PRODUCTION)
        Max_load=250
        Mail_to=wilma.production@acme.com
        ;;
    unknown)
        echo "server environment unknown, aborting."
        exit 1
        ;;
esac

:
:
```

2) use of server_environment -R

In this example **server_environment -R** is used to efficiently query the whole information record and to print it.

```

#!/bin/sh
:
:

eval `server_environment -R`

cat <<EOM
Customer:    $SERVER_ENVIRONMENT_CUSTOMER
Environment: $SERVER_ENVIRONMENT_NAME
Description: $SERVER_ENVIRONMENT_DESCRIPTION
EOM

:
:
```

SEE ALSO

edrcintro(1), **server_environment.cfg(4)**, **hostlist(3)**, **edrc/var/samples/hostlist/**

NOTES

The **server_environment** command uses the **hostname(1)** command internally to resolve the hostname.

BUGS

-

AUTHOR

server_environment was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

COPYRIGHT

Copyright © 2008 Christian Walther

NAME

server_environment.cfg – configuration file for server_environment

SYNOPSIS

edrc/etc/server_environment.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration for the **server_environment** command.

FILEFORMAT

The fileformat is a list of definitions that have the format

NAME:Description:server_regex:Customer:

Rows starting with a # are considered as comments.

The definitions are processed in the sequence as listed in the configuration file. If a regular expression (*server_regex*) matches, the remaining definitions are not processed any more.

OPTIONS

NAME Name of the environment. It has been proven as a good practice to use all capital letters for the environment name, but this is not imperative. Characters other then "a-zA-Z0-9_.,=%+-" are replaced by an underscore (_) in the output.

Description
Free-form text to describe environment.

server_regex
Regular expression for server selection. If a servername passes the regular expression the related information (*NAME*, *Description*, *Customer*) is returned.

To test if a regular expression is working as expected, the command:

server_environment -s hostname

or

echo hostname | egrep "server_regex"

can be used.

Be aware, that the output of **hostname(1)** is checked against the *server_regex* when **server_environment** is called without the **-s** options.

Customer Name of the customer. This has to be a single word that can be used as file- and directory name, too. Characters other than "a-zA-Z0-9_.,=%+-" are replaced by an underscore (**_**) in the output.

EXAMPLES

1) normal example configuration file

This configuration file defines the six environments **PRODUCTION**, **PREPRODUCTION**, **TEST**, **MAINTENANCE**, **BACKUP_BE** and **BACKUP_BB** and is used in normal operations:

```
#
# etc/server_environment.cfg - cfg for server_environment in NORMAL OPE
# etc/server_environment.cfg.NORMAL_OPERATION - cfg for server_envirom
#
# [00] 24.07.2004 CWa Initial Version
#

#
# Format:
#   <NAME>:<Description>:<server_regex>:<Customer>:
#
PRODUCTION:GDC Bern, new PRODUCTION Environment:dcdbsi(2[0-1]|3[0-3]):A

PREPRODUCTION:GDC Balsberg, new PREPRODUCTION Environment:dcdbsi(50|6[1
TEST:GDC Balsberg, new TEST Environment:dcdbsi(6[3-4]|7[3-4]):ACME:
MAINTENANCE:GDC Balsberg, new MAINTENANCE Environment:dcdbsi(60|70):ACM

BACKUP_BE:GDC Bern, BACKUP Environment:dcdbsi(05|10|4[0-1]):ACME:
BACKUP_BB:GDC Balsberg, BACKUP Environment:dcdbsi(5[1-2]|8[0-1]):ACME:
```

2) disaster case configuration file

This configuration file defines the five environments **PRODUCTION**, **TEST**, **MAINTENANCE**, **BACKUP_BE** and **BACKUP_BB** and is used in a disaster case situation. This file replaces the file in example 1) during a disaster recovery where the **PREPRODUCTION** servers are used to host the **PRODUCTION** services.

Therefore the **PREPRODUCTION** definition disappeared and the **PRODUCTION** definition now contains the *server_regex* of the former **PREPRODUCTION**.

```
#
# etc/server_environment.cfg - cfg for server_environment in a DISASTER
# etc/server_environment.cfg.DISASTER_CASE - cfg for server_environment
```

```
#
# [00] 24.07.2004 CWa Initial Version
#

#
# Format:
#   <NAME>:<Description>:<server_regex>:<Customer>:
#
PRODUCTION:GDC Balsberg, DISASTER CENTER Environment:dcdbsi(50|6[1-2]|7

TEST:GDC Balsberg, new TEST Environment:dcdbsi(6[3-4]|7[3-4]):ACME:
MAINTENANCE:GDC Balsberg, new MAINTENANCE Environment:dcdbsi(60|70):ACM

BACKUP_BE:GDC Bern, BACKUP Environment:dcdbsi(05|10|4[0-1]):ACME:
BACKUP_BB:GDC Balsberg, BACKUP Environment:dcdbsi(5[1-2]|8[0-1]):ACME:
```

Due to the fact that **server_environment** reads the config file **edrc/etc/server_environment.cfg** it makes sense to create a symbolic link to the active configuration file if a disaster recovery situation has to be covered:

```
[ /opt/edrc/etc ]
[ root@dcdbsi30 ][*edrc*/bash]: ls -al server_environment.cfg*

lrwxrwxrwx    Jan 28 23:01 server_environment.cfg -> server_environment
-rw-r--r--    Feb 28 16:59 server_environment.cfg.DISASTER_CASE
-rw-r--r--    Apr  2 13:32 server_environment.cfg.NORMAL_OPERATION
```

See also **hostlist(3)** and **hostlist.cfg(4)** for more information about the special usage in a disaster case.

SEE ALSO

NAME

sh, jsh – the standard command interpreter

SYNOPSIS

sh [**-acefhikmnprstuvx**] [*arg*] ...

jsh [**-acefhikmnprstuvx**] [*arg*] ...

DESCRIPTION

Sh is a command programming language that executes commands read from a terminal or a file. See the *invocation* section for the meaning of arguments to the shell.

Commands

A *simple-command* is a sequence of non blank *words* separated by blanks (a blank is a **tab** or a **space**). The first word specifies the name of the command to be executed. Except as specified below the remaining words are passed as arguments to the invoked command. The command name is passed as argument 0 (see *exec(2)*). The *value* of a simple-command is its exit status if it terminates normally or 200+*status* if it terminates abnormally (see *signal(2)* for a list of status values).

A *pipeline* is a sequence of one or more *commands* separated by **|**. The standard output of each command but the last is connected by a *pipe(2)* to the standard input of the next command. Each command is run as a separate process; the shell waits for the last command to terminate. The *value* of a pipeline is the exit status of its last command.

A *list* is a sequence of one or more *pipelines* separated by **;**, **&**, **&&** or **||** and optionally terminated by **;** or **&**. **;** and **&** have equal precedence which is lower than that of **&&** and **||**, **&&** and **||** also have equal precedence. A semicolon causes sequential execution; an ampersand causes the preceding *pipeline* to be executed without waiting for it to finish. The symbol **&&** (**||**) causes the *list* following to be executed only if the preceding *pipeline* returns a zero (non zero) value. Newlines may appear in a *list*, instead of semicolons, to delimit commands.

A **#** at the beginning of a word starts a comment and causes the rest of the line to be ignored.

A *command* is either a simple-command or one of the following. The value returned by a command is that of the last simple-command executed in the command.

for name [in word ...] do list done

Each time a **for** command is executed *name* is set to the next word in the **for** word list. If **in word** ... is omitted then **in "\$@"** is assumed. Execution ends when there are no more words in the list.

case word in [pattern [pattern] ...) list ;;] ... esac

A **case** command executes the *list* associated with the first pattern that matches *word*. The form of the patterns is the same as that used for file name generation.

if list then [elif list then list] ... [else list] fi

The *list* following **if** is executed and if it returns zero the *list* following **then** is executed. Otherwise, the *list* following **elif** is executed and if its value is zero the *list* following **then** is executed. Failing that the **else list** is executed.

while list [do list] done

A **while** command repeatedly executes the **while list** and if its value is zero executes the **do list**; otherwise the loop terminates. The value returned by a **while** command is that of the last executed command in the **do list**. **until** may be used in place of **while** to negate the loop termination test.

(*list*) Execute *list* in a subshell.

{ *list*; } *list* is simply executed.

name() { *list*; }

Defines the shell function *name*. Each time when *name* is recognized as a command, *list* is executed, with the positional parameters *\$1*, *\$2*... set to the arguments of the command. After the function returns, the previous positional parameters are restored.

The following words are only recognized as the first word of a command and when not quoted.

if then else elif fi case in esac for while until do done { }

Command substitution

The standard output from a command enclosed in a pair of grave accents (``) may be used as part or all of a word; trailing newlines are removed.

Parameter substitution

The character **\$** is used to introduce substitutable parameters. Positional parameters may be assigned values by **set**. Variables may be set by writing

name=value [*name=value*] ...

\${parameter}

A *parameter* is a sequence of letters, digits or underscores (a *name*), a digit, or any of the characters * @ # ? - \$!. The value, if any, of the parameter is substituted. The braces are required only when *parameter* is followed by a letter, digit, or underscore that is not to be interpreted as part of its name. If *parameter* is a digit then it is a positional parameter. If *parameter* is * or @ then all the positional parameters, starting with **\$1**, are substituted separated by spaces. **\$0** is set from argument zero when the shell is invoked.

\${parameter:-word}

If *parameter* is set and not empty then substitute its value; otherwise substitute *word*.

\${parameter:=word}

If *parameter* is not set and not empty then set it to *word*; the value of the parameter is then substituted. Positional parameters may not be assigned to in this way.

\${parameter:?word}

If *parameter* is set and not empty then substitute its value; otherwise, print *word* and exit from the shell. If *word* is omitted then a standard message is printed.

\${parameter:+word}

If *parameter* is set and not empty then substitute *word*; otherwise substitute nothing.

If the **:** is omitted, the substitutions are only executed if the *parameter* is set, even if it is empty.

In the above *word* is not evaluated unless it is to be used as the substituted string. (So that, for example, `echo ${d-`pwd`}` will only execute `pwd` if `d` is unset.)

The following *parameters* are automatically set by the shell.

| | |
|-----------|--|
| # | The number of positional parameters in decimal. |
| - | Options supplied to the shell on invocation or by set . |
| ? | The value returned by the last executed command in decimal. |
| \$ | The process number of this shell. |
| ! | The process number of the last background command invoked. |

The following *parameters* are used by the shell:

CDPATH

The search path for the `cd` command (see above).

HOME The default argument (home directory) for the `cd` command.

OPTARG

The value of the last option argument processed by the `getopts` special command.

OPTIND

The index of the last option processed by the `getopts` special command.

PATH The search path for commands (see **execution**).

MAIL If this variable is set to the name of a mail file then the shell informs the user of the arrival of mail in the specified file.

MAILCHECK

If this variable is set, it is interpreted as a value in seconds to wait between checks for new mail. The default is 600 (10 minutes). If the value is zero, mail is checked before each prompt.

MAILPATH

A colon-separated list of files that are checked for new mail. MAIL is ignored if this variable is set.

PS1 Primary prompt string, by default '\$ '.

PS2 Secondary prompt string, by default '> '.

IFS Internal field separators, normally **space**, **tab**, and **newline**.

LANG, LC_ALL

See *locale(7)*.

LC_CTYPE

Affects the mapping of bytes to characters for file name generation, for the interpretation of '\', and for handling \$IFS.

SHACCT

If this variable is set in the initial environment passed to the shell and points to a file writable by the user, accounting statistics are written to it.

TIMEOUT

The shell exists when prompting for input if no command is entered for more than the given value in seconds. A value of zero means no timeout and is the default.

Blank interpretation

After parameter and command substitution, any results of substitution are scanned for internal field separator characters (those found in **\$IFS**) and split into distinct arguments where such characters are found. Explicit null arguments ("" or ``) are retained. Implicit null arguments (those resulting from *parameters* that have no values) are removed.

File name generation

Following substitution, each command word is scanned for the characters *, ? and [. If one of these characters appears then the word is regarded as a pattern. The word is replaced with alphabetically sorted file names that match the pattern. If no file name is found that matches the pattern then the word is left unchanged. The character . at the start of a file name or immediately following a /, and the character /, must be matched explicitly.

* Matches any string, including the null string.

? Matches any single character.

[...] Matches any one of the characters enclosed. A pair of characters separated by – matches any character lexically between the pair.

[!...] Matches any character except the enclosed ones.

Quoting

The following characters have a special meaning to the shell and cause termination of a word unless quoted.

;**&** (**)** | **^** **<** **>** **newline** **space** **tab**

A character may be *quoted* by preceding it with a \. **newline** is ignored. All characters enclosed between a pair of quote marks (`''), except a single quote, are quoted. Inside double quotes (" ") parameter and command substitution occurs and \ quotes the characters \ ` " and \$.

"\$*" is equivalent to "\$1 \$2 ..." whereas

"\$@" is equivalent to "\$1" "\$2"

Prompting

When used interactively, the shell prompts with the value of \$PS1 before reading a command. If at any time a newline is typed and further input is needed to complete a command then the secondary prompt (\$PS2) is issued.

Input and output

Before a command is executed its input and output may be redirected using a special notation interpreted by the shell. The following may appear anywhere in a simple-command or may precede or follow a *command* and are not passed on to the invoked command. Substitution occurs before *word* or *digit* is used.

< *word* Use file *word* as standard input (file descriptor 0).

> *word* Use file *word* as standard output (file descriptor 1). If the file does not exist then it is created; otherwise it is truncated to zero length.

>> *word*

Use file *word* as standard output. If the file exists then output is appended (by seeking to the end); otherwise the file is created.

<<[-] *word*

The shell input is read up to a line the same as *word*, or end of file. The resulting document becomes the standard input. If any character of *word* is quoted then no interpretation is placed upon the characters of the document; otherwise, parameter and command substitution occurs, **\newline** is ignored, and \ is used to quote the characters \\$ ` and the first character of *word*. The optional - causes leading tabulator character to be stripped from the resulting document; *word* may then also be prefixed by a tabulator.

< & *digit*

The standard input is duplicated from file descriptor *digit*; see *dup(2)*. Similarly for the standard output using > .

< & - The standard input is closed. Similarly for the standard output using > .

If one of the above is preceded by a digit then the file descriptor created is that specified by the digit (instead of the default 0 or 1). For example,

```
... 2>&1
```

creates file descriptor 2 to be a duplicate of file descriptor 1.

If a command is followed by & then the default standard input for the command is the empty file (/dev/null), unless job control is enabled. Otherwise, the environment for the execution of a command contains the file descriptors of the invoking shell as modified by input output specifications.

Environment

The environment is a list of name-value pairs that is passed to an executed program in the same way as a normal argument list; see *exec(2)* and *environ(5)*. The shell interacts with the environment in several ways. On invocation, the shell scans the environment and creates a *parameter* for each name found, giving it the corresponding value. Executed commands inherit the same environment. If the user modifies the values of these *parameters* or creates new ones, none of these affects the environment unless the *export* command is used to bind the shell's *parameter* to the environment. The environment seen by any executed command is thus composed of any unmodified name-value pairs originally inherited by the shell, plus any modifications or additions, all of which must be noted in *export* commands.

The environment for any *simple-command* may be augmented by prefixing it with one or more assignments to *parameters*. Thus these two lines are equivalent

```
TERM=450 cmd args
(export TERM; TERM=450; cmd args)
```

If the *-k* flag is set, *all* keyword arguments are placed in the environment, even if they occur after the command name. The following prints 'a=b c' and 'c':

```
echo a=b c
set -k
echo a=b c
```

Signals

The INTERRUPT and QUIT signals for an invoked command are ignored if the command is followed by & (unless job control is enabled); otherwise signals have the values inherited by the shell from its parent. (But see also *trap*.)

Execution

Each time a command is executed the above substitutions are carried out. The shell then first looks if a function with the command name was defined; if so, it is chosen for execution. Otherwise, except for the ‘special commands’ listed below a new process is created and an attempt is made to execute the command via an *exec*(2).

The shell parameter *\$PATH* defines the search path for the directory containing the command. Each alternative directory name is separated by a colon (:). The default path is ‘*/usr/5bin:/bin:/usr/bin:*’. If the command name contains a / then the search path is not used. Otherwise, each directory in the path is searched for an executable file. If the file has execute permission but is not an *a.out* file, it is assumed to be a file containing shell commands. A subshell (i.e., a separate process) is spawned to read it. A parenthesized command is also executed in a subshell.

Special commands

The following commands are executed in the shell process itself:

: No effect; the command does nothing.
.file Read and execute commands from *file* and return. The search path *\$PATH* is used to find the directory containing *file*.

break [*n*]

Exit from the enclosing *for* or *while* loop, if any. If *n* is specified then break *n* levels.

continue [*n*]

Resume the next iteration of the enclosing *for* or *while* loop. If *n* is specified then resume at the *n*-th enclosing loop.

cd [*arg*]

Change the current directory to *arg*. The shell parameter *\$HOME* is the default *arg*. If no directory *arg* is found and the *\$CDPATH* parameter contains a list of directories separated by colons, each of these directories is used as a prefix to *arg* in the given order, and the current directory is set to the first one that is found.

If there has still no suitable directory been found, an interactive shell will try to fix spelling errors and propose an alternative directory name:

```
$ cd /usr/lb
cd /usr/lib? y
ok
```

If the answer is ‘y’ or anything other than ‘n’, the shell will set the current directory to the one proposed.

echo [*arg ...*]

Each *arg* is printed to standard output; afterwards, a newline is printed. The following escapes sequences are recognized in *arg*:

\b Prints a backspace character.
\c Causes the command to return immediately. Any following characters are ignored, and the terminating newline is not printed.
\f Prints a formfeed character.
\n Prints a newline character.
\r Prints a carriage-return character.
\t Prints a tabulator character.
\v Prints a vertical tabulator character.
**** Prints a backslash character.
\0nnn Prints the character (byte) with octal value *nnn*.

If */usr/ucb* precedes */usr/5bin* or */usr/bin* in the current setting of the *\$PATH* variable and the first argument is **-n**, the terminating newline is not printed, and no escape sequences are recognized. If the *\$SYSV3* variable is set in the initial environment passed to the shell, the **-n** argument is also interpreted, but escape sequences are processed as usual.

eval [*arg* ...]

The arguments are read as input to the shell and the resulting command(s) executed.

exec [*arg* ...]

The command specified by the arguments is executed in place of this shell without creating a new process. Input output arguments may appear and if no other arguments are given cause the shell input output to be modified.

exit [*n*] Causes the shell to exit with the exit status specified by *n*. If *n* is omitted then the exit status is that of the last command executed. (An end of file will also exit from the shell.)

export [*name* ...]

The given names are marked for automatic export to the *environment* of subsequently-executed commands. If no arguments are given then a list of exportable names is printed.

getopts **optstring** **variable** [*arg* ...]

Retrieves options and option-arguments from *arg* (or the positional parameters) similar to *getopt*(3). *optstring* is a list of characters (bytes); each character represents an option letter. A character followed by **:** indicates that the option has an argument. Calling *getopts* repeatedly causes one option to be retrieved per call. The index of the current option is stored in the variable *OPTIND*; it is initialized to 1 when the shell starts. The option-argument, if any, is stored in the *OPTARG* variable. The option character is stored in the *variable* named. When the end of the options is reached, *getopts* returns with a non-zero value. A missing argument or an illegal option also causes a non-zero return value, and an error message is printed to standard error.

hash [*name* ...]

The shell maintains a hash table of the locations of external commands. If *name* arguments are given, each one is looked up and is inserted into the table if it is found. Otherwise, a list of the commands currently in the table is printed.

newgrp [*arg* ...]

Equivalent to 'exec newgrp *arg* ...'.

pwd Prints the name of the current directory.

read [**-r**] *name* ...

One line is read from the standard input; successive words of the input are assigned to the variables *name* in order, with leftover words to the last variable. The return code is 0 unless the end-of-file is encountered. Normally, backslashes in the line read escape the following character; this is inhibited if the **-r** option is given.

readonly [*name* ...]

The given names are marked readonly and the values of these names may not be changed by subsequent assignment. If no arguments are given then a list of all readonly names is printed.

return [*n*]

Return from a shell function to the execution level above. With the argument *n*, the special variable *\$?* is set to the given value.

set [**--aefhknptuvx**] [*arg* ...]

- No effect; useful if the first *arg* begins with **-**.
- a** Export any variables that are modified or created from now on.
- e** If non interactive then exit immediately if a command fails.
- f** File name generation is disabled.
- h** When a function is defined, look up all external commands it contains as described for the *hash* special command. Normally, these commands are looked up when they are executed.
- k** All keyword arguments are placed in the environment for a command, not just those that precede the command name.
- m** Enables job control (see below).
- n** Read commands but do not execute them.

- p** Makes the shell privileged. A privileged shell does not execute the system and user profiles; if a non-privileged shell (the default) has an effective user or group id different to its real user or group id or if it has an effective user or group id below 100, it resets its effective user or group id, respectively, to the corresponding real id at startup.
- t** Exit after reading and executing one command.
- u** Treat unset variables as an error when substituting.
- v** Print shell input lines as they are read.
- x** Print commands and their arguments as they are executed.
- Turn off the **-x** and **-v** options.

These flags can also be used upon invocation of the shell. The current set of flags may be found in **\$-**.

If **+** is used instead of **-**, the given flags are disabled.

Remaining arguments are positional parameters and are assigned, in order, to **\$1**, **\$2**, etc. If no arguments are given then the values of all names are printed.

shift [*n*]

The positional parameters from **\$2...** are renamed **\$1...** The *n* argument causes a shift by the given number, i.e. **\$n+1** is renamed to **\$1** and so forth.

times Print the accumulated user and system times for processes run from the shell.

test [*expr*]

test evaluates the expression *expr*, and if its value is true then returns zero exit status; otherwise, a non zero exit status is returned. *test* returns a non zero exit if there are no arguments.

The following primitives are used to construct *expr*:

- r** file true if the file exists and is readable.
- w** file true if the file exists and is writable.
- u** file true if the file exists and has the setuid bit set.
- g** file true if the file exists and has the setgid bit set.
- k** file true if the file exists and has the sticky bit set.
- f** file true if the file exists and is a regular file (or any file other than a directory if */usr/ucb* occurs early in the current **\$PATH** parameter).
- d** file true if the file exists and is a directory.
- h** file true if the file exists and is a symbolic link.
- L** file true if the file exists and is a symbolic link.
- p** file true if the file exists and is a named pipe.
- b** file true if the file exists and is a block device.
- c** file true if the file exists and is a character device.
- s** file true if the file exists and has a size greater than zero.
- t** [*fildev*] true if the open file whose file descriptor number is *fildev* (1 by default) is associated with a terminal device.
- z** *s1* true if the length of string *s1* is zero.
- n** *s1* true if the length of the string *s1* is nonzero.
- s1* = *s2* true if the strings *s1* and *s2* are equal.
- s1* != *s2* true if the strings *s1* and *s2* are not equal.
- s1* true if *s1* is not the null string.
- n1* **-eq** *n2* true if the integers *n1* and *n2* are algebraically equal. Any of the comparisons **-ne**, **-gt**, **-ge**, **-lt**, or **-le** may be used in place of **-eq**.

These primaries may be combined with the following operators:

- !** unary negation operator
- a** binary *and* operator
- o** binary *or* operator
- (*expr*) parentheses for grouping.

-a has higher precedence than **-o**. Notice that all the operators and flags are separate arguments

to *test*. Notice also that parentheses are meaningful as command separators and must be escaped.

trap [*arg*] [*n*|*name*] ...

Arg is a command to be read and executed when the shell receives signal(s) *n*. (Note that *arg* is scanned once when the trap is set and once when the trap is taken.) Trap commands are executed in order of signal number. If *arg* is absent then all trap(s) *n* are reset to their original values. If *arg* is the null string then this signal is ignored by the shell and by invoked commands. If *n* is 0 then the command *arg* is executed on exit from the shell, otherwise upon receipt of signal *n* as numbered in *signal*(2). *Trap* with no arguments prints a list of commands associated with each signal number. A symbolic *name* can be used instead of the *n* argument; it is formed by the signal name in the 'C' language minus the SIG prefix, e. g. TERM for SIGTERM. EXIT is the same as a '0' argument.

type *name* ...

For each *name*, prints if it would be executed as a shell function, as a special command, or as an external command. In the last case, the full path name to the command is also printed.

ulimit [-[HS][a|cd|fm|nstuv]]

ulimit [-[HS][c|d|f|m|n|s|t|u|v]] [*limit*]

Handles resource limits for the shell and processes created by it, as described in *getrlimit*(2). Without a *limit* argument, the current settings are printed; otherwise, a new limit is set. The following options are accepted:

- H Sets a hard limit. Only the super-user may raise a hard limit.
- S Sets a soft limit. A soft limit must not exceed the hard limit.
If neither -H or -S is given, the soft limit is printed, or both limits are set, respectively.
- a Chooses all limits described.
- c The maximum size of a core dump in 512-byte blocks.
- d The maximum size of the data segment in kbytes.
- f The maximum size of a file in 512-byte blocks. This is the default if no limit is explicitly selected.
- l The maximum size of locked memory in kbytes.
- m The maximum resident set size in kbytes.
- n The maximum number of open file descriptors.
- s The maximum size of the stack segment in kbytes.
- t The maximum processor time in seconds.
- u The maximum number of child processes.
- v The maximum address space size in kbytes.

umask [-S] [*nnn*]

The user file creation mask is set to the octal value *nnn* (see *umask*(2)). Symbolic modes as described in *chmod*(1) are also accepted. If *nnn* is omitted, the current value of the mask is printed. With the -S option, the current mask is printed as a symbolic string.

unset *variable* ...

Unsets each *variable* named.

wait [*n*]

Wait for the specified process and report its termination status. If *n* is not given then all currently active child processes are waited for. The return code from this command is that of the process waited for. If *n* does not refer to a child process of the shell, *wait* returns immediately with code 0.

Invocation

If the first character of argument zero is -, commands are read from */etc/profile* and *\$HOME/.profile*, if the respective file exists. Commands are then read as described below. The following flags are interpreted by the shell when it is invoked.

- c *string* If the -c flag is present then commands are read from *string*.
- s If the -s flag is present or if no arguments remain then commands are read from the standard input. Shell output is written to file descriptor 2.

- i** If the **-i** flag is present or if the shell input and output are attached to a terminal (as told by *isatty(3)*) then this shell is *interactive*. In this case the terminate signal SIGTERM (see *signal(2)*) is ignored (so that 'kill 0' does not kill an interactive shell) and the interrupt signal SIGINT is caught and ignored (so that **wait** is interruptable). In all cases SIGQUIT is ignored by the shell.

The remaining flags and arguments are described under the **set** command.

Job Control

When an interactive shell is invoked as **jsh**, job control is enabled. Job control allows to stop and resume processes, and to switch between foreground and background jobs. A job consists of the commands of a single pipeline. Each job is placed in a separate process group; a login shell and all jobs created by it form a session. Interrupt, quit, and other terminal control characters only affect the current foreground process group. The foreground job can be stopped pressing the suspend key, typically **^Z**; any job can be stopped by sending the STOP signal to it. Jobs are identified by *job ids* of the following form:

% or **% %** or **% +**

The current job.

% - The job that was previously the current job.

?string The only job whose name contains *string*.

%number

The job with the given number.

number

The job with process group id *number*.

string The only job for which *string* is a prefix of its name.

The following built-in commands are additionally available with job control:

bg [*jobid* ...]

Places each *jobid* in the background. The default job id is the current job.

fg [*jobid* ...]

Sequentially selects each *jobid* as the foreground job. The default job id is the current job.

jobs **[-p|-l]** [*jobid* ...] **[-x command [arguments ...]]**

Prints information about each *jobid*, or executes *command*.

-l Includes the process group id and the starting directory.

-p Includes the process group id.

-x command [arguments ...]

Executes *command* with *arguments*; each *argument* that forms a job id is replaced by the process group id of the respective job. It is an error if a given job does not exist.

kill **[[**-s** *signal* | **-signal**] *jobid* ... | **-l** [*status*]**

A special version of the *kill(1)* command that recognizes job ids in its arguments.

stop *jobid* ...

Stops the given jobs (i. e. sends a STOP signal to them).

suspend

Stops the shell itself. This is not allowed if the shell is a session leader.

wait [*jobid*]

The *wait* command (see above) recognizes job ids in its arguments.

FILES

/etc/profile

\$HOME/.profile

/tmp/sh*

/dev/null

SEE ALSO

env(1), exec(2), signal(2)

DIAGNOSTICS

Errors detected by the shell, such as syntax errors or fatal errors in special commands, cause the shell to return a non zero exit status. If the shell is being used non interactively then execution of the shell file is abandoned. Otherwise, the shell returns the exit status of the last command executed (see also *exit*).

NOTES

For historical reasons, ^ is a synonym for | as pipeline separator. Its use in new applications is discouraged.

If a command other than a simple-command (i. e. ‘for ...’, ‘case ...’ etc.) is redirected, it is executed in a sub-shell. If variable assignments must be visible in the parent shell after the input has been redirected, the *exec* special command can be used:

```
exec 5<&0 <input
while read line
do
    ...
    variable=value
    ...
done
exec <&5 5<&-
```

If parameters that have been inherited from the initial environment are modified, they must be explicitly exported to make the change visible to external commands, as described under ‘Environment’ above.

The IFS parameter is applied to any unquoted word. Thus

```
IFS=X
echoXfoo
```

executes the ‘echo’ command with the argument ‘foo’.

The command ‘set —’ without further arguments is a no-op. The *shift* special command can be used to delete all positional parameters.

There is only one namespace for both functions and parameters. A function definition will delete a parameter with the same name and vice-versa.

Parameter assignments that precede a special command affect the shell itself; parameter assignments that precede the call of a function are ignored.

NAME

shell – start the interactive shell

SYNOPSIS

edrc -> shell

edrc/bin/shell [**-h** | *host* | *user@host*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

There are two variants of the **shell** command. The first one is the **shell** command started within **edrc(1m)**, the second one is the **edrc/bin/shell** command line command.

EDRC command: edrc -> shell

start a shell in **edrc**. You should use this command to exit to the operating system rather than to do an other **telnet**, **rlogin** or **ssh** to the system.

The prompt is:

```
[ /opt/edrc/scripts/ACME-sat/file:SystemFiles ]
[ root@acme001 ][*edrc*/bash]:
```

When you use the **shell** command, the current working directory is the location in the menu you are currently in. Furthermore the shell settings are tuned and customized to the WA2L/edrc environment and all **\$EDRC_** environment variables are exported to the shell.

Call the **edrcenv(1)** command to display the official WA2L/edrc environment variables.

On UNIX the Korn-Shell (ksh), on Linux the Bourne-Again-Shell (bash) will be started. To see all additional commands and aliases you have available in the shell type **usage** within the started shell.

Command line command: edrc/bin/shell [*user@*] *host*]

the **shell** command provides a slightly reduced environment as the **shell** command started within **edrc**, but you can profit from the environment and all commands available in WA2L/edrc without the need to start **edrc(1m)**.

The prompt is:

```
[ /data/ACME/apps ]
[ root@acme001 ][*eshell*/bash]:
```

The differences to the **shell** start in **edrc** is, that the environment variables **\$EDRC_SESSION**, **\$EDRC_SCRIPTS_BASEDIR**, **\$EDRC_ENV**, **\$EDRC_CONFIGFILE**, **\$EDRC_RECOVERYTIME**, **\$EDRC_NLS_DATE_FORMAT**, **\$EDRC_NLS_LANG**, **\$NLS_DATE_FORMAT** and **\$NLS_LANG**

are not set.

Call the **edrcenv**(1) command to display the official WA2L/edrc environment variables.

When connecting to *host* the **shell** is started directly on the remote system if WA2L/edrc is installed. If WA2L/edrc is not installed a connection to the remote system without the **shell** enhancements is established.

COMMANDS

The following commands are only available when the **shell** is started (~built in commands / aliases). Those commands are intended to ease up the work when working interactively in the shell. Therefore this commands cannot be used within scripts. The commands described here are also listed in the **usage**(1) output, when **usage** is called within the **shell**.

handle working variables:

```

a [ something ]
    set working variable $a with the current working directory or something

b [ something ]
    set working variable $b with the current working directory or something

c [ something ]
    set working variable $c with the current working directory or something

d [ something ]
    set working variable $d with the current working directory or something

e [ something ]
    set working variable $e with the current working directory or something

f [ something ]
    set working variable $f with the current working directory or something

g [ something ]
    set working variable $g with the current working directory or something

abc
    print $a $b $c $d $e $f $g $p $TODAY

abc (a|b|c|d|e|f|g)
    load $a $b $c $d $e $f $g from other edrc/bin/shell or edrc/bin/eshell session

abcd
    print $a $b $c $d $e $f $g $p $TODAY

abcd (a|b|c|d|e|f|g)
    load $a $b $c $d $e $f $g from other edrc/bin/shell or edrc/bin/eshell session

```

\$PATH manipulation/querying:

```

addcwd    append current working directory to $PATH (export PATH=$PATH:'pwd')

cwdadd    add current working directory to $PATH (export PATH='pwd':$PATH)

ap        add ADDITIONAL_SHELL_PATH as defined in shell.cfg to $PATH (export
PATH=$PATH:$ADDITIONAL_SHELL_PATH)

path      print $PATH

```

change directories:

ret jump back to previous working directory

debugging:

debug toggle script debug **\$DEBUG** between *True* and *False*

edrcdebug [*command...*]
toggle **\$EDRC_DEBUG**[*_COMMAND*] between *True* and *False*. It is possible to supply a space delimited list of commands.

session variables:

erase [*backspace*]
set tty erase character

term [*terminal*]
set/query **\$TERM**

termsize set **\$COLUMNS** and **\$LINES** based on the current terminal size.

tz [*timezone*]
set/query **\$TZ**

sid *ORACLE_SID*
set **\$ORACLE_SID** to *ORACLE_SID*

shd show **\$DISPLAY**

std *host* set **\$DISPLAY** to *host:0*

command history:

hist print shell history

r *hist_number* | *cmd*
re-execute *cmd* from history

histlist print a table of history files produced by **shell** when started outside of **shell** for the current user.

help and manual pages:

h [*cmd*] alias for **usage**(1)

help [*cmd*]
alias for **usage**(1)

man [*manpage*]
alias for **edrcman**(1)

manpath print **\$MANPATH**

list files and directories:

lc [*options*]
ls -aCF

lg [*options*]
ls -lagF

ll [*options*]
ls -laF

edit and view files:

vi [*options*] [*file ..*]
start **vi**(1) with prior initialization of the **\$COLUMNS** and **\$LINES** environment variables.

vim [*options*] [*file* ..]

start **vim**(1) with prior initialization of the **\$COLUMNS** and **\$LINES** environment variables.

view [*options*] [*file* ..]

start **view**(1) with prior initialization of the **\$COLUMNS** and **\$LINES** environment variables.

lgrep *pattern file*...

grep logfiles (having timestamps). The **lgrep** command is an alias to the **loggrep**(1) command.

manvi [*manpage*]

edit a manual page distributed in WA2L/edrc with **vi**(1). When editing a man page, first a backup copy in **.\$TODAY/** is created in the related **edrc/man/** subdirectory.

If no *manpage* is specified, the **edrcintro** man page is loaded into the editor.

The manual pages of the Perl modules bundled with WA2L/edrc cannot be edited with this command.

special commands:

exit exit the shell

ini *app* init environment for application *app*

lscolors toggle **ls** colors between *True* (= list files in color) and *False* (= do not list files in color).

grepcolors toggle **(e)grep** colors between *True* (= colorize results) and *False* (= do not colorize results).

pid select processes from the process command part of the process list. This is a convenience command to the **pslist**(1) command.

OPTIONS

Only command line variant.

-h usage message.

host system to connect to using SSH.

user@host using user on system to connect to.

ENVIRONMENT

For an explanation of all environment variables listed with **edrcenv**(1) see section **ENVIRONMENT** in **edrc(1m)**.

EXIT STATUS

| | |
|----------|---|
| 0 | no error. |
| 1 | shell is already started. |
| 2 | cannot find posix shell. |
| 4 | usage listed (only command line variant). |
| 5 | cannot connect to <i>host</i> . |

FILES

etc/kshrc main configuration file of **shell**. Do not edit this file, it might be patched on updates.

etc/shell.cfg
user configuration file of **shell**. This file can be adjusted.

NAME

shell.cfg – user configuration file for shell

SYNOPSIS

edrc/etc/shell.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **shell**, **eshell** and **edrc shell** commands.

This file can be edited (the **etc/kshrc** file shouldn't.).

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS

LOG Log output dir of **edrc**. If you specify a relative path name the path is relative to the root of the EDRC installation.

Example: LOG=var/log

Default: LOG=var/log

BACKUP_DIR

Backup directory of scriptextract. Here all script files are backedup, ahead of installing the new ones.

This setting is used when the **edbkp** command is used.

Example: BACKUP_DIR=var/backup

Default: BACKUP_DIR=var/backup

EDRC_DIST_USER

This is the user used to connect to remote hosts with **remote_shell**.

Example: EDRC_DIST_USER=\${EDRC_DIST_USER:=edrc}

Default: EDRC_DIST_USER

USER_DROPBOX_DIR

User's Dropbox directory.

This setting is used when the **cdbx** [*subdir*] command is used.

Example: USER_DROPBOX_DIR=~fred/var/dropbox

Default: USER_DROPBOX_DIR=

LC_TIME

Language specific settings.

Example: LC_TIME=C

Default: LC_TIME=

ADDITIONAL_SHELL_PATH

Additional \$PATH settings. This setting are applied to \$PATH when you invoke the **ap** command in the **shell**.

Example: ADDITIONAL_SHELL_PATH=~EDS/sh:~tools-eds/bin:~tools-eds/lib:/usr/local/bin:/usr/ccs/bin

Default: ADDITIONAL_SHELL_PATH=

SHELL_BANNER

Banner that is displayed when shell is executed outside of edrc.

Hint: When using commands to generate the banner, use the construct: "[\${EDRC_ENV}] || command" to speed up the shell execution when called within edrc.

Example: SHELL_BANNER="[\${EDRC_ENV}] || whereami 2>/dev/null"

Default: SHELL_BANNER=

README_DISPLAY

Display the **README** file (to **stderr**) that is present in a directory when changing the working directory to it using **cd**.

Example: README_DISPLAY=False

Default: README_DISPLAY=True

README_COLOR

Color (**RED**, **GREEN**, **BLUE**, **MAGENTA**, **CYAN**, **WHITE** or **YELLOW**) of the displayed **README** file.

Example: README_COLOR=RED

Default: README_COLOR=YELLOW

TPL_CFG

Additional config file for the **tpl**(1) command to add additional template locations beside the configurations in **etc/tpl.cfg** and **\$EDRC_SCRIPTS_BASEDIR/tpl.cfg**.

Example: TPL_CFG=/etc/system_templates.cfg

Default: TPL_CFG=\$HOME/etc/tpl.cfg

EDRC_SW_PATH

Path to WA2L/edrc software.

This path is resolved when invoking **cdsw** [*subdir*].

Example:

```
. 'aproot'/etc/edrcrevision.cfg
EDRC_SW_PATH="
'aproot'/var/sw/edrc-$VERSION.$PATCHLEVEL
/dat/sw/Generic/apps/edrc-patch
/dat/sw/apps/edrc-patch
/dat/sw/apps/edrc-$VERSION.$PATCHLEVEL
/software/tools/edrc-$VERSION.$PATCHLEVEL
/export/dat/sw/edrc-$VERSION.$PATCHLEVEL
/export/dat/sw
'aproot'/var/sw
"
```

Default: EDRC_SW_PATH=var/sw

SEE ALSO

edrcintro(1), **edrc**(1m), **eshell**(1), **shell**(1)

NAME

shellinaboxd – publish command line shell through AJAX interface

SYNOPSIS

shellinaboxd

```
[ -b | --background[=pidfile] ] [ --cert-fd=fd ] [ --css=filename ] [ --cgi[=portrange] ] [ -d |
--debug ] [ -f | --static-file=url:file ] [ -g | --group=gid ] [ -h | --help ] [ --linkify=[none|normal|aggressive] ] [ --localhost-only ] [ --no-beep ] [ -n | --numeric ] [ --pidfile=pidfile ] [ -p |
--port=port ] [ -s | --service=service ] [ --disable-ssl-menu ] [ -q | --quiet ] [ -u | --user=uid ]
[ --user-css=styles ] [ -v | --verbose ] [ --version ]
```

DESCRIPTION

The **shellinaboxd** daemon implements a webserver that listens on the specified *port*. The web server publishes one or more *services* that will be displayed in a VT100 emulator implemented as an AJAX web application. By default, the port is 4200 and the default service URL is *http://localhost:4200/*.

If no particular *service* was requested, the server launches **/bin/login** querying the user for their username and password. It then starts the user's default login shell.

Any modern JavaScript and CSS enabled browser will be able to access the published *service* without requiring additional plugins.

OPTIONS

The following command line parameters control the operation of the daemon:

-b | --background[=pidfile]

Launch **shellinaboxd** as a background daemon process. Optionally, write the process id to *pidfile*.

--css=filename

Sometimes, it is not necessary to replace the entire style sheet using the **--static-file** option. But instead a small incremental change should be made to the visual appearance of the terminal. The **--css** option provides a means to append additional style rules to the end of the default **styles.css** sheet. More than one **--css** option can be given on the same command line.

--cgi[=portrange]

Instead of running **shellinaboxd** as a permanent process, it can be demand-loaded as a CGI web server extension. When doing so, it will spawn a server that lives for the duration of the user's session. If an optional *portrange* of the form **MINPORT-MAXPORT** has been provided, the server limits itself to these port numbers. They should be configured to pass through the firewall.

The **--cgi** option is mutually exclusive with the **--background**, **--pidfile** and **--port** options.

In order to be useful as a CGI script, the **shellinaboxd** binary probably will have to be made **setuid-root**. This is currently a discouraged configuration. Use with care.

-d | --debug

Enables debugging mode, resulting in lots of log messages on *stderr*. This option is mutually exclusive with **--quiet** and **--verbose**.

-f | --static-file=url:file

The daemon serves various built-in resources from URLs underneath the *service* mount points. One or more **--static-file** options allow for overriding these resources with customized externally provided *files*. The *url* can either be an absolute or a relative path. In the former case, it overrides exactly one built-in resource for one specific *service*, whereas in the latter case it overrides resources for each defined *service*.

The following resources are available for customization:

| | |
|--------------------|---|
| beep.wav | audio sample that gets played whenever the terminal BEL is sounded. |
| favicon.ico | favicon image file that is displayed in the browser's navigation bar. |

ShellInABox.js JavaScript file implementing the AJAX terminal emulator.

styles.css CSS style file that controls the visual appearance of the terminal.

print-styles.css CSS style file that controls the visual appearance of printed pages when using the VT100 transparent printing feature.

It is not recommended to override the root HTML page for a particular *service*. Instead, move the service to an anonymous URL and serve a *static-file* that references the *service* in an `<iframe>`.

Instead of a *file*, it is possible to provide the name of a directory. This turns **shellinaboxd** into a simple web server that publishes all of the files in that particular directory. This option can be helpful when publishing a more complex root HTML page.

-g | --group=gid

When started as **root**, the server drops most privileges at start up. Unless overridden by the **--group** option, it switches to **nogroup**.

When already running as an unprivileged user, group changes are not possible.

If running with SSL/TLS support enabled, the certificates must be accessible to the unprivileged user and/or group that the daemon runs as.

-h | --help

Display a brief usage message showing the valid command line parameters.

--linkify=[none|normal|aggressive]

the daemon attempts to recognize URLs in the terminal output and makes them clickable. This is not necessarily a fool-proof process and both false negatives and false positives are possible. By default, only URLs starting with a well known protocol of **http://**, **https://**, **ftp://**, or **mailto:** are recognized. In **aggressive** mode, anything that looks like a hostname, URL or e-mail address is recognized, even if not preceded by a protocol.

--localhost-only

Normally, **shellinaboxd** listens on all available network interfaces. When operating behind a reverse-proxy that is not always desirable. This command line option tells the daemon to only listen on the loopback interface.

--no-beep

not only are audible signals undesired in some working environments, but browser support for media playback is often buggy, too. Setting this option suppresses all audio playback and enables the visual bell by default.

-n | --numeric

When running in **--verbose** mode, the daemon prints an *Apache*-style log file to *stderr*. By default, host names of peers get resolved before logging them. As DNS look-ups can be expensive, it is possible to request logging of numeric IP addresses, instead.

--pidfile=pidfile

The **shellinaboxd** daemon can be configured to store its process identifier in *pidfile*.

-p | --port=port

Unless overridden by this option, the web server listens on port 4200 for incoming HTTP and HTTPS requests.

shellinaboxd can distinguish between SSL/TLS requests and unencrypted requests. It also knows how to negotiate **Server Name Identification**, allowing the use of a single port for all types of requests even when virtual hosting.

-s | --service=service

One or more services can be registered on different URL paths:

SERVICE := <url-path> ':' *APPLICATION*

There is a pre-defined *application*, 'LOGIN', which causes the daemon to invoke **/bin/login** requesting the user's name and password, and starting his login shell. This is the default option for the **root** user, if no **--service** was defined. Starting **/bin/login** requires **root** privileges.

There is another pre-defined *application*, 'SSH'. Instead of invoking **/bin/login**, it calls **ssh**. This is the default option for unprivileged users, if no **--service** was defined. This operation is available to both privileged and regular users. If the optional *host* parameter is omitted, **shellinaboxd** connects to **localhost**.

Alternatively, an *application* can be specified by providing a *user* description, a working directory, and a command line:

```
APPLICATION := 'LOGIN' | 'SSH' [ ':' <host> ] | USER ':' CWD ':' CMD
```

```
USER := <username> ':' <groupname>
```

The working directory can either be given as an absolute path, or it can be the user's home directory:

```
CWD := 'HOME' : <dir>
```

The command that **shellinaboxd** executes can either be specified as the 'SHELL' keyword, denoting the user's default login shell, or an arbitrary command line:

```
CMD := 'SHELL' : <cmdline>
```

The <cmdline> supports expansion of variables of the form \${VAR}. Supported variables are:

\${columns} number of columns.

\${gid} numeric group id.

\${group} group name.

\${home} home directory.

\${lines} number of rows.

\${peer} name of remote peer.

\${uid} numeric user id.

\${url} the URL that serves the terminal session.

\${user} user name.

Other than the default environment variables of **\$TERM**, **\$COLUMNS** and **\$LINES**, services can have environment variables passed to them, by preceding the <cmdline> with space separated variable assignments of the form **KEY=VALUE**.

The <cmdline> supports single and double quotes, as well as backslashes for escaping characters in the familiar fashion.

Please note that when invoking **shellinaboxd** from a command line shell, additional quoting might be required to prevent the shell from expanding the variables prior to passing them to the daemon.

If no explicit **--service** has been requested, **shellinaboxd** defaults to attaching the default service to the root directory of the web server. For **root**, this is **/bin/login**, and for unprivileged users, this is **ssh localhost**. This is equivalent to saying **--service=/:LOGIN**, or **--service=/:SSH**, respectively.

--disable-ssl-menu

If the user should not be able to switch between HTTP and HTTPS modes, this choice can be removed from the context menu. The user can still make this choice by directly going to the appropriate URL.

-q | --quiet

Suppresses all messages to *stderr*. This option is mutually exclusive with **--debug** and **--verbose**.

-u | --user=uid

If started as **root**, the server drops privileges by changing to **nobody**, unless the *uid* has been overridden by this option.

For more details, refer to the description of the **--group** option.

--user-css=styles

The visual appearance of the terminal emulator can be customized through user-selectable style sheets. These style sheets will show up as options in the right-click context menu of the terminal emulator.

Styles sheet make up either independently selectable on/off options, or multiple style sheets can be grouped together. When forming a group, only one member of the group can be active at any given time. This is used for multiple-choice options.

Multiple independent groups are separated by semicolons:

```
STYLES := GROUP { ',' GROUP }*
```

The members of a group are separated by commas:

```
GROUP := OPTION { ',' OPTION }*
```

Groups with exactly one member are used for options that can be independently turned on and off.

Options include a human readable label that will be shown in the context menu, followed by the name of the CSS file. They also must include an indicator showing whether the option should initially be turned on or turned off. Within a group, exactly one option should be turned on:

```
OPTION := <label> ':' [ '-' | '+' ] <css-file>
```

The user's selection of options will be persisted in a cookie. This means, the default settings of options as passed on the command line only takes effect the very first time the user visits the terminal emulator in his browser. On all subsequent visits, the user's preferences take precedence.

-v | --verbose

Enables logging of *Apache*-style log file to *stderr*. This option is mutually exclusive with **--debug** and **--quiet**.

--version

Prints the version number of the binary and exits.

CONFIGURATION

There are no configuration files or permanent settings for **shellinaboxd**.

A small number of run-time configuration options are available from a context menu that becomes available when clicking the right mouse button. These options get persisted in a browser cookie.

Many sites already have a web server running and would like to integrate **shellinaboxd** into their existing site. This is most commonly done by means of a reverse-proxy entry for the main web server. For *Apache* this would require adding an option such as:

```
<Location /shell>
  ProxyPass http://localhost:4200/
  Order allow,deny
  Allow from all
</Location>
```

If you are using a different web server, refer to that server's documentation on how to configure reverse

proxy operations.

When using a reverse proxy, the **--localhost-only** option would normally be enabled as well. In addition, the **--disable-ssl** might also be considered depending on the exact configuration details of the reverse proxy.

EXAMPLES

shellinaboxd

Attaches a web-enabled login shell to *https://localhost:4200/*. If the user connected without SSL, the session will automatically be promoted. Unless SSL certificates can be found in the current directory, the daemon will automatically generate suitable self-signed certificates. If the command was invoked by a non-**root** user, the daemon uses **ssh** instead of **/bin/login** for the session.

shellinaboxd -t

Attaches a web-enabled login shell to *http://localhost:4200/* with SSL/TLS support disabled.

shellinaboxd -t -f beep.wav:/dev/null

Runs all services with the audible-bell permanently disabled.

shellinaboxd -s /:SSH:example.org

The terminal connects to a **ssh** session on *example.org*.

shellinaboxd -t -s /:AUTH:HOME:/bin/bash

Interactively request the user's name and password prior to launching a Bourne shell. This command can be run by unprivileged users. But if doing so, it only allows this particular user to log in.

shellinaboxd -c certificates -u shellinabox -g shellinabox

If the **certificates** directory exists and is writable by the **shellinabox** user and group, self-signed SSL certificates will be generated in this directory. This might require creating an appropriately named user first. Running this command as **root** allows any user on the system to log in at *http://localhost:4200/*. Sessions will automatically be promoted to SSL/TLS.

shellinaboxd -t -s /:LOGIN -s /who:nobody:nogroup:/w

In addition to the login shell at *http://localhost:4200*, show a list of currently logged in users when accessing *http://localhost:4200/who*. This command must be run as **root** in order to be able to change to **nobody:nogroup** as requested by the service description.

shellinaboxd -t -s '/:root:root:/wy60 -c /bin/login'

Instead of the standard **ANSI/VT100** terminal, publish a **Wyse 60™** terminal. Again, this command should be run as **root**.

shellinaboxd --css white-on-black.css

Loads the **white-on-black.css** style sheet from the current directory and appends it to the built-in **styles.css** sheet. This causes the terminal to always render white text on a black background.

shellinaboxd --user-css Normal:+black-on-white.css,Reverse:-white-on-black.css

Allow the user to select whether they want text to be rendered normally or in reverse video. This command line option adds a new entry to the right-click context menu.

DIAGNOSTICS

The daemon returns a non-zero exit code in case of failure. With the exception of a small number of common error cases that are handled explicitly, most errors result in printing a *"Check failed"* message. This does not typically indicate a bug in the program but is instead its normal way of reporting errors.

Common failure conditions are reusing a port that is already in use, lack of sufficient privileges to run a service, failure to find SSL/TLS certificates, and failure to write newly generated certificates to the certification directory.

SEE ALSO

chmod(1), last(1), login(1), sh(1), shells(5), openssl(1SSL), w(1), wy60(1), xterm(1).

SECURITY

The daemon uses privilege separation techniques to allow it to drop privileges early. It is aware of `setuid` flags and restricts some operations when launched as a `setuid` application.

Despite these safety features, a bug could conceivably lead to a determined attacker gaining elevated privileges. It is therefore strongly discouraged to set the `setuid` flag on the binary.

The expected deployment would be from a system `rc` script launched by `/sbin/init`. For extra security, the `--group` and `--user` options should be used to change to a dedicated user.

BUGS

Due to browser limitations, some features might not be available to users of all browsers.

Konqueror does not allow for reliable interception of `CTRL` keys. If you press a key together with the `CTRL` modifier, it continues performing the browser's predefined behavior for this particular key combination. In most cases, it also fails to report the correct key to the terminal emulator. As a work-around, pressing both the `CTRL` and the `WINDOWS` key sometimes works.

Some browsers, most notably IE on Windows, disallow interception of `ALT` keys and always interpret these keys as menu accelerators. As a work-around, many UNIX applications allow pressing `ESC`, instead of `ALT`.

When using non-US keyboard layouts, some browser do not allow for reliably determining shifted `ALT` keys. Please report these cases if they turn out to be a problem, as work-arounds might be possible.

Access to the native clipboard is typically not possible. Instead, an internal clipboard accessible from the right-button context menu is used for all but IE.

Some browsers restrict the number of concurrent connections to a server. This restricts how many AJAX terminals can be opened simultaneously. If this becomes a problem, users can typically reconfigure their browsers to raise the limit.

There have been reports of the VLC plugin on Linux/x86_64 crashing Firefox when the browser page gets reloaded. Setting the `--no-beep` option eliminates all references to VLC and thus appears to work around this crash.

NAME

shlib – print shared library path environment

SYNOPSIS

edrc/lib/shlib [-n]

AVAILABILITY

WA2L/edrc

DESCRIPTION

print the environment variables needed by the dynamic linker **ld**(1) to locate the shared libraries. If a script need to set this environment variables (**\$LD_LIBRARY_PATH** and **\$SHLIB_PATH**), use

```
eval `shlib`
```

instead of setting them by your own. This ensures, that all scripts will continue to run, even when the directory structure in WA2L/edrc changes.

OPTIONS

-n no **export** *VARIABLE* ... output.

ENVIRONMENT**\$LD_LIBRARY_PATH**

path of additional shared libraries loaded by the **ld** dynamic linker. This variable will be expanded with the shared library locations for a certain Os-Id distributed with WA2L/edrc when executing the **shlib** command.

\$SHLIB_PATH

this variable is expanded as the **\$LD_LIBRARY_PATH** is done. This variable has basically the same function as the **\$LD_LIBRARY_PATH** and is mostly active on HP-UX systems.

EXIT STATUS

0 always

FILES

[**edrc/lib/<Os-Id>/<GLIBC>/libs/**]**edrc/lib/<Os-Id>/libs/**

location of operating system dependent shared libraries. This directory is appended to the **\$LD_LIBRARY_PATH** and the **\$SHLIB_PATH** environment variables when executing **shlib**.

/usr/ccs/lib:/lib:/usr/lib:/usr/openwin/lib:/usr/local/lib
standard library path for Solaris.

\$LD_LIBRARY_PATH:/etc:/lib:/lib/tls:/usr/lib:/usr/X11R6/lib:/usr/local/lib
standard library path for Linux.

\$LD_LIBRARY_PATH \$SHLIB_PATH
standard library path for HP-UX.

\$LD_LIBRARY_PATH:/lib:/usr/lib:/usr/local/lib \$SHLIB_PATH:/lib:/usr/lib:/usr/local/lib
standard library path for other operating systems.

NAME

sortc – sort data using the "C" locale

SYNOPSIS

edrc/lib/sortc [*sort-options*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

sorting data in the "C" locale.

Internally the **sort**(1) command is called with the environment variable **LC_ALL=C** set.

OPTIONS

sort-options

all supported options of the **sort**(1) command.

ENVIRONMENT

-

EXIT STATUS

x exit code of the **sort**(1) command.

FILES

NAME

sortv – portable version sort (sort -V)

SYNOPSIS

edrc/lib/sortv [*sort-options*] < *data*

AVAILABILITY

WA2L/edrc

DESCRIPTION

Provide a version sort functionality as provided by the **sort -V** command to operating systems, where **sort(1)** lacks this functionality.

On operating systems providing the **sort -V** functionality, the **sort -V** command is used internally.

OPTIONS

sort-options

all supported options of the **sort(1)** command.

ENVIRONMENT

see **sort(1)**.

EXIT STATUS

x exit code of the **sort(1)** command.

NAME

sparse – filter to identify sparse files

SYNOPSIS

edrc/lib/sparse [**-h**]

sparse [**-v**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

filter to identify sparse files.

The file list received thru **stdin** is searched for sparse files and the file names of all identified sparse files, or all non-sparse file names (**-v**), are printed to **stdout**. This enables to use the output directly for further processing thru a pipe for instance.

OPTIONS

-h print usage message.

-v print all non-sparse files. This is the inverse output, as if no option is specified.

ENVIRONMENT

-

EXIT STATUS

0 no error.

1 could not stat all files in provided file list.

4 usage message printed.

FILES

-

EXAMPLES**1) Find sparse files in the current directory**

```
find . -print | sparse
```

2) Copy all sparse files

```
find . -print | sparse | cpio -pdvm --sparse /destination
```

3) Copy all non-sparse files

```
find . -print | sparse -v | cpio -pdvm /destination
```

NAME

splitvt - run two shells in a split window

SYNOPSIS

splitvt [**options**] [**shell**]

OPTIONS

-upper command

Runs 'command' in the upper window

-lower command

Runs 'command' in the lower window

-s numlines

Sets 'numlines' to the number of lines in the top window. This number will be modified if the screen isn't big enough to handle the full size.

-t title Sets an xterm title bar to 'title'

-login Runs the programs under each window as though they were login shells. This is useful to have csh source it's .login file, bash source .profile, etc.

-nologin

Overrides any "set login on" statement in the startup file.

-rcfile file

Loads 'file' as the startup file instead of ~/.splitvtrc.

-norc Suppresses loading your ~/.splitvtrc

-v Print out the version number of splitvt

DESCRIPTION

This program splits the screen into two windows, one above the other, and runs a shell in each one. The default shell is taken from the SHELL environment variable, or /bin/csh if SHELL isn't in the environment, but another shell can be specified on the command line.

The top window is the default current window, but you can change to the other by pressing ^W. Pressing ^V will quote the next character to the current shell. Pressing ^O will put splitvt into command mode.

These special characters (command mode, switch window, and quote next character) can be modified from within the .splitvtrc file.

When in command mode, splitvt will read one non-numeric character, perform the requested command, and then revert to normal operations. Numeric characters are interpreted as a parameter for the specified command. The currently supported commands are:

'h' Print a help window for the escape commands

'-' Shrink the current window

'+' Expand the current window

'c' Select a block of text in the current window

'p' Paste the selected text to the current window

'k' Kill the current window (hangup signal)

'x' Lock the screen, after prompting for password

'r' Repaint the screen (clearing screen garbage)

'q' Quickly quit splitvt, killing the running shells

More functions may be added in the future.

If the -s command line option is used, the upper window will be bound to the user defined number of lines even if the screen is resized. Otherwise, the screen will be split into two equal parts based on the new size of the screen.

The environment variable SPLITVT is set in the shells forked by splitvt. In the shell running in the upper window, this variable is set to the value "upper", while the shell running in the lower window has this variable set to the value "lower". This is useful in shell scripts to provide different behavior depending on which window the script is running in. An example of this is shown in the file "menu" in the examples directory in the splitvt distribution.

When splitvt starts up, it looks in your home directory for a file named *.splitvtrc*. You can set a number of parameters from within this file, including all of the special characters, the default number of lines in the upper window, whether or not to run the commands as login shells, and even default commands to run in each window.

Here is an example of a *.splitvtrc* file:

```
# This is an example .splitvtrc file.
set command_char      ^O
set quote_char        ^V
set switch_char        ^W
set upper_lines        12
run -upper             /bin/sh
run -lower             top
set login              on
# This next line would override the above run statements
#run /bin/tcsh
```

If programs like vi are doing strange things to the window while in splitvt, you probably need to set the LINES environment variable to a correct value, or set the terminal's window sizing correctly. This should be done automatically, but may need to be corrected.

If you are running under an xterm window, the title bar will probably be updated to show the version of splitvt that you are running. Under a true xterm window, you can also switch which half of the window you are typing into by clicking the mouse in the half of the window in which you want to type. You can also drag and drop the separator bar by pressing down on the mouse button over the separator bar, holding it down, moving the mouse to where you want the bar to end up, and then releasing the button.

splitvt will attempt to erase the current utmp entry, and replace it with entries for the two windows. This allows you to use programs such as 'talk' within the splitvt windows. If you do not have write permission to the /etc/utmp file, you will not be able to modify the utmp entries.

splitvt can be made set-uid root. splitvt will reset its user id to that of the person running it, just before it exec()'s the shell under the window. The splitvt process remains with root permissions, and will change ownership of the pseudo terminals to that of the person running splitvt, and then reset it to root when the window is closed.

SPLITVT IS NOT GUARANTEED TO BE A SAFE SET-UID PROGRAM!

I have done all I know to keep splitvt a safely usable set-uid program, but I do not know everything, and am not responsible for any security weaknesses splitvt might possess.

BUGS

When used with a certain public domain version of ksh, you have to manually kill -9 on the shell processes after you quit splitvt. This has to do with a bug in that version of ksh (Version 06/03/86a and possibly others).

If splitvt is compiled with xterm support, when run under an xterm, the cut and paste feature is semi-disabled. The title bar may also be reset to the string "xterm" after splitvt quits. See the comments at the top of splitvt.c for how to disable xterm support.

Ansi colors are not repainted on screen refresh.

CAVEATS

There may be conflicts between splitvt's characters and other programs. You can either change splitvt's default characters with command line options, or you can type Ctrl-V (the quote character) within splitvt, and the next character typed will be sent to the current window, no matter what it is.

splitvt can only be used by terminals using vt100 emulation, due to the use of specific vt100 escape codes. (vt300, xterm, Linux console, etc, emulation also works)

When running in an xterm, if you press the escape key, you will have to type another character in order for the escape to be seen by the running program.

Sam Lantinga slouken@cs.ucdavis.edu

NAME

sqlite – command-line access program for SQLite databases

SYNOPSIS

edrc/bin/sqlite [**-help** | **-version**]

sqlite [**-init** *filename*] [**-echo**] [**-[no]header**] [**-bail**] [**-interactive**] [**-batch**] [**-column**] [**-csv**] [**-html**] [**-line**] [**-list**] [**-separator** 'x'] [**-nullvalue** 'text'] [*FILENAME* [*SQL*]]

AVAILABILITY

WA2L/edrc

DESCRIPTION

SQLite is a software library that implements a self-contained, serverless, zero-configuration, transactional SQL database engine.

SQLite is the most widely deployed SQL database engine in the world. It is used in countless desktop computer applications as well as consumer electronic devices including cellphones, PDAs, and MP3 players. The source code for SQLite is in the public domain.

The SQLite library includes a simple command-line utility named **sqlite3** that allows the user to manually enter and execute SQL commands against an SQLite database.

In the WA2L/edrc package the command is provided under the name **sqlite**. Therefore whenever the command **sqlite3** is referenced in the HTML documentation, replace it with **sqlite**.

This man page provides a brief introduction to the options of **sqlite** and provides the link to the HTML documentation.

OPTIONS

-help usage message.

-echo print commands before execution.

-[no]header turn headers on or off.

-bail stop after hitting an error.

-interactive force interactive I/O.

-batch force batch I/O.

-column set output mode to '*column*' .

-csv set output mode to '*csv*' .

-html set output mode to '*HTML*' .

-init *filename*
 read/process commands from the *filename*.

-line set output mode to '*line*' .

-list set output mode to '*list*' .

-separator '*x*'
 set output field separator (*()*).

-nullvalue '*text*'
 set text string for NULL values.

-version show SQLite version.

FILENAME
 database file name.

SQL SQL statements.

ENVIRONMENT

See HTML SQLite documentation in <https://sqlite.org/cli.html>.

EXIT STATUS

See HTML SQLite documentation in <https://sqlite.org/cli.html>.

FILES

See HTML SQLite documentation in <https://sqlite.org/docs.html>.

lib/\$OSID/includes/sqlite3.h
 include file.

lib/\$OSID/includes/sqlite3ext.h
include file.

EXAMPLES

See HTML SQLite documentation in <https://sqlite.org/cli.html>.

SEE ALSO

[edrcintro\(1\)](#), [thttpd\(3\)](#), <http://www.sqlite.org>, <https://sqlite.org/cli.html>, <https://sqlite.org/docs.html>, <https://sqlite.org/lang.html>, <https://www.sqlitetutorial.net/>

NOTES

Parts of this manual page were extracted from the **sqlite3** HTML documentation distributed with the SQLite version 3.6.3, written by "The SQLite Development Team" led by D. Richard Hipp, Dan Kennedy and Shane Harrelson.

BUGS

-

AUTHOR

sqlite was developed by D. Richard Hipp, Dan Kennedy and Shane Harrelson and integrated into WA2L/edrc by Christian Walther. Send suggestions and bug reports related to the integration to wa2l@users.sourceforge.net.

NAME

ssh-exec – execute command provided thru stdin using ssh on remote host

SYNOPSIS

edrc/bin/ssh-exec [**-h**]

ssh-exec [**-b**] **-u** *user@hostname* < *commands*

ssh-exec [**-b**] **-u** *user* **-t** *hostname* < *commands*

ssh-exec **-p** [**-e** | **-l** *localuser*] **-u** *user@hostname*

ssh-exec **-p** [**-e** | **-l** *localuser*] **-u** *user* **-t** *hostname*

ssh-exec [**-s** | **-v**][**-n**][**-b**][**-e** | **-l** *localuser*] **-u** *user@hostname* < *commands*

ssh-exec [**-s** | **-v**][**-n**][**-b**][**-e** | **-l** *localuser*] **-u** *user* **-t** *hostname* < *commands*

AVAILABILITY

WA2L/edrc

DESCRIPTION

execute *commands*, a sequence of commands or a whole script provided thru **stdin** to **ssh-exec** on a remote system using the **SSH** protocol.

Prior to the remote command invocation it is checked if the remote target system with *hostname* is up and if it is possible to connect using the provided *user* to the remote target system.

In addition to the commands it is supported to submit answers to specific outputs (when it is not possible to do it using simple input redirection) or an **except(3)** script without the need to write extra "wrapper" scripts.

[COMMANDS] Execute commands:

Simple command invocation on a target system:

```
ssh-exec -u user@target <<EOM
ps -ef | grep oracle
EOM
```

or

```
ssh-exec -u user@target <<EOM
[COMMANDS]
ps -ef | grep oracle
EOM
```

The **[COMMANDS]** section keyword is optional as long as it is the first section provided to **ssh-exec**.

Command invocation with input redirection of needed command inputs:

```
ssh-exec -u user@target <<EOM

restore-data <<EOI
/dat/backup/acme-001/2020-01-10/etc/hosts
/etc/hosts
EOI

EOM
```

[ANSWERS] Providing answers to a tty command:

Remote control an interactive command that reads the input from a **tty** and not from **stdin**:

```
ssh-exec -u user@target <<EOM

[COMMANDS]
set-license-key

[ANSWERS]
;Input new license key;;VcB542RSXtMzM\r;
;Repeat new license key;;VcB542RSXtMzM\r;

EOM
```

Behind the scenes the provided answers in the **[ANSWERS]** section are translated automatically into an ad-hoc **expect** script, as:

```
expect "Input new license key:"
send -- "VcB542RSXtMzM\r"

expect "Repeat new license key:"
send -- "VcB542RSXtMzM\r"

expect eof
```

that is used to remote control the command.

This helps to efficiently handle the most cases of remote command control where the needed **expect** definition would be a **expect ... -> send -- ...** sequence.

The **[ANSWERS]** section has the format:

```
:Input prompt:Answer:
```

where the first character is treated as separator between the *Input prompt* and the *Answer* fields.

Therefore, if the *Input prompt* or the *Answer* contains the field separator character (the colon : in this example) the specification

```
;Input prompt;Answer;
```

is identical to the specification above.

[EXPECT] Providing an expect script to a tty command:

Remote control an interactive command that reads the input from a **tty** and not from **stdin**.

The **expect** script has to be provided only if the automatically generated script using the **[ANSWERS]** section is not sufficient to the needs to control a command.

```
ssh-exec -u user@target <<EOM

[COMMANDS]
set-license-key

[EXPECT]
expect "Input new license key:"
send -- "VcB542RSXtMZM\r"

expect "Repeat new license key:"
send -- "VcB542RSXtMZM\r"

expect eof

EOM
```

OPTIONS

- h** usage message.
- p** only probe connection to target *hostname* with *user* without reading commands from **stdin**.
- e** use **EDRC_USER** as defined in **etc/ssh-exec.cfg** (default=**edrc**) as local user.

When **-e** is used or the **EDRC_USER** (default=**edrc**) is used in the **-l localuser** option, the private keys as defined in **var/connection/security/edrc/OpenSSH/default/default/id_dsa** and **var/connection/security/edrc/OpenSSH/default/default/id_rsa** are used to connect to the remote *hostname*.

Prerequisite to a working connection is that the contents of the files **var/connection/security/edrc/OpenSSH/default/default/id_dsa.pub** and **var/connection/security/edrc/OpenSSH/default/default/id_rsa.pub** are appended to the **~user/.ssh/authorized_keys** file on the target *hostname*.

To efficiently add the public keys to **authorized_keys** files on hosts where the WA2L/edrc package is installed, use the **ssh-keyadd(1m)** command.

- s** output (to **stderr**) of commands and exit without executing any commands on *hostname*.
- v** verbose output (to **stderr**) of commands to be sent to target *hostname*.

- n** do not probe connection before executing the provided *commands*.
- b** eliminate the output of a banner of a remote system (when not providing a [ANSWERS] section).
- l *localuser***
use the local user *localuser* to initiate the connection. Default local user is **root**.

When using this option the private **SSH** keys of the specified *localuser* (as defined in *~localuser/.ssh/id_dsa* and *~localuser/.ssh/id_rsa* files) on the local system are used to connect to the target *hostname*.

See **-e** option description for additional information.
- u *user*** remote user to connect on the target system.
- t *hostname***
target system *hostname* to execute the *commands*.
- u *user@hostname***
remote *user* to connect on the target system *hostname*.

commands commands to be executed on the target *hostname*.

Commands can be read from file using the input redirection:

```
ssh-exec options < commands
```

providing the file contents thru the pipe:

```
cat commands | ssh-exec options
```

or the 'in here' mechanism in scripts without the creation of an extra file:

```
ssh-exec options <<EOM
command_1
command_2
command_n
EOM
```

ENVIRONMENT

-

EXIT STATUS

- 0** no error.
- 1** remote system is not up.

- 2** cannot connect to *hostname* with user *user*.
- 4** usage printed.
- 5** the execution has been aborted using *Ctrl+C*.
- 6** the configuration file **ssh-exec.cfg** does not exist.
- 7** errors in [ANSWERS] section. If you receive this error, use the **-v** to see more details.
- 8** command was started with the **-s** option.
- 11** temporary directory could not be claimed or created in **/tmp**. Check the system temporary directory **/tmp** if you get this error, it is an indicator of system intrusion.

FILES

etc/ssh-exec.cfg

configuration file of **ssh-exec**, see **ssh-exec.cfg(4)** for more information.

var/log/ssh-exec.log

default logfile of **ssh-exec**.

EXAMPLES

-

SEE ALSO

edrcintro(1), **edrcsetup(1m)**, **filedist(1)**, **hostlist(3)**, **input(3)**, **input_targets(3)**, **rcmd(1)**, **remote_shell(3)**, **remote_copy(3)**, **resolve_targetlist(3)**, **ssh-exec.cfg(4)**, **ssh-keygen(1)**, **ssh-keyadd(1m)**, **syspoll(1)**

NOTES

If you need to invoke ad-hoc commands on all systems in your environment (needs WA2L/edrc installed) most efficiently use the **rcmd(1)** command.

To poll a list of systems for reporting data most efficiently, use the **syspoll(1)** command.

BUGS

NAME

ssh-exec.cfg – configuration file for ssh-exec

SYNOPSIS

edrc/etc/ssh-exec.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **ssh-exec** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS

LOG Log output dir of **ssh-exec**. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation.

Example: LOG=/var/opt/edrc/log

Default: LOG=var/log

EDRC_USER

The home of this user is considered as the root of the WA2L/edrc installation. See **edrc-setup**(1m) for information about user settings needed by WA2L/edrc.

Example: EDRC_USER=edrc

Default: EDRC_USER=edrc

START_USER

User that is allowed to start **ssh-exec**.

This setting is of relevance if the user-id of the starting user is different from the local user used (**-l localuser** option) to connect to the remote system.

Example: **START_USER=eroot**

Default: **START_USER=root**

CONNECTION_TIMEOUT

ssh connection timeout in seconds.

Specifies the timeout (in seconds) used when connecting to the SSH server, instead of using the default system TCP timeout.

This value is used only when the target is down or really unreachable, not when it refuses the connection.

Example: **CONNECTION_TIMEOUT=2**

Default: **CONNECTION_TIMEOUT=4**

PROBE_COMMAND

Command to invoke on the remote system to probe a ssh connection with the given remote user.

The chosen command must be available on all target systems.

If it is needed to set the **PROBE_COMMAND** dynamically the environment variables **\$REMOTEUSER** and/or **\$TARGET** can be used to do so.

The **\$REMOTEUSER** variable contains the user name as given on the command line in lower case; the **\$TARGET** variable contains the target system as given on the command line also in lower case.

Example:

```
case $TARGET in
  acme007) PROBE_COMMAND="uname -n" ;;
  alpha60) PROBE_COMMAND="sysname" ;;
  joshua)  PROBE_COMMAND="identity" ;;
  hal9000) PROBE_COMMAND="avatar"  ;;
  bomb20) PROBE_COMMAND="WHO"      ;;
  *)      PROBE_COMMAND="hostname" ;;
esac
```

Example: **PROBE_COMMAND=hostname**

Default: **PROBE_COMMAND=hostname**

NAME

ssh-keyadd – add ssh keys needed for WA2L/edrc to authorized_keys file

SYNOPSIS

edrc/bin/ssh-keyadd [**-h**]

ssh-keyadd [**-y**] [**-u** *user*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

Add SSH public keys to a users (normally root's) **authorized_keys** file(s).

This command is used to help to efficiently add the needed SSH keys to ensure the connectivity for WA2L/edrc needed for the commands as **remote_shell**, **remote_copy**, **filedist**, **rcmd** and the **edrc** trunk functionality.

Furthermore the SSH daemon configuration file is modified that way that it is allowed to connect as root. To make the configuration change active, the HUP signal is sent to the SSH daemon.

With **ssh-keyadd** it is also possible to get an overview of the current SSH key situation due to the fact, that the tool gives an easy to read consolidated view of the applied keys.

OPTIONS

-h usage message.

-y answer to "yes" to all interactive questions.

-u *user* username if it is different from the default (root).

ENVIRONMENT

-

EXIT STATUS

0 no error.

1 configuration file does not exist.

- 4 Usage printed.
- 6 **ssh-keyadd** aborted pressing <Ctrl>+<C>.

FILES

edrc/etc/ssh-keyadd.cfg
ssh-keyadd configuration file.

edrc/etc/ssh-keyadd.pub
 global public keys to be added.

/etc/ssh/sshd_config
 configuration file of the SSH daemon.

/etc/ssh/etc/sshd_config
 configuration file of the SSH daemon.

edrc/var/connection/security/[<EDRC_USER>|<user>]/OpenSSH/*/[default|<hostname>]/*.pub
 local public keys to be added.

~<user>/.ssh/authorized_keys
 SSH authorized keys file of the user. See also **ssh-keyadd.cfg** for more information.

~<user>/.ssh/authorized_keys2
 SSH authorized keys file of the user. See also **ssh-keyadd.cfg** for more information.

EXAMPLES

-

SEE ALSO

NAME

ssh-keyadd.cfg – configuration file for ssh-keyadd

SYNOPSIS

edrc/etc/ssh-keyadd.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **ssh-keyadd** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**SSHD_CONFIGFILE**

List of SSH configuration files.

Example: SSHD_CONFIGFILE="/etc/ssh/sshd_config /opt/ssh/etc/sshd_config"

Default: SSHD_CONFIGFILE="/etc/ssh/sshd_config /opt/ssh/etc/sshd_config"

SSHD_PROCESSNAME

List of SSH process names.

Example: SSHD_PROCESSNAME="/usr/sbin/sshd /opt/ssh/sbin/sshd /usr/lib/ssh/sshd"

Default: SSHD_PROCESSNAME="/usr/sbin/sshd /opt/ssh/sbin/sshd /usr/lib/ssh/sshd"

SSHD_PIDFILE

List of SSH PID file names.

Example: SSHD_PIDFILE="/var/run/sshd.pid /var/run/sshd.init.pid"

Default: SSHD_PIDFILE="/var/run/sshd.pid /var/run/sshd.init.pid"

AUTHORIZED_KEYS_FILE

List of authorized key files in \$HOME/.ssh directory.

Example: AUTHORIZED_KEYS_FILE="authorized_keys"

Default: AUTHORIZED_KEYS_FILE="authorized_keys authorized_keys2"

LOG

Log output dir of ssh-keyadd. If you specify a relative path name the path is relative to the root of the EDRC installation.

Example: LOG=var/log

Default: LOG=var/log

EDRC_USER

Name of edrc user.

Example: EDRC_USER=edrc

Default: EDRC_USER=edrc

NAME

ssh-keyadd.pub – global SSH public keys

SYNOPSIS

edrc/etc/ssh-keyadd.pub

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **ssh-keyadd** command and contains all global public SSH keys which are used to connect from a central management environment to all environments.

FILEFORMAT

The fileformat is a plain file containing public keys.

Rows starting with a **#** are considered as comments.

OPTIONS

-

EXAMPLES

Example configuration file containing two global SSH keys to allow the administration environment 'Highlander' to access the systems in the environment.

One key is on one line without returns and goes from 'ssh-...' until 'edrc@Highlander'.

NAME

sshpass – noninteractive ssh password provider

SYNOPSIS

sshpass [-f*filename*|-d*num*|-p*password*|-e] [*options*] *command arguments*

DESCRIPTION

This manual page documents the **sshpass** command.

sshpass is a utility designed for running **ssh** using the mode referred to as "keyboard-interactive" password authentication, but in non-interactive mode.

ssh uses direct TTY access to make sure that the password is indeed issued by an interactive keyboard user. Sshpass runs ssh in a dedicated tty, fooling it into thinking it is getting the password from an interactive user.

The command to run is specified after sshpass' own options. Typically it will be "ssh" with arguments, but it can just as well be any other command. The password prompt used by ssh is, however, currently hard-coded into sshpass.

Options

If no option is given, sshpass reads the password from the standard input. The user may give at most one alternative source for the password:

-p*password*

The password is given on the command line. Please note the section titled "**SECURITY CONSIDERATIONS**".

-f*filename*

The password is the first line of the file *filename*.

-d*number*

number is a file descriptor inherited by sshpass from the runner. The password is read from the open file descriptor.

-e

The password is taken from the environment variable "SSHPASS".

-P

Set the password prompt. Sshpass searched for this prompt in the program's output to the TTY as an indication when to send the password. By default sshpass looks for the string "assword:" (which matches both "Password:" and "password:"). If your client's prompt does not fall under either of these, you can override the default with this option.

-v

Be verbose. sshpass will output to stderr information that should help debug cases where the connection hangs, seemingly for no good reason.

SECURITY CONSIDERATIONS

First and foremost, users of sshpass should realize that ssh's insistence on only getting the password interactively is not without reason. It is close to impossible to securely store the password, and users of sshpass should consider whether ssh's public key authentication provides the same end-user experience, while involving less hassle and being more secure.

The -p option should be considered the least secure of all of sshpass's options. All system users can see the password in the command line with a simple "ps" command. Sshpass makes a minimal attempt to hide the password, but such attempts are doomed to create race conditions without actually solving the problem. Users of sshpass are encouraged to use one of the other password passing techniques, which are all more secure.

In particular, people writing programs that are meant to communicate the password programatically are encouraged to use an anonymous pipe and pass the pipe's reading end to sshpass using the -d option.

RETURN VALUES

As with any other program, sshpass returns 0 on success. In case of failure, the following return codes are used:

- 1 Invalid command line argument
- 2 Conflicting arguments given
- 3 General runtime error
- 4 Unrecognized response from ssh (parse error)
- 5 Invalid/incorrect password
- 6 Host public key is unknown. sshpass exits without confirming the new key.

In addition, ssh might be complaining about a man in the middle attack. This complaint does not go to the tty. In other words, even with sshpass, the error message from ssh is printed to standard error. In such a case ssh's return code is reported back. This is typically an unimaginative (and non-informative) "255" for all error cases.

EXAMPLES

Run rsync over SSH using password authentication, passing the password on the command line:

```
rsync --rsh='sshpass -p 12345 ssh -l test' host.example.com:path .
```

To do the same from a bourne shell script in a marginally less exposed way:

```
SSHPASS=12345 rsync --rsh='sshpass -e ssh -l test' host.example.com:path .
```

BUGS

Sshpass is in its infancy at the moment. As such, bugs are highly possible. In particular, if the password is read from stdin (no password option at all), it is possible that some of the input aimed to be passed to ssh will be read by sshpass and lost.

Sshpass utilizes the **pty(7)** interface to control the TTY for ssh. This interface, at least on Linux, has a misfeature where if no slave file descriptors are open, the master pty returns **EIO**. This is the normal behavior, except a slave pty may be born at any point by a program opening **/dev/tty**. This makes it impossible to reliably wait for events without consuming 100% of the CPU.

Over the various versions different approaches were attempted at solving this problem. Any given version of sshpass is released with the belief that it is working, but experience has shown that these things do, occasionally, break. This happened with OpenSSH version 5.6. As of this writing, it is believed that sshpass is, again, working properly.

NAME

stat – display stat() information of a file

SYNOPSIS

edrc/bin/stat [**-h**]

stat -t

stat [**-L**] **-s** *stat_field* **-f** *file*

cat *filelist* | **stat** [**-L**] **-s** *stat_field* **-f** -

stat [**-L**] **-s** *stat_field* **-f** - < *filelist*

AVAILABILITY

WA2L/edrc

DESCRIPTION

This command returns the file status information returned by the **stat(2)** system call.

OPTIONS

-h usage message.

-t print the CSV header of all columns as returned when invoking **-s all**.

-L follow symlinks.

-s *stat_field*

as one of the following:

dev device number of the filesystem where the file resides.

ino inode number of the file.

mode file mode (type and permission) as numeric representation.

perm file permission in octal representation.

nlink number of hard links to the file.

| | |
|----------------|--|
| uid | numeric user ID of the file owner. |
| gid | numeric group ID of the file owner. |
| rdev | device identifier. This only applies for special files. |
| size | total size of the file in bytes. |
| atime | last access time since the epoch. |
| atimel | last access time in local time representation printed in military format YYYY-MM-DD hh:mm:ss (e.g. 2010-08-28 11:55:59). |
| mtime | last modify time since the epoch. |
| mtimel | last modify time in local time representation printed in military format YYYY-MM-DD hh:mm:ss (e.g. 2010-08-28 11:55:59). |
| ctime | inode change time (*not* the creation time!) since the epoch. |
| ctimel | inode change time (*not* the creation time!) in local time representation printed in military format YYYY-MM-DD hh:mm:ss (e.g. 2010-08-28 11:55:59). |
| blksize | preferred block size for file system I/O. |
| blocks | actual number of blocks allocated. |
| type | type of the file: |
| f | File is a plain file. |
| d | File is a directory. |
| l | File is a symbolic link. |
| p | File is a pipe (FIFO). |
| S | File is a socket. |
| b | File is a block special file. |
| c | File is a character special file. |
| t | File is opened by a tty. |

T File is a text file.

B File is a binary file.

all print all **stat** fields including the *file* as a CSV output. The order of the output fields is:
DEV;INO;MODE;PERM;NLINK;UID;GID;RDEV;SIZE;ATIME;MTIME;CTIME;BLK-SIZE;BLOCKS;FILE;ATIMEL;MTIMEL;CTIMEL;TYPE;.

-f file filename of the file for which the stat information should be printed. If **-** is given as **file stdin** is read for a list of files.

ENVIRONMENT

-

EXIT STATUS

- 0** no error.
- 1** file specified is not readable.
- 2** operating system is not supported, yet. See **osid(3)** if you get this error.
- 4** usage printed.

FILES

-

EXAMPLES

NAME

strupr, strlwr – additional string functions

SYNOPSIS

```
#include "strings.h"
```

```
char *strupr(char *string);
```

```
char *strlwr(char *string);
```

AVAILABILITY

WA2L/edrc

DESCRIPTION

strings.h provides additional string functions not provided in **<string.h>**.

strupr()

return provided string in upper case.

Example:

```
printf("upper case string: '%s'\n", strupr("a String to be converted"));
```

Output:

```
upper case string: 'A STRING TO BE CONVERTED'
```

strlwr()

return provided string in lower case.

Example:

```
printf("lower case string: '%s'\n", strlwr("a String to be converted"));
```

Output:

```
lower case string: 'a string to be converted'
```

RETURN VALUE

the return value of **strupr()** and **strlwr()** is a pointer to the converted variant of the given string.

ENVIRONMENT

-

FILES

`lib/$OSID/includes/strings.h`

NAME

strace – trace system calls and signals

SYNOPSIS

```
strace [ -dffhiqrtttTvxx ] [ -acolumn ] [ -eexpr ] ... [ -ofile ] [ -ppid ] ... [ -sstrsize ] [ -uusername ] [ command [ arg ... ] ]
```

```
strace -c [ -eexpr ] ... [ -Ooverhead ] [ -Ssortby ] [ command [ arg ... ] ]
```

DESCRIPTION

In the simplest case **strace** runs the specified *command* until it exits. It intercepts and records the system calls which are called by a process and the signals which are received by a process. The name of each system call, its arguments and its return value are printed on standard error or to the file specified with the **-o** option.

strace is a useful diagnostic, instructional, and debugging tool. System administrators, diagnosticians and trouble-shooters will find it invaluable for solving problems with programs for which the source is not readily available since they do not need to be recompiled in order to trace them. Students, hackers and the overly-curious will find that a great deal can be learned about a system and its system calls by tracing even ordinary programs. And programmers will find that since system calls and signals are events that happen at the user/kernel interface, a close examination of this boundary is very useful for bug isolation, sanity checking and attempting to capture race conditions.

Each line in the trace contains the system call name, followed by its arguments in parentheses and its return value. An example from stracing the command “cat /dev/null” is:

```
open("/dev/null", O_RDONLY) = 3
```

Errors (typically a return value of -1) have the errno symbol and error string appended.

```
open("/foo/bar", O_RDONLY) = -1 ENOENT (No such file or directory)
```

Signals are printed as a signal symbol and a signal string. An excerpt from stracing and interrupting the command “sleep 666” is:

```
sigsuspend([] <unfinished ...>
--- SIGINT (Interrupt) ---
+++ killed by SIGINT +++
```

Arguments are printed in symbolic form with a passion. This example shows the shell performing “>>xyzy” output redirection:

```
open("xyzy", O_WRONLY|O_APPEND|O_CREAT, 0666) = 3
```

Here the three argument form of open is decoded by breaking down the flag argument into its three bitwise-OR constituents and printing the mode value in octal by tradition. Where traditional or native usage differs from ANSI or POSIX, the latter forms are preferred. In some cases, **strace** output has proven to be more readable than the source.

Structure pointers are dereferenced and the members are displayed as appropriate. In all cases arguments are formatted in the most C-like fashion possible. For example, the essence of the command “ls -l /dev/null” is captured as:

```
lstat("/dev/null", {st_mode=S_IFCHR|0666, st_rdev=makedev(1, 3), ...}) = 0
```

Notice how the ‘struct stat’ argument is dereferenced and how each member is displayed symbolically. In particular, observe how the st_mode member is carefully decoded into a bitwise-OR of symbolic and

numeric values. Also notice in this example that the first argument to `lstat` is an input to the system call and the second argument is an output. Since output arguments are not modified if the system call fails, arguments may not always be dereferenced. For example, retrying the “`ls -l`” example with a non-existent file produces the following line:

```
lstat("/foo/bar", 0xb004) = -1 ENOENT (No such file or directory)
```

In this case the porch light is on but nobody is home.

Character pointers are dereferenced and printed as C strings. Non-printing characters in strings are normally represented by ordinary C escape codes. Only the first *strsize* (32 by default) bytes of strings are printed; longer strings have an ellipsis appended following the closing quote. Here is a line from “`ls -l`” where the **getpwuid** library routine is reading the password file:

```
read(3, "root::0:0:System Administrator:/...", 1024) = 422
```

While structures are annotated using curly braces, simple pointers and arrays are printed using square brackets with commas separating elements. Here is an example from the command “`id`” on a system with supplementary group ids:

```
getgroups(32, [100, 0]) = 2
```

On the other hand, bit-sets are also shown using square brackets but set elements are separated only by a space. Here is the shell preparing to execute an external command:

```
sigprocmask(SIG_BLOCK, [CHLD TTOU], []) = 0
```

Here the second argument is a bit-set of two signals, `SIGCHLD` and `SIGTTOU`. In some cases the bit-set is so full that printing out the unset elements is more valuable. In that case, the bit-set is prefixed by a tilde like this:

```
sigprocmask(SIG_UNBLOCK, ~[], NULL) = 0
```

Here the second argument represents the full set of all signals.

OPTIONS

- c** Count time, calls, and errors for each system call and report a summary on program exit.
- d** Show some debugging output of **strace** itself on the standard error.
- f** Trace child processes as they are created by currently traced processes as a result of the **fork(2)** system call. The new process is attached to as soon as its pid is known (through the return value of **fork(2)** in the parent process). This means that such children may run uncontrolled for a while (especially in the case of a **vfork(2)**), until the parent is scheduled again to complete its **(v)fork(2)** call. If the parent process decides to **wait(2)** for a child that is currently being traced, it is suspended until an appropriate child process either terminates or incurs a signal that would cause it to terminate (as determined from the child’s current signal disposition).
- ff** If the **-o filename** option is in effect, each processes trace is written to *filename.pid* where pid is the numeric process id of each process.
- F** Attempt to follow **vforks**. (On SunOS 4.x, this is accomplished with some dynamic linking trickery. On Linux, it requires some kernel functionality not yet in the standard kernel.) Otherwise, **vforks** will not be followed even if **-f** has been given.
- h** Print the help summary.

- i** Print the instruction pointer at the time of the system call.
- q** Suppress messages about attaching, detaching etc. This happens automatically when output is redirected to a file and the command is run directly instead of attaching.
- r** Print a relative timestamp upon entry to each system call. This records the time difference between the beginning of successive system calls.
- t** Prefix each line of the trace with the time of day.
- tt** If given twice, the time printed will include the microseconds.
- ttt** If given thrice, the time printed will include the microseconds and the leading portion will be printed as the number of seconds since the epoch.
- T** Show the time spent in system calls. This records the time difference between the beginning and the end of each system call.
- v** Print unabbreviated versions of environment, stat, termios, etc. calls. These structures are very common in calls and so the default behavior displays a reasonable subset of structure members. Use this option to get all of the gory details.
- V** Print the version number of **strace**.
- x** Print all non-ASCII strings in hexadecimal string format.
- xx** Print all strings in hexadecimal string format.
- a column** Align return values in a specific column (default column 40).
- e expr** A qualifying expression which modifies which events to trace or how to trace them. The format of the expression is:

`[qualifier=][!]value1[,value2]`...

where *qualifier* is one of **trace**, **abbrev**, **verbose**, **raw**, **signal**, **read**, or **write** and *value* is a qualifier-dependent symbol or number. The default qualifier is **trace**. Using an exclamation mark negates the set of values. For example, **-eopen** means literally **-e trace=open** which in turn means trace only the **open** system call. By contrast, **-etrace=!open** means to trace every system call except **open**. In addition, the special values **all** and **none** have the obvious meanings.

Note that some shells use the exclamation point for history expansion even inside quoted arguments. If so, you must escape the exclamation point with a backslash.

- e trace=set** Trace only the specified set of system calls. The **-c** option is useful for determining which system calls might be useful to trace. For example, **trace=open,close,read,write** means to only trace those four system calls. Be careful when making inferences about the user/kernel boundary if only a subset of system calls are being monitored. The default is **trace=all**.
- e trace=file** Trace all system calls which take a file name as an argument. You can think of this as an abbreviation for **-e trace=open,stat,chmod,unlink,...** which is useful to seeing what files the process is referencing. Furthermore, using the abbreviation will ensure that you don't accidentally forget to include a call like **lstat** in the list. Betchya woulda forgot that one.
- e trace=process** Trace all system calls which involve process management. This is useful for watching the fork, wait, and exec steps of a process.
- e trace=network** Trace all the network related system calls.
- e trace=signal** Trace all signal related system calls.
- e trace=ipc** Trace all IPC related system calls.

- e abbrev=*set***
Abbreviate the output from printing each member of large structures. The default is **abbrev=all**. The **-v** option has the effect of **abbrev=none**.
- e verbose=*set***
Dereference structures for the specified set of system calls. The default is **verbose=all**.
- e raw=*set***
Print raw, undecoded arguments for the specified set of system calls. This option has the effect of causing all arguments to be printed in hexadecimal. This is mostly useful if you don't trust the decoding or you need to know the actual numeric value of an argument.
- e signal=*set***
Trace only the specified subset of signals. The default is **signal=all**. For example, **signal=!SIGIO** (or **signal=!io**) causes SIGIO signals not to be traced.
- e read=*set***
Perform a full hexadecimal and ASCII dump of all the data read from file descriptors listed in the specified set. For example, to see all input activity on file descriptors 3 and 5 use **-e read=3,5**. Note that this is independent from the normal tracing of the **read(2)** system call which is controlled by the option **-e trace=read**.
- e write=*set***
Perform a full hexadecimal and ASCII dump of all the data written to file descriptors listed in the specified set. For example, to see all output activity on file descriptors 3 and 5 use **-e write=3,5**. Note that this is independent from the normal tracing of the **write(2)** system call which is controlled by the option **-e trace=write**.
- o *filename***
Write the trace output to the file *filename* rather than to stderr. Use *filename.pid* if **-ff** is used. If the argument begins with '|' or with '!' then the rest of the argument is treated as a command and all output is piped to it. This is convenient for piping the debugging output to a program without affecting the redirections of executed programs.
- O *overhead***
Set the overhead for tracing system calls to *overhead* microseconds. This is useful for overriding the default heuristic for guessing how much time is spent in mere measuring when timing system calls using the **-c** option. The accuracy of the heuristic can be gauged by timing a given program run without tracing (using **time(1)**) and comparing the accumulated system call time to the total produced using **-c**.
- p *pid***
Attach to the process with the process ID *pid* and begin tracing. The trace may be terminated at any time by a keyboard interrupt signal (CTRL-C). **strace** will respond by detaching itself from the traced process(es) leaving it (them) to continue running. Multiple **-p** options can be used to attach to up to 32 processes in addition to *command* (which is optional if at least one **-p** option is given).
- s *strsize***
Specify the maximum string size to print (the default is 32). Note that filenames are not considered strings and are always printed in full.
- S *sortby***
Sort the output of the histogram printed by the **-c** option by the specified criterion. Legal values are **time**, **calls**, **name**, and **nothing** (default **time**).
- u *username***
Run command with the user ID, group ID, and supplementary groups of *username*. This option is only useful when running as root and enables the correct execution of **setuid** and/or **setgid** binaries. Unless this option is used **setuid** and **setgid** programs are executed without effective privileges.

SETUID INSTALLATION

If **strace** is installed **setuid** to root then the invoking user will be able to attach to and trace processes owned by any user. In addition **setuid** and **setgid** programs will be executed and traced with the correct effective privileges. Since only users trusted with full root privileges should be allowed to do these things, it only makes sense to install **strace** as **setuid** to root when the users who can execute it are restricted to those users who have this trust. For example, it makes sense to install a special version of **strace** with mode 'rwsr-xr--', user **root** and group **trace**, where members of the **trace** group are trusted users. If you do use this feature, please remember to install a non-**setuid** version of **strace** for ordinary users to use.

SEE ALSO

ptrace(2), **proc(4)**, **time(1)**, **trace(1)**, **truss(1)**

NOTES

It is a pity that so much tracing clutter is produced by systems employing shared libraries.

It is instructive to think about system call inputs and outputs as data-flow across the user/kernel boundary. Because user-space and kernel-space are separate and address-protected, it is sometimes possible to make deductive inferences about process behavior using inputs and outputs as propositions.

In some cases, a system call will differ from the documented behavior or have a different name. For example, on System V-derived systems the true **time(2)** system call does not take an argument and the **stat** function is called **xstat** and takes an extra leading argument. These discrepancies are normal but idiosyncratic characteristics of the system call interface and are accounted for by C library wrapper functions.

On some platforms a process that has a system call trace applied to it with the **-p** option will receive a **SIGSTOP**. This signal may interrupt a system call that is not restartable. This may have an unpredictable effect on the process if the process takes no action to restart the system call.

BUGS

Programs that use the *setuid* bit do not have effective user ID privileges while being traced.

A traced process ignores **SIGSTOP** except on SVR4 platforms.

A traced process which tries to block **SIGTRAP** will be sent a **SIGSTOP** in an attempt to force continuation of tracing.

A traced process runs slowly.

Traced processes which are descended from *command* may be left running after an interrupt signal (**CTRL-C**).

On Linux, exciting as it would be, tracing the *init* process is forbidden.

The **-i** option is weakly supported.

HISTORY

strace The original **strace** was written by Paul Kranenburg for SunOS and was inspired by its trace utility. The SunOS version of **strace** was ported to Linux and enhanced by Branko Lankester, who also wrote the Linux kernel support. Even though Paul released **strace** 2.5 in 1992, Branko's work was based on Paul's **strace** 1.5 release from 1991. In 1993, Rick Sladkey merged **strace** 2.5 for SunOS and the second release of **strace** for Linux, added many of the features of **truss(1)** from SVR4, and produced an **strace** that worked on both platforms. In 1994 Rick ported **strace** to SVR4 and Solaris and wrote the automatic configuration support. In 1995 he ported **strace** to Irix and tired of writing about himself in the third person.

PROBLEMS

Problems with **strace** should be reported to the current **strace** maintainer, Wichert Akkerman, at <wakkerma@debian.org>.

NAME

sysvi – edit a file in sysconfig repository

SYNOPSIS

edrc/bin/sysvi [**-h**]

sysvi *file* ...

svi [**-h**]

svi *file* ...

AVAILABILITY

WA2L/edrc

DESCRIPTION

edit the file in a sysconfig repository which is related to the local (active) file on the system.

If a file is in multiple repositories it can be interactively chosen in which repository the file should be edited.

OPTIONS

-h usage message.

file ... list of files to be edited in the repository.

ENVIRONMENT

-

EXIT STATUS

- | | |
|----------|--|
| 0 | no error. |
| 2 | operating system is not supported, yet. See osid (3) if you get this error. |
| 4 | usage printed. |
| 5 | command aborted pressing <Ctrl>+<C> or using kill (1). |

- 11** temporary directory could not be claimed in **/tmp**. Check the system if you get this error, it is an indicator for system intrusion.

FILES

<root_dir>/EDRC.sysconfig<.name>

settings file(s) that contains information about current active configuration(s). This file is read when using **sysconfig -p**, **syscp**, **sysvi** and **sysdiff**.

NAME

sw_inventory – software inventory file

SYNOPSIS

<software installation path>/..sw_inventory

AVAILABILITY

WA2L/edrc

DESCRIPTION

"software inventory file" containing all software information of software installed in the directory where created.

This file is created when using the **swvi**(1) command.

FILEFORMAT

The fileformat is a list of definitions that have the format (all on one line):

```
SOFTWARE;VERSION;INST_USER;INST_GROUP;RUN_USER;\  
RUN_GROUP;CFG_DIR;VAR_DIR;LICENSE;LIC_MGMT;WEB;\  
DOC;INST_SRC;PRODUCT;INSTANCE;COMMENT;
```

Rows starting with a # are considered as comments. Empty lines are allowed, too.

OPTIONS**SOFTWARE**

NAME

sw_report – produce contrib.doc OUTPUT-EXAMPLE output from logfile

SYNOPSIS

edrc/bin/sw_report [**-h**]

sw_report [**-c**] [**-t** (**table** | **csv_header** | **csv**)

sw_report last

AVAILABILITY

WA2L/edrc

DESCRIPTION

create a software inventory report of a system. This command takes the **..sw_inventory** files as a base for information.

The **sw_report** travels thru the directories and searches for **..sw_inventory** files to produce the software inventory report.

The **sw_report** command must be started as **root** user.

OPTIONS

-h usage message.

-c use the cache file of previous **sw_report** runs to collect the **..sw_inventory** file information.

-t table produce a plain **ASCII** report for direct usage.

-t csv_header
 print **CSV** header row.

-t csv produce a **CSV** report (data only).

ENVIRONMENT

-

EXIT STATUS

| | |
|----------|--|
| 0 | no error. |
| 1 | command was not started as root user. |
| 4 | usage printed. |
| 5 | command aborted. |

FILES

| | |
|---------------------------------|--|
| ..sw_inventory | software inventory file. |
| /var/tmp/sw_report.cache | cache file of sw_report containing a list of resolved ..sw_inventory files on the system. |

EXAMPLES

NAME

swvi – edit/create the software inventory file

SYNOPSIS

edrc/bin/swvi [**-h**]

swvi [**-a**][**-r**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

With **swvi** and **sw_report** it is very easy to create a software inventory of a system without manually maintaining extra lists that document this.

With the **swvi** command the "software inventory file" is created or edited. This file (**..sw_inventory**) contains the information about the software installed in a certain directory.

A "software inventory file" can be created by everyone having the permissions to write into the directory where the software is installed to. So the task to maintain the "software inventory file" and finally the software inventory of a system is not only dependent of the system administrator which has the root password.

This "software inventory files" spread over many directories on the system are collected with the **sw_report** command to generate either a plain ASCII- or a CSV report of all installed software.

To place this information into the same directory as the software is installed has the advantage that it is moved/copied if the directory containing the software is moved/copied to an other location. Furthermore it is more likely updated then a manually maintained list residing on some documentation server.

To create a new "software inventory file" you have to change to the directory where the software is installed and call the **swvi** command. An interactive dialog will query you information needed. All information except the **SOFTWARE**, **VERSION**, **INST_USER** and **INST_GROUP** fields are optional.

If there is already an existing **..sw_inventory** file in the directory, the current file is loaded into **vi** for editing.

If a second software is installed into the same directory (what is often the case for **/usr/local**) you can invoke **swvi -a** to append a new record to the file answering the interactive dialog.

Be aware that using the **-a** option will ensure that only one identical **SOFTWARE**, **VERSION** pair exists in one **..sw_inventory** file.

The "software inventory file" is created with the permissions '644' and the user/group of the creating user. If the 'root' user invokes **swvi** the user/group setting of the overlying directory are set to ensure that the software owner (= the user ID that has been used to install the software) is able to modify the **..sw_inventory** file in the future.

The following fields will be queried (see also output of **swvi -h**):

* = required entries

SOFTWARE*

Software name

VERSION*

Software version

INST_USER*

Installation user

INST_GROUP*

Installation group

RUN_USER

User under which the software is started

COMMENT

Additional comments

OPTIONS

- "** create a new **..sw_inventory** file if it does not exist in the current directory or load an existing **..sw_inventory** file into **vi** for editing.
- h** usage message.
- a** add a new record to an existing **..sw_inventory** file using the interactive dialog.
- r** remove (clear) the contents of an already existing **..sw_inventory** file. This option is rarely used in manual invocation, but is useful if you perform automated installations. For automated installations see also **apply2sw_inventory(1)**.

EXIT STATUS

- 0** no error.
- 1** no write permission to current working directory.
- 2** operating system not supported. See **osid(3)** if you get this error.
- 4** usage displayed.
- 5** command aborted with Ctrl+C.

FILES

- ..sw_inventory** "software inventory file" containing all software information of software installed in the directory where created.
- etc/exrc** settings for the **vi** / **vim** editor.

SEE ALSO

edrcintro(1), **sw_report(1)**, **sw_inventory(4)**, **apply2sw_inventory(1)**, **fields2swvi(3)**, **vi(1)**, **duvi(1)**

NOTES

To see how to document (label) data and other directories efficiently, see **duvi(1)**.

You might hear the argument, that maintaining a software inventory that way is not needed at all, due to the fact that the operating system provides this information via the built in software package management mechanism. But from experience, this is not sufficient for the most systems. Many software is distributed in a variety of formats, and I personally know not a single system administrator which creates for *each* piece of software that is installed a software package that is recognized by the operating system (rpm for Linux, SW-Depots for HP-UX, pkg for Solaris, ...).

But at latest, when the date of migrating the system (and all installed software and applications) to a newer one comes, the big worries/questions/issues/no-go's/show-stoppers, however you like to name it, about not knowing what is installed on the current system and a not up-to-date software inventory, will come up. And this is one moment where the usage **swvi** and **sw_report** really pays back.

NAME

symlink – create symlink *link* → *original*

SYNOPSIS

edrc/bin/symlink [**-h**]

symlink [**-l**] *original link*

AVAILABILITY

WA2L/edrc

DESCRIPTION

the **symlink** command is used to create a symbolic link to an original destination, basically as the '**ln -s original link**' command does.

If the *link* item already exists, it is removed prior to the symbolic link creation. To avoid data deletion, the **-l** switch can be used to ensure, that the *link* already exists and is also a symbolic link.

The main purpose of **symlink** is to toggle a symbolic link from one to the other *original*.

If an existing symbolic link is replaced, the replacement is created with the identical owner and group, as the existing link was. If a new symbolic link is created, the owner and group of the new symbolic link is set as the item it is pointing to. A new standalone symbolic link, or if the user using the **symlink** command is not allowed to set the user and group memberships, the new symbolic link is created with the owner-ships of the creating user.

OPTIONS

-h

usage message.

-l

link must be an existing symbolic link. If it isn't an existing symbolic link, it will not be removed.

original

original file.

link

symbolic link.

ENVIRONMENT

-

EXIT STATUS

| | |
|----------|---|
| 0 | no error. |
| 1 | cannot remove existing symlink. |
| 2 | <i>link</i> does not exist or is not a symlink. |
| 3 | cannot create symlink. |
| 4 | usage printed. |

NAME

sys – start edrc with a special WA2L/edrc maintenance configuration

SYNOPSIS

edrc/bin/sys [**-h** | **-V**]

sys [**-s**] [**-t**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

Short start of **edrc** with an other configuration which points to an own script tree. Internally **sys** calls **edrc -c edrc.sys.cfg -n sys_@ID@** .

This configuration is part of the WA2L/edrc package and the menu should not be modified, due to the fact that updates are provided thru patches and all changes would be lost or the changes made would question the correct operation of the script tree.

The menu points provide an user interface to some installation, patching and package distribution tasks.

The session name (as shown in the menu) is automatically set to **sys_<id>** . Where **<id>** is the process id of the started **edrc** instance if not already a session with the same name exists, if so the **<id>** is set to a random number.

If additional short starts are needed, create a symlink from the new short start command to **sat** (see section **EXAMPLES**).

OPTIONS

- h** usage message.
- V** print version and patch level of **edrc**. For an explanation of the release numbering system see **edrcrevision(1)**.
- s** silent startup. Startup without showing the EDRC banner.
- t** no terminal initialization. Sometimes the terminal initialization causes unwanted behavior. To skip terminal initialization, invoke **edrc** with this option.

ENVIRONMENT

-

EXIT STATUS

see **edrc**(1m).

FILES

etc/edrc.sys.cfg

configuration file of **sys**, see **edrc.cfg**(4) for more information.

Other files see section **FILES** in **edrc**(1m).

EXAMPLES**1) create a new short start**

This creates a new short start command **new_shortstart** that will load the configuration file **edrc.new_shortstart.cfg**. The session name will automatically be set to **NEW_SHORTSTART_<id>** .

```
[ /root ]
[ root@rh7mzv7t001 ] [bash]: cd ~edrc/bin

[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ] [bash]: ln -s sat new_shortstart
```

NAME

sysconfig – configure a Unix/Linux system

SYNOPSIS

edrc/bin/sysconfig [**-h**]

sysconfig **-s** *src_dir* [**-r** *root_dir*] [**-b** *backup_dir*] [**-o** *OSID*] [**-f**]

sysconfig **-p** [**-r** *root_dir*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

With **sysconfig** you can configure a UNIX or Linux system with a single command using a set of prepared configuration files.

In addition to the prepared files, pre- and post exec scripts enable to run commands prior and after the application of the configuration files. Therefore the operating system configuration can be automated completely.

sysconfig should be used to configure the vanilla operating system as delivered by the vendor instead of including the configuration to the image as installed by Sun JumpStart, Hewlett-Packard Ignite, RedHat Kickstart, SuSE AutoYast etc. .

This has the advantage that the set of changed configurations is well known and it is more efficient to configure a future operating system version with the equal quality. Looking at the configuration repository it is easy to evaluate which files were adjusted to configure the operating system, without relying on configuration documentation. When including the configuration in the related image as mentioned above it is harder to see which files were changed and the possibility of not documenting the configuration changes is high. Furthermore it is more efficient to change the configuration in the **sysconfig** repository due to the fact that the repository has the same structure for all operating systems (HP-UX, Solaris, Linux, ...) and the user does not need to know the different image formats / install methods provided by the operating system vendor.

FEATURES

- Currently supported operating systems: Solaris, HP-UX, Linux
- Pre- and post exec support
- Backup of all removed/changed files
- Protection of files that change after initial system configuration
- Simple repository structure, identical to the target operating system directory structure
- Repository structure is identical for all supported operating systems
- Possibility of applying multiple configurations to a system
- Tools to maintain the configuration repository: **sysvi**(1), **syscp**(1), **sysdiff**(1)
- Tools to use in pre- and post exec scripts: **apply2file**(1), **is_config_byhand**(3)

CONFIGURATION STEPS

The following steps are performed during a system configuration. Some of them are optional.

- 1) execute the **check** script if it exists. This script is used to ensure that a certain configuration is only applied to a system if the criteria implemented in the **check** script are met. If this script returns 0 or if this script does not exist it is allowed to configure the system and the following steps are executed.
- 2) write all settings to the sysconfig-settings file. This file will later be read if you invoke **sysconfig -p** and **svi** and is therefore used to identify which configuration(s) has been applied to a system.
- 3) execute the **pre_exec** script if it exists.
- 4) backup files listed in the **backup** file.
- 5) remove files:
 - a) collect information about files protected by **config_byhand** settings applied to the system.
 - b) backup files listed in the **remove** file and not listed in any applied **config_byhand** file.
 - c) remove files listed in the **remove** file and not listed in any applied **config_byhand** file.
- 6) install files from the source root dir:
 - a) check which files has to be installed (only files which differ from the system or have different permissions or ownership and are not listed in any applied **config_byhand** file will be installed)
 - b) backup files which will be overwritten in the install process in step 6c).
 - c) install files evaluated in step 6a).
- 7) execute the **post_exec** script if it exists.
- 8) write **config_byhand** to **<root_dir>/EDRC.config_byhand<.name>** if it exists and it is not protected by an already applied **config_byhand** file.
If the **CONFIG_BYHAND** setting in the **sysconfig.cfg** file is set to **MERGE** the new entries and the already existing entries in the applied **config_byhand** file are merged and written to the **<root_dir>/EDRC.config_byhand<.name>** file, else the applied settings are replaced with the new entries.
- 9) compress **.cpio** file that contains the backedup files to a **.cpio.gz** file.

OPTIONS

- h** usage message.

- s** *source_directory*
path to the directory which contains the filestructure used by **sysconfig** to configure the system.

- p** print the current active configuration(s) of a system. It is possible that a system has multiple configurations active for certain directories. This is especially the case if you use named configurations or if you configure diskless clients on a server.

- r** *root_dir*
root directory where you apply or query the configuration. You can apply all configurations to any target *root directory* only if you write proper **pre_exec** and **post_exec** scripts and if you list only relative path names within the **backup** and **remove** files explained in section **SYSCONFIG-DATASTRUCTURE**. The default for *root_dir* is */*.

- b** *backup_dir*
directory where to save files backed up from the system ahead of overwriting. The default can be changed in **sysconfig.cfg**, see **sysconfig.cfg(4)** for more information.

- f** force configuration. If you specify this option all **config_byhand** settings are ignored.

- o** *OSID* in normal cases you don't have to set the operating system id (*OSID*) due to the fact that it will be resolved by **sysconfig** using the **osid** command internally. But for testing purposes or if you have to configure diskless clients with different operating system ids than the server, it might be required to set a specific *OSID*. See **osid(3)** for more information.

SYSCONFIG-DATASTRUCTURE

This directory- and filestructure is needed by **sysconfig**. Some files are optional.

<source_directory>

this directory contains the configuration directory structure and all definitions needed by **sysconfig**. This directory has to be specified in the **-s** *src_dir* option of **sysconfig**.

Optional: NO

Example: development.acme.com

Default: -

<source_directory>/<OSID>

operating system ID evaluated by **osid** or set with the **-o** option. If you have to configure different operating systems within an environment you have simply to create an additional *OSID* directory in the same *source_directory*. See **osid(3)** for more information.

Optional: NO

Example: HP-11

Default: -

<source_directory>/<OSID>/README

free-text description and notes to the configuration. This file is to document specialties of the configuration and is not computed by **sysconfig**.

Optional: YES

Example:

```
#
# README - Free text explanations/notes to the configuration
#
# [00] 02.05.2008 CWa    Initial Version
#
```

Default: -

<source_directory>/<OSID>/check

execute the check script if it exists. This script is used to ensure that a certain configuration is only applied to a system if the criteria implemented in the check script are met. If this script returns 0 it is allowed to configure the system and the following steps are executed. See also the description of the tool directory **var/sysconfig/tools/** to see how to save time and effort in writing check scripts.

Optional: YES

Example:

```
#!/bin/sh
#
# check - check if configuration is allowed
#
# [00] 08.02.2003 CWa    Initial Version
#
#
test "$DEBUG" = True && set -x

Targethost=acme054

if [ "`hostname`" = "$Targethost" ]; then
    exit 0
else
    echo "apply this config on $Targethost only!"
    exit 1
fi
```

Default: allow configuration (exitcode=0)

<source_directory>/<OSID>/description

this file contains a single line with a description of the configuration. This description is displayed if you invoke **sysconfig -p** on a configured system.

Optional: YES

Example: ACME Development Department Configuration

Default: no description defined

<source_directory>/<OSID>/name

name of a configuration. This gives you the possibility to apply multiple configurations to the same *root_dir*. This is useful if you have to configure cluster packages (e.g. MC/Service-Guard) which share the *root_dir* with the operating system configuration. Normally you will not name the operating system configuration, but you will name special configurations (such as cluster packages).

Optional: YES

Example: BO

Default: -

<source_directory>/<OSID>/pre_exec

execute pre configuration tasks which cannot be handled with the other mechanisms. A common task in a pre exec script could be: stopping daemon which should not run during configuration. See also in section **ENVIRONMENT** for additional important hints for writing post and pre exec scripts. If you modify files on the system you should use **is_config_byhand** to ensure not to overwrite a protected file. See also the description of the tool directory **var/sysconfig/tools/** to see how to save time and effort in writing pre- and post exec scripts.

Optional: YES

Example:

```
#!/bin/sh
#
# pre_exec - pre exec script
#
# [00] 04.04.2003 CWa    Initial Version
#
#

test "$DEBUG" = True && set -x

touch $SYSCONFIG_ROOTDIR/exAppl/connect.lck
/sbin/init.d/nfs.client stop
```

Default: -

<source_directory>/<OSID>/backup

a list of files to be backuped in step 4). Do not use absolute pathnames, use only relative ones. This ensures that your configuration can be applied to any *root_dir* which is important if you plan to configure diskless clients on a server or simply for testing your configuration. Lines starting with a # or empty lines are considered as comments.

Optional: YES

Example:

```
#
# backup - list of files to be backuped
#
# [00] 08.02.2003 CWa    Initial Version
#
etc/passwd
```

Default: no extra file backup

<source_directory>/<OSID>/config_byhand

a list of files to be protected from overwriting and removal after the initial run of **sysconfig**.

Do not use absolute pathnames, use only relative ones. This ensures that your configuration can be applied to any *root_dir* which is important if you plan to configure diskless clients on a server or simply for testing your configuration. Lines starting with a # or empty lines are considered as comments.

This file is copied to **<root_dir>/EDRC.config_byhand<.name>**. If you change a file on the system and you think it might be handled by **sysconfig** you should add the filename to **.EDRC.config_byhand<.name>** to protect it from overwriting. This is also true for the **.EDRC.config_byhand<.name>** itself.

To dynamically merge the settings defined in an applied **<root_dir>/EDRC.config_byhand<.name>** file and the settings of a **config_byhand** file in a **sysconfig** repository to be applied, set the **CONFIG_BYHAND** setting in the **sysconfig.cfg** configuration file to **MERGE**. In this case it has to be ensured that the **.EDRC.config_byhand<.name>** is not listed in the **.EDRC.config_byhand<.name>** or the **config_byhand** file, because this would protect the file from further change.

post_exec and **pre_exec** scripts should use **is_config_byhand** if they modify files to ensure it is not protected by a **config_byhand** setting.

Optional: YES

Example:

```
#
# config_byhand - list of config by hand files
#
```

```
# [00] 26.10.2003 CWa    Initial Version
#
etc/passwd
etc/dfs/dfstab
var/spool/cron/crontabs/root
```

Default: no files to be configured by hand

<source_directory>/<OSID>/remove

a list of files to be removed in step 5). Do not use absolute pathnames, use only relative ones. This ensures that your configuration can be applied to any *root_dir* which is important if you plan to configure diskless clients on a server or simply for testing your configuration. Lines starting with a # or empty lines are considered as comments.

Optional: YES

Example:

```
#
# remove - list of files to be removed
#
# [00] 08.02.2003 CWa    Initial Version
#
etc/opt/app/lock.lk
```

Default: no extra file backup

<source_directory>/<OSID>/root/

in this directory the system configuration files resist. All files in this directory are copied to the system during the configuration if the file differs from the file already present on the target system. Symlinks are copied always.

Optional: NO

<source_directory>/<OSID>/post_exec

execute post configuration tasks which cannot be handled with the other mechanisms. A common task in a post exec script could be: setting of the default router entry or starting daemon which should not run during configuration. See also in section **ENVIRONMENT** for additional important hints for writing post and pre exec scripts. If you modify files on the system you should use **is_config_byhand** to ensure not to overwrite a protected file. See also the description of the tool directory **var/sysconfig/tools/** to see how to save time and effort in writing post- and pre exec scripts.

Optional: YES

Example:

```
#!/bin/sh
#
# post_exec - post exec script
#
# [00] 04.04.2003 CWa Initial Version
#
#
test "$DEBUG" = True && set -x

rm $SYSCONFIG_ROOTDIR/exAppl/connect.lck
/sbin/init.d/nfs.client start
```

Default: -

ENVIRONMENT

The following environment variables are exported to the **pre_exec** and **post_exec** scripts. It is highly recommended to use those variables. Otherwise you cannot use all features of **sysconfig**.

\$SYSCONFIG_ROOTDIR

this variable equals to the value specified in the **-r** option. Your **pre_exec**, **post_exec** and **check** scripts will only work for every target directory if you use this variable wherever you access a file on the system.

\$SYSCONFIG_FORCE

this variable is set to 'True' if **sysconfig** is called with the **-f** option. If you use **is_config_byhand** it will return 'False' for each file in this case.

EXIT STATUS

- 0** no error.
- 1** you started **edrc** using the wrong operating system user.
- 2** operating system is not supported. See **osid(3)** if you get this error.
- 4** usage listed.
- 6** the configuration file does not exist.

FILES

etc/sysconfig.cfg

configuration file of **edrc**, see **sysconfig.cfg(4)** for more information.

var/log/sysconfig.log

logfile of **sysconfig**.

var/sysconfig/tools/<OSID>

additional tools (scripts) that can be called in the **check**, **pre_exec** and **post_exec** scripts. If a configuration supports multiple operating systems, what is normally the case in heterogeneous environments, you can place operating system dependent scripts in the related directory. If you like to set the default router entry on your Linux, HP-UX and Solaris systems (this is very different on those systems) in the **post_exec** script you can create a script called for instance **'set_default_router'** for each operating system and place it into the related directory. This enables you to save effort in writing the **post_exec** script for all the operating systems you like to configure and simplifies those scripts because you don't have to include the whole code into multiple post exec scripts. If multiple operating systems can be handled identical, a script can be placed into the **var/sysconfig/tools/default** folder and there is no need to have to place identical copies into more then one **<OSID>** directory. The search order is to first look for the tool script in the operating system related directory (**<OSID>**) and then in the **default** directory. You should (of course) synchronize the tool directory contents over all your WA2L/edrc installations to fully benefit from this feature. See **filedist(1)** for instructions how to distribute files easily.

See also: **sysconfig.tools(3)**.

var/sysconfig/tools/default

see description of directory **var/sysconfig/tools/<OSID>**.

See also: **sysconfig.tools(3)**.

var/sysconfig/development.acme.com

example and template **SYSCONFIG-DATASTRUCTURE** tree. This tree can be used as a template and copied to your specific configuration.

<source_directory>

this directory contains the configuration definitions. See section **SYSCONFIG-DATASTRUCTURE** for an explanation of every file within this directory.

<source_directory>/sysconfig.cfg

configuration file of **edrc**, see **sysconfig.cfg(4)** for more information. This file overrides settings made in **etc/sysconfig.cfg**.

<root_dir>/EDRC.sysconfig <root_dir>/EDRC.sysconfig.<name>

settings file which contains information about current active configuration. This file is read by **sysconfig -p** and **svi**.

<root_dir>/EDRC.config_byhand <root_dir>/EDRC.config_byhand.<name>

a list of files to be protected from overwriting after the initial run of **sysconfig**.

<root_dir>/config_byhand

a list of files to be protected from overwriting after the initial run of **rmtconfig** a system configuration tool provided by the SFI-Director. New entries should not be entered into this file, it is only considered to protect systems configured with **rmtconfig** from miss-configuration.

EXAMPLES

0) naming of the system configuration sources

There is no restriction of the naming of the configuration sources (**CONFIGURATION**).

However, it proved to make sense to use a naming scheme as known from the Domain Name Service (DNS) due to the fact that it is well known and the hierarchical structure that is expandable and allows to start with a very simple configuration setup and enables to specify also very specialized configurations with clear naming.

Configuration naming convention following the DNS example:

| CONFIGURATION | NAME | Explanation |
|-----------------------|------|--|
| acme.ch | base | The base configuration defines the system behaviour for the whole ACME enterprise. This configuration holds all files that are common in all Unix environments in the ACME corporation. All environment dependent configurations are done applying the related configuration on top of this one. |
| test.acme.ch | | This configuration holds only the files that are special to the TEST environment. For a complete system configuration, first the 'acme.ch' configuration and then the 'test.acme.ch' configuration has to be applied. |
| production.acme.ch | | This configuration holds only the files that are special to the PRODUCTION environment. |
| preproduction.acme.ch | | This configuration holds only the files that are special to the PREPRODUCTION environment. |

See also the following examples.

1) apply a system configuration to a vanilla system

This is an output example of the use of **sysconfig** on a vanilla HP-UX (OSID = HP-11) system. This configuration has no **pre_exec** script, but has a **post_exec** script. At this stage no **config_byhand** information is available. See also next example, where the configuration is re-applied.

If the hostname is not set, set it prior to applying the configuration using the **hostname(1)** command:

```
[ /root ]
[ root@unknown ][-sh]: hostname acme001
```

Apply the configuration:

```
[ /root ]
```

```
[ root@acme001 ][-sh]: ~edrc/bin/sysconfig \
-s /opt/edrc/scripts/ACME-sat/sysconfig/acme.ch
```

done.

```

2) re-apply a system configuration to a system already configured with sysconfig

This is the re-applying of the same configuration as applied in the example 1) above. See the now expanded list of files protected by **config_byhand**. In this example all files residing on the system are still identical with the files in the repository, therefore it was not needed to re-apply any file to the system.

```

```

3) print applied configuration

Print the configuration applied to a system using **sysconfig**. This system has one configuration applied:

```

[ / ]
[ root@acme001 ][-sh]: ~edrc/bin/sysconfig -p

sysconfig - configure a Unix/Linux system, by Chr. Walther

/ -

CONFIG:      acme.ch
NAME:
OSID:        HP-11

```

```

SOURCE:      /opt/edrc/scripts/ACME-sat/sysconfig/acme.ch
ROOTDIR:     /
BACKUPDIR:   /opt/edrc/var/backup
BACKUPFILE:  2007-06-04_16.13.27__sysconfig.cpio.gz
DESCRIPTION: BASE PRODUCTION SERVER CONFIGURATION for Operating System
EXECUTED:    Mon Jun  4 16:13:27 METDST 2007

```

4) system having multiple configurations applied

This is an efficient usage of **sysconfig** using two configurations.

The base configuration (acme.ch) defines the system behaviour for the whole ACME enterprise and the unnamed environment dependent configuration (production.acme.ch) defines the special configuration for the servers in the PRODUCTION environment.

```

[ /root ]
[ root@acme002 ][-sh]: ~edrc/bin/sysconfig -p

```

sysconfig - configure a Unix/Linux system, by Chr. Walther

/ -

```

CONFIG:      production.acme.ch
NAME:
OSID:        HP-11
SOURCE:      /opt/edrc/scripts/ACME-sat/sysconfig/production.acme.ch
ROOTDIR:     /
BACKUPDIR:   /opt/edrc/var/backup
BACKUPFILE:  2005-07-12_20.09.27__sysconfig.cpio.gz
DESCRIPTION: PRODUCTION SERVER CONFIGURATION for Operating System
EXECUTED:    Tue Jul 12 20:09:27 METDST 2005

```

/ - base

```

CONFIG:      acme.ch
NAME:        base
OSID:        HP-11
SOURCE:      /opt/edrc/scripts/ACME-sat/sysconfig/acme.ch
ROOTDIR:     /
BACKUPDIR:   /opt/edrc/var/backup
BACKUPFILE:  2004-11-23_05.28.15__sysconfig.cpio.gz
DESCRIPTION: BASE SERVER CONFIGURATION for Operating System
EXECUTED:    Tue Nov 23 05:28:15 EST 2004

```

5) system having multiple configurations plus cluster support

This is a more advanced usage of **sysconfig** also including the configuration of cluster packages.

This output is from a system used in normal operations for PREPRODUCTION and in a

disaster case as **PRODUCTION**. The system will be reconfigured (also using **sysconfig**) during disaster recovery to give it the **PRODUCTION** configuration.

This system has five configurations applied. In this case the *base* (acme.ch) configuration contains all basic configuration files of the ACME enterprise. The *preproduction* (preproduction.acme.ch) configuration is applied on top of the *base* configuration and contains all basic configuration of the **PREPRODUCTION** environment that will not be changed during a disaster recovery. The unnamed (normal.preproduction.acme.ch) configuration is applied on top of the *preproduction* configuration and contains only the files that are needed to configure the system as a **PREPRODUCTION** system in **NORMAL OPERATIONS**. This part of the configuration will be replaced with the unnamed (disaster.preproduction.acme.ch) configuration to reconfigure the system in case of disaster and give it the **PRODUCTION** identity.

The configurations *dwh_db1* and *dwh_db2* are the configurations of cluster packages, that are reconfigured during disaster recovery, too.

To ensure that the cluster package configuration is only displayed on the node where the cluster package is running, prior to the execution of **sysconfig** a symbolic link to the settings file has to be created. This will place the settings file to a moving file system:

```
[ / ]
[ root@acme003 ][-sh]: ln -s /data_dwh1/.EDRC.sysconfig.dwh_db1 \
                        .EDRC.sysconfig.dwh_db1
```

The symbolic link has to be created on each node where the cluster package is able to start.

In this case the filesystems **/data_dwh1/**, **/ora0[1-3]_dwh1/** are moved with the cluster package, that's also the reason why the configurations of the cluster packages are needed to be applied to the root directory (**/**).

```
[ /root ]
[ root@acme003 ][-sh]: ~edrc/bin/sysconfig -p
```

sysconfig - configure a Unix/Linux system, by Chr. Walther

/ -

```
CONFIG:      normal.preproduction.acme.ch

NAME

sysconfig.cfg – configuration file for sysconfig

SYNOPSIS

edrc/etc/sysconfig.cfg
<src_dir>/sysconfig.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **sysconfig** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**START_USER**

This is the user **edrc** has to be started with.

Example: **START_USER=eroot**

Default: **START_USER=root**

BACKUP_DIR

sysconfig saves all files ahead of removing or installing the new files scripts to this directory.

Example: **BACKUP_DIR=/var/opt/edrc/backup**

Default: **BACKUP_DIR=var/backup**

LOG

Log output dir of **sysconfig**. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation.

Example: **LOG=/var/opt/edrc/log**

Default: LOG=var/log

CONFIG_BYHAND

With this setting the behaviour of the applying of the **config_byhand** settings can be configured.

When it is set to *REPLACE* the already applied **config_byhand** file is replaced by the **config_byhand** file of the **sysconfig** repository to be applied.

If it is set to *MERGE*, the definitions of the already applied **config_byhand** file and the contents of the **config_byhand** file in the **sysconfig** repository is merged together.

Example: CONFIG_BYHAND=MERGE

Default: CONFIG_BYHAND=REPLACE

NAME

sysconfig.tools – list of all sysconfig tools distributed with WA2L/edrc

SYNOPSIS

-

AVAILABILITY

WA2L/edrc

DESCRIPTION

This man page lists all additional system configuration tools (scripts) that can be called in the **check**, **pre_exec** and **post_exec** scripts that are part of the core WA2L/edrc package and distributed with it.

If you write an own system configuration tool do not list it in this man page, due to the fact that your change would be lost after an upgrade of WA2L/edrc. If you send your tool to the author of WA2L/edrc and it is decided to include it into the core distribution, your command will be added to this list.

If a man page is written for a system configuration tool, the manpage name convention is **sysconfig.tools.my_command.3** and it has to be placed into the man page directory **man/all/man3**.

If a configuration supports multiple operating systems, what is normally the case in heterogeneous environments, you can place operating system dependent scripts into the directory **var/sysconfig/tools/<OSID>**, where **<OSID>** is the operating system id as returned by the **osid(1)** command, instead of coding everything directly into the **check**, **pre_exec** or **post_exec** script.

E.g.: if you like to set the default router entry on your Linux, HP-UX and Solaris systems (this is very different on those systems) in the **post_exec** script you can create a script called for instance **'set_default_router'** for each operating system and place it into the related directory. This enables you to save effort in writing the **post_exec** script for all the operating systems to be configured and simplifies those scripts because you don't have to include the whole code into multiple post exec scripts.

If multiple operating systems can be handled identical, a script can be placed into the **var/sysconfig/tools/default** folder and there is no need to have to place identical copies into more then one **<OSID>** directory.

The search order is to first look for the tool script in the operating system related directory (**<OSID>**) and then in the **default** directory. You should (of course) synchronize the tool directory contents over all your WA2L/edrc installations to fully benefit from this feature. See **filedist(1)** for instructions how to distribute files easily.

SYSCONFIG TOOLS OF CORE WA2L/edrc

default/create_users

SYNOPSIS

```
cat <<EOM | create_users [ passwd_file ]
tools-acme:*:901:7000:ACME Users Tools, Software, 2008-05-31 2008-05-
tools-all:*:902:7000:all Users Tools, Software, 2008-05-31 2008-05-31
ACME:*:904:7000:ACME Scripts, Software, 2008-05-31 2008-05-31:/opt/AC
EOM
```

DESCRIPTION

create user(s) on a system based on a **/etc/passwd** format input provided via **stdin**. A user created using **create_users** is first removed from the system and then added again to ensure the settings are correct. The user is removed with the system's native **userdel (8)** and added with **useradd(8)**, but if one of the commands fails, the related step is performed by modifying the **/etc/passwd** file directly.

SEE ALSO

sysconfig.tools.create_users(3)

NOTES

-

AUTHOR

create_users was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net .

{HP-11|HP-11i|HP-11ia}/edit_netconf

SYNOPSIS

```
edit_netconf netconf_file | ...
```

DESCRIPTION

interactively edit a file having the structure of the **/etc/rc.config.d/netconf** file as known on HP-UX.

In addition to the standard network interface fields (**INTERFACE_NAME**, **IP_ADDRESS**, **SUBNET_MASK**, **BROADCAST_ADDRESS**, **INTERFACE_MODULES**, **INTERFACE_STATE**, **DHCP_ENABLE**) the field **INTERFACE_DESCRIPTION** is computed to define a textual description of the purpose for each interface.

In addition to the standard routing definition fields (**ROUTE_DESTINATION**, **ROUTE_GATEWAY**, **ROUTE_COUNT**, **ROUTE_ARGS**) the field **ROUTE_DESCRIPTION** is computed to define a textual description of the purpose for each route entry.

The result of the editing is sent to **stdout** to allow further data processing.

SEE ALSO

sysconfig.tools.edit_netconf(3)

NOTES

the OS-ids **HP-11i** and **HP-11ia** are symbolic links to **HP-11** that's why the **edit_netconf** is not located in the **default** directory.

AUTHOR

edit_netconf was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net .

ENVIRONMENT

See **sysconfig(1)** section **ENVIRONMENT**.

EXIT STATUS

-

FILES

var/sysconfig/tools/<OSID>
operating system dependent system configuration tools.

var/sysconfig/tools/default
non operating system dependent system configuration tools or tools that can be used on multiple operating systems.

EXAMPLES

-

SEE ALSO

NAME

sysinfo – print information on overall system statistics

SYNOPSIS

edrc/bin/sysinfo [**-h** | **-a**]

sysinfo [**-u** | **-l** | **-r** | **-s** | **-n**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

With the **sysinfo** command information about the overall system statistics is printed.

If called with the **-a** option, all overall statistics information is provided in a plain human readable format.

However, the main purpose of the **sysinfo** command is to print out dedicated information with the options **-u**, **-l**, **-r**, **-s** or **-n**. The output of those options is formatted in a fashion that it is possible to compute it easily with other commands.

Especially the output of the **uptime(1)** command provided by the operating system is often very hard to use for further data processing, due to the fact that the output changes completely depending on the point in time when called. Therefore the output of **sysinfo -u** is much easier to process.

The format of all outputs (except **-a**) is:

<date>;<seconds since Epoch>{;<value>}

Example (**sysinfo -u**):

2006-09-30 00:04:50;1159567490;349541

OPTIONS

- h** usage message.
- a** all overall system statistics information in a plain human readable format. This output is not intended for further data processing.
- u** uptime (=time since last boot) in seconds [one value field].
- l** 1, 5 and 15 minute load average [three value fields].
- r** total usable main memory, total available memory, amount of shared memory and memory used by buffers in bytes [four value fields].

- s** total swap space and swap space still available in bytes [two value fields].
- n** number of current processes [one value field].

EXIT STATUS

- 0** no error.
- 1** the system call to resolve a certain value did not succeed. See accompanied error message for more detailed information.
- 4** usage displayed.
- 99** functionality not implemented yet.

FILES

The files involved to resolve the information are operating system dependent.

/var/adm/utmp
uptime on HP-UX.

EXAMPLES

The following examples is the result if all commands are executed at the same time.

0) system information

```
[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ][*edrc*/bash]: uname -a

Linux rh7mzv7t001 2.4.7-10 #1 Thu Sep 9 00:25:31 EDT 2006 i686 unknown
```

1) plain output

```
[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ][*edrc*/bash]: sysinfo -a

Date: 2006-09-30
Time: 00:25:31
Seconds since Epoch: 1159568731
Uptime: 4days, 1hours, 26minutes, 22seconds
Load Avgs: 1min(22240) 5min(6816) 15min(1952)
Total Ram: 513304k      Free: 76808k
Shared Ram: 0k
Buffered Ram: 104016k
Total Swap: 409616k    Free: 409616k
Number of processes: 78
```

2) uptime

```
[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ][*edrc*/bash]: sysinfo -u

2006-09-30 00:25:31;1159568731;350782

[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ][*edrc*/bash]: uptime

12:25am up 4 days,  1:26,  2 users,  load average: 0.34, 0.10, 0.03
```

3) system load averages

```
[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ][*edrc*/bash]: sysinfo -l

2006-09-30 00:25:31;1159568731;22240;6816;1952
```

4) RAM

```
[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ][*edrc*/bash]: sysinfo -r

2006-09-30 00:25:31;1159568731;525623296;78651392;0;106512384
```

5) swap

```
[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ][*edrc*/bash]: sysinfo -s

2006-09-30 00:25:31;1159568731;419446784;419446784
```

6) processes

```
[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ][*edrc*/bash]: sysinfo -n

2006-09-30 00:25:31;1159568731;78
```

SEE ALSO

ctime(3), date(1), edrcintro(1), sysinfo(2), sed(1), time(2), timer(1), uptime(1), utmp(5)

NOTES

The **sysinfo** command was derived from the source code example **sysinfo.c** provided by <detour@metalshell.com> on <http://www.metalshell.com> and has been enhanced by Christian Walther. See <http://www.metalshell.com> for additional coding examples.

BUGS

The field delimiter is fixated to `;` and is therefore not changeable with a command line option, yet. As a workaround the following command sequence can be issued:

```
sysinfo -u | sed -e 's/;/ delimiter /g'
```

Not all options or functions are implemented on all operating systems. The table below lists the options currently implemented for a certain operating system:

| OSID | -u | -l | -r | -s | -n |
|---------|-----|-----|-----|-----|-----|
| Linux | YES | YES | YES | YES | YES |
| HP-10 | YES | NO | NO | NO | NO |
| HP-11 | YES | NO | NO | NO | NO |
| HP-11i | YES | NO | NO | NO | NO |
| Solaris | YES | NO | NO | NO | NO |

NAME

syscp – copy system file to sysconfig repository

SYNOPSIS

edrc/bin/syscp [**-h**]

syscp *file* ...

AVAILABILITY

WA2L/edrc

DESCRIPTION

Copy an (active) file on the system to the **sysconfig** repository that has been used to configure the system.

If a file is in multiple repositories it can be interactively chosen to which repository the file should be copied.

If a system file does not differ (content or permissions) from the file residing in the repository a **WARNING** is displayed.

Each file copy has to be acknowledged.

If the system file differs from the repository file and the repository contains "replacement tags" in the format **@[-_A-Z]+@** (e.g. **@HOSTNAME@** in a **hosts** file) as used in **post_exec** and **pre_exec** scripts, a warning is displayed. Most likely it is not wished to overwrite such a repository file.

If a new file is added to a repository and a part of the path on the system is a symlink that is not already added to the repository, the new path to the file and the file is not added to the repository. This is a safety precaution. If you encounter this situation you most likely want to add the original path to the repository instead of the path thru the symlink.

An example of such a situation is to add **/etc/init.d/nginx** to the repository, where the **init.d** directory is on some systems a symlink to **rc.d/init.d**. In this case you should add **/etc/rc.d/init.d/nginx** to the repository.

OPTIONS

-h usage message.

file ... list of files to be copied to the repository.

ENVIRONMENT

-

EXIT STATUS

- 0** no error.
- 2** operating system is not supported, yet. See **osid**(3) if you get this error.
- 4** usage printed.
- 5** command aborted pressing <Ctrl>+<C> or using **kill**(1).

FILES

<root_dir>/EDRC.sysconfig <root_dir>/EDRC.sysconfig.<name>
 settings file which contains information about current active configuration. This file is read when using **sysconfig-p**, **sysvi**, **syscp** and **sysdiff**.

EXAMPLES**1) usage example****1.1) display the applied configurations**

```
[ / ]
[ root@acme002 ][*edrc*/ksh]: sysconfig -p

sysconfig - configure a Unix/Linux system, by Chr. Walther

/ -

NAME

sysdiff – compare system file(s) with file(s) in sysconfig repository

SYNOPSIS

edrc/bin/sysdiff [**-h**]

sysdiff [**-v**] *file* ...

AVAILABILITY

WA2L/edrc

DESCRIPTION

list if an (active) file on the system applied with **sysconfig** differs to the file(s) in the related repository. The files are considered as different if the content or the filepermissions differ. To obtain a plain list of files that differ from the applied file, redirect the output to **stderr**.

OPTIONS

-h usage message.

-v verbose output.

file ... system file(s) to compare to the related file in a **sysconfig** repository.

ENVIRONMENT

-

EXIT STATUS

0 no error.

2 operating system not supported.

4 usage printed.

5 the **sysdiff** command was aborted.

FILES

<root_dir>/EDRC.sysconfig<.name>

settings file(s) that contains information about current active configuration(s). This file is read when using **sysconfig -p**, **syscp**, **sysvi** and **sysdiff**.

NAME

syspoll – poll systems to execute a query

SYNOPSIS

edrc/bin/syspoll [**-h**]

syspoll [**-c** *configfile*] [**-r** *retries[:interval]*] **-a** { **start** | **retry** } **-j** *jobname* [**-s** *setname*] [**-t** *hostlist*] [**-o** *outputfile*]

syspoll [**-c** *configfile*] **-a** { **list_retry** } **-j** *jobname* [**-s** *setname*]

syspoll [**-c** *configfile*] **-a** { **list_jobs** | **list_sets** | **list_protos** | **list_perf** }

syspoll [**-c** *configfile*] **-a** { **print_log** [**-b** *begin_date*][**-e** *end_date*] }

AVAILABILITY

WA2L/edrc

DESCRIPTION

poll systems and execute a query.

The main purpose is to centrally control report data collection for different target operating systems.

syspoll writes all command status and information output to **stderr** and only the job header and the query results to **stdout** respectively the *outputfile* if specified.

The following phases are traversed when a **syspoll** *job* is executed (**start** or **retry**) in a certain *set*:

1) **general information**

print general information about the environment where **syspoll** is started, the configuration and the impact of some configuration- and command line options.

2) **set information**

print information about the set.

3) **job information**

print information about the job.

4) **job header**

write the job header as specified in the **JOB_HEADER** setting in **VARDIR/jobs/<job-name>/job.cfg** to the *outputfile* (if specified) and **stdout** if the action **-a start** is selected.

If if the action **-a retry** is selected, the job header is not written (again) to the *outputfile* and is printed for reference purposes to **stderr** only.

5) connect to systems

connect to all systems as specified in the system target list using **-t hostlist**, the retry file or the **POLL_HOSTLIST** setting in the **etc/syspoll.cfg** file depending on the command line options selected.

5.1) resolve connection information

try to resolve connection information, as the IP address, of the system to connect to. If the IP address cannot be resolved, no connection is possible (of course).

5.2) probe connection

If the IP address could be resolved in the previous step, probe the connection to the target system using **is_up(3)** internally.

5.3) probe operating system

when the connection has been probed successfully, probe the operating system of the target system. This is actually the first test to check if a login to the target system is possible respectively, depending on the protocol, information can be queried from the target system.

5.4) handle query

if the operating system has been probed successfully in the previous step, handle the job query.

5.4.1) deploy query payload

if there are payload files present for the job, deploy (copy) the payload files to the target system. Not all protocols might be capable to deploy payload files (see: **lib/syspoll/protocols/<VARIANT>/<PLUGIN>**).

Payload files are additional programs, scripts or other data that is needed by the query to do its work and are not present on the target system.

5.4.2) execute query

if a query is defined, execute the query on/for the target system. When queries are written it is important to output all relevant query result data to **stdout**. Data/information printed to **stderr** will be seen on the screen but not saved in the *outputfile*.

If a query could be executed **syspoll** rates the related target system as processed successfully and it is removed from the retry list.

5.4.3) clear query payload

remove the deployed files from the target systems again.

6) execution summary

print an execution summary of the *job*.

As soon as it is possible, **syspoll** forecasts a completion of the entire job run based on the elapsed time, the total number of systems to process and the number of already processed target systems. The forecast is adjusted constantly.

syspoll has a plugin mechanism, where new protocols or new variants of protocols can be integrated.

New protocols might be SNMP or a database plugins to connect to PostgreSQL, MySQL, MSSQL or Oracle.

Protocol variants are existing protocols, but customized in the fine details of the connection method and the execution of queries. This might be the case if in a certain compliance situation it is only allowed to execute queries on remote systems using **sudo**(8). For this a variant of an existing protocol can be created without adjusting jobs.

OPTIONS

-h usage message. Here the revision of **syspoll** is also displayed.

-c *config_file*
configuration file.

-r *retries[:interval]*
number of retries and interval between two immediate connection retries in seconds.

-s *setname*
set name.

A *set* is a handle to specify some specific additional general credentials that are valid for a job; as the login credentials used to execute the query and the protocol variant used. With sets it is possible to write a job **query** and use it without modifications for different target customer environments even if the user names, passwords and the details to connect to the systems change.

When a job is started first with the *setname* **ACME** and then with **Riptide**, for each *set* an own retry list is maintained. It is intended to use the customer name as *setname* or a combination of the customer name and the targeted customer environment, as: **ACME.TEST**.

The default *setname* is the customer name of the environment where **syspoll** is started as returned by **server_environment -C** or **default** if the set configuration for the customer name does not exist.

A *set* is represented by a configuration file in the **var/syspoll/sets/** directory.

See also: **server_environment(3)**.

-a action:

start -j *jobname* [**-s** *setname*] [**-t** *hostlist*]
start a job for a given *set*.

The job header as specified in the **JOB_HEADER** setting in **VARDIR/jobs/<job-name>/job.cfg** is written once to the *outputfile* at the beginning of the job execution when the **start** action is executed.

retry -j *jobname* [**-s** *setname*] [**-t** *hostlist*]
retry job on failed systems for a given *set*.

The job header as specified in the **JOB_HEADER** setting in **VARDIR/jobs/<job-name>/job.cfg** is not written to the *outputfile* when the **retry** action is executed.

list_retry -j *jobname* [**-s** *setname*]
print current retry target list for a *job* for a given *set*.

list_jobs
list all defined jobs.

list_sets
list all defined sets.

list_protos
list all available protocols and protocol variants.

Currently the protocols SSH (secure shell) and WMI (Windows Management Instrumentation) are distributed with WA2L/edrc for **syspoll**.

list_perf
list performance statistics of past job runs.

print_log [-b *begin_date*] [**-e** *end_date*]
print the **syspoll** log file between the *begin_date* and the *end_date*.
If the *begin_date* is not specified, the log file is printed from the beginning to the *end_date*. If the *end_date* is not entered, the log file is printed from the *begin_date* to the end. If neither of the two dates is specified the whole log is printed.

-j *jobname*
name of a job to be executed.

-t *hostlist* list of target hosts. This list can be a comma separated list (as returned by **hostlist -l**), a file containing a list of hosts or a hostgroup name (*@HOSTRGOUP*).

The file has to be specified with an absolute path name.

When a dash is specified as *hostlist* (example: **syspoll -a start -j poll -t -**) the system target list is read from **stdin**.

-o *outputfile*

output file where the query results are saved. It is also possible to capture the query results by redirecting the **stdout** output of **syspoll**.

The **outputfile** has to be specified as an absolute path name. See also: **rel2abs(3)** to see how to convert a relative path name to an absolute.

-b *begin_date*

begin date in the military format **YYYY-MM-DD**. To compute dates in this format, see: **input(3)**, **seconds(3)**, **timer(1)**, **today(3)**, **tomorrow(3)**, **yesterday(3)**.

-e *end_date*

end date in the military format **YYYY-MM-DD**. To compute dates in this format, see: **input(3)**, **seconds(3)**, **timer(1)**, **today(3)**, **tomorrow(3)**, **yesterday(3)**.

ENVIRONMENT

\$SYSPOLL_CONFIGFILE

configuration file of **syspoll**. The **-c** *configfile* command line option has preference.

\$PRINT_FIT2WIDTH

If this environment variable is not set to *False*, the output of lists is limited to the current width of the terminal window and rows extending the window width are marked with '>>'.

EXIT STATUS

- | | |
|----------|--|
| 0 | no error. |
| 1 | configuration file does not exist. |
| 2 | <i>setname</i> does not exist. |
| 3 | <i>jobname</i> does not exist. |
| 4 | Usage printed. |
| 5 | syspoll aborted pressing <Ctrl>+<C>. |
| 6 | cannot write to <i>outputfile</i> as specified in -o <i>outputfile</i> . |
| 7 | protocol variant as specified in SET_PROTOCOL_VARIANT setting in the set configuration file <i>setname.cfg</i> does not exist |

- 8** cannot write to logfile.
- 9** cannot write to **VARDIR**.
- 11** temporary directory could not be claimed or created in **/var/tmp**. Check the system temporary directory **/var/tmp** if you get this error, it is an indicator of system intrusion.

FILES

The **VARDIR** can be defined in the **syspoll.cfg** file. Default is **edrc/var/syspoll/**.

etc/syspoll.cfg

default **syspoll** configuration file.

lib/syspoll/protocols/<VARIANT>/<PLUGIN>

protocol plugins.

lib/syspoll/protocols/edrc/<PLUGIN>

default protocol plugins that profit from the connection setup of WA2L/edrc, where the key files are located in the **var/connection/security/** directory.

var/cache/syspoll/

cache files, do not edit them by hand.

var/log/syspoll.log

logfile of **syspoll**.

VARDIR/jobs/<jobname>/

directory containing the definition of a job.

VARDIR/jobs/<jobname>/job.cfg

some global settings for the job, as **JOB_DESCRIPTION** and **JOB_HEADER**.

VARDIR/jobs/<jobname>/<OSDIR>/<PROTOCOL>/query

<OSDIR> ::= **<os_name>.<os_release>.<os_machine>** | **<os_name>.<os_release>** | **<os_name>** | **default**

Query to be executed on a given operating system and the related protocol (**<PROTOCOL>**).

The following variables are exported to the query execution: **JOB_LOCALUSER**, **JOB_REMOTEUSER**, **JOB_PAYLOAD**, **JOB_QUERY**, **JOB_PROTOCOL**, **JOB_PASSWORD**, **JOB_LOCALTEMP**, **JOB_POSTQUERY**, **JOB_HOSTNAME**, **AWK**, **ECHO**, **TAIL** and **OSID**.

VARDIR/jobs/<jobname>/<OSDIR>/<PROTOCOL>/payload/

directory containing additional files that are temporarily needed on the target system to execute the query.

VARDIR/locks/

lockfiles, do not edit them by hand.

VARDIR/sets/<setname>.cfg

set configuration file.

VARDIR/sets/{<SERVER_ENVIRONMENT_CUSTOMER>.cfg[default.cfg]}

default set configuration file. If **-s setname** is not specified the *setname* defaults first to the customer name of the server environment (<SERVER_ENVIRONMENT_CUSTOMER>) as returned by **server_environment -C** where **syspoll** is started, if that **.cfg** does not exist to **default**.

VARDIR/state/

state information of **syspoll**, do not edit those files by hand.

VARDIR/state/<setname>.<jobname>.retry

retry file of systems that were not reached for a *jobname* in a given set (*setname*). The retry file contains all target systems that were not reachable plus all remaining systems if **syspoll** is aborted.

The retry file is reset when **-a start** is invoked.

When **-a retry** is issued once or multiple times, systems with a successful retry are removed from the retry file, unsuccessful systems remain in the file.

VARDIR/state/performance

record of job execution durations and success rates.

EXAMPLES

As always in WA2L/edrc, if the setup in **server_environment.cfg** and **hostlist.cfg** is done, the command runs within the environment without specifying targets. Therefore the options **-s setname** and **-t hostlist** can be omitted when the systems that are polled reside in the same environment as the host where **syspoll** is executed.

Thus, the most simplest invocation of **syspoll** is:

```
[ / ]
[ root@acme001 ][*eshell*/bash] syspoll -a start -j bdf

[ / ]
[ root@acme001 ][*eshell*/bash] syspoll -a retry -j bdf
```

The two example jobs referenced in this section are *probe* and *bdf*, where *probe* tests connections to target systems without executing a real query and *bdf* resolves the file system disk space usage as done by **df(1)** or **bdf(1)** and returns the result as csv file having the format **'HOST;FILESYS-TEM;TOTAL;FREE;USED;%USED;MOUNTPOINT;'**.

1) start the 'probe' job to check target connectivity

The *probe* job is a job that is considered to be part of the **syspoll** command (therefore do not change it, create a copy if you need a modified version of it). This job does not have a real

query, the purpose of this job is simply to test connections to the given targets and verify that the connection settings are correct.

```
[ / ]
[ root@acme001 ][*eshell*/bash] syspoll -a start \
-s ACME -j probe \
-t acme002,acme003,acme004
```

2) start 'bdf' job and save query results to new output file

```
[ / ]
[ root@acme001 ][*eshell*/bash] syspoll -a start \
-s ACME -j bdf \
-t acme002,acme003,acme004 \
-o /tmp/bdf.csv
```

3) retry 'bdf' job for failed targets and add query results to existing output file

```
[ / ]
[ root@acme001 ][*eshell*/bash] syspoll -a retry \
-s ACME -j bdf \
-o /tmp/bdf.csv
```

4) retry 'bdf' job for additional targets and add query results to existing output file

```
[ / ]
[ root@acme001 ][*eshell*/bash] syspoll -a retry \
-s ACME -j bdf \
-t acme005,acme006 \
-o /tmp/bdf.csv
```

5) list current retry list for job 'bdf' in 'ACME' set

```
[ / ]
[ root@acme001 ][*eshell*/bash] syspoll -a list_retry \
-s ACME -j bdf
```

6) start a job on targets defined in hostgroup '@WEB'

See also: Example 10).

```
[ / ]
[ root@acme001 ][*eshell*/bash] syspoll -a list_retry \
-s ACME -j bdf \
-t @WEB
```

7) start a job on targets defined in a file

```
[ / ]
[ root@acme001 ][*eshell*/bash] syspoll -a start \
-s ACME -j probe \
-t /tmp/hostlist.txt
```

8) start a job on targets received from stdin

There is a file having pairs of hostnames and customer names separated by whitespaces:

```
acme001    ACME
acme002    ACME
websrv01   Bedrock
erp5       Bedrock
acme008    ACME
:
```

Run the *job* only on targets that are used for the customer 'ACME':

```
[ / ]
[ root@acme001 ][*eshell*/bash] \
awk '/\sACME$/ {print $1}' < /tmp/assets.lst | \
syspoll -a start -s ACME -j probe -t -
```

9) start a job on targets defined in a sqlite database

Run the *job* only on targets that are used for the customer 'ACME':

```
[ / ]
[ root@acme001 ][*eshell*/bash] sqlite /tmp/assets.db \
"select name from hosts where customer='ACME'" | \
syspoll -a start -s ACME -j probe -t -
```

10) start a job on targets defined in hostlist

See also: Example 6).

Using the setting `USE_HOSTLIST_DAT=True` and `CMAN_ENVIRONMENT=Highlander.ADMIN` in `hostlist.cfg` and when `syspoll` is started on a host that is member of the central management environment *Highlander.ADMIN* **hostlist(3)** can be used to address all targets of a certain customer.

Check if logged on to central management environment *Highlander.ADMIN* :

```
[ / ]
[ root@adm001 ][*eshell*/bash]: whereami

LOGGED ON TO SERVER ENVIRONMENT:

Customer           : Highlander
Environment         : ADMIN
Description         : Beringen, EDRC Development
```

Run the *job* only on targets that are used for the customer 'ACME':

```
[ / ]
[ root@adm001 ][*eshell*/bash] syspoll -a start \
-s ACME -j bdf -t 'hostlist -l -g @ACME.ALL'
```

11) start 'bdf' job and directly compute query results

Print a formatted list from csv output:

```
[ / ]
[ root@acme001 ][*eshell*/bash] syspoll -a start \
-s ACME -j bdf | print_list
```

Print a formatted list from csv output with a reduced set of columns:

```
[ / ]
[ root@acme001 ][*eshell*/bash] syspoll -a start \
-s ACME -j bdf \
-t acme002,acme003,acme004 | \
select_columns ";" "HOST;MOUNTPOINT;TOTAL" | print_list
```

Omit status information output during data collection:

```
[ / ]
[ root@acme001 ][*eshell*/bash] syspoll -a start \
-s ACME -j bdf \
-t acme002,acme003,acme004 \
2>/dev/null | \
select_columns ";" "HOST;MOUNTPOINT;TOTAL" | print_list
```

12) start a job and provide collected query results on WA2L/edrc:report

See also: Example 13), NOTES.

```
[ / ]
[ root@acme001 ][*eshell*/bash] syspoll -a start \
-s ACME -j bdf \
-o ~edrc/var/www/report/006/ACME/bdf/acme__bdf_'date +%Y%m%d'.csv
```

13) crontab entry to handle monthly data collection and provision of results to WA2L/edrc:report

See also: Example 12), NOTES.

In this example the collected query results are saved to the **\$HOME** directory of the user **'report'** what allows to access the report output directories thru **~report** from shell, scripts etc. independent of the actual userhome location.

Preparations to provide the collected data with WA2L/edrc:report:

1) create the directory structure to save the collected data

```
[ / ]
[ root@acme001 ][*eshell*/bash] mkdir ~report/ACME/bdf/

[ / ]
[ root@acme001 ][*eshell*/bash] chmod 755 ~report/ACME/bdf/
```

2) create a symbolic link from WA2L/edrc:report to the report data

```
[ / ]
[ root@acme001 ][*eshell*/bash] symlink ~report ~edrc/var/www/report/006
```

Create the crontab entry:

```
1 0 25 * * [ -d ~report/ ] && ~edrc/bin/syspoll -a start -s ACME -j bdf \
-o ~report/ACME/bdf/acme__bdf_'date +%Y%m%d'.csv > /dev/null 2>&1

1 2-20 25 * * [ -d ~report/ ] && ~edrc/bin/syspoll -a retry -s ACME -j bdf \
-o ~report/ACME/bdf/acme__bdf_'date +%Y%m%d'.csv > /dev/null 2>&1
```

In this definition the job is started once at **00:01** on every 25th of every month.

Then on the same day the job retries to query the unsuccessful targets every hour between 02:01 and 20:01.

Due to the fact, that **syspoll** locks a *job* for a *set* during execution it also does not create a mess if this job here runs longer then an hour.

The output is saved to the **~report/ACME/bdf/** directory.

The output file uses the reverse date as filename element using the **date(1)** command **acme__bdf_`date +%Y%m%d`.csv** what results in a filename of **acme__bdf_20130225.csv** when executed on February 25th 2013 (see also: <http://www.tugsat.tugraz.at/launch>).

14) example output of syspoll

Start the *bdf* job for set *ACME* and save job query results to **/tmp/diskspace.csv**:

```
[ / ]
[ root@acme001 ][*eshell*/bash]: syspoll -a start -j bdf \
-s ACME -t acme001,acme002,acme003,acme004,acme005,acme006 -o /tmp/diskspace.csv

NOTES

To serve reports with the web application '**WA2L/edrc:report - The Operating System Report Portal**' included in WA2L/edrc, write the reports to a directory structure having the convention **<YOUR_REPORTBASE>/<SERVER_ENVIRONMENT_CUSTOMER>/<reportname>/<outputfile>** and the world readable flag set. Then create a symbolic link using **symlink(1)** from **var/www/report/rpt/<NUMBER>** to **<YOUR_REPORTBASE>**.

See also: Example 12) and 13) in **EXAMPLES**, **WA2Ledrc:report(1)**, **edrcinit(1m)**, and '**http://hostname:9900 -> Help**' for more information about **WA2L/edrc:report**.

BUGS

Abort handling is fully tested under Linux only. Therefore when running **syspoll** on other operating systems, refrain from aborting a running **syspoll** session if possible. However, the expected side effects are not severe.

AUTHOR

syspoll was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

syspoll.cfg – configuration file for syspoll

SYNOPSIS

edrc/etc/syspoll.cfg
\$SYSPOLL_CONFIGFILE

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **syspoll** command.

FILEFORMAT

Rows starting with a **#** are considered as comments.

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the **=** and the **VALUE** are no spaces.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a **VALUE**.

OPTIONS

VARDIR location of the **edrc/var/syspoll** directory containing all state information, job files and set configurations. When the **VARDIR** is changed from the default location it has to be ensured that the whole structure of the **VARDIR** is present at the altered location. Ensure that the directory permissions are identical to the ones as set at the default location.

See also description in **syspoll(1)** concerning this topic.

Example: **VARDIR=/dat/syspoll/var/syspoll**

Default: **VARDIR=edrc/var/syspoll**

LOG Log output dir of syspoll. If you specify a relative path name the path is relative to the WA2L/edrc installation directory.

Example: **LOG=/var/opt/syspoll/log**

Default: **LOG=edrc/log**

POLL_HOSTLIST

Space separated list of hosts. This hosts will be polled if not specified on command line.

Example: POLL_HOSTLIST="hostlist -g @ALL"

Default: POLL_HOSTLIST='hostlist'

RETRY_COUNTER

Number of immediate connection retries.

Example: RETRY_COUNTER=10

Default: RETRY_COUNTER=2

RETRY_INTERVAL

Interval (pause between retries) of connection retries in seconds.

Example: RETRY_INTERVAL=10

Default: RETRY_INTERVAL=5

LOCK_TIMEOUT

timeout in seconds. This is the maximum lifetime of a job lock. This setting has to be adjusted only, if the data processing duration exceeds the default.

If the jobs are scheduled, the **LOCK_TIMEOUT** should not exceed the minimum scheduling interval.

Example: LOCK_TIMEOUT=10800

Default: LOCK_TIMEOUT=43200

NAME

sysvi – edit a file in sysconfig repository

SYNOPSIS

edrc/bin/sysvi [**-h**]

sysvi *file* ...

svi [**-h**]

svi *file* ...

AVAILABILITY

WA2L/edrc

DESCRIPTION

edit the file in a sysconfig repository which is related to the local (active) file on the system.

If a file is in multiple repositories it can be interactively chosen in which repository the file should be edited.

OPTIONS

-h usage message.

file ... list of files to be edited in the repository.

ENVIRONMENT

-

EXIT STATUS

- | | |
|----------|--|
| 0 | no error. |
| 2 | operating system is not supported, yet. See osid (3) if you get this error. |
| 4 | usage printed. |
| 5 | command aborted pressing <Ctrl>+<C> or using kill (1). |

- 11** temporary directory could not be claimed in **/tmp**. Check the system if you get this error, it is an indicator for system intrusion.

FILES

<root_dir>/EDRC.sysconfig<.name>

settings file(s) that contains information about current active configuration(s). This file is read when using **sysconfig -p**, **syscp**, **sysvi** and **sysdiff**.

etc/exrc settings for the **vi** / **vim** editor.

EXAMPLES

-

NAME

sys2html – collect system configuration and create a HTML report

SYNOPSIS

edrc/bin/sys2html [**-h**]

sys2html **-o** *outdir* [*user@*]*hostname*...

sys2html [*options*] **-o** *outdir* [*user@*]*hostname*...

sys2html [*options*] **-r** [*user@*]*hostname*... > *data.raw*

sys2html **-o** *outdir* - < *data.raw*

sys2html [**-c** *config_file*] **-l**

sys2html [**-c** *config_file*] **-p** *OSID*

options ::= [**-m**] [**-n** *name_resolver*] [**-i** *info_resolver*] [**-c** *config_file*] [**-s** *info_file*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

The **sys2html** command collects the system configuration into a 'System Documentation' HTML file.

It includes the collection of **cron** and **at**, installed hardware and software, filesystems, dump- and swap-configuration, LVM, network settings, kernel, system enhancements and applications.

The HTML 'System Documentation' report is also suited for viewing using **lynx**(1) on the command line.

sys2html aims to collect the same information as the well known **cfg2html**(1m) does, but without the need to install it on the (remote) systems where the configuration is collected.

To connect to the target system SSH (with **ssh-exec**) is used.

The generation of the HTML 'System Documentation' report is performed and saved on the system where the **sys2html** is invoked.

OPTIONS

-h usage message.

- c** *config_file* specify an alternate configuration collection configuration **sys2html.dat**(4) file.
- i** *info_resolver* custom host name to system description resolver. The *info_resolver* is used to dynamically resolve the system description.

If it cannot return a system description, the system description is looked-up in the **sys2html.inf** file, if possible.

The *info_resolver* must be an executable that receives a *hostname* as argument and returns the system description to **stdout**, whereas the output can consist of multiple lines.
- l** list currently configured operating systems (*OSID*) to collect system information from.
- m** force **MULTISTEP** query mode, where for each configuration row with defined *commands* an SSH connection to the target system is made in sequence.
- n** *name_resolver* custom host name to IP address resolver. The *name_resolver* is used if the IP address cannot be resolved by the system (using **getent hosts hostname** internally). It must be an executable that receives a *hostname* as argument and returns the resolved IP address as first field, whereas the fields are white-space separated.
- o** *outdir* output directory where to save the **HTML** 'System Documentation' reports.
- p** *OSID* print collection definition (**TITLE**, **COMMAND**) for the given *OSID*.
- r** print raw data of collected configuration to **stdout**.
- s** *info_file* specify an alternate central system information description **sys2html.inf**(4) file.
- read from **stdin**.
- data.raw* raw data returned by **sys2html** not formatted to **HTML**.
- user* user to connect to on the remote system. If no *user* is specified, this defaults to **root**.
- hostname* space separated list of systems where to remotely collect the system configuration.

ENVIRONMENT

-

EXIT STATUS

- | | |
|----------|---|
| 0 | no error. |
| 1 | cannot write to the <i>outdir</i> directory specified in the -o option. |
| 2 | operating system not supported. See osid (3) if you get this error. |
| 3 | on command line specified sys2html.cfg or sys2html.inf could not be read. |
| 4 | usage displayed. |

FILES

- etc/sys2html.dat**
configuration collection configuration file for **sys2html**(1m).
- etc/sys2html.inf**
central system information description file for **sys2html**(1m).
- /etc/cfg2html/systeminfo**
local system description file as known from the **cfg2html**(1m) command.

EXAMPLES

-

SEE ALSO

edrcintro(1), **cfg2html**(1m), **getent**(1), **osid**(3), **ssh-exec**(1), **sys2html.dat**(4), **sys2html.inf**(4), **lynx**(1), <https://www.cfg2html.com>

NOTES

The **sys2html** command is a simplified "clone" of the **cfg2html**(1m) command and it is highly inspired by it.

Most obvious differences to the **cfg2html** are, that **sys2html**:

- collects the system configuration from remote systems,
- allows to define the elements to be collected on the remote system in a configuration file and
- is currently configured to collect system information from **Linux** (OSID: Linux-64) and **Dell/EMC Data Domain** (OSID: DELLDataDomain) systems.

BUGS

The configuration collection of **sys2html** is not that sophisticated as the one from **cfg2html** due to the configuration file approach.

NAME

sys2html.dat – configuration query definition for sys2html

SYNOPSIS

edrc/etc/sys2html.dat

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration query definition for the **sys2html** command.

This file specifies all configuration query commands to be executed on the target system and the **HTML** report structure.

FILEFORMAT

The fileformat is a list of definitions that have the format

OSID;TITLE;COMMAND

Rows starting with a **#** are considered as comments. Empty lines are allowed, too.

OPTIONS

OSID operating system id of the target system. See also **osid**(3) and **rosid**(3).

TITLE section title or subtitle in the **HTML** report.

If no *COMMAND* is specified, the entry is treated as a section title.

Title entries starting with an **@** are options and its *COMMAND* entry is not executed on the target system.

Options are:

@MODE Query mode.

Set **SINGLESTEP** in **COMMAND** (is the default) to submit the whole configuration query definition as one command sequence to the target system.

MULTISTEP causes to submit each definition row separately to the target system. This mode is slower as **SINGLESTEP** and is only needed if the target system does not provide the **echo** command.

This mode can be forced using the **-m** option and can be used to debug query

configurations and identify a long running or hanging *COMMAND* .

@FILTER

this option allows to define a filter in **COMMAND** that is applied to the whole query result data and can be used to filter out unwanted texts.

@REPORTTITLE

this option allows to change the report title different to the default **System Documentation**.

COMMAND

command to query the configuration. It is allowed to use the semicolon character (;) in this field.

NAME

`tcpdump` – dump traffic on a network

SYNOPSIS

```
tcpdump [ -adefnNOpqRStuvxX ] [ -c count ]
          [ -C file_size ] [ -F file ]
          [ -i interface ] [ -m module ] [ -r file ]
          [ -s snaplen ] [ -T type ] [ -w file ]
          [ -E algo:secret ] [ expression ]
```

DESCRIPTION

Tcpdump prints out the headers of packets on a network interface that match the boolean *expression*. It can also be run with the **-w** flag, which causes it to save the packet data to a file for later analysis, and/or with the **-r** flag, which causes it to read from a saved packet file rather than to read packets from a network interface. In all cases, only packets that match *expression* will be processed by *tcpdump*.

Tcpdump will, if not run with the **-c** flag, continue capturing packets until it is interrupted by a SIGINT signal (generated, for example, by typing your interrupt character, typically control-C) or a SIGTERM signal (typically generated with the **kill**(1) command); if run with the **-c** flag, it will capture packets until it is interrupted by a SIGINT or SIGTERM signal or the specified number of packets have been processed.

When *tcpdump* finishes capturing packets, it will report counts of:

packets “received by filter” (the meaning of this depends on the OS on which you’re running *tcpdump*, and possibly on the way the OS was configured - if a filter was specified on the command line, on some OSes it counts packets regardless of whether they were matched by the filter expression, and on other OSes it counts only packets that were matched by the filter expression and were processed by *tcpdump*);

packets “dropped by kernel” (this is the number of packets that were dropped, due to a lack of buffer space, by the packet capture mechanism in the OS on which *tcpdump* is running, if the OS reports that information to applications; if not, it will be reported as 0).

On platforms that support the SIGINFO signal, such as most BSDs, it will report those counts when it receives a SIGINFO signal (generated, for example, by typing your “status” character, typically control-T) and will continue capturing packets.

Reading packets from a network interface may require that you have special privileges:

Under SunOS 3.x or 4.x with NIT or BPF:

You must have read access to */dev/nit* or */dev/bpf**.

Under Solaris with DLPI:

You must have read/write access to the network pseudo device, e.g. */dev/le*. On at least some versions of Solaris, however, this is not sufficient to allow *tcpdump* to capture in promiscuous mode; on those versions of Solaris, you must be root, or *tcpdump* must be installed setuid to root, in order to capture in promiscuous mode. Note that, on many (perhaps all) interfaces, if you don’t capture in promiscuous mode, you will not see any outgoing packets, so a capture not done in promiscuous mode may not be very useful.

Under HP-UX with DLPI:

You must be root or *tcpdump* must be installed setuid to root.

Under IRIX with snoop:

You must be root or *tcpdump* must be installed setuid to root.

Under Linux:

You must be root or *tcpdump* must be installed setuid to root.

Under Ultrix and Digital UNIX/Tru64 UNIX:

Any user may capture network traffic with *tcpdump*. However, no user (not even the super-user) can capture in promiscuous mode on an interface unless the super-user has enabled promiscuous-mode operation on that interface using *pfconfig*(8), and no user (not even the super-user) can

capture unicast traffic received by or sent by the machine on an interface unless the super-user has enabled copy-all-mode operation on that interface using *pfconfig*, so *useful* packet capture on an interface probably requires that either promiscuous-mode or copy-all-mode operation, or both modes of operation, be enabled on that interface.

Under BSD:

You must have read access to */dev/bpf**.

Reading a saved packet file doesn't require special privileges.

OPTIONS

- a** Attempt to convert network and broadcast addresses to names.
- c** Exit after receiving *count* packets.
- C** Before writing a raw packet to a savefile, check whether the file is currently larger than *file_size* and, if so, close the current savefile and open a new one. Savefiles after the first savefile will have the name specified with the **-w** flag, with a number after it, starting at 2 and continuing upward. The units of *file_size* are millions of bytes (1,000,000 bytes, not 1,048,576 bytes).
- d** Dump the compiled packet-matching code in a human readable form to standard output and stop.
- dd** Dump packet-matching code as a C program fragment.
- ddd** Dump packet-matching code as decimal numbers (preceded with a count).
- e** Print the link-level header on each dump line.
- E** Use *algo:secret* for decrypting IPsec ESP packets. Algorithms may be **des-cbc**, **3des-cbc**, **blow-fish-cbc**, **rc3-cbc**, **cast128-cbc**, or **none**. The default is **des-cbc**. The ability to decrypt packets is only present if *tcpdump* was compiled with cryptography enabled. *secret* the ascii text for ESP secret key. We cannot take arbitrary binary value at this moment. The option assumes RFC2406 ESP, not RFC1827 ESP. The option is only for debugging purposes, and the use of this option with truly 'secret' key is discouraged. By presenting IPsec secret key onto command line you make it visible to others, via *ps*(1) and other occasions.
- f** Print 'foreign' internet addresses numerically rather than symbolically (this option is intended to get around serious brain damage in Sun's yp server — usually it hangs forever translating non-local internet numbers).
- F** Use *file* as input for the filter expression. An additional expression given on the command line is ignored.
- i** Listen on *interface*. If unspecified, *tcpdump* searches the system interface list for the lowest numbered, configured up interface (excluding loopback). Ties are broken by choosing the earliest match.

On Linux systems with 2.2 or later kernels, an *interface* argument of "any" can be used to capture packets from all interfaces. Note that captures on the "any" device will not be done in promiscuous mode.
- l** Make stdout line buffered. Useful if you want to see the data while capturing it. E.g., "tcpdump -l | tee dat" or "tcpdump -l > dat & tail -f dat".
- m** Load SMI MIB module definitions from file *module*. This option can be used several times to load several MIB modules into *tcpdump*.
- n** Don't convert addresses (i.e., host addresses, port numbers, etc.) to names.
- N** Don't print domain name qualification of host names. E.g., if you give this flag then *tcpdump* will print "nic" instead of "nic.ddn.mil".
- O** Do not run the packet-matching code optimizer. This is useful only if you suspect a bug in the optimizer.

- p** *Don't* put the interface into promiscuous mode. Note that the interface might be in promiscuous mode for some other reason; hence, '-p' cannot be used as an abbreviation for 'ether host {local-hw-addr} or ether broadcast'.
- q** Quick (quiet?) output. Print less protocol information so output lines are shorter.
- R** Assume ESP/AH packets to be based on old specification (RFC1825 to RFC1829). If specified, *tcpdump* will not print replay prevention field. Since there is no protocol version field in ESP/AH specification, *tcpdump* cannot deduce the version of ESP/AH protocol.
- r** Read packets from *file* (which was created with the -w option). Standard input is used if *file* is "-".
- S** Print absolute, rather than relative, TCP sequence numbers.
- s** Snarf *snaplen* bytes of data from each packet rather than the default of 68 (with SunOS's NIT, the minimum is actually 96). 68 bytes is adequate for IP, ICMP, TCP and UDP but may truncate protocol information from name server and NFS packets (see below). Packets truncated because of a limited snapshot are indicated in the output with "[*proto*]", where *proto* is the name of the protocol level at which the truncation has occurred. Note that taking larger snapshots both increases the amount of time it takes to process packets and, effectively, decreases the amount of packet buffering. This may cause packets to be lost. You should limit *snaplen* to the smallest number that will capture the protocol information you're interested in. Setting *snaplen* to 0 means use the required length to catch whole packets.
- T** Force packets selected by "*expression*" to be interpreted the specified *type*. Currently known types are **cnfp** (Cisco NetFlow protocol), **rpc** (Remote Procedure Call), **rtp** (Real-Time Applications protocol), **rtcp** (Real-Time Applications control protocol), **snmp** (Simple Network Management Protocol), **vat** (Visual Audio Tool), and **wb** (distributed White Board).
- t** *Don't* print a timestamp on each dump line.
- tt** Print an unformatted timestamp on each dump line.
- ttt** Print a delta (in micro-seconds) between current and previous line on each dump line.
- tttt** Print a timestamp in default format proceeded by date on each dump line.
- u** Print undecoded NFS handles.
- v** (Slightly more) verbose output. For example, the time to live, identification, total length and options in an IP packet are printed. Also enables additional packet integrity checks such as verifying the IP and ICMP header checksum.
- vv** Even more verbose output. For example, additional fields are printed from NFS reply packets, and SMB packets are fully decoded.
- vvv** Even more verbose output. For example, telnet **SB** ... **SE** options are printed in full. With **-X** telnet options are printed in hex as well.
- w** Write the raw packets to *file* rather than parsing and printing them out. They can later be printed with the -r option. Standard output is used if *file* is "-".
- x** Print each packet (minus its link level header) in hex. The smaller of the entire packet or *snaplen* bytes will be printed. Note that this is the entire link-layer packet, so for link layers that pad (e.g. Ethernet), the padding bytes will also be printed when the higher layer packet is shorter than the required padding.
- X** When printing hex, print ascii too. Thus if **-x** is also set, the packet is printed in hex/ascii. This is very handy for analysing new protocols. Even if **-x** is not also set, some parts of some packets may be printed in hex/ascii.

expression

selects which packets will be dumped. If no *expression* is given, all packets on the net will be dumped. Otherwise, only packets for which *expression* is 'true' will be dumped.

The *expression* consists of one or more *primitives*. Primitives usually consist of an *id* (name or number) preceded by one or more qualifiers. There are three different kinds of qualifier:

- type* qualifiers say what kind of thing the *id* name or number refers to. Possible types are **host**, **net** and **port**. E.g., 'host foo', 'net 128.3', 'port 20'. If there is no type qualifier, **host** is assumed.
- dir* qualifiers specify a particular transfer direction to and/or from *id*. Possible directions are **src**, **dst**, **src or dst** and **src and dst**. E.g., 'src foo', 'dst net 128.3', 'src or dst port ftp-data'. If there is no *dir* qualifier, **src or dst** is assumed. For 'null' link layers (i.e. point to point protocols such as slip) the **inbound** and **outbound** qualifiers can be used to specify a desired direction.
- proto* qualifiers restrict the match to a particular protocol. Possible protos are: **ether**, **fddi**, **tr**, **ip**, **ip6**, **arp**, **rarp**, **decnet**, **tcp** and **udp**. E.g., 'ether src foo', 'arp net 128.3', 'tcp port 21'. If there is no *proto* qualifier, all protocols consistent with the type are assumed. E.g., 'src foo' means '(ip or arp or rarp) src foo' (except the latter is not legal syntax), 'net bar' means '(ip or arp or rarp) net bar' and 'port 53' means '(tcp or udp) port 53'.

['fddi' is actually an alias for 'ether'; the parser treats them identically as meaning "the data link level used on the specified network interface." FDDI headers contain Ethernet-like source and destination addresses, and often contain Ethernet-like packet types, so you can filter on these FDDI fields just as with the analogous Ethernet fields. FDDI headers also contain other fields, but you cannot name them explicitly in a filter expression.

Similarly, 'tr' is an alias for 'ether'; the previous paragraph's statements about FDDI headers also apply to Token Ring headers.]

In addition to the above, there are some special 'primitive' keywords that don't follow the pattern: **gateway**, **broadcast**, **less**, **greater** and arithmetic expressions. All of these are described below.

More complex filter expressions are built up by using the words **and**, **or** and **not** to combine primitives. E.g., 'host foo and not port ftp and not port ftp-data'. To save typing, identical qualifier lists can be omitted. E.g., 'tcp dst port ftp or ftp-data or domain' is exactly the same as 'tcp dst port ftp or tcp dst port ftp-data or tcp dst port domain'.

Allowable primitives are:

dst host *host*

True if the IPv4/v6 destination field of the packet is *host*, which may be either an address or a name.

src host *host*

True if the IPv4/v6 source field of the packet is *host*.

host *host*

True if either the IPv4/v6 source or destination of the packet is *host*. Any of the above host expressions can be prepended with the keywords, **ip**, **arp**, **rarp**, or **ip6** as in:

ip host *host*

which is equivalent to:

ether proto *ip* and **host** *host*

If *host* is a name with multiple IP addresses, each address will be checked for a match.

ether dst *ehost*

True if the ethernet destination address is *ehost*. *Ehost* may be either a name from /etc/ethers or a number (see *ethers*(3N) for numeric format).

ether src *ehost*

True if the ethernet source address is *ehost*.

ether host *ehost*

True if either the ethernet source or destination address is *ehost*.

gateway *host*

True if the packet used *host* as a gateway. I.e., the ethernet source or destination address was *host* but neither the IP source nor the IP destination was *host*. *Host* must be a name and must be found both by the machine's host-name-to-IP-address resolution mechanisms (host name file, DNS, NIS, etc.) and by the machine's host-name-to-Ethernet-address resolution mechanism (/etc/ethers, etc.). (An equivalent expression is

ether host *ehost* and not host *host*

which can be used with either names or numbers for *host* / *ehost*.) This syntax does not work in IPv6-enabled configuration at this moment.

dst net *net*

True if the IPv4/v6 destination address of the packet has a network number of *net*. *Net* may be either a name from /etc/networks or a network number (see *networks(4)* for details).

src net *net*

True if the IPv4/v6 source address of the packet has a network number of *net*.

net net True if either the IPv4/v6 source or destination address of the packet has a network number of *net*.

net net mask *netmask*

True if the IP address matches *net* with the specific *netmask*. May be qualified with **src** or **dst**. Note that this syntax is not valid for IPv6 *net*.

net netlen

True if the IPv4/v6 address matches *net* with a netmask *len* bits wide. May be qualified with **src** or **dst**.

dst port *port*

True if the packet is ip/tcp, ip/udp, ip6/tcp or ip6/udp and has a destination port value of *port*. The *port* can be a number or a name used in /etc/services (see *tcp(4P)* and *udp(4P)*). If a name is used, both the port number and protocol are checked. If a number or ambiguous name is used, only the port number is checked (e.g., **dst port 513** will print both tcp/login traffic and udp/who traffic, and **port domain** will print both tcp/domain and udp/domain traffic).

src port *port*

True if the packet has a source port value of *port*.

port *port*

True if either the source or destination port of the packet is *port*. Any of the above port expressions can be prepended with the keywords, **tcp** or **udp**, as in:

tcp src port *port*

which matches only tcp packets whose source port is *port*.

less *length*

True if the packet has a length less than or equal to *length*. This is equivalent to:

len <= length.

greater *length*

True if the packet has a length greater than or equal to *length*. This is equivalent to:

len >= length.

ip proto *protocol*

True if the packet is an IP packet (see *ip(4P)*) of protocol type *protocol*. *Protocol* can be a number or one of the names *icmp*, *icmp6*, *igmp*, *igrp*, *pim*, *ah*, *esp*, *vrp*, *udp*, or *tcp*. Note that the identifiers *tcp*, *udp*, and *icmp* are also keywords and must be escaped via backslash (\), which is \ in the C-shell. Note that this primitive does not chase the protocol header chain.

ip6 proto *protocol*

True if the packet is an IPv6 packet of protocol type *protocol*. Note that this primitive does not chase the protocol header chain.

ip6 protochain *protocol*

True if the packet is IPv6 packet, and contains protocol header with type *protocol* in its protocol header chain. For example,

ip6 protochain 6

matches any IPv6 packet with TCP protocol header in the protocol header chain. The packet may contain, for example, authentication header, routing header, or hop-by-hop option header, between IPv6 header and TCP header. The BPF code emitted by this primitive is complex and cannot be optimized by BPF optimizer code in *tcpdump*, so this can be somewhat slow.

ip protochain *protocol*

Equivalent to **ip6 protochain *protocol***, but this is for IPv4.

ether broadcast

True if the packet is an ethernet broadcast packet. The *ether* keyword is optional.

ip broadcast

True if the packet is an IP broadcast packet. It checks for both the all-zeroes and all-ones broadcast conventions, and looks up the local subnet mask.

ether multicast

True if the packet is an ethernet multicast packet. The *ether* keyword is optional. This is shorthand for '**ether[0] & 1 != 0**'.

ip multicast

True if the packet is an IP multicast packet.

ip6 multicast

True if the packet is an IPv6 multicast packet.

ether proto *protocol*

True if the packet is of ether type *protocol*. *Protocol* can be a number or one of the names *ip*, *ip6*, *arp*, *rarp*, *atalk*, *aarp*, *decnet*, *sca*, *lat*, *mopdl*, *moprc*, *iso*, *stp*, *ipx*, or *netbeui*. Note these identifiers are also keywords and must be escaped via backslash (\).

[In the case of FDDI (e.g., '**fdi protocol arp**') and Token Ring (e.g., '**tr protocol arp**'), for most of those protocols, the protocol identification comes from the 802.2 Logical Link Control (LLC) header, which is usually layered on top of the FDDI or Token Ring header.

When filtering for most protocol identifiers on FDDI or Token Ring, *tcpdump* checks only the protocol ID field of an LLC header in so-called SNAP format with an Organizational Unit Identifier (OUI) of 0x000000, for encapsulated Ethernet; it doesn't check whether the packet is in SNAP format with an OUI of 0x000000.

The exceptions are *iso*, for which it checks the DSAP (Destination Service Access Point) and SSAP (Source Service Access Point) fields of the LLC header, *stp* and *netbeui*, where it checks the DSAP of the LLC header, and *atalk*, where it checks for a SNAP-format packet with an OUI of 0x080007 and the Appletalk etype.

In the case of Ethernet, *tcpdump* checks the Ethernet type field for most of those protocols; the exceptions are *iso*, *sap*, and *netbeui*, for which it checks for an 802.3 frame and then checks the LLC header as it does for FDDI and Token Ring, *atalk*, where it checks both for the Appletalk etype in an Ethernet frame and for a SNAP-format packet as it does for FDDI and Token Ring, *aarp*, where it checks for the Appletalk ARP etype in either an Ethernet frame or an 802.2 SNAP frame with an OUI of 0x000000, and *ipx*, where it checks for the IPX etype in an Ethernet frame, the IPX DSAP in the LLC header, the 802.3 with no LLC header encapsulation of IPX, and the IPX etype in a SNAP

frame.]

decnet src *host*

True if the DECNET source address is *host*, which may be an address of the form “10.123”, or a DECNET host name. [DECNET host name support is only available on Ultrix systems that are configured to run DECNET.]

decnet dst *host*

True if the DECNET destination address is *host*.

decnet host *host*

True if either the DECNET source or destination address is *host*.

ip, ip6, arp, rarp, atalk, aarp, decnet, iso, stp, ipx, netbeui

Abbreviations for:

ether proto *p*

where *p* is one of the above protocols.

lat, moprc, mopdl

Abbreviations for:

ether proto *p*

where *p* is one of the above protocols. Note that *tcpdump* does not currently know how to parse these protocols.

vlan [*vlan_id*]

True if the packet is an IEEE 802.1Q VLAN packet. If [*vlan_id*] is specified, only true is the packet has the specified *vlan_id*. Note that the first **vlan** keyword encountered in *expression* changes the decoding offsets for the remainder of *expression* on the assumption that the packet is a VLAN packet.

tcp, udp, icmp

Abbreviations for:

ip proto *p* or **ip6 proto** *p*

where *p* is one of the above protocols.

iso proto *protocol*

True if the packet is an OSI packet of protocol type *protocol*. *Protocol* can be a number or one of the names *clnp*, *esis*, or *isis*.

clnp, esis, isis

Abbreviations for:

iso proto *p*

where *p* is one of the above protocols. Note that *tcpdump* does an incomplete job of parsing these protocols.

expr relop expr

True if the relation holds, where *relop* is one of **>**, **<**, **>=**, **<=**, **=**, **!=**, and *expr* is an arithmetic expression composed of integer constants (expressed in standard C syntax), the normal binary operators **+**, **-**, *****, **/**, **&**, **[]**, a length operator, and special packet data accessors. To access data inside the packet, use the following syntax:

proto [*expr* : *size*]

Proto is one of **ether**, **fddi**, **tr**, **ppp**, **slip**, **link**, **ip**, **arp**, **rarp**, **tcp**, **udp**, **icmp** or **ip6**, and indicates the protocol layer for the index operation. (**ether**, **fddi**, **tr**, **ppp**, **slip** and **link** all refer to the link layer.) Note that *tcp*, *udp* and other upper-layer protocol types only apply to IPv4, not IPv6 (this will be fixed in the future). The byte offset, relative to the indicated protocol layer, is given by *expr*. *Size* is optional and indicates the number of bytes in the field of interest; it can be either one, two, or four, and defaults to one. The length operator, indicated by the keyword **len**, gives the length of the packet.

For example, **‘ether[0] & 1 != 0’** catches all multicast traffic. The expression **‘ip[0] &**

0xf != 5' catches all IP packets with options. The expression **'ip[6:2] & 0x1fff = 0'** catches only unfragmented datagrams and frag zero of fragmented datagrams. This check is implicitly applied to the **tcp** and **udp** index operations. For instance, **tcp[0]** always means the first byte of the TCP *header*, and never means the first byte of an intervening fragment.

Some offsets and field values may be expressed as names rather than as numeric values. The following protocol header field offsets are available: **icmptype** (ICMP type field), **icmpcode** (ICMP code field), and **tcpflags** (TCP flags field).

The following ICMP type field values are available: **icmp-echoreply**, **icmp-unreach**, **icmp-sourcequench**, **icmp-redirect**, **icmp-echo**, **icmp-routeradvert**, **icmp-routersolicit**, **icmp-timxceed**, **icmp-paramprob**, **icmp-tstamp**, **icmp-tstampreply**, **icmp-ireq**, **icmp-ireqreply**, **icmp-maskreq**, **icmp-maskreply**.

The following TCP flags field values are available: **tcp-fin**, **tcp-syn**, **tcp-rst**, **tcp-push**, **tcp-push**, **tcp-ack**, **tcp-urg**.

Primitives may be combined using:

A parenthesized group of primitives and operators (parentheses are special to the Shell and must be escaped).

Negation ('!' or **'not'**).

Concatenation ('&&' or **'and'**).

Alternation ('||' or **'or'**).

Negation has highest precedence. Alternation and concatenation have equal precedence and associate left to right. Note that explicit **and** tokens, not juxtaposition, are now required for concatenation.

If an identifier is given without a keyword, the most recent keyword is assumed. For example,

not host vs and ace

is short for

not host vs and host ace

which should not be confused with

not (host vs or ace)

Expression arguments can be passed to *tcpdump* as either a single argument or as multiple arguments, whichever is more convenient. Generally, if the expression contains Shell metacharacters, it is easier to pass it as a single, quoted argument. Multiple arguments are concatenated with spaces before being parsed.

EXAMPLES

To print all packets arriving at or departing from *sundown*:

tcpdump host sundown

To print traffic between *helios* and either *hot* or *ace*:

tcpdump host helios and \(hot or ace \)

To print all IP packets between *ace* and any host except *helios*:

tcpdump ip host ace and not helios

To print all traffic between local hosts and hosts at Berkeley:

tcpdump net ucb-ether

To print all ftp traffic through internet gateway *snup*: (note that the expression is quoted to prevent the shell from (mis-)interpreting the parentheses):

tcpdump 'gateway snup and (port ftp or ftp-data)'

To print traffic neither sourced from nor destined for local hosts (if you gateway to one other net, this stuff

should never make it onto your local net).

tcpdump ip and not net localnet

To print the start and end packets (the SYN and FIN packets) of each TCP conversation that involves a non-local host.

tcpdump 'tcp[tcpflags] & (tcp-syn|tcp-fin) != 0 and not src and dst net localnet'

To print IP packets longer than 576 bytes sent through gateway *snup*:

tcpdump 'gateway snup and ip[2:2] > 576'

To print IP broadcast or multicast packets that were *not* sent via ethernet broadcast or multicast:

tcpdump 'ether[0] & 1 = 0 and ip[16] >= 224'

To print all ICMP packets that are not echo requests/replies (i.e., not ping packets):

tcpdump 'icmp[icmptype] != icmp-echo and icmp[icmptype] != icmp-echoreply'

OUTPUT FORMAT

The output of *tcpdump* is protocol dependent. The following gives a brief description and examples of most of the formats.

Link Level Headers

If the '-e' option is given, the link level header is printed out. On ethernet, the source and destination addresses, protocol, and packet length are printed.

On FDDI networks, the '-e' option causes *tcpdump* to print the 'frame control' field, the source and destination addresses, and the packet length. (The 'frame control' field governs the interpretation of the rest of the packet. Normal packets (such as those containing IP datagrams) are 'async' packets, with a priority value between 0 and 7; for example, 'async4'. Such packets are assumed to contain an 802.2 Logical Link Control (LLC) packet; the LLC header is printed if it is *not* an ISO datagram or a so-called SNAP packet.

On Token Ring networks, the '-e' option causes *tcpdump* to print the 'access control' and 'frame control' fields, the source and destination addresses, and the packet length. As on FDDI networks, packets are assumed to contain an LLC packet. Regardless of whether the '-e' option is specified or not, the source routing information is printed for source-routed packets.

(N.B.: The following description assumes familiarity with the SLIP compression algorithm described in RFC-1144.)

On SLIP links, a direction indicator ("I" for inbound, "O" for outbound), packet type, and compression information are printed out. The packet type is printed first. The three types are *ip*, *utcp*, and *ctcp*. No further link information is printed for *ip* packets. For TCP packets, the connection identifier is printed following the type. If the packet is compressed, its encoded header is printed out. The special cases are printed out as *S+n and *SA+n, where *n* is the amount by which the sequence number (or sequence number and ack) has changed. If it is not a special case, zero or more changes are printed. A change is indicated by U (urgent pointer), W (window), A (ack), S (sequence number), and I (packet ID), followed by a delta (+n or -n), or a new value (=n). Finally, the amount of data in the packet and compressed header length are printed.

For example, the following line shows an outbound compressed TCP packet, with an implicit connection identifier; the ack has changed by 6, the sequence number by 49, and the packet ID by 6; there are 3 bytes of data and 6 bytes of compressed header:

O ctcp * A+6 S+49 I+6 3 (6)

ARP/RARP Packets

Arp/rarp output shows the type of request and its arguments. The format is intended to be self explanatory. Here is a short sample taken from the start of an 'rlogin' from host *rtsg* to host *csam*:

```
arp who-has csam tell rtsg
arp reply csam is-at CSAM
```

The first line says that *rtsg* sent an arp packet asking for the ethernet address of internet host *csam*. *Csam* replies with its ethernet address (in this example, ethernet addresses are in caps and internet addresses in lower case).

This would look less redundant if we had done *tcpdump -n*:

```
arp who-has 128.3.254.6 tell 128.3.254.68
arp reply 128.3.254.6 is-at 02:07:01:00:01:c4
```

If we had done *tcpdump -e*, the fact that the first packet is broadcast and the second is point-to-point would be visible:

```
RTSG Broadcast 0806 64: arp who-has csam tell rtsg
CSAM RTSG 0806 64: arp reply csam is-at CSAM
```

For the first packet this says the ethernet source address is *RTSG*, the destination is the ethernet broadcast address, the type field contained hex 0806 (type *ETHER_ARP*) and the total length was 64 bytes.

TCP Packets

(*N.B.:The following description assumes familiarity with the TCP protocol described in RFC-793. If you are not familiar with the protocol, neither this description nor tcpdump will be of much use to you.*)

The general format of a tcp protocol line is:

```
src > dst: flags data-seqno ack window urgent options
```

Src and *dst* are the source and destination IP addresses and ports. *Flags* are some combination of S (SYN), F (FIN), P (PUSH) or R (RST) or a single '.' (no flags). *Data-seqno* describes the portion of sequence space covered by the data in this packet (see example below). *Ack* is sequence number of the next data expected the other direction on this connection. *Window* is the number of bytes of receive buffer space available the other direction on this connection. *Urg* indicates there is 'urgent' data in the packet. *Options* are tcp options enclosed in angle brackets (e.g., <mss 1024>).

Src, *dst* and *flags* are always present. The other fields depend on the contents of the packet's tcp protocol header and are output only if appropriate.

Here is the opening portion of an rlogin from host *rtsg* to host *csam*.

```
rtsg.1023 > csam.login: S 768512:768512(0) win 4096 <mss 1024>
csam.login > rtsg.1023: S 947648:947648(0) ack 768513 win 4096 <mss 1024>
rtsg.1023 > csam.login: . ack 1 win 4096
rtsg.1023 > csam.login: P 1:2(1) ack 1 win 4096
csam.login > rtsg.1023: . ack 2 win 4096
rtsg.1023 > csam.login: P 2:21(19) ack 1 win 4096
csam.login > rtsg.1023: P 1:2(1) ack 21 win 4077
csam.login > rtsg.1023: P 2:3(1) ack 21 win 4077 urg 1
csam.login > rtsg.1023: P 3:4(1) ack 21 win 4077 urg 1
```

The first line says that tcp port 1023 on *rtsg* sent a packet to port *login* on *csam*. The **S** indicates that the *SYN* flag was set. The packet sequence number was 768512 and it contained no data. (The notation is 'first:last(nbytes)' which means 'sequence numbers *first* up to but not including *last* which is *nbytes* bytes of user data'.) There was no piggy-backed ack, the available receive window was 4096 bytes and there was a max-segment-size option requesting an mss of 1024 bytes.

Csam replies with a similar packet except it includes a piggy-backed ack for *rtsg*'s SYN. *Rtsg* then acks *csam*'s SYN. The '.' means no flags were set. The packet contained no data so there is no data sequence number. Note that the ack sequence number is a small integer (1). The first time *tcpdump* sees a tcp 'conversation', it prints the sequence number from the packet. On subsequent packets of the conversation, the difference between the current packet's sequence number and this initial sequence number is printed. This means that sequence numbers after the first can be interpreted as relative byte positions in the conversation's data stream (with the first data byte each direction being '1'). '-S' will override this feature, causing

the original sequence numbers to be output.

On the 6th line, rtsg sends csam 19 bytes of data (bytes 2 through 20 in the rtsg → csam side of the conversation). The PUSH flag is set in the packet. On the 7th line, csam says it's received data sent by rtsg up to but not including byte 21. Most of this data is apparently sitting in the socket buffer since csam's receive window has gotten 19 bytes smaller. Csam also sends one byte of data to rtsg in this packet. On the 8th and 9th lines, csam sends two bytes of urgent, pushed data to rtsg.

If the snapshot was small enough that *tcpdump* didn't capture the full TCP header, it interprets as much of the header as it can and then reports "[*tcp*]" to indicate the remainder could not be interpreted. If the header contains a bogus option (one with a length that's either too small or beyond the end of the header), *tcpdump* reports it as "[*bad opt*]" and does not interpret any further options (since it's impossible to tell where they start). If the header length indicates options are present but the IP datagram length is not long enough for the options to actually be there, *tcpdump* reports it as "[*bad hdr length*]".

Capturing TCP packets with particular flag combinations (SYN-ACK, URG-ACK, etc.)

There are 8 bits in the control bits section of the TCP header:

CWR | *ECE* | *URG* | *ACK* | *PSH* | *RST* | *SYN* | *FIN*

Let's assume that we want to watch packets used in establishing a TCP connection. Recall that TCP uses a 3-way handshake protocol when it initializes a new connection; the connection sequence with regard to the TCP control bits is

- 1) Caller sends SYN
- 2) Recipient responds with SYN, ACK
- 3) Caller sends ACK

Now we're interested in capturing packets that have only the SYN bit set (Step 1). Note that we don't want packets from step 2 (SYN-ACK), just a plain initial SYN. What we need is a correct filter expression for *tcpdump*.

Recall the structure of a TCP header without options:

| | | |
|-----------------------|------------------|-------------------------------|
| 0 | 15 | 31 |
| ----- | | |
| source port | destination port | |
| ----- | | |
| sequence number | | |
| ----- | | |
| acknowledgment number | | |
| ----- | | |
| HL | rsvd | C E U A P R S F window size |
| ----- | | |
| TCP checksum | | urgent pointer |
| ----- | | |

A TCP header usually holds 20 octets of data, unless options are present. The first line of the graph contains octets 0 - 3, the second line shows octets 4 - 7 etc.

Starting to count with 0, the relevant TCP control bits are contained in octet 13:

| | | | | |
|------------|------|-----------------|-------------|----|
| 0 | 7 | 15 | 23 | 31 |
| ----- | | | | |
| HL | rsvd | C E U A P R S F | window size | |
| ----- | | | | |
| 13th octet | | | | |

Let's have a closer look at octet no. 13:

|

```

|-----|
|C|E|U|A|P|R|S|F|
|-----|
|7 5 3 0|

```

These are the TCP control bits we are interested in. We have numbered the bits in this octet from 0 to 7, right to left, so the PSH bit is bit number 3, while the URG bit is number 5.

Recall that we want to capture packets with only SYN set. Let's see what happens to octet 13 if a TCP datagram arrives with the SYN bit set in its header:

```

|C|E|U|A|P|R|S|F|
|-----|
|0 0 0 0 0 1 0|
|-----|
|7 6 5 4 3 2 1 0|

```

Looking at the control bits section we see that only bit number 1 (SYN) is set.

Assuming that octet number 13 is an 8-bit unsigned integer in network byte order, the binary value of this octet is

00000010

and its decimal representation is

```

 7 6 5 4 3 2 1 0
0*2 + 0*2 + 0*2 + 0*2 + 0*2 + 0*2 + 1*2 + 0*2 = 2

```

We're almost done, because now we know that if only SYN is set, the value of the 13th octet in the TCP header, when interpreted as a 8-bit unsigned integer in network byte order, must be exactly 2.

This relationship can be expressed as

tcp[13] == 2

We can use this expression as the filter for *tcpdump* in order to watch packets which have only SYN set:

tcpdump -i xl0 tcp[13] == 2

The expression says "let the 13th octet of a TCP datagram have the decimal value 2", which is exactly what we want.

Now, let's assume that we need to capture SYN packets, but we don't care if ACK or any other TCP control bit is set at the same time. Let's see what happens to octet 13 when a TCP datagram with SYN-ACK set arrives:

```

|C|E|U|A|P|R|S|F|
|-----|
|0 0 0 1 0 0 1 0|
|-----|
|7 6 5 4 3 2 1 0|

```

Now bits 1 and 4 are set in the 13th octet. The binary value of octet 13 is

00010010

which translates to decimal

```

 7 6 5 4 3 2 1 0
0*2 + 0*2 + 0*2 + 1*2 + 0*2 + 0*2 + 1*2 + 0*2 = 18

```

Now we can't just use 'tcp[13] == 18' in the *tcpdump* filter expression, because that would select only those packets that have SYN-ACK set, but not those with only SYN set. Remember that we don't care if ACK or any other control bit is set as long as SYN is set.

In order to achieve our goal, we need to logically AND the binary value of octet 13 with some other value to preserve the SYN bit. We know that we want SYN to be set in any case, so we'll logically AND the

value in the 13th octet with the binary value of a SYN:

```

      00010010 SYN-ACK      00000010 SYN
      AND 00000010 (we want SYN) AND 00000010 (we want SYN)
      -----
      = 00000010          = 00000010

```

We see that this AND operation delivers the same result regardless whether ACK or another TCP control bit is set. The decimal representation of the AND value as well as the result of this operation is 2 (binary 00000010), so we know that for packets with SYN set the following relation must hold true:

$$((\text{value of octet 13}) \text{ AND } (2)) == (2)$$

This points us to the *tcpdump* filter expression

```
tcpdump -i xl0 'tcp[13] & 2 == 2'
```

Note that you should use single quotes or a backslash in the expression to hide the AND ('&') special character from the shell.

UDP Packets

UDP format is illustrated by this *rwho* packet:

```
actinide.who > broadcast.who: udp 84
```

This says that port *who* on host *actinide* sent a udp datagram to port *who* on host *broadcast*, the Internet broadcast address. The packet contained 84 bytes of user data.

Some UDP services are recognized (from the source or destination port number) and the higher level protocol information printed. In particular, Domain Name service requests (RFC-1034/1035) and Sun RPC calls (RFC-1050) to NFS.

UDP Name Server Requests

(N.B.:The following description assumes familiarity with the Domain Service protocol described in RFC-1035. If you are not familiar with the protocol, the following description will appear to be written in greek.)

Name server requests are formatted as

```
src > dst: id op? flags qtype qclass name (len)

h2opolo.1538 > helios.domain: 3+ A? ucbvax.berkeley.edu. (37)
```

Host *h2opolo* asked the domain server on *helios* for an address record (qtype=A) associated with the name *ucbvax.berkeley.edu*. The query id was '3'. The '+' indicates the *recursion desired* flag was set. The query length was 37 bytes, not including the UDP and IP protocol headers. The query operation was the normal one, *Query*, so the op field was omitted. If the op had been anything else, it would have been printed between the '3' and the '+'. Similarly, the qclass was the normal one, *C_IN*, and omitted. Any other qclass would have been printed immediately after the 'A'.

A few anomalies are checked and may result in extra fields enclosed in square brackets: If a query contains an answer, authority records or additional records section, *ancount*, *nscount*, or *arcount* are printed as '[na]', '[nm]' or '[nau]' where *n* is the appropriate count. If any of the response bits are set (AA, RA or rcode) or any of the 'must be zero' bits are set in bytes two and three, '[b2&3=x]' is printed, where *x* is the hex value of header bytes two and three.

UDP Name Server Responses

Name server responses are formatted as

```
src > dst: id op rcode flags a/n/au type class data (len)
```

```
helios.domain > h2opolo.1538: 3 3/3/7 A 128.32.137.3 (273)
helios.domain > h2opolo.1537: 2 NXDomain* 0/1/0 (97)
```

In the first example, *helios* responds to query id 3 from *h2opolo* with 3 answer records, 3 name server records and 7 additional records. The first answer record is type A (address) and its data is internet address 128.32.137.3. The total size of the response was 273 bytes, excluding UDP and IP headers. The op (Query) and response code (NoError) were omitted, as was the class (C_IN) of the A record.

In the second example, *helios* responds to query 2 with a response code of non-existent domain (NXDomain) with no answers, one name server and no authority records. The '*' indicates that the *authoritative answer* bit was set. Since there were no answers, no type, class or data were printed.

Other flag characters that might appear are '-' (recursion available, RA, *not* set) and '|' (truncated message, TC, set). If the 'question' section doesn't contain exactly one entry, '[nq]' is printed.

Note that name server requests and responses tend to be large and the default *snaplen* of 68 bytes may not capture enough of the packet to print. Use the *-s* flag to increase the *snaplen* if you need to seriously investigate name server traffic. '*-s 128*' has worked well for me.

SMB/CIFS decoding

tcpdump now includes fairly extensive SMB/CIFS/NBT decoding for data on UDP/137, UDP/138 and TCP/139. Some primitive decoding of IPX and NetBEUI SMB data is also done.

By default a fairly minimal decode is done, with a much more detailed decode done if *-v* is used. Be warned that with *-v* a single SMB packet may take up a page or more, so only use *-v* if you really want all the gory details.

If you are decoding SMB sessions containing unicode strings then you may wish to set the environment variable *USE_UNICODE* to 1. A patch to auto-detect unicode strings would be welcome.

For information on SMB packet formats and what all the fields mean see www.cifs.org or the [pub/samba/specs/](http://pub.samba/specs/) directory on your favourite samba.org mirror site. The SMB patches were written by Andrew Tridgell (tridge@samba.org).

NFS Requests and Replies

Sun NFS (Network File System) requests and replies are printed as:

```
src.xid > dst.nfs: len op args
src.nfs > dst.xid: reply stat len op results

sushi.6709 > wr1.nfs: 112 readlink fh 21,24/10.73165
wr1.nfs > sushi.6709: reply ok 40 readlink "../var"
sushi.201b > wr1.nfs:
    144 lookup fh 9,74/4096.6878 "xcolors"
wr1.nfs > sushi.201b:
    reply ok 128 lookup fh 9,74/4134.3150
```

In the first line, host *sushi* sends a transaction with id 6709 to *wr1* (note that the number following the *src* host is a transaction id, *not* the source port). The request was 112 bytes, excluding the UDP and IP headers. The operation was a *readlink* (read symbolic link) on file handle (*fh*) 21,24/10.731657119. (If one is lucky, as in this case, the file handle can be interpreted as a major,minor device number pair, followed by the inode number and generation number.) *Wr1* replies 'ok' with the contents of the link.

In the third line, *sushi* asks *wr1* to lookup the name '*xcolors*' in directory file 9,74/4096.6878. Note that the data printed depends on the operation type. The format is intended to be self explanatory if read in

conjunction with an NFS protocol spec.

If the `-v` (verbose) flag is given, additional information is printed. For example:

```
sushi.1372a > wr1.nfs:
      148 read fh 21,11/12.195 8192 bytes @ 24576
wr1.nfs > sushi.1372a:
      reply ok 1472 read REG 100664 ids 417/0 sz 29388
```

(`-v` also prints the IP header TTL, ID, length, and fragmentation fields, which have been omitted from this example.) In the first line, *sushi* asks *wrl* to read 8192 bytes from file 21,11/12.195, at byte offset 24576. *Wrl* replies 'ok'; the packet shown on the second line is the first fragment of the reply, and hence is only 1472 bytes long (the other bytes will follow in subsequent fragments, but these fragments do not have NFS or even UDP headers and so might not be printed, depending on the filter expression used). Because the `-v` flag is given, some of the file attributes (which are returned in addition to the file data) are printed: the file type ("REG", for regular file), the file mode (in octal), the uid and gid, and the file size.

If the `-v` flag is given more than once, even more details are printed.

Note that NFS requests are very large and much of the detail won't be printed unless *snapplen* is increased. Try using '`-s 192`' to watch NFS traffic.

NFS reply packets do not explicitly identify the RPC operation. Instead, *tcpdump* keeps track of "recent" requests, and matches them to the replies using the transaction ID. If a reply does not closely follow the corresponding request, it might not be parsable.

AFS Requests and Replies

Transarc AFS (Andrew File System) requests and replies are printed as:

```
src.sport > dst.dport: rx packet-type
src.sport > dst.dport: rx packet-type service call call-name args
src.sport > dst.dport: rx packet-type service reply call-name args

elvis.7001 > pike.afsfs:
      rx data fs call rename old fid 536876964/1/1 ".newsrsrc.new"
      new fid 536876964/1/1 ".newsrsrc"
pike.afsfs > elvis.7001: rx data fs reply rename
```

In the first line, host elvis sends a RX packet to pike. This was a RX data packet to the fs (fileserver) service, and is the start of an RPC call. The RPC call was a rename, with the old directory file id of 536876964/1/1 and an old filename of '.newsrsrc.new', and a new directory file id of 536876964/1/1 and a new filename of '.newsrsrc'. The host pike responds with a RPC reply to the rename call (which was successful, because it was a data packet and not an abort packet).

In general, all AFS RPCs are decoded at least by RPC call name. Most AFS RPCs have at least some of the arguments decoded (generally only the 'interesting' arguments, for some definition of interesting).

The format is intended to be self-describing, but it will probably not be useful to people who are not familiar with the workings of AFS and RX.

If the `-v` (verbose) flag is given twice, acknowledgement packets and additional header information is printed, such as the the RX call ID, call number, sequence number, serial number, and the RX packet flags.

If the `-v` flag is given twice, additional information is printed, such as the the RX call ID, serial number, and the RX packet flags. The MTU negotiation information is also printed from RX ack packets.

If the `-v` flag is given three times, the security index and service id are printed.

Error codes are printed for abort packets, with the exception of Ubik beacon packets (because abort packets are used to signify a yes vote for the Ubik protocol).

Note that AFS requests are very large and many of the arguments won't be printed unless *snaplen* is increased. Try using **'-s 256'** to watch AFS traffic.

AFS reply packets do not explicitly identify the RPC operation. Instead, *tcpdump* keeps track of "recent" requests, and matches them to the replies using the call number and service ID. If a reply does not closely follow the corresponding request, it might not be parsable.

KIP Appletalk (DDP in UDP)

Appletalk DDP packets encapsulated in UDP datagrams are de-encapsulated and dumped as DDP packets (i.e., all the UDP header information is discarded). The file */etc/atalk.names* is used to translate appletalk net and node numbers to names. Lines in this file have the form

```
number name
1.254      ether
16.1       icsd-net
1.254.110  ace
```

The first two lines give the names of appletalk networks. The third line gives the name of a particular host (a host is distinguished from a net by the 3rd octet in the number – a net number *must* have two octets and a host number *must* have three octets.) The number and name should be separated by whitespace (blanks or tabs). The */etc/atalk.names* file may contain blank lines or comment lines (lines starting with a '#').

Appletalk addresses are printed in the form

```
net.host.port
144.1.209.2 > icsd-net.112.220
office.2 > icsd-net.112.220
jssmag.149.235 > icsd-net.2
```

(If the */etc/atalk.names* doesn't exist or doesn't contain an entry for some appletalk host/net number, addresses are printed in numeric form.) In the first example, NBP (DDP port 2) on net 144.1 node 209 is sending to whatever is listening on port 220 of net icsd node 112. The second line is the same except the full name of the source node is known ('office'). The third line is a send from port 235 on net jssmag node 149 to broadcast on the icsd-net NBP port (note that the broadcast address (255) is indicated by a net name with no host number – for this reason it's a good idea to keep node names and net names distinct in */etc/atalk.names*).

NBP (name binding protocol) and ATP (Appletalk transaction protocol) packets have their contents interpreted. Other protocols just dump the protocol name (or number if no name is registered for the protocol) and packet size.

NBP packets are formatted like the following examples:

```
icsd-net.112.220 > jssmag.2: nbp-lkup 190: "=:LaserWriter@*"
jssmag.209.2 > icsd-net.112.220: nbp-reply 190: "RM1140:LaserWriter@*" 250
techpit.2 > icsd-net.112.220: nbp-reply 190: "techpit:LaserWriter@*" 186
```

The first line is a name lookup request for laserwriters sent by net icsd host 112 and broadcast on net jssmag. The nbp id for the lookup is 190. The second line shows a reply for this request (note that it has the same id) from host jssmag.209 saying that it has a laserwriter resource named "RM1140" registered on port 250. The third line is another reply to the same request saying host techpit has laserwriter "techpit" registered on port 186.

ATP packet formatting is demonstrated by the following example:

```
jssmag.209.165 > helios.132: atp-req 12266<0-7> 0xae030001
```

```

helios.132 > jssmag.209.165: atp-resp 12266:0 (512) 0xae040000
helios.132 > jssmag.209.165: atp-resp 12266:1 (512) 0xae040000
helios.132 > jssmag.209.165: atp-resp 12266:2 (512) 0xae040000
helios.132 > jssmag.209.165: atp-resp 12266:3 (512) 0xae040000
helios.132 > jssmag.209.165: atp-resp 12266:4 (512) 0xae040000
helios.132 > jssmag.209.165: atp-resp 12266:5 (512) 0xae040000
helios.132 > jssmag.209.165: atp-resp 12266:6 (512) 0xae040000
helios.132 > jssmag.209.165: atp-resp*12266:7 (512) 0xae040000
jssmag.209.165 > helios.132: atp-req 12266<3,5> 0xae030001
helios.132 > jssmag.209.165: atp-resp 12266:3 (512) 0xae040000
helios.132 > jssmag.209.165: atp-resp 12266:5 (512) 0xae040000
jssmag.209.165 > helios.132: atp-rel 12266<0-7> 0xae030001
jssmag.209.133 > helios.132: atp-req* 12267<0-7> 0xae030002

```

Jssmag.209 initiates transaction id 12266 with host helios by requesting up to 8 packets (the '<0-7>'). The hex number at the end of the line is the value of the 'userdata' field in the request.

Helios responds with 8 512-byte packets. The ':digit' following the transaction id gives the packet sequence number in the transaction and the number in parens is the amount of data in the packet, excluding the atp header. The '*' on packet 7 indicates that the EOM bit was set.

Jssmag.209 then requests that packets 3 & 5 be retransmitted. Helios resends them then jssmag.209 releases the transaction. Finally, jssmag.209 initiates the next request. The '*' on the request indicates that XO ('exactly once') was *not* set.

IP Fragmentation

Fragmented Internet datagrams are printed as

```

(frag id:size@offset+)
(frag id:size@offset)

```

(The first form indicates there are more fragments. The second indicates this is the last fragment.)

Id is the fragment id. *Size* is the fragment size (in bytes) excluding the IP header. *Offset* is this fragment's offset (in bytes) in the original datagram.

The fragment information is output for each fragment. The first fragment contains the higher level protocol header and the frag info is printed after the protocol info. Fragments after the first contain no higher level protocol header and the frag info is printed after the source and destination addresses. For example, here is part of an ftp from arizona.edu to lbl-rtsg.arpa over a CSNET connection that doesn't appear to handle 576 byte datagrams:

```

arizona.ftp-data > rtsg.1170: . 1024:1332(308) ack 1 win 4096 (frag 595a:328@0+)
arizona > rtsg: (frag 595a:204@328)
rtsg.1170 > arizona.ftp-data: . ack 1536 win 2560

```

There are a couple of things to note here: First, addresses in the 2nd line don't include port numbers. This is because the TCP protocol information is all in the first fragment and we have no idea what the port or sequence numbers are when we print the later fragments. Second, the tcp sequence information in the first line is printed as if there were 308 bytes of user data when, in fact, there are 512 bytes (308 in the first frag and 204 in the second). If you are looking for holes in the sequence space or trying to match up acks with packets, this can fool you.

A packet with the IP *don't fragment* flag is marked with a trailing **(DF)**.

Timestamps

By default, all output lines are preceded by a timestamp. The timestamp is the current clock time in the

form

hh:mm:ss.frac

and is as accurate as the kernel's clock. The timestamp reflects the time the kernel first saw the packet. No attempt is made to account for the time lag between when the ethernet interface removed the packet from the wire and when the kernel serviced the 'new packet' interrupt.

<ftp://ftp.ee.lbl.gov/tcpdump.tar.Z>

IPv6/IPsec support is added by WIDE/KAME project. This program uses Eric Young's SSLeay library, under specific configuration.

BUGS

Please send problems, bugs, questions, desirable enhancements, etc. to:

tcpdump-workers@tcpdump.org

Please send source code contributions, etc. to:

patches@tcpdump.org

NIT doesn't let you watch your own outbound traffic, BPF will. We recommend that you use the latter.

On Linux systems with 2.0[.x] kernels:

packets on the loopback device will be seen twice;

packet filtering cannot be done in the kernel, so that all packets must be copied from the kernel in order to be filtered in user mode;

all of a packet, not just the part that's within the snapshot length, will be copied from the kernel (the 2.0[.x] packet capture mechanism, if asked to copy only part of a packet to userland, will not report the true length of the packet; this would cause most IP packets to get an error from **tcpdump**);

capturing on some PPP devices won't work correctly.

We recommend that you upgrade to a 2.2 or later kernel.

Some attempt should be made to reassemble IP fragments or, at least to compute the right length for the higher level protocol.

Name server inverse queries are not dumped correctly: the (empty) question section is printed rather than real query in the answer section. Some believe that inverse queries are themselves a bug and prefer to fix the program generating them rather than *tcpdump*.

A packet trace that crosses a daylight savings time change will give skewed time stamps (the time change is ignored).

Filter expressions that manipulate FDDI or Token Ring headers assume that all FDDI and Token Ring packets are SNAP-encapsulated Ethernet packets. This is true for IP, ARP, and DECNET Phase IV, but is not true for protocols such as ISO CLNS. Therefore, the filter may inadvertently accept certain packets that do not properly match the filter expression.

Filter expressions on fields other than those that manipulate Token Ring headers will not correctly handle source-routed Token Ring packets.

ip6 proto should chase header chain, but at this moment it does not. **ip6 protochain** is supplied for this behavior.

Arithmetic expression against transport layer headers, like **tcp[0]**, does not work against IPv6 packets. It only looks at IPv4 packets.

NAME

termcap – terminal capability database

DESCRIPTION

The termcap database is an obsolete facility for describing the capabilities of character-cell terminals and printers. It is retained only for capability with old programs; new ones should use the **terminfo**(5) database and associated libraries.

edrc/etc/termcap or */etc/termcap* is an ASCII file (the database master) that lists the capabilities of many different types of terminals. Programs can read termcap to find the particular escape codes needed to control the visual attributes of the terminal actually in use. (Other aspects of the terminal are handled by **stty**(1).) The termcap database is indexed on the **TERM** environment variable.

Termcap entries must be defined on a single logical line, with '\ ' used to suppress the newline. Fields are separated by ':'. The first field of each entry starts at the left-hand margin, and contains a list of names for the terminal, separated by '| '.

The first subfield may (in BSD termcap entries from versions 4.3 and prior) contain a short name consisting of two characters. This short name may consist of capital or small letters. In 4.4BSD termcap entries this field is omitted.

The second subfield (first, in the newer 4.4BSD format) contains the name used by the environment variable **TERM**. It should be spelled in lowercase letters. Selectable hardware capabilities should be marked by appending a hyphen and a suffix to this name. See below for an example. Usual suffixes are w (more than 80 characters wide), am (automatic margins), nam (no automatic margins), and rv (reverse video display). The third subfield contains a long and descriptive name for this termcap entry.

Subsequent fields contain the terminal capabilities; any continued capability lines must be indented one tab from the left margin.

Although there is no defined order, it is suggested to write first boolean, then numeric, and then string capabilities, each sorted alphabetically without looking at lower or upper spelling. Capabilities of similar functions can be written in one line.

Example for:

```
Head line: vt|vt101|DEC VT 101 terminal in 80 character mode:\
Head line: Vt|vt101-w|DEC VT 101 terminal in (wide) 132 character mode:\
Boolean: :bs:\
Numeric: :co#80:\
String: :sr=\E[H:\
```

Boolean Capabilities

| | |
|----|--|
| 5i | Printer will not echo on screen |
| am | Automatic margins which means automatic line wrap |
| bs | Control-H (8 dec.) performs a backspace |
| bw | Backspace on left margin wraps to previous line and right margin |
| da | Display retained above screen |
| db | Display retained below screen |
| eo | A space erases all characters at cursor position |
| es | Escape sequences and special characters work in status line |
| gn | Generic device |
| hc | This is a hardcopy terminal |
| HC | The cursor is hard to see when not on bottom line |
| hs | Has a status line |
| hz | Hazeltine bug, the terminal can not print tilde characters |
| in | Terminal inserts null bytes, not spaces, to fill whitespace |
| km | Terminal has a meta key |
| mi | Cursor movement works in insert mode |
| ms | Cursor movement works in standout/underline mode |

| | |
|----|---|
| NP | No pad character |
| NR | ti does not reverse te |
| nx | No padding, must use XON/XOFF |
| os | Terminal can overstrike |
| ul | Terminal underlines although it can not overstrike |
| xb | Beehive glitch, f1 sends ESCAPE, f2 sends ^C |
| xn | Newline/wraparound glitch |
| xo | Terminal uses xon/xoff protocol |
| xs | Text typed over standout text will be displayed in standout |
| xt | Telera glitch, destructive tabs and odd standout mode |

Numeric Capabilities

| | |
|----|---|
| co | Number of columns |
| dB | Delay in milliseconds for backspace on hardcopy terminals |
| dC | Delay in milliseconds for carriage return on hardcopy terminals |
| dF | Delay in milliseconds for form feed on hardcopy terminals |
| dN | Delay in milliseconds for new line on hardcopy terminals |
| dT | Delay in milliseconds for tabulator stop on hardcopy terminals |
| dV | Delay in milliseconds for vertical tabulator stop on hardcopy terminals |
| it | Difference between tab positions |
| lh | Height of soft labels |
| lm | Lines of memory |
| lw | Width of soft labels |
| li | Number of lines |
| Nl | Number of soft labels |
| pb | Lowest baud rate which needs padding |
| sg | Standout glitch |
| ug | Underline glitch |
| vt | virtual terminal number |
| ws | Width of status line if different from screen width |

String Capabilities

| | |
|----|-------------------------|
| !1 | shifted save key |
| !2 | shifted suspend key |
| !3 | shifted undo key |
| #1 | shifted help key |
| #2 | shifted home key |
| #3 | shifted input key |
| #4 | shifted cursor left key |
| %0 | redo key |
| %1 | help key |
| %2 | mark key |
| %3 | message key |
| %4 | move key |
| %5 | next-object key |
| %6 | open key |
| %7 | options key |
| %8 | previous-object key |
| %9 | print key |
| %a | shifted message key |
| %b | shifted move key |
| %c | shifted next key |
| %d | shifted options key |
| %e | shifted previous key |
| %f | shifted print key |

| | |
|----|--|
| %g | shifted redo key |
| %h | shifted replace key |
| %i | shifted cursor right key |
| %j | shifted resume key |
| &0 | shifted cancel key |
| &1 | reference key |
| &2 | refresh key |
| &3 | replace key |
| &4 | restart key |
| &5 | resume key |
| &6 | save key |
| &7 | suspend key |
| &8 | undo key |
| &9 | shifted begin key |
| *0 | shifted find key |
| *1 | shifted command key |
| *2 | shifted copy key |
| *3 | shifted create key |
| *4 | shifted delete character |
| *5 | shifted delete line |
| *6 | select key |
| *7 | shifted end key |
| *8 | shifted clear line key |
| *9 | shifted exit key |
| @0 | find key |
| @1 | begin key |
| @2 | cancel key |
| @3 | close key |
| @4 | command key |
| @5 | copy key |
| @6 | create key |
| @7 | end key |
| @8 | enter/send key |
| @9 | exit key |
| al | Insert one line |
| AL | Insert %1 lines |
| ac | Pairs of block graphic characters to map alternate character set |
| ae | End alternative character set |
| as | Start alternative character set for block graphic characters |
| bc | Backspace, if not ^H |
| bl | Audio bell |
| bt | Move to previous tab stop |
| cb | Clear from beginning of line to cursor |
| cc | Dummy command character |
| cd | Clear to end of screen |
| ce | Clear to end of line |
| ch | Move cursor horizontally only to column %1 |
| cl | Clear screen and cursor home |
| cm | Cursor move to row %1 and column %2 (on screen) |
| CM | Move cursor to row %1 and column %2 (in memory) |
| cr | Carriage return |
| cs | Scroll region from line %1 to %2 |
| ct | Clear tabs |
| cv | Move cursor vertically only to line %1 |

| | |
|-----|--|
| dc | Delete one character |
| DC | Delete %1 characters |
| dl | Delete one line |
| DL | Delete %1 lines |
| dm | Begin delete mode |
| do | Cursor down one line |
| DO | Cursor down #1 lines |
| ds | Disable status line |
| eA | Enable alternate character set |
| ec | Erase %1 characters starting at cursor |
| ed | End delete mode |
| ei | End insert mode |
| ff | Formfeed character on hardcopy terminals |
| fs | Return character to its position before going to status line |
| F1 | The string sent by function key f11 |
| F2 | The string sent by function key f12 |
| F3 | The string sent by function key f13 |
| ... | ... |
| F9 | The string sent by function key f19 |
| FA | The string sent by function key f20 |
| FB | The string sent by function key f21 |
| ... | ... |
| FZ | The string sent by function key f45 |
| Fa | The string sent by function key f46 |
| Fb | The string sent by function key f47 |
| ... | ... |
| Fr | The string sent by function key f63 |
| hd | Move cursor a half line down |
| ho | Cursor home |
| hu | Move cursor a half line up |
| i1 | Initialization string 1 at login |
| i3 | Initialization string 3 at login |
| is | Initialization string 2 at login |
| ic | Insert one character |
| IC | Insert %1 characters |
| if | Initialization file |
| im | Begin insert mode |
| ip | Insert pad time and needed special characters after insert |
| iP | Initialization program |
| K1 | upper left key on keypad |
| K2 | center key on keypad |
| K3 | upper right key on keypad |
| K4 | bottom left key on keypad |
| K5 | bottom right key on keypad |
| k0 | Function key 0 |
| k1 | Function key 1 |
| k2 | Function key 2 |
| k3 | Function key 3 |
| k4 | Function key 4 |
| k5 | Function key 5 |
| k6 | Function key 6 |
| k7 | Function key 7 |
| k8 | Function key 8 |
| k9 | Function key 9 |

| | |
|-----|--|
| k; | Function key 10 |
| ka | Clear all tabs key |
| kA | Insert line key |
| kb | Backspace key |
| kB | Back tab stop |
| kC | Clear screen key |
| kd | Cursor down key |
| kD | Key for delete character under cursor |
| ke | turn keypad off |
| kE | Key for clear to end of line |
| kF | Key for scrolling forward/down |
| kh | Cursor home key |
| kH | Cursor hown down key |
| kI | Insert character/Insert mode key |
| kl | Cursor left key |
| kL | Key for delete line |
| kM | Key for exit insert mode |
| kN | Key for next page |
| kP | Key for previous page |
| kr | Cursor right key |
| kR | Key for scrolling backward/up |
| ks | Turn keypad on |
| kS | Clear to end of screen key |
| kt | Clear this tab key |
| kT | Set tab here key |
| ku | Cursor up key |
| l0 | Label of zeroth function key, if not f0 |
| l1 | Label of first function key, if not f1 |
| l2 | Label of first function key, if not f2 |
| ... | ... |
| la | Label of tenth function key, if not f10 |
| le | Cursor left one character |
| ll | Move cursor to lower left corner |
| LE | Cursor left %1 characters |
| LF | Turn soft labels off |
| LO | Turn soft labels on |
| mb | Start blinking |
| MC | Clear soft margins |
| md | Start bold mode |
| me | End all mode like so, us, mb, md and mr |
| mh | Start half bright mode |
| mk | Dark mode (Characters invisible) |
| ML | Set left soft margin |
| mm | Put terminal in meta mode |
| mo | Put terminal out of meta mode |
| mp | Turn on protected attribute |
| mr | Start reverse mode |
| MR | Set right soft margin |
| nd | Cursor right one character |
| nw | Carriage return command |
| pc | Padding character |
| pf | Turn printer off |
| pk | Program key %1 to send string %2 as if typed by user |
| pl | Program key %1 to execute string %2 in local mode |

| | |
|----|--|
| pn | Program soft label %1 to show string %2 |
| po | Turn the printer on |
| pO | Turn the printer on for %1 (<256) bytes |
| ps | Print screen contents on printer |
| px | Program key %1 to send string %2 to computer |
| r1 | Reset string 1 to set terminal to sane modes |
| r2 | Reset string 2 to set terminal to sane modes |
| r3 | Reset string 3 to set terminal to sane modes |
| RA | disable automatic margins |
| rc | Restore saved cursor position |
| rf | Reset string filename |
| RF | Request for input from terminal |
| RI | Cursor right %1 characters |
| rp | Repeat character %1 for %2 times |
| rP | Padding after character sent in replace mode |
| rs | Reset string |
| RX | Turn off XON/XOFF flow control |
| sa | Set %1 %2 %3 %4 %5 %6 %7 %8 %9 attributes |
| SA | enable automatic margins |
| sc | Save cursor position |
| se | End standout mode |
| sf | Normal scroll one line |
| SF | Normal scroll %1 lines |
| so | Start standout mode |
| sr | Reverse scroll |
| SR | scroll back %1 lines |
| st | Set tabulator stop in all rows at current column |
| SX | Turn on XON/XOFF flow control |
| ta | move to next hardware tab |
| tc | Read in terminal description from another entry |
| te | End program that uses cursor motion |
| ti | Begin program that uses cursor motion |
| ts | Move cursor to column %1 of status line |
| uc | Underline character under cursor and move cursor right |
| ue | End underlining |
| up | Cursor up one line |
| UP | Cursor up %1 lines |
| us | Start underlining |
| vb | Visible bell |
| ve | Normal cursor visible |
| vi | Cursor invisible |
| vs | Standout cursor |
| wi | Set window from line %1 to %2 and column %3 to %4 |
| XF | XOFF character if not ^S |

There are several ways of defining the control codes for string capabilities:

Every normal character represents itself, except '^', '\', and '%'.

A '^x' means Control-x. Control-A equals 1 decimal.

\x means a special code. x can be one of the following characters:

- E Escape (27)
- n Linefeed (10)
- r Carriage return (13)
- t Tabulation (9)
- b Backspace (8)

| | | |
|---|---|--|
| | f | Form feed (12) |
| | 0 | Null character. A \xxx specifies the octal character xxx. |
| i | | Increments parameters by one. |
| r | | Single parameter capability |
| + | | Add value of next character to this parameter and do binary output |
| 2 | | Do ASCII output of this parameter with a field with of 2 |
| d | | Do ASCII output of this parameter with a field with of 3 |
| % | | Print a '%' |

If you use binary output, then you should avoid the null character because it terminates the string. You should reset tabulator expansion if a tabulator can be the binary output of a parameter.

Warning:

The above metacharacters for parameters may be wrong, they document Minix termcap which may not be compatible with Linux termcap.

The block graphic characters can be specified by three string capabilities:

| | |
|----|---|
| as | start the alternative charset |
| ae | end it |
| ac | pairs of characters. The first character is the name of the block graphic symbol and the second characters is its definition. |

The following names are available:

| | |
|---|----------------------------|
| + | right arrow (>) |
| , | left arrow (<) |
| . | down arrow (v) |
| 0 | full square (#) |
| I | lantern (#) |
| - | upper arrow (^) |
| , | rhombus (+) |
| a | chess board (:) |
| f | degree (') |
| g | plus-minus (#) |
| h | square (#) |
| j | right bottom corner (+) |
| k | right upper corner (+) |
| l | left upper corner (+) |
| m | left bottom corner (+) |
| n | cross (+) |
| o | upper horizontal line (-) |
| q | middle horizontal line (-) |
| s | bottom horizontal line (_) |
| t | left tee (+) |
| u | right tee (+) |
| v | bottom tee (+) |
| w | normal tee (+) |
| x | vertical line () |
| ~ | paragraph (???) |

The values in parentheses are suggested defaults which are used by curses, if the capabilities are missing.

NAME

textblock – format stream to a justified text block

SYNOPSIS

edrc/lib/textblock [**-h**]

textblock [*blockwidth* [*hangingwidth*]]

AVAILABILITY

WA2L/edrc

DESCRIPTION

format a stream from **stdin** into a justified text block with an optional hanging first line.

OPTIONS

-h print usage message.

blockwidth width of the text block.

Default is **80**.

hangingwidth

width of the hanging indent.

Default is **0**.

EXIT STATUS

0 no error

4 usage displayed

FILES

NAME

thttpd - tiny/turbo/throttling HTTP server

SYNOPSIS

thttpd [-C *configfile*] [-p *port*] [-d *dir*] [-dd *data_dir*] [-r|-nor] [-s|-nos] [-v|-nov] [-g|-nog] [-u *user*] [-c *cgipat*] [-t *throttles*] [-h *host*] [-l *logfile*] [-i *pidfile*] [-T *charset*] [-P *P3P*] [-M *maxage*] [-V] [-D]

DESCRIPTION

thttpd is a simple, small, fast, and secure HTTP server. It doesn't have a lot of special features, but it suffices for most uses of the web, it's about as fast as the best full-featured servers (Apache, NCSA, Netscape), and it has one extremely useful feature (URL-traffic-based throttling) that no other server currently has.

OPTIONS

- C** Specifies a config-file to read. All options can be set either by command-line flags or in the config file. See below for details.
- p** Specifies an alternate port number to listen on. The default is 80. The config-file option name for this flag is "port", and the config.h option is DEFAULT_PORT.
- d** Specifies a directory to chdir() to at startup. This is merely a convenience - you could just as easily do a cd in the shell script that invokes the program. The config-file option name for this flag is "dir", and the config.h options are WEBDIR, USE_USER_DIR.
- r** Do a chroot() at initialization time, restricting file access to the program's current directory. If -r is the compiled-in default, then -nor disables it. See below for details. The config-file option names for this flag are "chroot" and "nochroot", and the config.h option is ALWAYS_CHROOT.
- dd** Specifies a directory to chdir() to after chrooting. If you're not chrooting, you might as well do a single chdir() with the -d flag. If you are chrooting, this lets you put the web files in a subdirectory of the chroot tree, instead of in the top level mixed in with the chroot files. The config-file option name for this flag is "data_dir".
- nos** Don't do explicit symbolic link checking. Normally, thttpd explicitly expands any symbolic links in filenames, to check that the resulting path stays within the original document tree. If you want to turn off this check and save some CPU time, you can use the -nos flag, however this is not recommended. Note, though, that if you are using the chroot option, the symlink checking is unnecessary and is turned off, so the safe way to save those CPU cycles is to use chroot. The config-file option names for this flag are "symlinkcheck" and "nosymlinkcheck".
- v** Do el-cheapo virtual hosting. If -v is the compiled-in default, then -nov disables it. See below for details. The config-file option names for this flag are "vhost" and "novhost", and the config.h option is ALWAYS_VHOST.
- g** Use a global passwd file. This means that every file in the entire document tree is protected by the single .htpasswd file at the top of the tree. Otherwise the semantics of the .htpasswd file are the same. If this option is set but there is no .htpasswd file in the top-level directory, then thttpd proceeds as if the option was not set - first looking for a local .htpasswd file, and if that doesn't exist either then serving the file without any password. If -g is the compiled-in default, then -nog disables it. The config-file option names for this flag are "globalpasswd" and "noglobalpasswd", and the config.h option is ALWAYS_GLOBAL_PASSWD.
- u** Specifies what user to switch to after initialization when started as root. The default is "nobody". The config-file option name for this flag is "user", and the config.h option is DEFAULT_USER.
- c** Specifies a wildcard pattern for CGI programs, for instance "***.cgi" or "/cgi-bin/*". See below for details. The config-file option name for this flag is "cgipat", and the config.h option is CGI_PATTERN.
- t** Specifies a file of throttle settings. See below for details. The config-file option name for this flag is "throttles".
- h** Specifies a hostname to bind to, for multihoming. The default is to bind to all hostnames supported on the local machine. See below for details. The config-file option name for this flag is

"host", and the config.h option is SERVER_NAME.

- l** Specifies a file for logging. If no -l argument is specified, thttpd logs via syslog(). If "-l /dev/null" is specified, thttpd doesn't log at all. The config-file option name for this flag is "logfile".
- i** Specifies a file to write the process-id to. If no file is specified, no process-id is written. You can use this file to send signals to thttpd. See below for details. The config-file option name for this flag is "pidfile".
- T** Specifies the character set to use with text MIME types. The default is iso-8859-1. The config-file option name for this flag is "charset", and the config.h option is DEFAULT_CHARSET.
- P** Specifies a P3P server privacy header to be returned with all responses. See <http://www.w3.org/P3P/> for details. Thttpd doesn't do anything at all with the string except put it in the P3P: response header. The config-file option name for this flag is "p3p".
- M** Specifies the number of seconds to be used in a "Cache-Control: max-age" header to be returned with all responses. An equivalent "Expires" header is also generated. The default is no Cache-Control or Expires headers, which is just fine for most sites. The config-file option name for this flag is "max_age".
- V** Shows the current version info.
- D** This was originally just a debugging flag, however it's worth mentioning because one of the things it does is prevent thttpd from making itself a background daemon. Instead it runs in the foreground like a regular program. This is necessary when you want to run thttpd wrapped in a little shell script that restarts it if it exits.

CONFIG-FILE

All the command-line options can also be set in a config file. One advantage of using a config file is that the file can be changed, and thttpd will pick up the changes with a restart.

The syntax of the config file is simple, a series of "option" or "option=value" separated by whitespace. The option names are listed above with their corresponding command-line flags.

CHROOT

chroot() is a system call that restricts the program's view of the filesystem to the current directory and directories below it. It becomes impossible for remote users to access any file outside of the initial directory. The restriction is inherited by child processes, so CGI programs get it too. This is a very strong security measure, and is recommended. The only downside is that only root can call chroot(), so this means the program must be started as root. However, the last thing it does during initialization is to give up root access by becoming another user, so this is safe.

The program can also be compile-time configured to always do a chroot(), without needing the -r flag.

Note that with some other web servers, such as NCSA httpd, setting up a directory tree for use with chroot() is complicated, involving creating a bunch of special directories and copying in various files. With thttpd it's a lot easier, all you have to do is make sure any shells, utilities, and config files used by your CGI programs and scripts are available. If you have CGI disabled, or if you make a policy that all CGI programs must be written in a compiled language such as C and statically linked, then you probably don't have to do any setup at all.

However, one thing you should do is tell syslogd about the chroot tree, so that thttpd can still generate syslog messages. Check your system's syslogd man page for how to do this. In FreeBSD you would put something like this in /etc/rc.conf:

```
syslogd_flags="-l /usr/local/www/data/dev/log"
```

Substitute in your own chroot tree's pathname, of course. Don't worry about creating the log socket, syslogd wants to do that itself. (You may need to create the dev directory.) In Linux the flag is -a instead of -l, and there may be other differences.

Relevant config.h option: ALWAYS_CHROOT.

CGI

thttpd supports the CGI 1.1 spec.

In order for a CGI program to be run, its name must match the pattern specified either at compile time or on the command line with the `-c` flag. This is a simple shell-style filename pattern. You can use `*` to match any string not including a slash, or `**` to match any string including slashes, or `?` to match any single character. You can also use multiple such patterns separated by `|`. The patterns get checked against the filename part of the incoming URL. Don't forget to quote any wildcard characters so that the shell doesn't mess with them.

Restricting CGI programs to a single directory lets the site administrator review them for security holes, and is strongly recommended. If there are individual users that you trust, you can enable their directories too.

If no CGI pattern is specified, neither here nor at compile time, then CGI programs cannot be run at all. If you want to disable CGI as a security measure, that's how you do it, just comment out the patterns in the config file and don't run with the `-c` flag.

Note: the current working directory when a CGI program gets run is the directory that the CGI program lives in. This isn't in the CGI 1.1 spec, but it's what most other HTTP servers do.

Relevant config.h options: `CGI_PATTERN`, `CGI_TIMELIMIT`, `CGI_NICE`, `CGI_PATH`, `CGI_LD_LIBRARY_PATH`, `CGIBINDIR`.

BASIC AUTHENTICATION

Basic Authentication is available as an option at compile time. If enabled, it uses a password file in the directory to be protected, called `.htpasswd` by default. This file is formatted as the familiar colon-separated username/encrypted-password pair, records delimited by newlines. The protection does not carry over to subdirectories. The utility program `htpasswd(1)` is included to help create and modify `.htpasswd` files.

Relevant config.h option: `AUTH_FILE`

THROTTLING

The throttle file lets you set maximum byte rates on URLs or URL groups. You can optionally set a minimum rate too. The format of the throttle file is very simple. A `#` starts a comment, and the rest of the line is ignored. Blank lines are ignored. The rest of the lines should consist of a pattern, whitespace, and a number. The pattern is a simple shell-style filename pattern, using `?/**/*`, or multiple such patterns separated by `|`.

The numbers in the file are byte rates, specified in units of bytes per second. For comparison, a v.90 modem gives about 5000 B/s depending on compression, a double-B-channel ISDN line about 12800 B/s, and a T1 line is about 150000 B/s. If you want to set a minimum rate as well, use number-number.

Example:

```
# throttle file for www.acme.com

**          2000-100000 # limit total web usage to 2/3 of our T1,
                # but never go below 2000 B/s
**.jpg|.gif 50000 # limit images to 1/3 of our T1
**.mpg      20000 # and movies to even less
jef/**      20000 # jef's pages are too popular
```

Throttling is implemented by checking each incoming URL filename against all of the patterns in the throttle file. The server accumulates statistics on how much bandwidth each pattern has accounted for recently (via a rolling average). If a URL matches a pattern that has been exceeding its specified limit, then the data returned is actually slowed down, with pauses between each block. If that's not possible (e.g. for CGI programs) or if the bandwidth has gotten way larger than the limit, then the server returns a special code saying 'try again later'.

The minimum rates are implemented similarly. If too many people are trying to fetch something at the same time, throttling may slow down each connection so much that it's not really useable. Furthermore, all those slow connections clog up the server, using up file handles and connection slots. Setting a minimum

rate says that past a certain point you should not even bother - the server returns the "try again later" code and the connection isn't even started.

There is no provision for setting a maximum connections/second throttle, because throttling a request uses as much CPU as handling it, so there would be no point. There is also no provision for throttling the number of simultaneous connections on a per-URL basis. However you can control the overall number of connections for the whole server very simply, by setting the operating system's per-process file descriptor limit before starting thttpd. Be sure to set the hard limit, not the soft limit.

MULTIHOSTING

Multihoming means using one machine to serve multiple hostnames. For instance, if you're an internet provider and you want to let all of your customers have customized web addresses, you might have `www.joe.acme.com`, `www.jane.acme.com`, and your own `www.acme.com`, all running on the same physical hardware. This feature is also known as "virtual hosts". There are three steps to setting this up.

One, make DNS entries for all of the hostnames. The current way to do this, allowed by HTTP/1.1, is to use CNAME aliases, like so:

```
www.acme.com IN A 192.100.66.1
www.joe.acme.com IN CNAME www.acme.com
www.jane.acme.com IN CNAME www.acme.com
```

However, this is incompatible with older HTTP/1.0 browsers. If you want to stay compatible, there's a different way - use A records instead, each with a different IP address, like so:

```
www.acme.com IN A 192.100.66.1
www.joe.acme.com IN A 192.100.66.200
www.jane.acme.com IN A 192.100.66.201
```

This is bad because it uses extra IP addresses, a somewhat scarce resource. But if you want people with older browsers to be able to visit your sites, you still have to do it this way.

Step two. If you're using the modern CNAME method of multihoming, then you can skip this step. Otherwise, using the older multiple-IP-address method you must set up IP aliases or multiple interfaces for the extra addresses. You can use `ifconfig(8)`'s `alias` command to tell the machine to answer to all of the different IP addresses. Example:

```
ifconfig le0 www.acme.com
ifconfig le0 www.joe.acme.com alias
ifconfig le0 www.jane.acme.com alias
```

If your OS's version of `ifconfig` doesn't have an `alias` command, you're probably out of luck (but see <http://www.acme.com/software/thttpd/notes.html>).

Third and last, you must set up thttpd to handle the multiple hosts. The easiest way is with the `-v` flag, or the `ALWAYS_VHOST` config.h option. This works with either CNAME multihosting or multiple-IP multihosting. What it does is send each incoming request to a subdirectory based on the hostname it's intended for. All you have to do in order to set things up is to create those subdirectories in the directory where thttpd will run. With the example above, you'd do like so:

```
mkdir www.acme.com www.joe.acme.com www.jane.acme.com
```

If you're using old-style multiple-IP multihosting, you should also create symbolic links from the numeric addresses to the names, like so:

```
ln -s www.acme.com 192.100.66.1
ln -s www.joe.acme.com 192.100.66.200
ln -s www.jane.acme.com 192.100.66.201
```

This lets the older HTTP/1.0 browsers find the right subdirectory.

There's an optional alternate step three if you're using multiple-IP multihosting: run a separate thttpd process for each hostname, using the `-h` flag to specify which one is which. This gives you more flexibility, since you can run each of these processes in separate directories, with different throttle files, etc. Example:

```
thttpd -r -d /usr/www -h www.acme.com
thttpd -r -d /usr/www/joe -u joe -h www.joe.acme.com
thttpd -r -d /usr/www/jane -u jane -h www.jane.acme.com
```

But remember, this multiple-process method does not work with CNAME multihosting - for that, you must

use a single thttpd process with the -v flag.

CUSTOM ERRORS

thttpd lets you define your own custom error pages for the various HTTP errors. There's a separate file for each error number, all stored in one special directory. The directory name is "errors", at the top of the web directory tree. The error files should be named "errNNN.html", where NNN is the error number. So for example, to make a custom error page for the authentication failure error, which is number 401, you would put your HTML into the file "errors/err401.html". If no custom error file is found for a given error number, then the usual built-in error page is generated.

If you're using the virtual hosts option, you can also have different custom error pages for each different virtual host. In this case you put another "errors" directory in the top of that virtual host's web tree. thttpd will look first in the virtual host errors directory, and then in the server-wide errors directory, and if neither of those has an appropriate error file then it will generate the built-in error.

NON-LOCAL REFERERS

Sometimes another site on the net will embed your image files in their HTML files, which basically means they're stealing your bandwidth. You can prevent them from doing this by using non-local referer filtering. With this option, certain files can only be fetched via a local referer. The files have to be referenced by a local web page. If a web page on some other site references the files, that fetch will be blocked. There are three config-file variables for this feature:

urlpat A wildcard pattern for the URLs that should require a local referer. This is typically just image files, sound files, and so on. For example:

```
urlpat=*.jpg|*.gif|*.au|*.wav
```

For most sites, that one setting is all you need to enable referer filtering.

noemptyreferers

By default, requests with no referer at all, or a null referer, or a referer with no apparent hostname, are allowed. With this variable set, such requests are disallowed.

localpat

A wildcard pattern that specifies the local host or hosts. This is used to determine if the host in the referer is local or not. If not specified it defaults to the actual local hostname.

SYMLINKS

thttpd is very picky about symbolic links. Before delivering any file, it first checks each element in the path to see if it's a symbolic link, and expands them all out to get the final actual filename. Along the way it checks for things like links with ".." that go above the server's directory, and absolute symlinks (ones that start with a /). These are prohibited as security holes, so the server returns an error page for them. This means you can't set up your web directory with a bunch of symlinks pointing to individual users' home web directories. Instead you do it the other way around - the user web directories are real subdirs of the main web directory, and in each user's home dir there's a symlink pointing to their actual web dir.

The CGI pattern is also affected - it gets matched against the fully-expanded filename. So, if you have a single CGI directory but then put a symbolic link in it pointing somewhere else, that won't work. The CGI program will be treated as a regular file and returned to the client, instead of getting run. This could be confusing.

PERMISSIONS

thttpd is also picky about file permissions. It wants data files (HTML, images) to be world readable. Readable by the group that the thttpd process runs as is not enough - thttpd checks explicitly for the world-readable bit. This is so that no one ever gets surprised by a file that's not set world-readable and yet somehow is readable by the HTTP server and therefore the *whole* world.

The same logic applies to directories. As with the standard Unix "ls" program, thttpd will only let you look at the contents of a directory if its read bit is on; but as with data files, this must be the world-read bit, not just the group-read bit.

thttpd also wants the execute bit to be *off* for data files. A file that is marked executable but doesn't match the CGI pattern might be a script or program that got accidentally left in the wrong directory.

Allowing people to fetch the contents of the file might be a security breach, so this is prohibited. Of course if an executable file **does** match the CGI pattern, then it just gets run as a CGI.

In summary, data files should be mode 644 (rw-r--r--), directories should be 755 (rwxr-xr-x) if you want to allow indexing and 711 (rwx--x--x) to disallow it, and CGI programs should be mode 755 (rwxr-xr-x) or 711 (rwx--x--x).

LOGS

thttpd does all of its logging via syslog(3). The facility it uses is configurable. Aside from error messages, there are only a few log entry types of interest, all fairly similar to CERN Common Log Format:

```
Aug 6 15:40:34 acme thttpd[583]: 165.113.207.103 - - "GET /file" 200 357
```

```
Aug 6 15:40:43 acme thttpd[583]: 165.113.207.103 - - "HEAD /file" 200 0
```

```
Aug 6 15:41:16 acme thttpd[583]: referer http://www.acme.com/ -> /dir
```

```
Aug 6 15:41:16 acme thttpd[583]: user-agent Mozilla/1.1N
```

The package includes a script for translating these log entries into CERN-compatible files. Note that thttpd does not translate numeric IP addresses into domain names. This is both to save time and as a minor security measure (the numeric address is harder to spoof).

Relevant config.h option: LOG_FACILITY.

If you'd rather log directly to a file, you can use the `-l` command-line flag. But note that error messages still go to syslog.

SIGNALS

thttpd handles a couple of signals, which you can send via the standard Unix kill(1) command:

INT,TERM

These signals tell thttpd to shut down immediately. Any requests in progress get aborted.

USR1 This signal tells thttpd to shut down as soon as it's done servicing all current requests. In addition, the network socket it uses to accept new connections gets closed immediately, which means a fresh thttpd can be started up immediately.

USR2 This signal tells thttpd to generate the statistics syslog messages immediately, instead of waiting for the regular hourly update.

HUP This signal tells thttpd to close and re-open its (non-syslog) log file, for instance if you rotated the logs and want it to start using the new one. This is a little tricky to set up correctly, for instance if you are using chroot() then the log file must be within the chroot tree, but it's definitely doable.

NAME

timer – print seconds since the Epoch

SYNOPSIS

Version = 1.0.00:

edrc/bin/timer [**-h**]

timer [[**-d**] *seconds*]

Version >= 1.0.01:

edrc/bin/timer [**-h** | **-V**]

timer [[**-d**] *seconds* | *YYYY-MM-DD* | "*YYYY-MM-DD hh:mm:ss*"]

AVAILABILITY

WA2L/edrc

DESCRIPTION

return the number of seconds since the Epoch or return the date based on the given number of seconds since the Epoch.

Since version 1.0.01 of the **timer** command, the Epoch for a given date or date and time can be resolved.

OPTIONS

-d return the date and time in the standard format as printed when the **date**(1) command is issued without options.

seconds seconds to return the date for it. If the **-d** option is not specified, the date is returned in military format (**YYYY-MM-DD hh:mm:ss**).

YYYY-MM-DD
return the Epoch for the given date at *00:00:00*.

"YYYY-MM-DD hh:mm:ss"
return the Epoch for the given date and time.

ENVIRONMENT

\$TZ time zone.

EXIT STATUS

| | |
|-----------|---|
| 4 | usage printed |
| 11 | no error, seconds since Epoch printed. |
| 16 | no error, seconds of given date time printed. |
| 20 | no error, date based on given seconds printed. |
| 25 | no error, date based on given seconds printed in standard format. |

FILES

-

EXAMPLES

The following examples are given as if they are all executed at the same point in time.

1) print the date

```
[ / ]
[ root@acme007 ][*edrc*/bash]: date

Sun Sep 29 22:36:04 CEST 2008
```

2) print seconds since the Epoch

```
[ / ]
[ root@acme007 ][*edrc*/bash]: timer

1222720564
```

3) calculate the timer of yesterday

```
[ / ]
[ root@acme007 ][*edrc*/bash]: expr `timer` - 60 60 24

1222634164
```

4) print the date based on a (calculated) timer

```
[ / ]
[ root@acme007 ][*edrc*/bash]: timer -d 1222634164

Sun Sep 28 22:36:04 2008
```

5) print the date in military format based on a (calculated) timer

```
[ / ]  
[ root@acme007 ][*edrc*/bash]: timer 1222634164  
  
2008-09-28 22:36:04
```

NAME

timezone – return the timezone

SYNOPSIS

edrc/lib/timezone [**-h** | **-v**]

timezone

AVAILABILITY

WA2L/edrc

DESCRIPTION

return the timezone as defined system wide, set in the **\$TZ** environment variable or set in the configuration file **timezone.cfg**.

This command is used to return the time zone using a cross operating system compatible interface, due to the fact that on many unix flavors the setting of the time zone is implemented differently.

The following pseudo code explains the precise resolution of the return value of **timezone** (**TIMEZONE** and **TIMEZONE_DEFAULT** are settings in the **timezone.cfg** file):

```
if TIMEZONE <> "" then
    return TIMEZONE
else
    if $TZ <> "" then
        return $TZ
    else
        if 'system wide time zone setting' <> "" then
            return 'system wide time zone'
        else
            if TIMEZONE_DEFAULT <> "" then
                return TIMEZONE_DEFAULT
            else
                return "GMT"
            endif
        endif
    endif
endif
```

See also **timezone.cfg**(4) for the description of the possible settings and the influence to the **timezone** return value.

OPTIONS

- h** print usage message.
- v** print verbose information.

ENVIRONMENT

- \$TZ** Timezone environment variable setting.

EXIT STATUS

- 0** no error.
- 4** usage message printed.
- 6** config file does not exist.

FILES**/etc/TIMEZONE**

system wide time zone setting on Solaris. This file must contain the entry **TZ=a_timezone** .

/etc/default/tz

time zone setting on HPUX. This file must contain a single line specifying the time zone entry *a_timezone*.

/etc/localtime

On Linux **/etc/localtime** defines the time zone. Normally this file is a symbolic link to the real time zone file in **/usr/share/zoneinfo**.

/etc/default/tz

time zone setting on all other operating systems. This file must contain a single line specifying the time zone entry *a_timezone*.

edrc/etc/timezone.cfg

config file for **timezone**.

edrc/etc/timezone.dat

timezone map file **timezone** on Linux.

EXAMPLES

-

SEE ALSO

edrcintro(1), **timezone.cfg(4)**, **timezone.dat(4)**, **TIMEZONE(4)**

NOTES

The **timezone** command is used internally in many WA2L/edrc commands to ensure a consistent output of all dates within the whole package.

NAME

timezone.cfg – configuration file for timezone

SYNOPSIS

edrc/etc/timezone.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **timezone** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**TIMEZONE**

Time zone. This value is returned when the **timezone** command is invoked.

If this setting is not set, the content of the **\$TZ** environment variable is used, if the **\$TZ** environment variable is also not set, the system wide time zone setting is used. If the system wide time zone is not set, the setting in **TIMEZONE_DEFAULT** is used.

Example: **TIMEZONE=""**

Default: **TIMEZONE=TIMEZONE_DEFAULT**

TIMEZONE_DEFAULT

Default time zone if **TIMEZONE** is not set, the **\$TZ** environment variable is not set and the system wide time zone could not be resolved.

If this setting is also not set, *GMT* is used as a final default.

Example: **TIMEZONE_DEFAULT="MET-1METDST"**

Default: TIMEZONE_DEFAULT=GMT

NAME

timezone.dat – timezone configuration file for timezone

SYNOPSIS

edrc/etc/timezone.dat

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the timezone configuration definition for the **timezone(3)** command.

FILEFORMAT

The fileformat is a list of definitions that have the format

OSID:TIMEZONE:ALIAS:

Rows starting with a **#** are considered as comments. Empty lines are allowed, too.

OPTIONS

OSID operating system id as returned by **osid(3)**.

TIMEZONE

timezone string as used in the **\$TZ** environment variable.

ALIAS timezone alias.

EXAMPLES

```
#
# timezone.dat - timezone mapping configuration file
#
# [00] 11.05.2010 CWa   Initial Version
# [01] 24.09.2010 CWa   +Linux-ia
#
#
# Fileformat:

NAME

title – set terminal window title

SYNOPSIS

edrc/bin/title [**-h**]

title [**short** | **long** | "*text*"]

AVAILABILITY

WA2L/edrc

DESCRIPTION

set the title of the terminal window. There are two predefined titles that can be chosen using the **short** or **long** option. It is also possible to define an own title text.

The title of the terminal window is only set, if you are logged on to a tty using a **/dev/pts/*** device.

OPTIONS

-h usage message.

short set title to 'user@hostname'. This is also the default if no option is specified.
Example: 'root@acme001'

long set title to 'user@hostname -- Customer: [ENVIRONMENT] Description' where Customer, ENVIRONMENT and Description is resolved by **server_environment(3)** internally.
Example: 'root@acme001 -- ACME: [PRODUCTION] Beringen, Acme Production'

"text" free form title text.

ENVIRONMENT

-

EXIT STATUS

0 always.

FILES

-

EXAMPLES

-

SEE ALSO**edrcintro(1)**, **hostname(1)**, **server_environment(3)****NOTES**

The **title** command is also used within **edrc** to set the terminal window title.

NAME

today – return the date of today

SYNOPSIS

edrc/lib/today [**-h**]

today ["*date_format*"]

AVAILABILITY

WA2L/edrc

DESCRIPTION

return the date of today. By default the date is returned in the format *YYYY-MM-DD*.

OPTIONS

-h print usage message.

"*date_format*"

date format as known from the **date**(1) command.

The following format place holders are the most compatible ones:

%Y year (1970...)

%y last two digits of year (00..99)

%m month (01..12)

%d day of month (01..31)

%H hour (00..23)

%M minute (00..59)

%S second (00..60)

%w day of week (0..6); 0 represents Sunday

ENVIRONMENT

\$TZ Timezone setting.

EXIT STATUS

0 no error.

today(3)

NAME

tpl – select and print template file

SYNOPSIS

edrc/bin/tpl [*select*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

give a selection of template files to be printed to **stdout**.

The **tpl** command can also be called directly from within **vi** when editing a recovery script, as:

```
1 #!/bin/bash
2 #
3 # new:new_script - <enter the description here>
4 #
5 # [00] 22.10.2021 root      Initial Version
6 #
7 #
8 test "$DEBUG" = True && set -x
9
~
~
~
:.. !tpl
```

After receiving the template data in **vi**, press **[Ctrl] + [L]** to redraw the terminal.

OPTIONS

-h usage.

select pre-select files from list of template files.

ENVIRONMENT

\$TPL_CFG

additional configuration file (to **\$EDRC_SCRIPTS_BASEDIR/tpl.cfg** and **edrc/etc/tpl.cfg**) with template locations for **tpl**.

EXIT STATUS

- 0** no error.
- 4** usage printed.

FILES**edrc/etc/tpl.cfg**

list of files to be listed in the selection. The files are relative to the application root.

edrc/var/samples/templates/

some default templates distributed with WA2L/edrc.

\$EDRC_SCRIPTS_BASEDIR/tpl.cfg

list of files to be listed in the selection. The files are relative to the recovery scripts base directory.

\$TPL_CFG

additional list of files to be listed in the selection. The files are relative to the configuration file defined in **\$TPL_CFG**.

EXAMPLES

-

SEE ALSO

NAME

tpl.cfg – template file list for tpl

SYNOPSIS

edrc/etc/tpl.cfg

\$EDRC_SCRIPTS_BASEDIR/tpl.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the template file definition for the **tpl** command.

FILEFORMAT

The fileformat is a plain list of template files, where wildcards as understood by the **ls(1)** command are supported.

The template files must not exist on the system, the **tpl** command resolves the existing template files and only presents the existing readable ones to the user.

Rows starting with a **#** are considered as comments. Empty lines are allowed, too.

The template files list are relative to the root of the WA2L/edrc package installation, as returned by the **app-root(3)** or the **\$EDRC_SCRIPTS_BASEDIR** depending on the location of the **tpl.cfg** file.

OPTIONS

-

EXAMPLES

```
#
# tpl.cfg - list of template files for tpl
#
# [00] 22.10.2021 CWa Initial Version
#
var/samples/templates/*
```

NAME

top – display and update information about the top cpu processes

SYNOPSIS

top [**-CISTbcinqv**] [**-dcount**] [**-stime**] [**-o field**] [**-Uusername**] [*number*]

DESCRIPTION

Top displays the top 10 processes on the system and periodically updates this information. Raw cpu percentage is used to rank the processes. If *number* is given, then the top *number* processes will be displayed instead of the default.

Top makes a distinction between terminals that support advanced capabilities and those that do not. This distinction affects the choice of defaults for certain options. In the remainder of this document, an “intelligent” terminal is one that supports cursor addressing, clear screen, and clear to end of line. Conversely, a “dumb” terminal is one that does not support such features. If the output of *top* is redirected to a file, it acts as if it were being run on a dumb terminal.

OPTIONS

- C** Turn off the use of color in the display.
- I** Do not display idle processes. By default, *top* displays both active and idle processes.
- S** Show system processes in the display. Normally, system processes such as the pager and the swapper are not shown. This option makes them visible.
- T** List all available color tags and the current set of tests used for color highlighting, then exit.
- b** Use “batch” mode. In this mode, all input from the terminal is ignored. Interrupt characters (such as ^C and ^_) still have an effect. This is the default on a dumb terminal, or when the output is not a terminal.
- c** Show the full command line for each process. Default is to show just the command name. This option is not supported on all platforms.
- i** Use “interactive” mode. In this mode, any input is immediately read for processing. See the section on “Interactive Mode” for an explanation of which keys perform what functions. After the command is processed, the screen will immediately be updated, even if the command was not understood. This mode is the default when standard output is an intelligent terminal.
- n** Use “non-interactive” mode. This is identical to “batch” mode.
- q** Renice *top* to -20 so that it will run faster. This can be used when the system is being very sluggish to improve the possibility of discovering the problem. This option can only be used by root.
- u** Do not take the time to map uid numbers to usernames. Normally, *top* will read as much of the file “/etc/passwd” as is necessary to map all the user id numbers it encounters into login names. This option disables all that, while possibly decreasing execution time. The uid numbers are displayed instead of the names.
- v** Write version number information to stderr then exit immediately. No other processing takes place when this option is used. To see current revision information while *top* is running, use the help command “?”.
- dcount** Show only *count* displays, then exit. A display is considered to be one update of the screen. This option allows the user to select the number of displays he wants to see before *top* automatically exits. For intelligent terminals, no upper limit is set. The default is 1 for dumb terminals.
- stime** Set the delay between screen updates to *time* seconds. The default delay between updates is 5 seconds.
- o field** Sort the process display area on the specified field. The field name is the name of the column as seen in the output, but in lower case. Likely values are “cpu”, “size”, “res”, and “time”, but may vary on different operating systems. Note that not all operating systems support this option.

-Uusername

Show only those processes owned by *username*. This option currently only accepts usernames and will not understand uid numbers.

Both *count* and *number* fields can be specified as “infinite”, indicating that they can stretch as far as possible. This is accomplished by using any proper prefix of the keywords “infinity”, “maximum”, or “all”. The default for *count* on an intelligent terminal is, in fact, **infinity**.

The environment variable **TOP** is examined for options before the command line is scanned. This enables a user to set his or her own defaults. The number of processes to display can also be specified in the environment variable **TOP**. The options **-C**, **-I**, **-S**, and **-u** are actually toggles. A second specification of any of these options will negate the first. Thus a user who has the environment variable **TOP** set to “**-I**” may use the command “top **-I**” to see idle processes.

INTERACTIVE MODE

When *top* is running in “interactive mode”, it reads commands from the terminal and acts upon them accordingly. In this mode, the terminal is put in “CBREAK”, so that a character will be processed as soon as it is typed. Almost always, a key will be pressed when *top* is between displays; that is, while it is waiting for *time* seconds to elapse. If this is the case, the command will be processed and the display will be updated immediately thereafter (reflecting any changes that the command may have specified). This happens even if the command was incorrect. If a key is pressed while *top* is in the middle of updating the display, it will finish the update and then process the command. Some commands require additional information, and the user will be prompted accordingly. While typing this information in, the user’s erase and kill keys (as set up by the command *stty*) are recognized, and a newline terminates the input.

These commands are currently recognized (^L refers to control-L):

- ^L** Redraw the screen.
- h** or **?** Display a summary of the commands (help screen). Version information is included in this display.
- q** Quit *top*.
- d** Change the number of displays to show (prompt for new number). Remember that the next display counts as one, so typing **d1** will make *top* show one final display and then immediately exit.
- n** or **#** Change the number of processes to display (prompt for new number).
- s** Change the number of seconds to delay between displays (prompt for new number).
- k** Send a signal (“kill” by default) to a list of processes. This acts similarly to the command *kill(1)*.
- r** Change the priority (the “nice”) of a list of processes. This acts similarly to the command *renice(8)*.
- u** Display only processes owned by a specific username (prompt for username). If the username specified is simply “+”, then processes belonging to all users will be displayed.
- o** Change the order in which the display is sorted. This command is not available on all systems. The sort key names vary from system to system but usually include: “cpu”, “res”, “size”, “time”. The default is cpu.
- e** Display a list of system errors (if any) generated by the last **kill** or **renice** command.
- i** (or **I**) Toggle the display of idle processes.
- c** Toggle the display of the full command line.
- C** Toggle the use of color in the display.

THE DISPLAY

The actual display varies depending on the specific variant of Unix that the machine is running. This description may not exactly match what is seen by *top* running on this particular machine. Differences are listed at the end of this manual entry.

The top few lines of the display show general information about the state of the system, including the last process id assigned to a process (on most systems), the three load averages, the current time, the number of existing processes, the number of processes in each state (sleeping, running, starting, zombies, and stopped), and a percentage of time spent in each of the processor states (user, nice, system, and idle). It also includes information about physical and virtual memory allocation.

The remainder of the screen displays information about individual processes. This display is similar in spirit to *ps(1)* but it is not exactly the same. The columns displayed by top will differ slightly between operating systems. Generally, the following fields are displayed:

PID The process id.

USERNAME

Username of the process's owner (if **-u** is specified, a UID column will be substituted for USERNAME).

PRI Current priority of the process.

NICE Nice amount in the range -20 to 20, as established by the use of the command *nice*.

SIZE Total size of the process (text, data, and stack) given in kilobytes.

RES Resident memory: current amount of process memory that resides in physical memory, given in kilobytes.

STATE Current state (typically one of "sleep", "run", "idl", "zomb", or "stop").

TIME Number of system and user cpu seconds that the process has used.

CPU Percentage of available cpu time used by this process.

COMMAND

Name of the command that the process is currently running.

COLOR

Top supports the use of ANSI color in its output. By default, color is available but not used. The environment variable **TOPCOLORS** specifies colors to use and conditions for which they should be used. At the present time, only numbers in the summary display area can be colored. In a future version it will be possible to highlight numbers in the process display area as well. The environment variable is the only way to specify color: there is no equivalent command line option. Note that the environment variable **TOP-COLOURS** is also understood. The British spelling takes precedence. The use of color only works on terminals that understand and process ANSI color escape sequences.

The environment variable is a sequence of color specifications, separated by colons. Each specification takes the form *tag*=*min*,*max*#*code* where *tag* is the name of the value to check, *min* and *max* specify a range for the value, and *code* is an ANSI color code. Multiple color codes can be listed and separated with semi-colons. A missing *min* implies the lowest possible value (usually 0) and a missing *max* implies infinity. The comma must always be present. When specifying numbers for load averages, they should be multiplied by 100. For example, the specification **1min=500,1000#31** indicates that a 1 minute load average between 5 and 10 should be displayed in red. Color attributes can be combined. For example, the specification **5min=1000,#37;41** indicates that a 5 minute load average higher than 10 should be displayed with white characters on a red background. A special tag named *header* is used to control the color of the header for process display. It should be specified with no lower and upper limits, specifically **header=,#** followed by the ANSI color code.

You can see a list of color codes recognized by this installation of top with the **-T** option. This will also show the current set of tests used for color highlighting, as specified in the environment.

AUTHOR

William LeFebvre

ENVIRONMENT

TOP user-configurable defaults for options. **TOPCOLORS** color specification

BUGS

As with *ps*(1), things can change while *top* is collecting information for an update. The picture it gives is only a close approximation to reality.

SEE ALSO

kill(1), ps(1), stty(1), mem(4), renice(8)

SUNOS 5 NOTES

CPU percentage is calculated as a fraction of total available computing resources. Hence on a multiprocessor machine a single threaded process can never consume cpu time in excess of 1 divided by the number of processors. For example, on a 4 processor machine, a single threaded process will never show a cpu percentage higher than 25%. The CPU percentage column will always total approximately 100, regardless of the number of processors.

The memory summary line displays the following: "phys mem" is the total amount of physical memory that can be allocated for use by processes (it does not include memory reserved for the kernel's use), "free mem" is the amount of unallocated physical memory, "total swap" is the amount of swap area on disk that is being used, "free swap" is the amount of swap area on disk that is still available. Unlike previous versions of *top*, The swap figures will differ from the summary output of *swap*(1M) since the latter includes physical memory as well.

The column "THR" indicates the number of execution threads in the process.

In BSD Unix, process priority was represented internally as a signed offset from a zero value with an unsigned value. The "zero" value was usually something like 20, allowing for a range of priorities from -20 to 20. As implemented on SunOS 5, older versions of *top* continued to interpret process priority in this manner, even though it was no longer correct. Starting with *top* version 3.5, this was changed to agree with the rest of the system.

The SunOS 5 (Solaris 2) port was originally written by Torsten Kasch, <torsten@techfak.uni-bielefeld.de>. Many contributions have been provided by Casper Dik <Casper.Dik@sun.com>. Support for multi-cpu, calculation of CPU% and memory stats provided by Robert Boucher <boucher@sofkin.ca>, Marc Cohen <marc@aai.com>, Charles Hedrick <hedrick@geneva.rutgers.edu>, and William L. Jones <jones@chpc>.

NAME

toupper – return given string in upper case

SYNOPSIS

NAME

tput_examples – examples on the use of the tput(1) command to control terminal outputs

SYNOPSIS

tput [*options*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

This man page gives examples of **tput**(1) usages.

The **tput**(1) utility uses the terminfo database to make the values of terminal-dependent capabilities and information available to the shell, to initialize, reset the terminal, set colors, font weight and much more.

OPTIONS

-

ENVIRONMENT

-

EXIT STATUS

-

FILES

-

EXAMPLES**COLOUR COMMANDS**

tput setab [1-7] # Set a background colour using ANSI escape

tput setaf [1-7] # Set a foreground colour using ANSI escape

Colors are as follows:

| Num | Colour | #define | RGB |
|-----|--------|---------|-----|
|-----|--------|---------|-----|

| | | | |
|---|---------|---------------|---------------|
| 0 | black | COLOR_BLACK | 0, 0, 0 |
| 1 | red | COLOR_RED | max, 0, 0 |
| 2 | green | COLOR_GREEN | 0, max, 0 |
| 3 | yellow | COLOR_YELLOW | max, max, 0 |
| 4 | blue | COLOR_BLUE | 0, 0, max |
| 5 | magenta | COLOR_MAGENTA | max, 0, max |
| 6 | cyan | COLOR_CYAN | 0, max, max |
| 7 | white | COLOR_WHITE | max, max, max |

There are also non-ANSI versions of the colour setting functions (setb instead of setab, and setf instead of setaf) which use different numbers, not given here.

TEXT MODE COMMANDS

```
tput bold      # Select bold mode
tput dim       # Select dim (half-bright) mode
tput smul      # Enable underline mode
tput rmul      # Disable underline mode
tput rev       # Turn on reverse video mode
tput smso      # Enter standout (bold) mode
tput rmso      # Exit standout mode
tput sgr 0     # Reset all attributes
```

CURSOR MOVEMENT COMMANDS

```
tput cup Y X # Move cursor to screen position X,Y (top left is 0,0)
tput cuf N   # Move N characters forward (right)
tput cub N   # Move N characters back (left)
tput cuu N   # Move N lines up
tput ll      # Move to last line, first column (if no cup)
tput sc      # Save the cursor position
tput rc      # Restore the cursor position
tput lines   # Output the number of lines of the terminal
tput cols    # Output the number of columns of the terminal
```

CLEAR AND INSERT COMMANDS

```
tput ech N   # Erase N characters
tput clear   # Clear screen and move the cursor to 0,0
tput el 1    # Clear to beginning of line
tput el      # clear to end of line
tput ed      # clear to end of screen
tput ich N   # Insert N characters (moves rest of line forward!)
tput il N    # Insert N lines
```

OTHER COMMANDS

```
tput bel     # play a bell
```

With compiz wobbly windows, the bel command makes the terminal wobble for a second to draw the user's attention.

EXAMPLE USAGE

```
echo "$(tput setaf 1)Red text $(tput setab 7)and white background$(tput sgr 0)"
```

PERFORMING MULTIPLE OPERATIONS AT ONCE

tput accepts scripts containing one command per line, which are executed in order before **tput** exits.

Avoid temporary files by echoing a multi-line string and piping it:

```
echo -e "setf 70etb 1" | tput -S # set fg white and bg red
```

NAME

traceroute – print the route packets take to network host

SYNOPSIS

traceroute [**-m** max_ttl] [**-n**] [**-p** port] [**-q** nqueries] [**-r**] [**-s** src_addr] [**-t** tos] [**-w**] [**-w** wait-time] *host* [*packetsize*]

DESCRIPTION

The Internet is a large and complex aggregation of network hardware, connected together by gateways. Tracking the route one's packets follow (or finding the miscreant gateway that's discarding your packets) can be difficult. *Traceroute* utilizes the IP protocol 'time to live' field and attempts to elicit an ICMP TIME_EXCEEDED response from each gateway along the path to some host.

The only mandatory parameter is the destination host name or IP number. The default probe datagram length is 38 bytes, but this may be increased by specifying a packet size (in bytes) after the destination host name.

Other options are:

- m** Set the max time-to-live (max number of hops) used in outgoing probe packets. The default is 30 hops (the same default used for TCP connections).
- n** Print hop addresses numerically rather than symbolically and numerically (saves a nameserver address-to-name lookup for each gateway found on the path).
- p** Set the base UDP port number used in probes (default is 33434). Traceroute hopes that nothing is listening on UDP ports *base* to *base+nhops-1* at the destination host (so an ICMP PORT_UNREACHABLE message will be returned to terminate the route tracing). If something is listening on a port in the default range, this option can be used to pick an unused port range.
- r** Bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly-attached network, an error is returned. This option can be used to ping a local host through an interface that has no route through it (e.g., after the interface was dropped by *routed*(8C)).
- s** Use the following IP address (which must be given as an IP number, not a hostname) as the source address in outgoing probe packets. On hosts with more than one IP address, this option can be used to force the source address to be something other than the IP address of the interface the probe packet is sent on. If the IP address is not one of this machine's interface addresses, an error is returned and nothing is sent.
- t** Set the *type-of-service* in probe packets to the following value (default zero). The value must be a decimal integer in the range 0 to 255. This option can be used to see if different types-of-service result in different paths. (If you are not running 4.4bsd, this may be academic since the normal network services like telnet and ftp don't let you control the TOS). Not all values of TOS are legal or meaningful – see the IP spec for definitions. Useful values are probably '-t 16' (low delay) and '-t 8' (high throughput).
- v** Verbose output. Received ICMP packets other than TIME_EXCEEDED and UNREACHABLEs are listed.
- w** Set the time (in seconds) to wait for a response to a probe (default 3 sec.).

This program attempts to trace the route an IP packet would follow to some internet host by launching UDP probe packets with a small ttl (time to live) then listening for an ICMP "time exceeded" reply from a gateway. We start our probes with a ttl of one and increase by one until we get an ICMP "port unreachable" (which means we got to "host") or hit a max (which defaults to 30 hops & can be changed with the **-m** flag). Three probes (change with **-q** flag) are sent at each ttl setting and a line is printed showing the ttl, address of the gateway and round trip time of each probe. If the probe answers come from different gateways, the address of each responding system will be printed. If there is no response within a 3 sec. timeout interval (changed with the **-w** flag), a "*" is printed for that probe.

We don't want the destination host to process the UDP probe packets so the destination port is set to an unlikely value (if some clod on the destination is using that value, it can be changed with the `-p` flag).

A sample use and output might be:

```
[yak 71]% traceroute nis.nsf.net.
traceroute to nis.nsf.net (35.1.1.48), 30 hops max, 56 byte packet
 1 helios.ee.lbl.gov (128.3.112.1) 19 ms 19 ms 0 ms
 2 lilac-dmc.Berkeley.EDU (128.32.216.1) 39 ms 39 ms 19 ms
 3 lilac-dmc.Berkeley.EDU (128.32.216.1) 39 ms 39 ms 19 ms
 4 ccngw-ner-cc.Berkeley.EDU (128.32.136.23) 39 ms 40 ms 39 ms
 5 ccn-nerif22.Berkeley.EDU (128.32.168.22) 39 ms 39 ms 39 ms
 6 128.32.197.4 (128.32.197.4) 40 ms 59 ms 59 ms
 7 131.119.2.5 (131.119.2.5) 59 ms 59 ms 59 ms
 8 129.140.70.13 (129.140.70.13) 99 ms 99 ms 80 ms
 9 129.140.71.6 (129.140.71.6) 139 ms 239 ms 319 ms
10 129.140.81.7 (129.140.81.7) 220 ms 199 ms 199 ms
11 nic.merit.edu (35.1.1.48) 239 ms 239 ms 239 ms
```

Note that lines 2 & 3 are the same. This is due to a buggy kernel on the 2nd hop system – `lbl-csam.arpa` – that forwards packets with a zero ttl (a bug in the distributed version of 4.3BSD). Note that you have to guess what path the packets are taking cross-country since the NSFNet (129.140) doesn't supply address-to-name translations for its NSSes.

A more interesting example is:

```
[yak 72]% traceroute allspice.lcs.mit.edu.
traceroute to allspice.lcs.mit.edu (18.26.0.115), 30 hops max
 1 helios.ee.lbl.gov (128.3.112.1) 0 ms 0 ms 0 ms
 2 lilac-dmc.Berkeley.EDU (128.32.216.1) 19 ms 19 ms 19 ms
 3 lilac-dmc.Berkeley.EDU (128.32.216.1) 39 ms 19 ms 19 ms
 4 ccngw-ner-cc.Berkeley.EDU (128.32.136.23) 19 ms 39 ms 39 ms
 5 ccn-nerif22.Berkeley.EDU (128.32.168.22) 20 ms 39 ms 39 ms
 6 128.32.197.4 (128.32.197.4) 59 ms 119 ms 39 ms
 7 131.119.2.5 (131.119.2.5) 59 ms 59 ms 39 ms
 8 129.140.70.13 (129.140.70.13) 80 ms 79 ms 99 ms
 9 129.140.71.6 (129.140.71.6) 139 ms 139 ms 159 ms
10 129.140.81.7 (129.140.81.7) 199 ms 180 ms 300 ms
11 129.140.72.17 (129.140.72.17) 300 ms 239 ms 239 ms
12 * * *
13 128.121.54.72 (128.121.54.72) 259 ms 499 ms 279 ms
14 * * *
15 * * *
16 * * *
17 * * *
18 ALLSPICE.LCS.MIT.EDU (18.26.0.115) 339 ms 279 ms 279 ms
```

Note that the gateways 12, 14, 15, 16 & 17 hops away either don't send ICMP "time exceeded" messages or send them with a ttl too small to reach us. 14 – 17 are running the MIT C Gateway code that doesn't send "time exceeded"s. God only knows what's going on with 12.

The silent gateway 12 in the above may be the result of a bug in the 4.[23]BSD network code (and its derivatives): 4.x (x <= 3) sends an unreachable message using whatever ttl remains in the original datagram. Since, for gateways, the remaining ttl is zero, the ICMP "time exceeded" is guaranteed to not make it back to us. The behavior of this bug is slightly more interesting when it appears on the destination system:

```

1 helios.ee.lbl.gov (128.3.112.1) 0 ms 0 ms 0 ms
2 lilac-dmc.Berkeley.EDU (128.32.216.1) 39 ms 19 ms 39 ms
3 lilac-dmc.Berkeley.EDU (128.32.216.1) 19 ms 39 ms 19 ms
4 ccngw-ner-cc.Berkeley.EDU (128.32.136.23) 39 ms 40 ms 19 ms
5 ccn-nerif35.Berkeley.EDU (128.32.168.35) 39 ms 39 ms 39 ms
6 csgw.Berkeley.EDU (128.32.133.254) 39 ms 59 ms 39 ms
7 * * *
8 * * *
9 * * *
10 * * *
11 * * *
12 * * *
13 rip.Berkeley.EDU (128.32.131.22) 59 ms ! 39 ms ! 39 ms !

```

Notice that there are 12 "gateways" (13 is the final destination) and exactly the last half of them are "missing". What's really happening is that rip (a Sun-3 running Sun OS3.5) is using the ttl from our arriving datagram as the ttl in its ICMP reply. So, the reply will time out on the return path (with no notice sent to anyone since ICMP's aren't sent for ICMP's) until we probe with a ttl that's at least twice the path length. I.e., rip is really only 7 hops away. A reply that returns with a ttl of 1 is a clue this problem exists. Traceroute prints a "!" after the time if the ttl is ≤ 1 . Since vendors ship a lot of obsolete (DEC's Ultrix, Sun 3.x) or non-standard (HPUX) software, expect to see this problem frequently and/or take care picking the target host of your probes.

Other possible annotations after the time are **!H**, **!N**, **!P** (got a host, network or protocol unreachable, respectively), **!S** or **!F** (source route failed or fragmentation needed – neither of these should ever occur and the associated gateway is busted if you see one). If almost all the probes result in some kind of unreachable, traceroute will give up and exit.

This program is intended for use in network testing, measurement and management. It should be used primarily for manual fault isolation. Because of the load it could impose on the network, it is unwise to use *traceroute* during normal operations or from automated scripts.

AUTHOR

Implemented by Van Jacobson from a suggestion by Steve Deering. Debugged by a cast of thousands with particularly cogent suggestions or fixes from C. Philip Wood, Tim Seaver and Ken Adelman.

NAME

trash – move files to a central recycle bin (trash)

SYNOPSIS

edrc/bin/trash [**-h**]

trash -f *filename_1* { *filename_n* }

AVAILABILITY

WA2L/edrc

DESCRIPTION

The **trash** and **untrash** command implement a trash can or recycle bin similar to the "Recycle Bin" of Microsoft Windows (TM) or the "Common Desktop Environment, CDE" (TM) as command line tools.

When a file is "trashed" with the **trash -f file** command instead of using the **rm** command, the following actions take place:

- 1.) the *file* to be trashed is copied to a configurable trash location, that, of course, should have sufficient disk space.

An economic variant of such a trash location is an automounted NFS share, so a global trash for a whole environment can be used to put trashed files and the "wasted" disk space is in general not that huge. The **trash** and **untrash** commands are designed to handle a global trash due to the fact that the trashed file is associated with a node-, MC/ServiceGuard- or similar script cluster package name. See also **trash.cfg**(4) for information about the possible configuration settings and **cltrash**(1) for information about cleaning up the trash.

- 2.) the *file* is emptied (not removed, to preserve the file handle).
- 3.) the *file* is moved to *file.TRASHED* .
- 4.) Now information about what has happened to the original *file* and how to retrieve it (with **untrash**) is written to *file.TRASHED* .

Therefore this command provides an easy and consistent way to "remove" files which, for example, cause filesystem fill ups, as database exports written to a small filesystem, and transparently document to the end user what has happened to the *file*.

This is a more reliable method then the often used practice among system administrators to move the problem causing file to a filesystem with more disk space and to create a symbolic link to it, due to the fact that an end user might not notice that the file creation 1st, caused a problem and 2nd, the created file might be incomplete/corrupt due to an export or program abort because of the filesystem fill up. Furthermore often those symlinks and especially the moved files have the tendency to get forgotten to be cleaned up (because those interventions often happen during on call times) and lots of disk space is wasted over time.

Suppose the process that caused the fill up will restart and create a new *file* with the same name. If the system administrator again trashes the *file*, then two versions of the same *file* are available for retrieval (with **untrash**).

OPTIONS

- h** usage message.
- f *filelist*** list of files to be trashed.

EXIT STATUS

- 0** no error.
- 1** LOGDIR or TRASHDIR does not exist. See **trash.cfg(4)** if you get this error.
- 2** operating system is not supported. See **osid(3)** if you get this error.
- 3** rootdir does not exist.
- 4** usage listed.
- 6** configuration file **edrc/etc/trash.cfg** does not exist.

FILES

edrc/etc/trash.cfg
configuration file for **trash**, **untrash** and **cltrash**.

edrc/var/trash/log/
default logfile location of **trash**, **untrash** and **cltrash**.

edrc/var/trash/files/
default location for trashed files.

***filename*.TRASHED**
information and instruction file to document the file trashing and to give instructions how to recover (**untrash**) the trashed file.

EXAMPLES

1) trash a file:

1.1) list files in the directory:

```
[ /data_dwh1/dat/exports ]
[ root@dwh_db1_prod ][ksh]: ls -al

:
-rw-r----- 1 dwh_db1 dwh      17884 Jul  1 03:36 a_list.txt
-rw-r----- 1 dwh_db1 dwh  4636592 Jul  1 03:34 dwhprod.dmp
-rwxr-x--x  1 dwh_db1 dwh        500 Jul  1 03:35 export_dwhprod.sh*
-rw-r----- 1 dwh_db1 dwh        250 Jul  1 03:35 exp.par
:
```

1.2) trash the **dwhprod.dmp** file:

```
[ /data_dwh1/dat/exports ]
[ root@dwh_db1_prod ][ksh]: trash -f dwhprod.dmp

trash files ...
      remove dwhprod.dmp ... done.
done.
```

1.3) situation in directory after invoking **trash** :

```
[ /data_dwh1/dat/exports ]
[ root@dwh_db1_prod ][ksh]: ls -al

:
-rw-r----- 1 dwh_db1 dwh      17884 Jul  1 03:36 a_list.txt
-rw-r----- 1 dwh_db1 dwh         300 Jul  1 03:42 dwhprod.dmp.TRASHE
-rwxr-x--x  1 dwh_db1 dwh         500 Jul  1 03:35 export_dwhprod.sh*
-rw-r----- 1 dwh_db1 dwh         250 Jul  1 03:35 exp.par
:
```

1.4) content of the **dwhprod.dmp.TRASHED** file:

```
#
# dwhprod.dmp.TRASHED - trash info file for trashed files
#
# [00] 01.01.2006      created by root using trash
#
```

The file:

```
-rw-r----- 1 dwh_db1 dwh    4636592 Jul  1 03:34 dwhprod.dmp
```

has been removed by administrator 'root'. To recover the file from trash, invoke:

```
untrash -f dwhprod.dmp
```

SEE ALSO

cltrash(1), **edrcintro**(1), **trash.cfg**(4), **untrash**(1)

NOTES

To resolve the node- or MC/ServiceGuard package name the **pkg_hostname**(3) command is used. Therefore the usage of the **trash** command is not restricted to systems that have MC/ServiceGuard installed.

BUGS

NAME

trash.cfg – configuration file for trash, untrash and cltrash

SYNOPSIS

edrc/etc/trash.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **trash** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**TRASHDIR**

Trash basedir. This directory holds all trashed files.

Example: TRASHDIR=/dat/trash/files

Default: TRASHDIR=/var/trash/files

LOGDIR In this directory the log files of **trash(1)**, **untrash(1)** and **cltrash(1)** are saved.

Example: LOGDIR=/dat/trash/logs

Default: LOGDIR=/var/trash/logs

SEE ALSO

trash(1), **untrash(1)**, **cltrash(1)**, **edrcintro(1)**

NOTES

NAME

tusc – trace unix system calls

SYNOPSIS

tusc [options] command [args ...] | pid [pid ...]

truss [options] command | -p pid ...

DESCRIPTION

Tusc traces the system calls a process invokes and the signals it receives. It displays arguments in a symbolic way, shows the first bytes of read and write buffers as well as signal information when available. *Tusc* can attach to live processes by providing PIDs (process IDs) as argument(s).

If desired, *tusc* can be invoked as *truss*, by linking one binary to the other, in order to provide reasonable compatibility with the **UnixWare/Solaris** tracing tool (see "TRUSS COMPATIBILITY" below).

When invoked as *tusc*, the options are:

- a** Print exec arguments. If **execv(2)** syscall is being traced, print all exec arguments and their addresses.
- A** Append to output file. This option has no effect if an output file has not been specified using the **-o** option.
- B** Show branch events, on IPF (this option is not supported on PA-RISC). To obtain meaningful data, the **-i** should be used with this option.
- b bytes** Set max data size for **-r** and **-w** options. By default, when using these options, the whole read/write buffers are dumped. This option causes a maximum *bytes* number of bytes to be displayed.
- c** Count syscalls and signals. If a single **-c** is present, *tusc* will only report the number of system calls executed by the process(es), the number of errors, if any, the accumulated CPU time for each syscall, and the number of signals. If more than one **-c** is present, *tusc* will behave as if this option was not used (i.e. display its normal output) but will report these statistics upon completion. If more than two **-c**'s are present, the CPU time for each syscall instance is also reported, in seconds, between angle brackets at the beginning of each line.
- C** Is similar to **-c** option but provides more precision and more information, in particular, the low, high and average system call times.
- d [+][!]*fds*** Select file descriptors. This option allows the user to display syscalls using certain file descriptors. If the first character of the string is a plus sign (+), syscalls that do not return or whose argument list doesn't contain file descriptors are also displayed. For the remaining part of the argument string, see the **ARGUMENT LISTS** section below. Note that, unlike with the **-s** option, the system call filtering is done by *tusc*, not by the kernel. See also the **-r** and **-w** options.

For instance, using **tusc -d8 date** will only display syscalls using file descriptor 8 but using **tusc -d+8 date** will also display syscalls which do not involve file descriptors.
- e** Print environment variables. If **execv(2)** syscall is being traced, print all environment variables and their addresses.
- E** Show syscall entries. *Tusc* doesn't require OS notification for system call entry. It collects all the data it needs when the system call returns. This option will cause *tusc* to stop upon syscall entry and produce a trace. This option is only useful for processes encountering invalid syscall errors as it will show the number of the invalid syscall.
- f** Follow forks. Normally *tusc* only traces the parent side of **fork(2)**s. With this option, it will trace all children. Note that debuggers or tracers (like *tusc*) cannot be followed since only one debugger is allowed to attach to a process at any given time.

- F** Print feature level. Newer kernels provide a way to obtain the *ttrace* feature level. This option will return that level. See <sys/ttrace.h>.
- g** Do not allow attaching to any process in *tusc*'s session (see **getsid(2)**). This option is only meaningful when providing process IDs as arguments.
- G** Print syscall list (#define, id and number of arguments) for validation purposes.
- h** Print the status of the entire process hierarchy when idle. Normally, unless the **-i** is specified, *tusc* reports the waiting syscall for the last active process only. With this option the state of all processes currently traced is reported.
- i** Don't show sleeping (interruptible) syscalls. By default, if a system call takes more than 1 to 2 seconds to complete, or if the traced process is spinning in user mode, an indication of the state of the process is displayed. If this option is used, these traces are suppressed. See **ENVIRONMENT** section.

I n1[/n2]

Single-step and display instructions. This option allows the user to single-step through the target program between all or some of the system calls. The output can be fed to a disassembler to provide more information. The **n1** argument specifies that single-stepping should occur after the **n1**'th syscall. The **n2** argument specifies the number of syscalls after which single-stepping will stop (default is the remainder of the process).

The PC and instructions that are displayed (not available with older kernels) are obtained from the SIGTRAP siginfo and are the PC/instruction where the single-step originated from. If a single **-v** flag is provided, the current PC and instruction will also be displayed. If two **-v** flags are present, the register context at the time of the single-step is also printed.

- k** Keep tracing after main process exits. Normally, when specifying a binary (not a process ID) to trace and following children, *tusc* will terminate when that process exits. This option forces it to wait until all children have exited. This is especially useful when tracing daemon processes that place themselves in the background by forking and exiting the parent. When this option is used, *tusc* exits with the exit code of the process that was last traced.
- l** Print all lwpids. This option is most useful when tracing multi-threaded processes.
- n** Print process names. This option is most useful when tracing a large number of processes.

o [file|fd]

Send trace output to given file or file descriptor. Normally, *tusc*'s output goes to standard output. This option provides a way to separate *tusc*'s standard output from that of the process(es) it traces. If the argument is a valid number greater than zero, it is assumed to be a file descriptor, not a file name. For instance, "*tusc -o2*" will cause the traces to go to stderr.

- p** Print pids. By default, process IDs are not printed.

- Q** Quiet. Most informational warnings are not printed.

- r [!]**fds**** Print read buffers for given file descriptors. If this option is used, all (unless the dump size is modified using the **-b** option) read data performed by the specified file descriptor(s) is dumped. See the **ARGUMENT LISTS** section below.

The data, by default, is displayed 32 byte wide using characters followed by a blank, if the character is printable, a "C" escape sequence notation or a 2 digit hexadecimal value. See the **ENVIRONMENT** section for ways to dump data in different formats.

Note that the **-d** option has precedence: no buffer data will be displayed if the file descriptor has been selected out.

- R** Show syscall restarts. This option shows system call restarts. It is not clear how useful it is at this point.

s [!]syscalls

Select syscalls. By default, all system calls are traced. This option allows a user to trace a limited number of calls. See the **ARGUMENT LISTS** section below. The arguments can be a combination of numbers, full system call names or global expressions.

S [!]signals

Select signals. By default, all signals are traced. This option allows tracing of a limited number of signals. See the **ARGUMENT LISTS** section below. The arguments can be a combination of numbers, full signal names or signal names without the **SIG** prefix (i.e. **SIGINT** or **INT** both work). Specifying uncatchable signals has no effect.

t Detach process if it enters traced mode. If this option is used, *tusc* silently checks system call entry events and releases the process if it is performing a *ttrace(TT_PROC_SETTRC)* or a *ptrace(PT_SETTRC)* syscall. If the call is *ttrace(TT_PROC_ATTACH)* or *ptrace(PT_ATTACH)*, the process being attached to is also released if *tusc* was tracing it.

T format

Show time stamp for each syscall and signal. If the *format* argument is an empty string or if it is the string "**hires**", the time of day in *tv_sec.tv_usec* format will be displayed. Else, *format* is expected to be a string containing time formatting directives. For details, refer to the **strftime(3C)** man page.

u User thread IDs. If this option is present, user thread IDs (see pthreads) are displayed.

v Verbose. If this option is present, more verbose data is produced for some system calls. Additional **-v** options will provide more data for a subset of those syscalls (the *stat*, *statfs*, *statvfs* and *pstat* families). Three **-v** options provides the most verbosity at this time.

V Print version. This option simply prints the current *tusc* version.

w [!]fds Print write buffers for given file descriptors. Identical to **r** option but for write buffers.

x Print raw (hex) arguments. *Tusc* produces symbolic output for a large number of system calls. This option causes all arguments to be displayed in hexadecimal rather than in symbolic form. If used with the **-v** option, data that are normally displayed in symbolic form are also displayed in hexadecimal.

X Print syscall traces in an exportable format. When this option is used, *Tusc* will print the syscall traces in a format that will allow them to be imported by a spreadsheet: IDs, time stamps, syscall name, syscall argument(s) in a single parenthesized block and return value(s) are separated with tabs. Signal traces are split in 2 blocks, the first one being the signal received, the second the remainder of the data. Refer to the **ENVIRONMENT** section if another field separator is desired. All verbose or buffer data is unchanged.

y Verbose option for registers. A single **-y** will print the PC (and disassemble the instruction, on IPF), an additional **-y** will dump all registers. This option is only meaningful when **-I** is used. For backward compatibility, the **-v** option has the same effect on register display but will also produce verbose system call data where available.

z Do not print information about successful syscalls. Print only failed syscalls as well as all signals.

ARGUMENT LISTS

Several *tusc* options require a list of objects (syscalls, file descriptors, signals). The argument lists are in the form:

[!]arg1[,arg2[,...]]

The optional leading '!', means "all but". The rest of the string is a list of arguments separated by commas (',') or the *all* keyword which, except for syscall names, has the expected behavior.

The **-d** option supports multiple file descriptor ranges in the form:

[!]low-high,[low2-high2],...

The **-s** option supports a single **begin-end** range as argument:

[!]syscall-[syscall]

where syscall can be a system call number or an exact system call name. If the second value is omitted, the last system call number is implied. This is mostly useful to debug newly added syscalls internally.

SEE ALSO

ttrace(2), **ttrace_wait(2)**, **strftime(3c)**, **regcomp(3)**, **fnmatch(3)**.

A front end script, **sstep**, is available to provide on-the-fly symbolic disassembly.

EXAMPLES

tusc date Trace the **date(1)** command.

tusc 1 Trace **init(1M)**, if super-user.

tusc -f -o make.trace make

Trace **make(1)** and all the processes it invokes and send the output to the file **make.trace**.

tusc -s read,write cat /etc/passwd

Show the read and write syscalls from the command 'cat /etc/passwd'.

tusc -s !sig,mmap sleep 10

Show all system calls except **mmap** and those having 'sig' in their name.

CAVEATS

Tusc cannot trace a process being debugged or traced by another process since a process may only have one debugger at a time.

Historically, debuggers (applications using tracing interfaces) have destroyed their children, or the processes they are attached to, when exiting, or, rather, the operating system has provided this service to them. This is clearly not always a desirable behavior and *tusc* catches signals in order to detach itself from processes it may have attached to, before exiting. However, in the case of multiple tracers tracing each other and the last one attaching to a live process (for instance, "tusc tusc <PID>"), it is possible that the first tracer will exit first, taking the entire process chain with it and not allowing the last one to detach from the PID before exiting.

Newer (currently unreleased) versions of the OS allow a debugger to specify what action should be taken upon debugger exit. *Tusc* uses the **detach-on-exit** option when running on OSes that provide that option.

When tracing the crooked shell (aka C-shell, aka csh) and following children, on 11.0, one should ignore SIGUSR1 to avoid races between parent and child processes. This problem is fixed in the 11i kernel.

NOTE

The *tusc* interface and features may evolve in the future.

TRUSS COMPATIBILITY

If *tusc* is invoked as *truss*, it provide some level of compatibility with the latter:

- o The default trace output becomes stderr.
- o The default filler character is changed from dot to space.
- o The pid/lwpid display more closely resembles output from *truss*.

The following *truss* options are supported (see **truss(1)** on **UnixWare** or **Solaris** for details):

- a** Same as *tusc*'s. Compatible with *truss*.
- c** Same as *tusc*'s but only one level supported.
- d** Compatible with *truss*.
- D** Same as *tusc*'s -ccc but without the syscall summary.
- e** Same as *tusc*'s. Compatible with *truss*.
- f** Same as *tusc*'s but also turns on process ID display as it does with *truss*.
- i** Same as *tusc*'s. Compatible with *truss*.

| | |
|----------|--|
| l | Same as <i>tusc</i> 's. Compatible with <i>truss</i> . |
| o | Same as <i>tusc</i> 's. Compatible with <i>truss</i> . |
| p | Compatible with <i>truss</i> . |
| r | Same as <i>tusc</i> 's. Compatible with <i>truss</i> . |
| s | Same as <i>tusc</i> 's -S option. Compatible with <i>truss</i> . |
| t | Same as <i>tusc</i> 's -s option. Compatible with <i>truss</i> . |
| v | Argument is ignored. -v is turned on for all syscalls. |
| w | Same as <i>tusc</i> 's. Compatible with <i>truss</i> . |
| x | Argument is ignored. -x is turned on for all syscalls. |

The following *truss* options are not supported: **-m**, **-M**, **-T**, **-S**, **-u**, **-U**.

ENVIRONMENT

Tusc aligns return values, when possible, and uses dots as filler. If the **TUSCFILLER** variable is set, that string is used as filler instead if it doesn't contain tabs or non printable characters.

Unless the **-i** option is used, *tusc* uses a 2 second alarm to report sleeping system calls in the process that was last continued. The **TUSCALARM** variable may be used to change the default alarm.

Tusc has preset values to horizontally divide the output into syscall data and return value. The **TUSCMARGIN** variable may be set to specify a number of columns for the latter. Values greater than the number of columns are ignored.

The width used to print process names, when the **-n** option is used, can be adjusted by setting the **TUSC-NMW** variable to a positive number.

If the **-n** option is used, **TUSCSN** can be set to *true* to convert commands' full path names into simple names.

By default, read/write buffers contents are displayed in character pairs, using the following algorithm: ascii printable characters are printed with a space on the right, the "C" language's escape character constants (\0, \n, \r, etc...) are printed as such and all other characters are printed in hexadecimal. The **TUSCBUFMODE** variable alters this behavior. If it is set to **hex**, all words will be printed in hexadecimal. If it is set to **ascii**, printable characters will be printed without spaces on the right and non-printable characters will be shown as dots. If it is set to **dual**, hexadecimal values are printed on the left of the pipe sign, ascii on the right. In **dual** mode, output resulting from the **-r** and **-w** options is also boxed, the hex values are space separated and the columns are numbered.

Some system calls have variable argument lists. If **TUSCVARARGS** is set to *true*, these syscalls will only display the arguments examined by the OS to avoid displaying garbage. Currently, only **open(2)**, **ptrace(2)** and **sysfs(2)** have been registered as supporting variable arguments.

Tusc reports inconsistent number of arguments between what it expects and what the OS reports. Undeclared syscalls (reported as SC-### where ### is the syscall number) do not generate this warning unless **TUSCMMAW**, which stands for "mismatch argument warning", is set to **all**. Note that these warnings or any "SC-###" report indicates that *tusc*'s internal syscall table should be updated.

By default, when running in *truss* compatibility mode, unsupported options cause a warning to be printed to stderr. If **TRUSSSTRICT** is set to *true*, unsupported options will cause *truss* to exit.

Setting the **TUSCLI0N** variable to *true* will cause system error messages, time stamps and floating numbers to be localized on systems that support it.

By default, the verbose output is center justified and aligned on the colon, if the LHS is wide enough, and always includes at least 2 spaces on the left. The **TUSCVWIDTH** variable controls the position of the colon. If that variable is set to zero, the output will be left justified. The verbose data for the *getdents* syscall is always left justified, due to the nature of the output.

The **TUSCMATCH** variable controls what type of pattern matching is used. If the value is **reg**, *tusc*

evaluates regular expressions using **regcomp**(3) with the **REG_ICASE** and **REG_NOSUB** options. If the value is **sh**, *tusc* uses shell (see **sh**(1)) pattern matching. If the value is **both**, the latter is used if the former doesn't provide a match. When running in *truss* emulation mode, the variable is not evaluated and **sh** pattern matching is used.

Unless the **-x** option is used, IPv6 addresses are printed using the double colon (::) notation to skip contiguous zero elements (for instance, the IPv6 loopback would be displayed as ::1). If this behavior is not desired, setting **TUSCRAWIPV6** to **true** will cause *tusc* to print all elements.

By default, *tusc* ignores failing system calls when setting high/low execution times (**-C** option). Setting the **TUSCHILOERRS** variable to **true** will cause *tusc* to include failing syscalls.

By default, *tusc* uses tabs as field separators when the **-X** option is used. The **TUSCSEP** can be used to specify a character string (including a null string) to be used instead of the tabs.

When single-stepping on IPF, the default is to use symbolic register names. If the **TUSCPHYSREG-NAMES** variable is set to true, physical register names will be used.

Newer versions of *tusc* print user, interrupt and elapsed times upon exit when syscall statistics are requested. If the **TUSCNOUSTATS** variable is set to true, this additional information won't be printed.

By default, the **-T hires** prints the time starting at the current time. If the **TUSCTRUSSTAMPSTIMESTAMPS** variable is set to true, it will start at zero like the **-d** option of *truss* does.

NAME

tscat – filter to add a timestamp to the stream

SYNOPSIS

edrc/lib/tscat [**-h** | **-V**]

stream | **tscat** *options*

tscat *options* < *stream*

tail -f logfile... | **tscat** *options*

tail -f logfile -v | **tscat** *options*

tail -f logfile | **tscat -f logfile** *options*

options ::= [**-z**] [**-r**] [**-m** | **-l**] [**-n** | **-f filename**] [**-d delimiter**] [**-s session**] [[**-q**] **-a appendfile**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

filter to add a timestamp and a filename to a *stream*.

OPTIONS

-h usage message.

-V print command version.

-n no file name output.

-z no output of zero length lines.

-r print raw time stamp seconds.microseconds (*s.uuuuuu*) instead of the formatted version (*YYYY-MM-DD hh:mm:s.uuuuuu*).

-m medium time stamp resolution (*s.uuuuu*).

-l low time stamp resolution, where no fraction of seconds are resolved.

-f filename (default) filename to add to *stream*.

-d delimiter
field delimiter between timestamp, filename and *stream* data.

-s *session* set session in square brackets.

-q no output to **stdout** when appending to a file.

-a *appendfile*
append timestamped output to file. When this option is specified the output to **stdout** is without timestamp.

ENVIRONMENT

\$EDRC_SESSION

set session as when using the **-s** *session* option.

EXIT STATUS

0 match

1 cannot write to the file specified in **-a** *appendfile* option.

4 usage printed.

5 version printed.

FILES

NAME

tsize – print terminal size

SYNOPSIS

edrc/lib/tsize

AVAILABILITY

WA2L/edrc

DESCRIPTION

this command returns the current width and height of the terminal in the COLUMNS and LINES variables. This output can be used directly to initialize the environment variables using the **eval** command:

```
eval `tsize`
```

The output of **tsize** is identical to the **resize(1)** command as provided when X11 is installed. As long as **resize** is available on the system it is used internally to resolve the terminal size, if not, a fallback exists to evaluate the terminal without the use of **resize**. Therefore it is not imperative to have X11 installed on the system when using **tsize** to resolve the terminal size.

OPTIONS

-

EXIT STATUS

0 always.

NAME

tttplay – player of the tty session recorded by **tttrec**

SYNOPSIS

tttplay [*-s SPEED*] [*-n*] [*-p*] *file*

DESCRIPTION

Tttplay plays the tty session in *file*, which was recorded previously by **tttrec**(1).

When **-p** option is given, **tttplay** output the *file* as it grows. It means that you can see the "live" shell session running by another user.

If you hit any key during playback, it will go right to the next character typed. This is handy when examining sessions where a user spends a lot of time at a prompt.

Additionally, there are some special keys defined:

- + or f** double the speed of playback.
- or s** halve the speed of playback.
- 1** set playback to speed 1.0 again.

OPTIONS

- s SPEED** multiple the playing speed by *SPEED* (default is 1).
- n** no wait mode. Ignore the timing information in *file*.
- p** peek another person's tty session.

SEE ALSO

script(1), **tttrec**(1), **ttttime**(1)

NAME

`ttyrec` – a tty recorder

SYNOPSIS

ttyrec [*-a*][*-u*] [*file*]

DESCRIPTION

Ttyrec is a tty recorder. It is a derivative of **script**(1) command for recording timing information with microsecond accuracy as well. It can record emacs -nw, vi, lynx, or any programs running on tty.

Ttyrec invokes a shell and records the session until the shell exits. Recorded data can be played back with **tttyplay**(1). If the argument *file* is given, the session will be recorded in that file. Otherwise, *ttyrecord* is used as default.

OPTIONS

- a** Append the output to *file* or *ttyrecord*, rather than overwriting it.
- u** With this option, **tttyrec** automatically calls **uudecode**(1) and saves its output when uuencoded data appear on the session. It allow you to transfer files from remote host. You can call **tttyrec** with this option, login to the remote host and invoke **uuencode**(1) on it for the file you want to transfer.
- e** *command*
Invoke *command* when **tttyrec** starts.

ENVIRONMENT

SHELL If the variable *SHELL* exists, the shell forked by **tttyrec** will be that shell. If it's not set, the Bourne shell is assumed. (Most shells set this variable automatically).

SEE ALSO

script(1), **tttyplay**(1), **tttytime**(1), **uuencode**(1), **uudecode**(1)

NAME

`ttytime` – print the time of the recorded session data by `ttyrec(1)`

SYNOPSIS

`ttytime` *file...*

DESCRIPTION

Ttytime tells you the time of recorded data in seconds. For example:

```
% ttytime *.tty
173 foo.tty
1832 bar.tty
```

SEE ALSO

`script(1)`, `ttyrec(1)`, `ttypplay(1)`

NAME

tty_columns – return the current width of the terminal (tty)

SYNOPSIS

edrc/lib/tty_columns [-h]

tty_columns

AVAILABILITY

WA2L/edrc

DESCRIPTION

returns the current width of the terminal (tty).

In some circumstances the **\$COLUMN** environment variable does not contain the correct width of the terminal, **tty_columns** does.

OPTIONS

-h print usage message.

ENVIRONMENT

-

EXIT STATUS

0 no error.

4 usage message printed.

FILES

/dev/tty terminal device file. This device file is read if the resolution of the current pseudo device of the terminal is not possible.

EXAMPLES

-

SEE ALSO

edrcintro(1), **tty_variable**(3), **tty**(1), **stty**(1)

NOTES

tty_columns calls the command **tty_variable columns** internally, to resolve the terminal width. Therefore **tty_variable**(3) can be used to replace the call to **tty_columns**.

BUGS

-

AUTHOR

tty_columns was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

tty_variable – return the current width of the terminal (tty)

SYNOPSIS

edrc/lib/tty_variable [**-h**]

tty_variable *variable* [*device*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

returns the current value of a terminal (tty) setting.

This command allows to process the output of the **stty**(1) command in a cross operating system compatible format.

OPTIONS

-h print usage message.

variable tty variable value to be printed. Possible variables, among others, are: **speed**, **rows**, **columns**, **line**, **intr**, **quit**, **erase**, **kill**, **eof**, **eol**, **eol2**, **start**, **stop**, **susp**, **rprnt**, **werase**, **lnext**, **flush**, **min** and **time**.

device tty device file to be read from. If not specified the device is resolved by the **tty**(1) command. If **tty** does not return a value, the default terminal device **/dev/tty** is used.

ENVIRONMENT

-

EXIT STATUS

0 no error.

4 usage message printed.

FILES

/dev/tty terminal device file. This device file is read if the resolution of the current pseudo device of the terminal is not possible.

EXAMPLES

-

NAME

unipath – remove duplicates in colon separated strings (\$PATH)

SYNOPSIS

edrc/lib/unipath [**-h**]

unipath *string*

AVAILABILITY

WA2L/edrc

DESCRIPTION

The main purpose of **unipath** is to remove duplicates in a colon separated strings as known from the command path (**\$PATH**) or manual path (**\$MANPATH**).

The order of the elements remains, but duplicates are removed from the list.

Therefore ' **unipath** *a:b:c:b:c* ' returns *a:b:c*.

OPTIONS

-h usage message.

string colon separated string as known from the command path (**\$PATH**).

ENVIRONMENT

-

EXIT STATUS

0 no error.

4 usage listed.

FILES

-

EXAMPLES**1) usage of unipath in a script**

The following cut-out is from a Born shell script. The usage is to tidy up the command path:

```
:
:

PATH=/bin:/sbin:/usr/bin:/usr/sbin:/usr/libin:$PATH
export PATH

Scriptname=`basename $0`
Scriptpath=`dirname $0`
Basedir=`$Scriptpath/../../lib/approot`

:
:

PATH=`$Basedir/lib/unipath $Basedir/bin:$Basedir/lib:$PATH`
export PATH

:
:
```

NAME

unzip – list, test and extract compressed files in a ZIP archive

SYNOPSIS

unzip [**-Z**] [**-cflptTuvz**[**abjnoqsCDKLMUVWX\$%^**]] *file* [.zip] [*file(s)* ...] [**-x** *xfile(s)* ...] [**-d** *exdir*]

DESCRIPTION

unzip will list, test, or extract files from a ZIP archive, commonly found on MS-DOS systems. The default behavior (with no options) is to extract into the current directory (and subdirectories below it) all files from the specified ZIP archive. A companion program, *zip*(1L), creates ZIP archives; both programs are compatible with archives created by PKWARE's *PKZIP* and *PKUNZIP* for MS-DOS, but in many cases the program options or default behaviors differ.

ARGUMENTS

file [.zip]

Path of the ZIP archive(s). If the file specification is a wildcard, each matching file is processed in an order determined by the operating system (or file system). Only the filename can be a wildcard; the path itself cannot. Wildcard expressions are similar to those supported in commonly used Unix shells (*sh*, *ksh*, *csh*) and may contain:

* matches a sequence of 0 or more characters

? matches exactly 1 character

[...] matches any single character found inside the brackets; ranges are specified by a beginning character, a hyphen, and an ending character. If an exclamation point or a caret ('!' or '^') follows the left bracket, then the range of characters within the brackets is complemented (that is, anything *except* the characters inside the brackets is considered a match). To specify a verbatim left bracket, the three-character sequence "[[]]" has to be used.

(Be sure to quote any character that might otherwise be interpreted or modified by the operating system, particularly under Unix and VMS.) If no matches are found, the specification is assumed to be a literal filename; and if that also fails, the suffix .zip is appended. Note that self-extracting ZIP files are supported, as with any other ZIP archive; just specify the .exe suffix (if any) explicitly.

[*file(s)*] An optional list of archive members to be processed, separated by spaces. (VMS versions compiled with VMSCLI defined must delimit files with commas instead. See **-v** in **OPTIONS** below.) Regular expressions (wildcards) may be used to match multiple members; see above. Again, be sure to quote expressions that would otherwise be expanded or modified by the operating system.

[**-x** *xfile(s)*]

An optional list of archive members to be excluded from processing. Since wildcard characters normally match ('/') directory separators (for exceptions see the option **-W**), this option may be used to exclude any files that are in subdirectories. For example, "unzip foo *. [ch] -x */*" would extract all C source files in the main directory, but none in any subdirectories. Without the **-x** option, all C source files in all directories within the zipfile would be extracted.

[**-d** *exdir*]

An optional directory to which to extract files. By default, all files and subdirectories are recreated in the current directory; the **-d** option allows extraction in an arbitrary directory (always assuming one has permission to write to the directory). This option need not appear at the end of the command line; it is also accepted before the zipfile specification (with the normal options), immediately after the zipfile specification, or between the *file(s)* and the **-x** option. The option and directory may be concatenated without any white space between them, but note that this may cause normal shell behavior to be suppressed. In particular, "**-d** ~" (tilde) is expanded by Unix C shells into the name of the user's home directory, but "**-d** ~" is treated as a literal subdirectory "~" of the current directory.

OPTIONS

Note that, in order to support obsolescent hardware, *unzip*'s usage screen is limited to 22 or 23 lines and should therefore be considered only a reminder of the basic *unzip* syntax rather than an exhaustive list of all possible flags. The exhaustive list follows:

- Z** *zipinfo*(1L) mode. If the first option on the command line is **-Z**, the remaining options are taken to be *zipinfo*(1L) options. See the appropriate manual page for a description of these options.
- A** [OS/2, Unix DLL] print extended help for the DLL's programming interface (API).
- c** extract files to stdout/screen ("CRT"). This option is similar to the **-p** option except that the name of each file is printed as it is extracted, the **-a** option is allowed, and ASCII-EBCDIC conversion is automatically performed if appropriate. This option is not listed in the *unzip* usage screen.
- f** freshen existing files, i.e., extract only those files that already exist on disk and that are newer than the disk copies. By default *unzip* queries before overwriting, but the **-o** option may be used to suppress the queries. Note that under many operating systems, the TZ (timezone) environment variable must be set correctly in order for **-f** and **-u** to work properly (under Unix the variable is usually set automatically). The reasons for this are somewhat subtle but have to do with the differences between DOS-format file times (always local time) and Unix-format times (always in GMT/UTC) and the necessity to compare the two. A typical TZ value is "PST8PDT" (US Pacific time with automatic adjustment for Daylight Savings Time or "summer time").
- l** list archive files (short format). The names, uncompressed file sizes and modification dates and times of the specified files are printed, along with totals for all files specified. If UnZip was compiled with OS2_EAS defined, the **-l** option also lists columns for the sizes of stored OS/2 extended attributes (EAs) and OS/2 access control lists (ACLs). In addition, the zipfile comment and individual file comments (if any) are displayed. If a file was archived from a single-case file system (for example, the old MS-DOS FAT file system) and the **-L** option was given, the filename is converted to lowercase and is prefixed with a caret (^).
- p** extract files to pipe (stdout). Nothing but the file data is sent to stdout, and the files are always extracted in binary format, just as they are stored (no conversions).
- t** test archive files. This option extracts each specified file in memory and compares the CRC (cyclic redundancy check, an enhanced checksum) of the expanded file with the original file's stored CRC value.
- T** [most OSes] set the timestamp on the archive(s) to that of the newest file in each one. This corresponds to *zip*'s **-go** option except that it can be used on wildcard zipfiles (e.g., "*unzip -T *.zip*") and is much faster.
- u** update existing files and create new ones if needed. This option performs the same function as the **-f** option, extracting (with query) files that are newer than those with the same name on disk, and in addition it extracts those files that do not already exist on disk. See **-f** above for information on setting the timezone properly.
- v** list archive files (verbose format) or show diagnostic version info. This option has evolved and now behaves as both an option and a modifier. As an option it has two purposes: when a zipfile is specified with no other options, **-v** lists archive files verbosely, adding to the basic **-l** info the compression method, compressed size, compression ratio and 32-bit CRC. In contrast to most of the competing utilities, *unzip* removes the 12 additional header bytes of encrypted entries from the compressed size numbers. Therefore, compressed size and compression ratio figures are independent of the entry's encryption status and show the correct compression performance. (The complete size of the encrypted compressed data stream for zipfile entries is reported by the more verbose *zipinfo*(1L) reports, see the separate manual.) When no zipfile is specified (that is, the complete command is simply "*unzip -v*"), a diagnostic screen is printed. In addition to the normal header with release date and version, *unzip* lists the home Info-ZIP ftp site and where to find a list of other ftp and non-ftp sites; the target operating system for which it was compiled, as well as

(possibly) the hardware on which it was compiled, the compiler and version used, and the compilation date; any special compilation options that might affect the program's operation (see also **DECRYPTION** below); and any options stored in environment variables that might do the same (see **ENVIRONMENT OPTIONS** below). As a modifier it works in conjunction with other options (e.g., **-t**) to produce more verbose or debugging output; this is not yet fully implemented but will be in future releases.

-z display only the archive comment.

MODIFIERS

-a convert text files. Ordinarily all files are extracted exactly as they are stored (as "binary" files). The **-a** option causes files identified by *zip* as text files (those with the 't' label in *zipinfo* listings, rather than 'b') to be automatically extracted as such, converting line endings, end-of-file characters and the character set itself as necessary. (For example, Unix files use line feeds (LFs) for end-of-line (EOL) and have no end-of-file (EOF) marker; Macintoshes use carriage returns (CRs) for EOLs; and most PC operating systems use CR+LF for EOLs and control-Z for EOF. In addition, IBM mainframes and the Michigan Terminal System use EBCDIC rather than the more common ASCII character set, and NT supports Unicode.) Note that *zip*'s identification of text files is by no means perfect; some "text" files may actually be binary and vice versa. *unzip* therefore prints "[text]" or "[binary]" as a visual check for each file it extracts when using the **-a** option. The **-aa** option forces all files to be extracted as text, regardless of the supposed file type. On VMS, see also **-S**.

-b [general] treat all files as binary (no text conversions). This is a shortcut for **---a**.

-b [Tandem] force the creation files with filecode type 180 ('C') when extracting Zip entries marked as "text". (On Tandem, **-a** is enabled by default, see above).

-b [VMS] auto-convert binary files (see **-a** above) to fixed-length, 512-byte record format. Doubling the option (**-bb**) forces all files to be extracted in this format. When extracting to standard output (**-c** or **-p** option in effect), the default conversion of text record delimiters is disabled for binary (**-b**) resp. all (**-bb**) files.

-B [when compiled with UNIXBACKUP defined] save a backup copy of each overwritten file. The backup file is gets the name of the target file with a tilde and optionally a unique sequence number (up to 5 digits) appended. The sequence number is applied whenever another file with the original name plus tilde already exists. When used together with the "overwrite all" option **-o**, numbered backup files are never created. In this case, all backup files are named as the original file with an appended tilde, existing backup files are deleted without notice. This feature works similarly to the default behavior of *emacs*(1) in many locations.

Example: the old copy of "foo" is renamed to "foo~".

Warning: Users should be aware that the **-B** option does not prevent loss of existing data under all circumstances. For example, when *unzip* is run in overwrite-all mode, an existing "foo~" file is deleted before *unzip* attempts to rename "foo" to "foo~". When this rename attempt fails (because of a file locks, insufficient privileges, or ...), the extraction of "foo~" gets cancelled, but the old backup file is already lost. A similar scenario takes place when the sequence number range for numbered backup files gets exhausted (99999, or 65535 for 16-bit systems). In this case, the backup file with the maximum sequence number is deleted and replaced by the new backup version without notice.

-C use case-insensitive matching for the selection of archive entries from the command-line list of extract selection patterns. *unzip*'s philosophy is "you get what you ask for" (this is also responsible for the **-L/-U** change; see the relevant options below). Because some file systems are fully case-sensitive (notably those under the Unix operating system) and because both ZIP archives and *unzip* itself are portable across platforms, *unzip*'s default behavior is to match both wildcard and literal filenames case-sensitively. That is, specifying "makefile" on the command line will *only* match "makefile" in the archive, not "Makefile" or "MAKEFILE" (and similarly for wildcard specifications). Since this does not correspond to the behavior of many other operating/file

systems (for example, OS/2 HPFS, which preserves mixed case but is not sensitive to it), the **-C** option may be used to force all filename matches to be case-insensitive. In the example above, all three files would then match “makefile” (or “make*”, or similar). The **-C** option affects file specs in both the normal file list and the excluded-file list (xlist).

Please note that the **-C** option does neither affect the search for the zipfile(s) nor the matching of archive entries to existing files on the extraction path. On a case-sensitive file system, *unzip* will never try to overwrite a file “FOO” when extracting an entry “foo”!

- D** skip restoration of timestamps for extracted items. Normally, *unzip* tries to restore all meta-information for extracted items that are supplied in the Zip archive (and do not require privileges or impose a security risk). By specifying **-D**, *unzip* is told to suppress restoration of timestamps for directories explicitly created from Zip archive entries. This option only applies to ports that support setting timestamps for directories (currently ATheOS, BeOS, MacOS, OS/2, Unix, VMS, Win32, for other *unzip* ports, **-D** has no effect). The duplicated option **-DD** forces suppression of timestamp restoration for all extracted entries (files and directories). This option results in setting the timestamps for all extracted entries to the current time.

On VMS, the default setting for this option is **-D** for consistency with the behaviour of BACKUP: file timestamps are restored, timestamps of extracted directories are left at the current time. To enable restoration of directory timestamps, the negated option **--D** should be specified. On VMS, the option **-D** disables timestamp restoration for all extracted Zip archive items. (Here, a single **-D** on the command line combines with the default **-D** to do what an explicit **-DD** does on other systems.)

- E** [MacOS only] display contents of MacOS extra field during restore operation.
- F** [Acorn only] suppress removal of NFS filetype extension from stored filenames.
- F** [non-Acorn systems supporting long filenames with embedded commas, and only if compiled with ACORN_FTYPE_NFS defined] translate filetype information from ACORN RISC OS extra field blocks into a NFS filetype extension and append it to the names of the extracted files. (When the stored filename appears to already have an appended NFS filetype extension, it is replaced by the info from the extra field.)
- i** [MacOS only] ignore filenames stored in MacOS extra fields. Instead, the most compatible filename stored in the generic part of the entry’s header is used.
- j** junk paths. The archive’s directory structure is not recreated; all files are deposited in the extraction directory (by default, the current one).
- J** [BeOS only] junk file attributes. The file’s BeOS file attributes are not restored, just the file’s data.
- J** [MacOS only] ignore MacOS extra fields. All Macintosh specific info is skipped. Data-fork and resource-fork are restored as separate files.
- K** [AtheOS, BeOS, Unix only] retain SUID/SGID/Tacky file attributes. Without this flag, these attribute bits are cleared for security reasons.
- L** convert to lowercase any filename originating on an uppercase-only operating system or file system. (This was *unzip*’s default behavior in releases prior to 5.11; the new default behavior is identical to the old behavior with the **-U** option, which is now obsolete and will be removed in a future release.) Depending on the archiver, files archived under single-case file systems (VMS, old MS-DOS FAT, etc.) may be stored as all-uppercase names; this can be ugly or inconvenient when extracting to a case-preserving file system such as OS/2 HPFS or a case-sensitive one such as under Unix. By default *unzip* lists and extracts such filenames exactly as they’re stored (excepting truncation, conversion of unsupported characters, etc.); this option causes the names of all files from certain systems to be converted to lowercase. The **-LL** option forces conversion of every filename to lowercase, regardless of the originating file system.
- M** pipe all output through an internal pager similar to the Unix *more*(1) command. At the end of a screenful of output, *unzip* pauses with a “—More—” prompt; the next screenful may be viewed

by pressing the Enter (Return) key or the space bar. *unzip* can be terminated by pressing the “q” key and, on some systems, the Enter/Return key. Unlike Unix *more*(1), there is no forward-searching or editing capability. Also, *unzip* doesn’t notice if long lines wrap at the edge of the screen, effectively resulting in the printing of two or more lines and the likelihood that some text will scroll off the top of the screen before being viewed. On some systems the number of available lines on the screen is not detected, in which case *unzip* assumes the height is 24 lines.

- n never overwrite existing files. If a file already exists, skip the extraction of that file without prompting. By default *unzip* queries before extracting any file that already exists; the user may choose to overwrite only the current file, overwrite all files, skip extraction of the current file, skip extraction of all existing files, or rename the current file.
- N [Amiga] extract file comments as Amiga filenotes. File comments are created with the –c option of *zip*(1L), or with the –N option of the Amiga port of *zip*(1L), which stores filenotes as comments.
- o overwrite existing files without prompting. This is a dangerous option, so use it with care. (It is often used with –f, however, and is the only way to overwrite directory EAs under OS/2.)
- P *password*
use *password* to decrypt encrypted zipfile entries (if any). **THIS IS INSECURE!** Many multi-user operating systems provide ways for any user to see the current command line of any other user; even on stand-alone systems there is always the threat of over-the-shoulder peeking. Storing the plaintext password as part of a command line in an automated script is even worse. Whenever possible, use the non-echoing, interactive prompt to enter passwords. (And where security is truly important, use strong encryption such as Pretty Good Privacy instead of the relatively weak encryption provided by standard zipfile utilities.)
- q perform operations quietly (–qq = even quieter). Ordinarily *unzip* prints the names of the files it’s extracting or testing, the extraction methods, any file or zipfile comments that may be stored in the archive, and possibly a summary when finished with each archive. The –q[q] options suppress the printing of some or all of these messages.
- s [OS/2, NT, MS-DOS] convert spaces in filenames to underscores. Since all PC operating systems allow spaces in filenames, *unzip* by default extracts filenames with spaces intact (e.g., “EA DATA. SF”). This can be awkward, however, since MS-DOS in particular does not gracefully support spaces in filenames. Conversion of spaces to underscores can eliminate the awkwardness in some cases.
- S [VMS] convert text files (–a, –aa) into Stream_LF record format, instead of the text-file default, variable-length record format. (Stream_LF is the default record format of VMS *unzip*. It is applied unless conversion (–a, –aa and/or –b, –bb) is requested or a VMS-specific entry is processed.)
- U [UNICODE_SUPPORT only] modify or disable UTF-8 handling. When UNICODE_SUPPORT is available, the option –U forces *unzip* to escape all non-ASCII characters from UTF-8 coded filenames as “#Uxxxx” (for UCS-2 characters, or “#Lxxxxxx” for unicode codepoints needing 3 octets). This option is mainly provided for debugging purpose when the fairly new UTF-8 support is suspected to mangle up extracted filenames.

The option –UU allows to entirely disable the recognition of UTF-8 encoded filenames. The handling of filename codings within *unzip* falls back to the behaviour of previous versions.

[old, obsolete usage] leave filenames uppercase if created under MS-DOS, VMS, etc. See –L above.
- V retain (VMS) file version numbers. VMS files can be stored with a version number, in the format *file.ext;##*. By default the “;##” version numbers are stripped, but this option allows them to be retained. (On file systems that limit filenames to particularly short lengths, the version numbers may be truncated or stripped regardless of this option.)
- W [only when WILD_STOP_AT_DIR compile-time option enabled] modifies the pattern matching routine so that both ‘?’ (single-char wildcard) and ‘*’ (multi-char wildcard) do not match the

directory separator character '/'. (The two-character sequence "***" acts as a multi-char wildcard that includes the directory separator in its matched characters.) Examples:

```
"*.c" matches "foo.c" but not "mydir/foo.c"
"**.*" matches both "foo.c" and "mydir/foo.c"
"*/.*" matches "bar/foo.c" but not "baz/bar/foo.c"
"?*/.*" matches "ab/foo" and "abc/foo"
        but not "a/foo" or "a/b/foo"
```

This modified behaviour is equivalent to the pattern matching style used by the shells of some of UnZip's supported target OSs (one example is Acorn RISC OS). This option may not be available on systems where the Zip archive's internal directory separator character '/' is allowed as regular character in native operating system filenames. (Currently, UnZip uses the same pattern matching rules for both wildcard zipfile specifications and zip entry selection patterns in most ports. For systems allowing '/' as regular filename character, the -W option would not work as expected on a wildcard zipfile specification.)

- X [VMS, Unix, OS/2, NT, Tandem] restore owner/protection info (UICs and ACL entries) under VMS, or user and group info (UID/GID) under Unix, or access control lists (ACLs) under certain network-enabled versions of OS/2 (Warp Server with IBM LAN Server/Requester 3.0 to 5.0; Warp Connect with IBM Peer 1.0), or security ACLs under Windows NT. In most cases this will require special system privileges, and doubling the option (-XX) under NT instructs *unzip* to use privileges for extraction; but under Unix, for example, a user who belongs to several groups can restore files owned by any of those groups, as long as the user IDs match his or her own. Note that ordinary file attributes are always restored--this option applies only to optional, extra ownership info available on some operating systems. [NT's access control lists do not appear to be especially compatible with OS/2's, so no attempt is made at cross-platform portability of access privileges. It is not clear under what conditions this would ever be useful anyway.]
- Y [VMS] treat archived file name endings of ".nnn" (where "nnn" is a decimal number) as if they were VMS version numbers (";nnn"). (The default is to treat them as file types.) Example:
 "a.b.3" -> "a.b;3".
- \$ [MS-DOS, OS/2, NT] restore the volume label if the extraction medium is removable (e.g., a diskette). Doubling the option (-\$\$) allows fixed media (hard disks) to be labelled as well. By default, volume labels are ignored.

-I extensions

[Acorn only] overrides the extension list supplied by Unzip\$Ext environment variable. During extraction, filename extensions that match one of the items in this extension list are swapped in front of the base name of the extracted file.

- : [all but Acorn, VM/CMS, MVS, Tandem] allows to extract archive members into locations outside of the current "extraction root folder". For security reasons, *unzip* normally removes "parent dir" path components ("..") from the names of extracted file. This safety feature (new for version 5.50) prevents *unzip* from accidentally writing files to "sensitive" areas outside the active extraction folder tree head. The -: option lets *unzip* switch back to its previous, more liberal behaviour, to allow exact extraction of (older) archives that used ".." components to create multiple directory trees at the level of the current extraction folder. This option does not enable writing explicitly to the root directory ("/"). To achieve this, it is necessary to set the extraction target folder to root (e.g. -d /). However, when the -: option is specified, it is still possible to implicitly write to the root directory by specifying enough ".." path components within the zip archive. Use this option with extreme caution.
- ^ [Unix only] allow control characters in names of extracted ZIP archive entries. On Unix, a file name may contain any (8-bit) character code with the two exception '/' (directory delimiter) and NUL (0x00, the C string termination indicator), unless the specific file system has more restrictive conventions. Generally, this allows to embed ASCII control characters (or even sophisticated control sequences) in file names, at least on 'native' Unix file systems. However, it may be highly

suspicious to make use of this Unix "feature". Embedded control characters in file names might have nasty side effects when displayed on screen by some listing code without sufficient filtering. And, for ordinary users, it may be difficult to handle such file names (e.g. when trying to specify it for open, copy, move, or delete operations). Therefore, *unzip* applies a filter by default that removes potentially dangerous control characters from the extracted file names. The *-^* option allows to override this filter in the rare case that embedded filename control characters are to be intentionally restored.

- 2 [VMS] force unconditionally conversion of file names to ODS2-compatible names. The default is to exploit the destination file system, preserving case and extended file name characters on an ODS5 destination file system; and applying the ODS2-compatibility file name filtering on an ODS2 destination file system.

ENVIRONMENT OPTIONS

unzip's default behavior may be modified via options placed in an environment variable. This can be done with any option, but it is probably most useful with the *-a*, *-L*, *-C*, *-q*, *-o*, or *-n* modifiers: make *unzip* auto-convert text files by default, make it convert filenames from uppercase systems to lowercase, make it match names case-insensitively, make it quieter, or make it always overwrite or never overwrite files as it extracts them. For example, to make *unzip* act as quietly as possible, only reporting errors, one would use one of the following commands:

```
Unix Bourne shell:
    UNZIP=-qq; export UNZIP

Unix C shell:
    setenv UNZIP -qq

OS/2 or MS-DOS:
    set UNZIP=-qq

VMS (quotes for lowercase):
    define UNZIP_OPTS "-qq"
```

Environment options are, in effect, considered to be just like any other command-line options, except that they are effectively the first options on the command line. To override an environment option, one may use the "minus operator" to remove it. For instance, to override one of the quiet-flags in the example above, use the command

```
unzip --q[other options] zipfile
```

The first hyphen is the normal switch character, and the second is a minus sign, acting on the *q* option. Thus the effect here is to cancel one quantum of quietness. To cancel both quiet flags, two (or more) minuses may be used:

```
unzip -t--q zipfile
unzip ---qt zipfile
```

(the two are equivalent). This may seem awkward or confusing, but it is reasonably intuitive: just ignore the first hyphen and go from there. It is also consistent with the behavior of Unix *nice*(1).

As suggested by the examples above, the default variable names are UNZIP_OPTS for VMS (where the symbol used to install *unzip* as a foreign command would otherwise be confused with the environment variable), and UNZIP for all other operating systems. For compatibility with *zip*(1L), UNZIPOPT is also accepted (don't ask). If both UNZIP and UNZIPOPT are defined, however, UNZIP takes precedence. *unzip*'s diagnostic option (*-v* with no zipfile name) can be used to check the values of all four possible *unzip* and *zipinfo* environment variables.

The timezone variable (TZ) should be set according to the local timezone in order for the *-f* and *-u* to operate correctly. See the description of *-f* above for details. This variable may also be necessary to get timestamps of extracted files to be set correctly. The WIN32 (Win9x/ME/NT4/2K/XP/2K3) port of *unzip* gets the timezone configuration from the registry, assuming it is correctly set in the Control Panel. The TZ variable is ignored for this port.

DECRYPTION

Encrypted archives are fully supported by Info-ZIP software, but due to United States export restrictions, de-/encryption support might be disabled in your compiled binary. However, since spring 2000, US export restrictions have been liberated, and our source archives do now include full crypt code. In case you need binary distributions with crypt support enabled, see the file “WHERE” in any Info-ZIP source or binary distribution for locations both inside and outside the US.

Some compiled versions of *unzip* may not support decryption. To check a version for crypt support, either attempt to test or extract an encrypted archive, or else check *unzip*’s diagnostic screen (see the `-v` option above) for “[*decryption*]” as one of the special compilation options.

As noted above, the `-P` option may be used to supply a password on the command line, but at a cost in security. The preferred decryption method is simply to extract normally; if a zipfile member is encrypted, *unzip* will prompt for the password without echoing what is typed. *unzip* continues to use the same password as long as it appears to be valid, by testing a 12-byte header on each file. The correct password will always check out against the header, but there is a 1-in-256 chance that an incorrect password will as well. (This is a security feature of the PKWARE zipfile format; it helps prevent brute-force attacks that might otherwise gain a large speed advantage by testing only the header.) In the case that an incorrect password is given but it passes the header test anyway, either an incorrect CRC will be generated for the extracted data or else *unzip* will fail during the extraction because the “decrypted” bytes do not constitute a valid compressed data stream.

If the first password fails the header check on some file, *unzip* will prompt for another password, and so on until all files are extracted. If a password is not known, entering a null password (that is, just a carriage return or “Enter”) is taken as a signal to skip all further prompting. Only unencrypted files in the archive(s) will thereafter be extracted. (In fact, that’s not quite true; older versions of *zip*(1L) and *zipcloak*(1L) allowed null passwords, so *unzip* checks each encrypted file to see if the null password works. This may result in “false positives” and extraction errors, as noted above.)

Archives encrypted with 8-bit passwords (for example, passwords with accented European characters) may not be portable across systems and/or other archivers. This problem stems from the use of multiple encoding methods for such characters, including Latin-1 (ISO 8859-1) and OEM code page 850. DOS *PKZIP* 2.04g uses the OEM code page; Windows *PKZIP* 2.50 uses Latin-1 (and is therefore incompatible with DOS *PKZIP*); Info-ZIP uses the OEM code page on DOS, OS/2 and Win3.x ports but ISO coding (Latin-1 etc.) everywhere else; and Nico Mak’s *WinZip* 6.x does not allow 8-bit passwords at all. *UnZip* 5.3 (or newer) attempts to use the default character set first (e.g., Latin-1), followed by the alternate one (e.g., OEM code page) to test passwords. On EBCDIC systems, if both of these fail, EBCDIC encoding will be tested as a last resort. (EBCDIC is not tested on non-EBCDIC systems, because there are no known archivers that encrypt using EBCDIC encoding.) ISO character encodings other than Latin-1 are not supported. The new addition of (partially) Unicode (resp. UTF-8) support in *UnZip* 6.0 has not yet been adapted to the encryption password handling in *unzip*. On systems that use UTF-8 as native character encoding, *unzip* simply tries decryption with the native UTF-8 encoded password; the built-in attempts to check the password in translated encoding have not yet been adapted for UTF-8 support and will consequently fail.

EXAMPLES

To use *unzip* to extract all members of the archive *letters.zip* into the current directory and subdirectories below it, creating any subdirectories as necessary:

```
unzip letters
```

To extract all members of *letters.zip* into the current directory only:

```
unzip -j letters
```

To test *letters.zip*, printing only a summary message indicating whether the archive is OK or not:

```
unzip -tq letters
```

To test *all* zipfiles in the current directory, printing only the summaries:

```
unzip -tq \*.zip
```

(The backslash before the asterisk is only required if the shell expands wildcards, as in Unix; double quotes could have been used instead, as in the source examples below.) To extract to standard output all members of *letters.zip* whose names end in *.tex*, auto-converting to the local end-of-line convention and piping the output into *more*(1):

```
unzip -ca letters \*.tex | more
```

To extract the binary file *paper1.dvi* to standard output and pipe it to a printing program:

```
unzip -p articles paper1.dvi | dvips
```

To extract all FORTRAN and C source files--*.f, *.c, *.h, and Makefile--into the /tmp directory:

```
unzip source.zip "[fch]" Makefile -d /tmp
```

(the double quotes are necessary only in Unix and only if globbing is turned on). To extract all FORTRAN and C source files, regardless of case (e.g., both *.c and *.C, and any makefile, Makefile, MAKEFILE or similar):

```
unzip -C source.zip "[fch]" makefile -d /tmp
```

To extract any such files but convert any uppercase MS-DOS or VMS names to lowercase and convert the line-endings of all of the files to the local standard (without respect to any files that might be marked "binary"):

```
unzip -aaCL source.zip "[fch]" makefile -d /tmp
```

To extract only newer versions of the files already in the current directory, without querying (NOTE: be careful of unzipping in one timezone a zipfile created in another--ZIP archives other than those created by Zip 2.1 or later contain no timezone information, and a "newer" file from an eastern timezone may, in fact, be older):

```
unzip -fo sources
```

To extract newer versions of the files already in the current directory and to create any files not already there (same caveat as previous example):

```
unzip -uo sources
```

To display a diagnostic screen showing which *unzip* and *zipinfo* options are stored in environment variables, whether decryption support was compiled in, the compiler with which *unzip* was compiled, etc.:

```
unzip -v
```

In the last five examples, assume that UNZIP or UNZIP_OPTS is set to -q. To do a singly quiet listing:

```
unzip -l file.zip
```

To do a doubly quiet listing:

```
unzip -ql file.zip
```

(Note that the ".zip" is generally not necessary.) To do a standard listing:

```
unzip --ql file.zip
```

or

```
unzip -l-q file.zip
```

or

```
unzip -l--q file.zip
```

(Extra minuses in options don't hurt.)

TIPS

The current maintainer, being a lazy sort, finds it very useful to define a pair of aliases: *tt* for "unzip -tq" and *ii* for "unzip -Z" (or "zipinfo"). One may then simply type "*tt* zipfile" to test an archive, something that is worth making a habit of doing. With luck *unzip* will report "No errors detected in compressed data of zipfile.zip," after which one may breathe a sigh of relief.

The maintainer also finds it useful to set the UNZIP environment variable to “-aL” and is tempted to add “-C” as well. His ZIPINFO variable is set to “-z”.

DIAGNOSTICS

The exit status (or error level) approximates the exit codes defined by PKWARE and takes on the following values, except under VMS:

- | | |
|----|---|
| 0 | normal; no errors or warnings detected. |
| 1 | one or more warning errors were encountered, but processing completed successfully anyway. This includes zipfiles where one or more files was skipped due to unsupported compression method or encryption with an unknown password. |
| 2 | a generic error in the zipfile format was detected. Processing may have completed successfully anyway; some broken zipfiles created by other archivers have simple work-arounds. |
| 3 | a severe error in the zipfile format was detected. Processing probably failed immediately. |
| 4 | <i>unzip</i> was unable to allocate memory for one or more buffers during program initialization. |
| 5 | <i>unzip</i> was unable to allocate memory or unable to obtain a tty to read the decryption password(s). |
| 6 | <i>unzip</i> was unable to allocate memory during decompression to disk. |
| 7 | <i>unzip</i> was unable to allocate memory during in-memory decompression. |
| 8 | [currently not used] |
| 9 | the specified zipfiles were not found. |
| 10 | invalid options were specified on the command line. |
| 11 | no matching files were found. |
| 50 | the disk is (or was) full during extraction. |
| 51 | the end of the ZIP archive was encountered prematurely. |
| 80 | the user aborted <i>unzip</i> prematurely with control-C (or similar) |
| 81 | testing or extraction of one or more files failed due to unsupported compression methods or unsupported decryption. |
| 82 | no files were found due to bad decryption password(s). (If even one file is successfully processed, however, the exit status is 1.) |

VMS interprets standard Unix (or PC) return values as other, scarier-looking things, so *unzip* instead maps them into VMS-style status codes. The current mapping is as follows: 1 (success) for normal exit, 0x7fff0001 for warning errors, and (0x7fff000? + 16*normal_unzip_exit_status) for all other errors, where the “?” is 2 (error) for *unzip* values 2, 9-11 and 80-82, and 4 (fatal error) for the remaining ones (3-8, 50, 51). In addition, there is a compilation option to expand upon this behavior: defining RETURN_CODES results in a human-readable explanation of what the error status means.

BUGS

Multi-part archives are not yet supported, except in conjunction with *zip*. (All parts must be concatenated together in order, and then “*zip -F*” (for *zip 2.x*) or “*zip -FF*” (for *zip 3.x*) must be performed on the concatenated archive in order to “fix” it. Also, *zip 3.0* and later can combine multi-part (split) archives into a combined single-file archive using “*zip -s- inarchive -O outarchive*”. See the *zip 3* manual page for more information.) This will definitely be corrected in the next major release.

Archives read from standard input are not yet supported, except with *funzip* (and then only the first member of the archive can be extracted).

Archives encrypted with 8-bit passwords (e.g., passwords with accented European characters) may not be portable across systems and/or other archivers. See the discussion in **DECRYPTION** above.

unzip's **-M** ("more") option tries to take into account automatic wrapping of long lines. However, the code may fail to detect the correct wrapping locations. First, TAB characters (and similar control sequences) are not taken into account, they are handled as ordinary printable characters. Second, depending on the actual system / OS port, *unzip* may not detect the true screen geometry but rather rely on "commonly used" default dimensions. The correct handling of tabs would require the implementation of a query for the actual tabulator setup on the output console.

Dates, times and permissions of stored directories are not restored except under Unix. (On Windows NT and successors, timestamps are now restored.)

[MS-DOS] When extracting or testing files from an archive on a defective floppy diskette, if the "Fail" option is chosen from DOS's "Abort, Retry, Fail?" message, older versions of *unzip* may hang the system, requiring a reboot. This problem appears to be fixed, but control-C (or control-Break) can still be used to terminate *unzip*.

Under DEC Ultrix, *unzip* would sometimes fail on long zipfiles (bad CRC, not always reproducible). This was apparently due either to a hardware bug (cache memory) or an operating system bug (improper handling of page faults?). Since Ultrix has been abandoned in favor of Digital Unix (OSF/1), this may not be an issue anymore.

[Unix] Unix special files such as FIFO buffers (named pipes), block devices and character devices are not restored even if they are somehow represented in the zipfile, nor are hard-linked files relinked. Basically the only file types restored by *unzip* are regular files, directories and symbolic (soft) links.

[OS/2] Extended attributes for existing directories are only updated if the **-o** ("overwrite all") option is given. This is a limitation of the operating system; because directories only have a creation time associated with them, *unzip* has no way to determine whether the stored attributes are newer or older than those on disk. In practice this may mean a two-pass approach is required: first unpack the archive normally (with or without freshening/updating existing files), then overwrite just the directory entries (e.g., "*unzip -o foo */*").

[VMS] When extracting to another directory, only the *[.foo]* syntax is accepted for the **-d** option; the simple Unix *foo* syntax is silently ignored (as is the less common VMS *foo.dir* syntax).

[VMS] When the file being extracted already exists, *unzip*'s query only allows skipping, overwriting or renaming; there should additionally be a choice for creating a new version of the file. In fact, the "overwrite" choice does create a new version; the old version is not overwritten or deleted.

AUTHORS

The primary Info-ZIP authors (current semi-active members of the Zip-Bugs workgroup) are: Ed Gordon (Zip, general maintenance, shared code, Zip64, Win32, Unix, Unicode); Christian Spieler (UnZip maintenance coordination, VMS, MS-DOS, Win32, shared code, general Zip and UnZip integration and optimization); Onno van der Linden (Zip); Mike White (Win32, Windows GUI, Windows DLLs); Kai Uwe Rommel (OS/2, Win32); Steven M. Schweda (VMS, Unix, support of new features); Paul Kienitz (Amiga, Win32, Unicode); Chris Herborth (BeOS, QNX, Atari); Jonathan Hudson (SMS/QDOS); Sergio Monesi (Acorn RISC OS); Harald Denker (Atari, MVS); John Bush (Solaris, Amiga); Hunter Goatley (VMS, Info-ZIP Site maintenance); Steve Salisbury (Win32); Steve Miller (Windows CE GUI), Johnny Lee (MS-DOS, Win32, Zip64); and Dave Smith (Tandem NSK).

The following people were former members of the Info-ZIP development group and provided major contributions to key parts of the current code: Greg "Cave Newt" Roelofs (UnZip, unshrink decompression); Jean-loup Gailly (deflate compression); Mark Adler (inflate decompression, fUnZip).

The author of the original unzip code upon which Info-ZIP's was based is Samuel H. Smith; Carl Mascott did the first Unix port; and David P. Kirschbaum organized and led Info-ZIP in its early days with Keith Petersen hosting the original mailing list at WSMR-SimTel20. The full list of contributors to UnZip has grown quite large; please refer to the CONTRIBS file in the UnZip source distribution for a relatively complete version.

NAME

updatedb – update a file name database

SYNOPSIS

updatedb [*options*]

DESCRIPTION

This manual page documents the GNU version of **updatedb**, which updates file name databases used by GNU **locate**. The file name databases contain lists of files that were in particular directory trees when the databases were last updated. The file name of the default database is determined when **locate** and **updatedb** are configured and installed. The frequency with which the databases are updated and the directories for which they contain entries depend on how often **updatedb** is run, and with which arguments.

In networked environments, it often makes sense to build a database at the root of each filesystem, containing the entries for that filesystem. **updatedb** is then run for each filesystem on the fileserver where that filesystem is on a local disk, to prevent thrashing the network. Users can select which databases **locate** searches using an environment variable or command line option; see **locate**(1). Databases cannot be concatenated together.

The **LOCATE02** database format was introduced in GNU findutils version 4.0 in order to allow machines with different byte orderings to share the databases. GNU **locate** can read both the old and **LOCATE02** database formats, though support for the old pre-4.0 database format will be removed shortly.

OPTIONS

--findoptions=*'-option1 -option2...'*

Global options to pass on to **find**. The environment variable **FINDOPTIONS** also sets this value. Default is none.

--localpaths=*'path1 path2...'*

Non-network directories to put in the database. Default is */*.

--netpaths=*'path1 path2...'*

Network (NFS, AFS, RFS, etc.) directories to put in the database. The environment variable **NETPATHS** also sets this value. Default is none.

--prunepaths=*'path1 path2...'*

Directories to not put in the database, which would otherwise be. Remove any trailing slashes from the path names, otherwise **updatedb** won't recognise the paths you want to omit (because it uses them as regular expression patterns). The environment variable **PRUNEPATHS** also sets this value. Default is */tmp /usr/tmp /var/tmp /afs*.

--pruneefs=*'path...'*

File systems to not put in the database, which would otherwise be. Note that files are pruned when a file system is reached; any file system mounted under an undesired file system will be ignored. The environment variable **PRUNEFS** also sets this value. Default is *nfs NFS proc*.

--output=*dbfile*

The database file to build. Default is *edrc/var/locate/locate.hostname.db*.

--localuser=*user*

The user to search non-network directories as, using **su**(1). Default is to search the non-network directories as the current user. You can also use the environment variable **LOCALUSER** to set this user.

--netuser=*user*

The user to search network directories as, using **su**(1). Default is **daemon**. You can also use the environment variable **NETUSER** to set this user.

--dbformat=*F*

Create the database in format *F*. The default format is called **LOCATE02**. Alternatively the **slocate** format is also supported. When the **slocate** format is in use, the database produced is marked as having security level 1. If you want to build a system-wide **slocate** database, you may want to

run **updatedb** as root.

--version

Print the version number of **updatedb** and exit.

--help Print a summary of the options to **updatedb** and exit.

BUGS

The **updatedb** program correctly handles filenames containing newlines, but only if the system's sort command has a working **-z** option. If you suspect that **locate** may need to return filenames containing newlines, consider using its **--null** option.

REPORTING BUGS

NAME

usage – print short usage or command/alias cmd

SYNOPSIS

edrc/bin/usage [-h | -t]

usage [*what*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

print a short usage of additional commands and aliases available on the system which are not common on the operating system.

To print the usage of the additional commands, all ASCII files in the defined directories and the user login files **\$ENV** and **\$HOME/.cshrc** (depending on the used shell) are searched for the pattern **# usage: command ...**.

To list commands in the **usage** output, add the following line to your commands:

```
# usage: my_command [ options ]      - short command description
```

Ensure that the alignment is precisely done as in this example, otherwise the output of **usage** is not aligned and looks messy.

For binary files or not self developed commands to be listed with **usage** the convention is to add a **usage.list** file into a searched directory containing the **# usage:** entries.

Add the **[helper]** "tag" to the usage string

```
# usage: my_command [ options ]      - [helper] short command description
```

to indicate that the command is not a fully honed command, but a "helper" script which provides output or functionality which needs further manual intervention.

OPTIONS

-h usage message. The usage message also prints a template of the searched **# usage:** string that can be added to new commands.

-t print usage entry template.

what select commands starting with *what* from the whole **usage** list output.

ENVIRONMENT

\$USAGE_PATH

colon separated path of directories where to scan files for the **# usage:** pattern and to search for the **usage.list** files.

If **\$USAGE_PATH** is not set the directories **edrc/bin/**, **edrc/lib/**, **edrc/lib/ksh/**, **edrc/lib/perl/**, **edrc/lib/python/**, **edrc/lib/lua/** and **edrc/lib/daemon/** are searched by default.

EXIT STATUS

0 no error.

4 usage printed.

FILES

usage.list usage list of 3rd party commands or compiled commands.

\$HOME/.cshrc

C-shell initialization file.

\$ENV

Bourne-, Bourne-Again shell initialization file.

NAME

usage.list – usage definition for 3rd party commands

SYNOPSIS

edrc/bin/usage.list

edrc/lib/usage.list

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the usage definition for the **usage** command.

To avoid to edit the 3rd party commands, the usage string can be added to the **usage.list** file. This protects the work after upgrading the 3rd party command.

FILEFORMAT

The fileformat is a plain list of usage definitions as read by the **usage(1)** command.

For a description of the format, see **usage(1)**.

OPTIONS

-

EXAMPLES

```
#
# bin/usage.list - usage for compiled and 3rd party commands
#
# [00] 30.01.2003 CWa   Initial Version
# [36] 27.09.2020 CWa   +xml2csv
#

# usage: asup [ options ]           - start edrc for application support
# usage: bunzip2 options            - unzip a block-sorting .bz2 file
# usage: bzip2 options              - compresses .bz2 files to stdout
# usage: bzcat options              - decompresses .bz2 files to stdout
# usage: bzdifff options            - compare bzip2 compressed files
# usage: bzgrep options             - search possibly bzip2 compressed files for
# usage: bzip2 options              - a block-sorting file compressor to generate
# usage: bzip2recover options       - recovers data from damaged bzip2 compressed
```

```
# usage: bzmorc options      - file perusal filter for crt viewing of bzi
# usage: ccrypt options      - encrypt and decrypt files and streams
# usage: cfg2html [ options ] - collect system config information
# usage: wmic options        - Windows Management Instrumentality client
```

SEE ALSO

edrcintro(1), **usage(1)**

NOTES

The file **edrc/etc/usage.list** contains all usage strings of all commands and the **edrc/bin/usage.list** and **edrc/lib/usage.list** files.

Therefore do not edit the **edrc/etc/usage.list** file.

BUGS

NAME

`user` – return the user name for a numeric user-id (uid)

SYNOPSIS

`edrc/lib/user [-h]`

`user user-id`

AVAILABILITY

WA2L/edrc

DESCRIPTION

return the user name for a given numeric user-id (uid).

If the user does not exist on the system (or in an equivalent coming from some server somewhere) an empty string is returned.

OPTIONS

`-h` print usage message.

`user-id` numeric user id of an existing user on the system.

ENVIRONMENT

-

EXIT STATUS

0 no error.

1 user for given *user-id* does not exist.

4 usage message printed.

NAME

userclass.index – index file for userclasses read by makeuser

SYNOPSIS

\$CLASSES_DIR/index

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the index file for userclasses. This file is read by the **makeuser**(1) command to give additional information to all.

FILEFORMAT

The fileformat is a list of entries that have the format

userclass:description:company:

OPTIONS

userclass userclass, this entry has to be identical to the directory name where the files for the related userclass are stored.

description description for the *userclass*.

company Company for which the userclass is in scope. This is especially useful if more companies are supported.

EXAMPLES**1) example index file:**

```
# Templates
_template:Userclass Template, do *not* apply this userclass to a User Acc

# ACME Userclasses
acmesys:System Management Team:ACME:
acmedba:Database Administrator (Oracle Owner):ACME:

notfall:Local Emergency System User:ACME:
```

```
monitoring:Monitoring Software System User:ACME:
root:Root System User for all Operating Systems:ACME:
patrol:Patrol Software System User:ACME:

# Generic Userclasses
adba:Application DBA User Account:Customer:
user:Normal Enduser User Account:Customer:
app:Application Admin User Account (Application Owner):Customer:
ftp-login:FTP User Account (Shell login expected):Customer:
ftp-nologin:FTP User Account (Shell login not expected):Customer:
```

NAME

user_info – print user information

SYNOPSIS

edrc/bin/user_info [**-h**]

user_info [**-u** *username*] [**-c** *configfile*] [**-R**]

user_info **-F** *FIELDNAME* [**-u** *username*] [**-c** *configfile*]

user_info **-L**

AVAILABILITY

WA2L/edrc

DESCRIPTION

The **user_info** command is used to display all information for a given user. With this command a single interface is given to query all permissions granted to a user. Therefore it is not needed to query each file that represent a certain permission (passwd, ftpusers, ...) separately.

OPTIONS

” When invoking **user_info** without an option, all information/permissions of a user are printed. If the *root* user starts the **user_info** command, all permissions are printed, if a non-root user uses **user_info** only the permissions that are readable by that user are printed. Therefore **user_info** does not add an extra security level, all information that would be possible to be read by a user accessing the information directly (as viewing the */etc/passwd* file) are accessible thru **user_info**, too.

-h usage message.

-n *username*
The user whose permissions to display.

-R Print the complete user record (all fields) in **FIELDNAME='value'** format. This output is intended to be used for further data processing when there is a need to compute all fields of a user. This is faster then accessing all fields sequentially using the **-F** option. To display all possible fields, use the **-L**

-F *FIELDNAME*
Query the value for the given **FIELDNAME**.

-L Print the complete list of all available fields including a short description of the field.

-c *configfile*

Specify a configfile deviating from the default *edrc/etc/user_info.cfg*.

ENVIRONMENT

-

EXIT STATUS

- | | |
|-----------|--|
| 0 | no error. |
| 2 | operating system is not supported, yet. See osid (3) if you get this error. |
| 4 | usage printed. |
| 6 | the configuration file user_info.cfg does not exist. |
| 11 | temporary directory could not be claimed or created in /tmp . Check the system temporary directory /tmp if you get this error, it is an indicator of system intrusion. |

FILES

etc/user_info.cfg

configuration file of **user_info**, see **user_info.cfg**(4) for more information.

EXAMPLES

-

SEE ALSO

edrcintro(1), **user_info.cfg**(4)

NOTES

-

BUGS

If a non-root user issues "**user_info -u** *username -F FIELDNAME* " and the *FIELDNAME* is a field where the calling user has no access to the information (as to the encrypted password) **user_info** returns an empty string without informing, that the calling user has no permission to view the value of that field.

user_info is currently completely implemented for HP-UX only.

AUTHOR

user_info was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

COPYRIGHT

Copyright © 2008 Christian Walther

NAME

user_info.cfg – configuration file for user_info

SYNOPSIS

edrc/etc/user_info.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **user_info** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS

PASSWD User account definition file.

Example: PASSWD=/etc/passwd

Default: PASSWD=/etc/passwd

SHADOW

Encrypted password file.

Example: SHADOW=/etc/shadow

Default: SHADOW=/etc/shadow

USERS_MAP

SAMBA user map.

Example: USERS_MAP=/etc/opt/samba/users.map

Default: USERS_MAP=/etc/opt/samba/users.map

FTPUSERS

Ftpusers. Users which are denied from executing FTP to a host.

Example: FTPUSERS=/etc/ftpd/ftpusers

Default: FTPUSERS=/etc/ftpd/ftpusers

GROUP Group definitions.

Example: GROUP=/etc/group

Default: GROUP=/etc/group

NOAGE_EXCLUDE

Users whose passwords are not aged, but who are allowed to do a direct login.

Example: NOAGE_EXCLUDE=/etc/user-db/noage_exclude

Default: NOAGE_EXCLUDE=/opt/EDS/data/exclude

TCB_AUTH

Authentication basedir of a HP trusted system.

Example: TCB_AUTH=/tcb/files/auth

Default: TCB_AUTH=/tcb/files/auth

SU_ALLOW

Allow switch user file.

Example: SU_ALLOW=/etc/user-db/su.allow

Default: SU_ALLOW=/etc/su.allow

SU_ANY Any user "user". This user is a pseudonym for every user and should not be defined on the system and is used to allow a switch user to any user in SU_ALLOW.

Example: SU_ANY=any

Default: SU_ANY=any

GENUSER_OWNERMAP

Ownership of general application users.

Example: GENUSER_OWNERMAP=/etc/user-db/passwd.ownermap

Default: GENUSER_OWNERMAP=/etc/passwd.ownermap

GENUSER_NO_OWNER

Not owned "user". This user is a pseudonym if a generic user is used but has no owner currently. This user should not be defined on the system.

Example: GENUSER_NO_OWNER=no_owner

Default: GENUSER_NO_OWNER=no_owner

GENUSER_NOT_USED

Not used "user". This user is a pseudonym if a generic user is created on the system but if this user is not used currently.

Example: GENUSER_NOT_USED=not_used

Default: GENUSER_NOT_USED=not_used

CRON_ALLOW

Local system file that contains a list of users which are allowed to define crontab entries.

Example: CRON_ALLOW=/usr/lib/cron/cron.allow

Default: CRON_ALLOW=/usr/lib/cron/cron.allow

AT_ALLOW

System file that contains a list of users which are allowed to define own at jobs.

Example: AT_ALLOW=/usr/lib/cron/at.allow

Default: AT_ALLOW=/usr/lib/cron/at.allow

CRON_ALLOW_GLOBAL

Global file holding a list of users which are allowed to define crontab entries under certain circumstances. This file is normally used as input for a user creation script writing the selected users to the **CRON_ALLOW** file.

Example: CRON_ALLOW_GLOBAL=/etc/user-db/cron.allow.global

Default: CRON_ALLOW_GLOBAL=/usr/lib/cron/cron.allow.global

AT_ALLOW_GLOBAL

Global file holding a list of users which are allowed to define crontab entries under certain circumstances. This file is normally used as input for a user creation script writing the selected users to the CRON_ALLOW file.

Example: AT_ALLOW_GLOBAL=/etc/user-db/at.allow.global

Default: AT_ALLOW_GLOBAL=/usr/lib/cron/at.allow.global

ROLE_MAP

File which holds the roles a user is assigned to.

Example: ROLE_MAP=/etc/user-db/passwd.rolemap

Default: ROLE_MAP=/etc/passwd.rolemap

SMBACCESSLOG

File containing the last samba access for a user.

Example: SMBACCESSLOG=/opt/ACME/log/smbaccess.log

Default: SMBACCESSLOG=/opt/EDS/log/smbaccess.log

SEE ALSO

edrcintro(1), **user_info(1)**

NOTES

The defaults given in this manpage are the ones that are true for the HP-UX operating system, the defaults for other operating systems might be different.

NAME

showbits – utility functions

SYNOPSIS

```
#include "utility.h"
```

```
char *showbits(unsigned int *value);
```

AVAILABILITY

WA2L/edrc

DESCRIPTION

utility.h provides utility functions.

showbits()

return a string representing the set/unset bits of the given unsigned integer *value*.

Example:

```
printf(" decimal: '%d'\n binary:  '%s'\n", 1291, showbits(1291));
```

Output:

```
decimal: '1291'  
binary:  '000000000000000000000000010100001011'
```

RETURN VALUE

NAME

uuencode – decode an encoded file

SYNOPSIS

uuencode [**-flags**] [**-flag** [*value*]] [**--option-name**[[**=**] *value*]] [<file>...]

If no *file*(s) are provided, then standard input is decoded.

DESCRIPTION

uuencode transforms uuencoded files into their original form.

The encoded file(s) may be specified on the command line, or one may be read from standard input. The output file name is specified in the encoded file, but may be overridden with the **-o** option. It will have the mode of the original file, except that *setuid* and *execute* bits are not retained. If the output file is specified to be */dev/stdout* or *-*, the result will be written to standard output. If there are multiple input files and the second or subsequent file specifies standard output, the decoded data will be written to the same file as the previous output. Don't do that.

uuencode ignores any leading and trailing lines. It looks for a line that starts with "**begin**" and proceeds until the end-of-encoding marker is found. The program determines from the header line of the encoded file which of the two supported encoding schemes was used and whether or not the output file name has been encoded with base64 encoding. See *uuencode*(5).

OPTIONS

-o *file*, **--output-file**=*file*
direct output to *file*.

If specified, decoded data are written to this file. When multiple inputs are specified on the command line, this option cannot be specified. All decoded data must be written to the file name encoded in the data.

-c, **--ignore-chmod**
ignore **fchmod**(3P) errors.

By default, if the output file permissions cannot be changed to the permissions specified in the encoded data, the file will not be written out and execution stops. This option will cause that error to be ignored. The resulting file will have all the data, but the incorrect mode settings.

fchmod() errors are also ignored if **POSIXLY_CORRECT** is set in the environment. RE: <http://austingroupbugs.net/view.php?id=635>

A warning is always emitted when **fchmod**() fails.

-h, **--help**
Display usage information and exit.

-., **--more-help**
Pass the extended usage information through a pager.

-R [*cfgfile*], **--save-opts** [=*cfgfile*]
Save the option state to *cfgfile*. The default is the *last* configuration file listed in the **OPTION PRESETS** section, below. The command will exit after updating the config file.

-r *cfgfile*, **--load-opts**=*cfgfile*, **--no-load-opts**
Load options from *cfgfile*. The *no-load-opts* form will disable the loading of earlier config/rc/ini files. *--no-load-opts* is handled early, out of order.

-v [{*v*|*c*|*n* --version [{*v*|*c*|*n*}]]
Output version of program and exit. The default mode is 'v', a simple version. The 'c' mode will print copyright information and 'n' will print the full copyright notice.

OPTION PRESETS

Any option that is not marked as *not presettable* may be preset by loading values from configuration ("RC" or ".INI") file(s). The file "\$HOME/.sharrc" will be used, if present.

STANDARDS

This implementation is compliant with P1003.2b/D11.

FILES

See **OPTION PRESETS** for configuration files.

EXIT STATUS

One of the following exit values will be returned:

0 (EXIT_SUCCESS)

Successful program execution.

1 (EXIT_OPTION_ERROR)

The command options were misconfigured.

2 (EXIT_INVALID)

(warning) One or more input files contained no valid data

4 (EXIT_NO_INPUT)

(warning) The specified input file was not found

8 (EXIT_NO_OUTPUT)

The specified output file could not be created (error); or else one of the output files could not be written or its access mode could not be changed (warnings). The accompanying message(s) will distinguish.

9 (EXIT_NO_MEM)

No process memory available

66 (EX_NOINPUT)

A specified configuration file could not be loaded.

70 (EX_SOFTWARE)

libopts had an internal operational error. Please report it to autogen-users@lists.sourceforge.net. Thank you.

The exit status codes are (mostly) warning codes. As such, each code is "or"-ed into the final exit code as the input files are processed. For example, an exit code of '6' is not listed above. It is the sum of **EXIT_INVALID** and **EXIT_NO_INPUT**. It would mean that at least one input file contained invalid data and also at least one input file could not be found at all.

SEE ALSO

uuencode(1), **uuencode(4)**

AUTHORS

Free Software Foundation, Inc.

COPYRIGHT

Copyright (C) 1994-2015 Free Software Foundation, Inc. all rights reserved. This program is released under the terms of the GNU General Public License, version 3 or later.

BUGS

Please put **sharutils** in the subject line for emailed bug reports. It helps to spot the message.

If more than one *name* in the encoded files are the same, or if the second or following input files specifies standard output for the output file, then the result is probably not what is expected. Specifically, standard output will be appended to and named output files will be replaced.

Please send bug reports to: bug-gnu-utils@gnu.org

NOTES

This manual page was *AutoGen*-erated from the **uudecode** option definitions.

NAME

uuencode – encode a file into email friendly text

SYNOPSIS

uuencode [**-flags**] [**-flag** *[value]*] [**--option-name**[[=] *[value]*] [*<in-file>*] *<output-name>*

DESCRIPTION

uuencode is used to create an ASCII representation of a file that can be sent over channels that may otherwise corrupt the data. Specifically, email cannot handle binary data and will often even insert a character when the six character sequence "Orom " is seen.

uuencode will read *in-file* if provided and otherwise read data from standard in and write the encoded form to standard out. The output will begin with a header line for use by *uudecode* giving it the resulting suggested file *output-name* and access mode. If the *output-name* is specifically */dev/stdout*, then *uudecode* will emit the decoded file to standard out.

Note: *uuencode* uses buffered input and assumes that it is not hand typed from a tty. The consequence is that at a tty, you may need to hit Ctl-D several times to terminate input.

OPTIONS

-m, --base64

convert using base64.

By default, *uuencode* will encode using the traditional conversion. It is slower and less compact than base64. The encoded form of the file is expanded by 37% for UU encoding and by 35% for base64 encoding (3 bytes become 4 plus control information).

-e, --encode-file-name

encode the output file name.

Since output file names may contain characters that are not handled well by various transmission modes, you may specify that the *output-name* be base64 encoded as well. (Traditional uuencoding of the file name is not supported.)

-h, --help

Display usage information and exit.

-.!, --more-help

Pass the extended usage information through a pager.

-R *[cfgfile]*, **--save-opts** [=*cfgfile*]

Save the option state to *cfgfile*. The default is the *last* configuration file listed in the **OPTION PRESETS** section, below. The command will exit after updating the config file.

-r *cfgfile*, **--load-opts**=*cfgfile*, **--no-load-opts**

Load options from *cfgfile*. The *no-load-opts* form will disable the loading of earlier config/rc/ini files. **--no-load-opts** is handled early, out of order.

-v [{*v*|*c*|*n*} **--version** [{*v*|*c*|*n*}]]

Output version of program and exit. The default mode is 'v', a simple version. The 'c' mode will print copyright information and 'n' will print the full copyright notice.

OPTION PRESETS

Any option that is not marked as *not presettable* may be preset by loading values from configuration ("RC" or ".INI") file(s). The file "*\$HOME/.sharrc*" will be used, if present.

STANDARDS

This implementation is compliant with P1003.2b/D11.

FILES

See **OPTION PRESETS** for configuration files.

EXIT STATUS

One of the following exit values will be returned:

0 (EXIT_SUCCESS)

Successful program execution.

1 (EXIT_FAILURE)

The operation failed or the command syntax was not valid.

66 (EX_NOINPUT)

A specified configuration file could not be loaded.

70 (EX_SOFTWARE)

libopts had an internal operational error. Please report it to autogen-users@lists.sourceforge.net. Thank you.

NOTES

This manual page was *AutoGen*-erated from the **uuencode** option definitions.

NAME

uuencode – format of an encoded uuencode file

DESCRIPTION

Files output by uuencode(1) consist of a header line, followed by a number of body lines, and a trailer line. The uudecode(1) command will ignore any lines preceding the header or following the trailer. Lines preceding a header must not, of course, look like a header.

The header line is distinguished by having the first 5 characters be *begin* followed by a space, or else a hyphen and either *base64* or *encoded* or both (also separated with a hyphen). The *base64* option says the file has been encoded using base64. The *encoded* option says the output file *name* has been base64 encoded. It is never encoded with traditional uuencoding. This is a GNU extension. These are followed by a mode (in octal), and a string which names the remote file. The mode is separated from the *begin* clause and the file name by a single space character.

Traditional uuencoding

The traditional *uuencoded* file body consists of a number of lines, each at most 62 characters long (including the trailing newline). These consist of a character count letter, followed by the encoded characters, followed by a newline. The character count is a single printing character, and represents an integer, the number of bytes the rest of the line represents. Such integers are always in the range from 0 to 63 and can be determined by subtracting the character space (octal 40) from the character.

Groups of 3 bytes are stored in 4 characters, 6 bits per character. All are offset by a space to make the characters printing. The last line may be shorter than the normal 45 bytes. If the size is not a multiple of 3, this fact can be determined by the value of the count on the last line. Extra garbage will be included to make the character count a multiple of 4. The body is terminated by a line with a count of zero. This line consists of one ASCII space.

The trailer line consists of *end* on a line by itself.

base64 encoding

base64 encoded files follow the specified format for the body, but also include a *begin-base64* header and a trailer line of four = characters.

EXAMPLES

```
begin-base64-encoded 644 VE9ETw==
```

This introduces a base64 encoded file named, *TODO* with that name encoded using base64 encoding.

```
begin-encoded 644 5$J$3P“
```

This introduces an encoded file named, *TODO* with that name encoded using uuencoding. The encoding is a lot less friendly. Please prefer base64 encoding.

CONFORMING TO

IEEE Std 1003.1, plus extensions

The *-encoded* suffix to the *begin* header line is a GNU extension. Recipients must have the GNU *uudecode* program to decode them.

SEE ALSO

uuencode(1), uudecode(1), base64(1)

HISTORY

The *uuencode* file format appeared in BSD 4.0 .

NAME

ux2dos – convert ASCII file format from UNIX to DOS format

SYNOPSIS

edrc/lib/ux2dos [**-h**]

ux2dos *unixfile* > *dosfile*

cat *unixfile* | *ux2dos* > *dosfile*

AVAILABILITY

WA2L/edrc

DESCRIPTION

ux2dos reads the specified *unixfile* and writes it to **stdout**, converting to DOS format.

If no input file is given or if a *unixfile* is specified as -, **ux2dos** reads from **stdin**.

OPTIONS

-h print usage message.

unixfile file in UNIX file format.

dosfile file in DOS file format.

ENVIRONMENT

-

EXIT STATUS

0 no error.

1 given file does not exist.

4 usage message printed.

NAME

volume.dat – volume definition for lots

SYNOPSIS

edrc/var/lots/objects/volume.dat
VARDIR/objects/volume.dat

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the storage volume definition for the **lots** command.

This definitions allow to save data to different locations when for instance storage capacity is shortening or due to possible conceptual considerations.

FILEFORMAT

The fileformat is a list of definitions that have the format

YEAR ; DESCRIPTION ; PATH ;

Rows starting with a **#** are considered as comments. Empty lines are allowed, too.

It is allowed to have multiple volume definitions for a year (= multiple definition lines having the same *YEAR* entry but different *PATH* definitions). The first matching *YEAR* definition will be used to save the data to, all other matching entries will be used to read and purge the data from.

OPTIONS

YEAR

to this location all data that will expire on the year specified is saved to.

If a retention exceeds the *YEAR* definitions, the data save will not be performed.

The **RETENTION_MAX** setting in the **lots.cfg** configuration file has also influence to the **save** and **lock** behaviour of **lots**. See **lots.cfg(4)**.

DESCRIPTION

description of the volume.

PATH

base path where the data is saved to. The complete path where the data is saved to is:
<PATH>/<YEAR>/<MMDD>/<DATA LIST>/<COUNTER>/data/ (example:

/dat/worm_all/2010/0426/DB_ASYPROD/000/data).

EXAMPLES

```
#
# var/lots/objects/volume.dat - data save volume destination
#
# [00] 30.09.2009 CWa   Initial Version
# [01] 29.10.2009 CWa   +2013..2019
#
#YEAR      ;DESCRIPTION                                ;PATH;
2009      ;WORM volume that expires end of 2009      ;/dat/worm_all;
2010      ;WORM volume that expires end of 2010      ;/dat/worm_all;
2011      ;WORM volume that expires end of 2011      ;/dat/worm_all;
2012      ;WORM volume that expires end of 2012      ;/dat/worm_all;
2013      ;WORM volume that expires end of 2013      ;/dat/worm_all;
2014      ;WORM volume that expires end of 2014      ;/dat/worm_all;
2015      ;WORM volume that expires end of 2015      ;/dat/worm_all;
2016      ;WORM volume that expires end of 2016      ;/dat/worm_all;
2017      ;WORM volume that expires end of 2017      ;/dat/worm_all;
2018      ;WORM volume that expires end of 2018      ;/dat/worm_all;
2019      ;WORM volume that expires end of 2019      ;/dat/worm_all;
```

NAME

vsav – versioned file save
 vcat – cat saved file version
 vdiff – diff to saved file version
 vgrep – grep pattern in saved file version
 vlist – list all saved file versions
 vls – list last saved file versions
 vmore – more saved file version
 vpurge – purge saved file versions
 vrestore – restore saved file version

SYNOPSIS

edrc/bin/v(sav|cat|more|diff|grep|list|ls|purge|restore) [-h]

vsav *file*...

v(list|ls) *file*

v(cat|more|diff|purge|restore) *file* [*version*]

vgrep *pattern file* [*version*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

The **vsav**, **vcat**, **vmore**, **vdiff**, **vgrep**, **vlist**, **vls**, **vpurge**, and **vrestore** commands enable to save, print, compare, grep, list, purge and restore *versions* of a given *file*.

When saving a *file*, a new *version* is stored, if the most recent saved *file* is not identical to the current *file*.

When restoring a *file*, automatically the *file* to be overwritten is saved.

OPTIONS

-h usage.

file file to be saved, printed, restored, compared, purged or listed.

version version of saved *file* to be restored, printed, purged or compared.

If no *version* is specified, the most recent saved *version* of the *file* is chosen.

pattern regular expression pattern.

ENVIRONMENT

\$VSAV_COMPRESS

Set to **False** if the saved file versions shall not be saved compressed.

When not set or set to **True** a saved file versions will be compressed using **gzip**(1).

EXIT STATUS

0 no error.

1 error.

4 usage printed.

FILES

edrc/var/vsav/files/

location where the saved *versions* of the *files* are stored.

edrc/var/vsav/files/<md5sum(/path/file)>-<version>[.gz]

saved *version* of *file*.

NAME

vsdfml – very simple document formatting language

SYNOPSIS

edrc/lib/vsdfml [**-h**]

vsdfml *filename* [*format*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

The purpose of **vsdfml** is to highlight documentation files on terminal output when writing recovery scripts whose purpose is to display information and not to execute commands.

To benefit from **vsdfml** you have to add it to the magic key of your information "recovery script": **#!/bin/sh vsdfml**.

Lines starting with a hash (**#**) are considered as comments and are not printed. Repetitive empty lines are reduced to one line.

All text lines beginning in the first column are set as bold font, all other text lines are set in normal font.

The text is not formatted to a certain number of columns, all text output is done as typed, this enables you to include also some ASCII graphics in the documentation.

There are some markup tags defined to set text in bold, underlined, etc. font, see section **MARKUP TAGS** for the markup tags available.

OPTIONS

-h usage message.

filename documentation file filename. When calling **vsdfml** in the magic key as shown above and in the example below, do not specify this option, it contains the filename automatically. To feed **vsdfml** with documentation text thru a pipe via **stdin**, use the pseudo file name **-**.

format Optional output format identifier. If this option is not specified, the output is formatted for manual page output (**MAN**).

TROFF the output is a man-troff format body (without header).

MAN format the output as manual page and display it using **man**.

TTY format text for terminal output.

MEDIAWIKI

the output is in MediaWiki markup.

MARKUP TAGS

Text

set *Text* in bold font.

<u>Text</u>

set *Text* in underlined font. This text is printed italic in HTML output.

<i>Text</i>

set *Text* in underlined font. This text is printed italic in HTML output.

<so>Text</so>

set *Text* in stamped out font (inverse) when using the TTY output. This text is printed bold in HTML and MAN output.

ENVIRONMENT

\$TERM terminal emulation of the current terminal. If this setting is not set correctly the whole documentation is printed, but certain font formatting (bold, underline, ...) might not be visible.

EXIT STATUS

0 no error.

4 usage listed.

11 a temporary directory could not be claimed or created in **/tmp**. Check the system temporary directory **/tmp** if you get this error, it is an indicator of system intrusion.

FILES

/tmp temporary directory.

/usr/share/terminfo

terminal capability database on systems with terminfo.

/etc/termcap

terminal capability database on systems with termcap.

EXAMPLES

1) Example of a documentation menu point.

It might makes sense to add also some **doc** tags (D:) to inform the user about the purpose of the menu point when calling the **doc** contributed command on it, see **contrib.doc(1m)**.

```
#!/usr/bin/env vsdfml
#
# 0:info_contacts - Contact Information
#
# [00] 22.05.2007 CWa    Initial Version
# [01] 03.06.2007 CWa    ++
#
# D: This is a documentation menu point, to view
# D: the documentation, start it.
#
```

NAME

vvi – versioned file edit

SYNOPSIS

edrc/bin/vvi

vvi [*options*] [*file...*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

versioned file edit.

Prior to starting the editor, the files specified in *file...* are saved using the **vsav**(1) command internally.

This enables to use the **vls**, **vcats**, **vdiffs**, and **vreloads** commands for the edited *file*.

OPTIONS

options editor options.

file... list of files to edit.

ENVIRONMENT

\$EDITOR editor to start in **vvi** (default=**vi**).

\$VVI_MAXSAVESIZE

maximum file save size in kilo bytes. Default is **2048** kBytes.

EXIT STATUS

x exit state of **\$EDITOR**.

NAME

WA2L/edrc:edrcapi – EDRC REST API

SYNOPSIS

http://server.acme.ch:9902/vn/command[?option]

https://server.acme.ch:9903/vn/command[?option]

edrc/lib/thttpd { start | stop | ... } edrcapi

edrc/bin/edrcinit { start | stop | ... } thttpd_edrcapi

edrc/bin/edrcinit { start | stop | ... } nginx_edrcapi

AVAILABILITY

WA2L/edrc

DESCRIPTION

web application **WA2L/edrc:edrcapi** (EDRC REST API) to serve WA2L/edrc information in API fashion.

/v1/hostlist

return WA2L/edrc hostlist in different formats.

See also: **hostlist(3)**.

/v1/hostlist

- *Ansible inventory json format*

/v1/hostlist?json

- *Ansible inventory json format*

/v1/hostlist?yaml

- *Ansible inventory yaml format*

/v1/hostlist?ini

- *Ansible inventory ini format*

OPTIONS

start start webserver.

stop stop webserver.

edrcapi web application name of WA2L/edrc:edrcapi.

thttpd_edrcapi

http service name of WA2L/edrc:edrcapi.

nginx_edrcapi

https service name of WA2L/edrc:edrcapi.

ENVIRONMENT

-

EXIT STATUS

-

FILES

edrc/etc/thttpd.edrcapi.cfg

configuration file for the HTTP server daemon **thttpd** which serves the application. See also **thttpd(3)** for more information.

edrc/etc/nginx.edrcapi.cfg

configuration file for the HTTPS server daemon **nginx** which serves the application. The **thttpd_edrcapi** service is a prerequisite for **nginx_edrcapi**. See also **nginx(3)** for more information.

edrc/etc/edrcinit.cfg

configuration file of the WA2L/edrc service handler. See also **edrcinit(1m)** for more information.

edrc/www/edrcapi/

base directory of WA2L/edrc:edrcapi.

edrc/www/edrcapi/.meta/

directory containing meta data for WA2L/edrc:edrcapi as application version and description.

edrc/www/edrcapi/v1/

directory containing all cgi scripts of WA2L/edrc:edrcapi with version 1.

EXAMPLES

-

SEE ALSO

edrcintro(1), **edrcinit(1m)**, **edrcinit.cfg(3)**, **nginx(3)**, **nginx.edrcapi.cfg(3)**, **thttpd(3)**, **thttpd.edrcapi.cfg(3)**

NOTES

The web application is served using **thttpd**, because it is a fast, small, secure and simple HTTP server that is available and compilable on many operating systems without problems and therefore predestined for a

multi platform framework as WA2L/edrc. See **thttpd**(3) and **<http://www.acme.com/software/thttpd>** for more information.

NAME

WA2L/edrc:report – THE OPERATING SYSTEM REPORT PORTAL

SYNOPSIS

http://server.acme.ch:9900

https://server.acme.ch:9901

edrc/lib/thttpd { start | stop | ... } report

edrc/bin/edrcinit { start | stop | ... } thttpd_report

edrc/bin/edrcinit { start | stop | ... } nginx_report

AVAILABILITY

WA2L/edrc

DESCRIPTION

The main purpose of the WA2L/edrc:report web application is to present operating system reports of one or more customers that are saved in a directory structure on the system where the application is running.

WA2L/edrc:report provides an easy to handle web interface for user administration. To point to customer report directories, create a symbolic link in the **/rpt** directory, to change the contents of the links displayed in the 'Links' menu, edit the file **/etc/links**, else no additional configuration is needed.

If you get the web server error **'404; Forbidden; You do not have permission to get URL from this server'** you are most likely connecting to a non-official URL of the web server. To verify this and to get the correct URL, click to the 'About' control and watch out for a red **'ensure to connect to ...'** message that informs if the application is called using a wrong URL.

See application help thru the 'Help' menu in the WA2L/edrc:report web application for more information regarding application usage.

OPTIONS

start start webserver.

stop stop webserver.

report web application name of WA2L/edrc:report.

thttpd_report
 service name of WA2L/edrc:report.

ENVIRONMENT

-

EXIT STATUS

-

FILES

edrc/etc/thttpd.report.cfg

configuration file for the HTTP server daemon **thttpd** which serves the application. See also **thttpd**(3) for more information.

edrc/etc/nginx.report.cfg

configuration file for the HTTPS server daemon **thttpd** which serves the application. The **thttpd_report** service is a prerequisite for **nginx_report**. See also **nginx**(3) for more information.

edrc/etc/edrcinit.cfg

configuration file of the WA2L/edrc service handler. See also **edrcinit**(1m) for more information.

edrc/www/report/

base directory of WA2L/edrc:report.

edrc/www/report.meta/

directory containing meta data for WA2L/edrc:report as application version and description.

edrc/www/report.htpasswd

this file holds the user password information of the WA2L/edrc:report web application. The content of this file is maintained thru the 'User Administration' menu points in the web application together with the **/etc/users** file.

When installing the WA2L/edrc package the user **admin** has the password **admin**. After the installation a personal user with the role **ADM (Admin)** should be created (with the **Users** menu) and the user **admin** should be removed.

edrc/www/report/cgi/

directory containing all cgi scripts of WA2L/edrc:report.

edrc/www/report/css/

directory containing all cascaded style sheets of WA2L/edrc:report.

edrc/www/report/errors/

error files for the **thttpd** web server of WA2L/edrc:report.

edrc/www/report/etc/

configuration directory of WA2L/edrc:report.

edrc/www/report/etc/links

configuration file for the 'Links' menu point in the WA2L/edrc:report web application. This configuration file has to be edited directly by hand.

edrc/www/report/etc/users

this file holds the user information of the WA2L/edrc:report web application. The content of this file is maintained thru the 'User Administration' menu points in the web application together with the **/.htpasswd** file.

edrc/www/report/fonts/

directory containing all additional fonts of WA2L/edrc:report.

edrc/www/report/img/

directory containing all application images of WA2L/edrc:report.

edrc/www/report/js/

directory containing all JavaScripts of WA2L/edrc:report.

edrc/www/report/main/

directory containing the static web pages of WA2L/edrc:report.

edrc/www/report/rpt/

directory containing the symbolic links to the directories containing the operating system reports.

The structure of the target report directories must be **<Customer>/<Report_Name>/<Report_File(s)>**. To add a more comprehensive description of a report, use the **duvi; chown edrc ..du_index** command in the related **<Report_Name>/** directory (use the **en:** section of the **..du_index** file).

To display and list reports in the web application, the permissions of all directories must be **drwxr-xr-x** and the permissions of the report files must be **-rw-r--r--**.

If you run a configuration, where you serve the reports in a customer's environment to a customer, but you don't want to show all reports to him/her, you can set the permissions of the related **<Report_Name>** directory you want to hide to **drwxr-x---**, sync all reports to a central reporting portal for system administration personnel (using **rsync(1)** in a script started thru a cron entry) and change the permissions on your central back to **drwxr-xr-x** (in the same script).

Example report file structure on a central report portal:

```
[ /opt/edrc/var/www/report/rpt ]
[ root@fc17mzv7t0.acme.ch ][*eshell*/bash]: ll
lrwxrwxrwx.  1 root edrc   11 Jan 12  2012 001 -> /dat/report_USA/
lrwxrwxrwx.  1 root edrc   16 Jan 12  2012 002 -> /dat/report_Switzerla
lrwxrwxrwx.  1 root edrc   10 Jan 12  2012 003 -> /dat/report_CostaRica
lrwxrwxrwx.  1 root edrc   10 Jan 12  2012 004 -> /dat/report_NewZealan
-rw-r--r--.  1 root edrc  935 Sep  1  2010 index.html
```

```
[ /opt/edrc/var/www/report/rpt/001 ]
[ root@fcl7mzv7t0.acme.ch ][*eshell*/bash]: ll
drwxr-xr-x. 2 root root 4096 Dec  2 14:00 RedrockQuarry/
drwxr-xr-x. 2 root root 4096 Dec  9 16:40 PureWater/
drwxr-xr-x. 2 root root 4096 Dec  2 15:44 SimpleFurniture/
drwxr-xr-x. 5 root root 4096 Nov  4 14:38 WA2L/
drwxr-xr-x. 2 root root 4096 Dec  8 12:54 Xenon/

[ /opt/edrc/var/www/report/rpt/001/RedrockQuarry ]
[ root@fcl7mzv7t0.acme.ch ][*eshell*/bash]: ll
drwxr-xr-x. 3 root root 4096 Dec  2 15:35 cfg2html/
drwxr-xr-x. 3 root root 4096 Nov 18 17:04 fssum/
drwxr-xr-x. 2 root root 4096 Nov  3 00:40 lots/
drwxr-xr-x. 3 root root 4096 Nov 16 19:04 performancegraph/

drwxr-xr-x. 2 root root 4096 Nov  3 00:50 20121103/
drwxr-xr-x. 2 root root 4096 Nov  4 00:54 20121104/
drwxr-xr-x. 2 root root 4096 Nov  5 00:52 20121105/
-rw-r-----. 1 edrc root  126 Dec  2 15:35 ..du_index

[ /opt/edrc/var/www/report/rpt/001/RedrockQuarry/cfg2html/20121103 ]
[ root@fcl7mzv7t0.acme.ch ][*eshell*/bash]: ll
-rw-r--r--. 1 root root  8983 Nov  3 00:35 pepples.redrock.com.err
-rw-r--r--. 1 root root 481265 Nov  3 00:35 pepples.redrock.com.html
-rw-r--r--. 1 root root    259 Nov  3 00:35 pepples.redrock.com.partiti
-rw-r--r--. 1 root root 448872 Nov  3 00:35 pepples.redrock.com.txt
-rw-r--r--. 1 root root   8900 Nov  3 00:40 boulder.redrock.com.err
-rw-r--r--. 1 root root 486465 Nov  3 00:40 boulder.redrock.com.html
-rw-r--r--. 1 root root    200 Nov  3 00:40 boulder.redrock.com.partiti
-rw-r--r--. 1 root root 446852 Nov  3 00:40 boulder.redrock.com.txt
```

Example report file structure in the RedrockQuarry environment, where you want to hide the **cfg2html** reports from the customer's eyes but show all other reports:

```
[ /opt/edrc/var/www/report/rpt ]
[ root@sand.redrock.com ][*eshell*/bash]: ll
lrwxrwxrwx. 1 root edrc  11 Jan 12  2012 001 -> /dat/report/
-rw-r--r--. 1 root edrc  935 Sep  1  2010 index.html

[ /opt/edrc/var/www/report/rpt/001/RedrockQuarry ]
[ root@sand.redrock.com ][*eshell*/bash]: ll
drwxr-x---. 3 root root 4096 Dec  2 15:35 cfg2html/
drwxr-xr-x. 3 root root 4096 Nov 18 17:04 fssum/
drwxr-xr-x. 2 root root 4096 Nov  3 00:40 lots/
drwxr-xr-x. 3 root root 4096 Nov 16 19:04 performancegraph/
```

edrc/www/report/tmp/

directory for temporary files generated by a cgi script. This directory is currently not used.

edrc/www/report/var/

directory containing additional static web content.

edrc/www/report/var/logos/

directory containing the factory logos of customers. The logo must have the name as returned by the **server_environment -C** command in the customer's environment and the file suffix **.png, .jpg, .jpeg** or **.gif**.

edrc/www/report/var/mylogos/

directory containing your own factory logos of customers. Files in this directory have preference over the files in **edrc/www/report/var/logos/**. Files in this directory are not touched by WA2L/edrc patch updates. The logo must have the name as returned by the **server_environment -C** command in the customer's environment and the file suffix **.png, .jpg, .jpeg** or **.gif**.

EXAMPLES

1) port setting in webserver config file **edrc/etc/tthttpd.report.cfg** of WA2L/edrc:report:

```
#
# tthttpd.report.cfg - config file for tthttpd of application 'report'
#
# [00] 07.09.2007 CWa Initial Version
#
:
port=9900
:
```

2) service definition of WA2L/edrc:report in **edrc/etc/edrcinit.cfg**:

```
#
# etc/edrcinit.cfg - configuration file for edrcinit
#
# [00] 26.05.2009 CWa Initial Version
#
:
#
# Format:
#
# <sequence>;<activated>;<guarded>;<name>;<description>;<handler>;<handl
#
:
150;Y;Y;tthttpd_report;tiny HTTP server (WA2L/edrc:report);WA2Ledrc.tthttpd

NOTES

The web application is served using **thttpd**, because it is a fast, small, secure and simple HTTP server that is available and compilable on many operating systems without problems and therefore predestined for a multi platform framework as WA2L/edrc. See **thttpd(3)** and **<http://www.acme.com/software/thttpd>** for more information.

NAME

WA2L/edrc:shellinaboxd – shellinaboxd application

SYNOPSIS

http://server.acme.ch:8806/

https://server.acme.ch:8807/

edrc/bin/edrcinit { start | stop | ... } shellinaboxd

edrc/bin/edrcinit { start | stop | ... } nginx_shellinaboxd

AVAILABILITY

WA2L/edrc

DESCRIPTION

web application **WA2L/edrc:shellinaboxd** to serve WA2L/edrc command line over over a Web browser.

OPTIONS

start start application service.

stop stop application service.

shellinaboxd
web application name of WA2L/edrc:shellinaboxd.

shellinaboxd
http service name of WA2L/edrc:shellinaboxd.

nginx_shellinaboxd
https service name of WA2L/edrc:shellinaboxd.

ENVIRONMENT

-

EXIT STATUS

-

FILES

edrc/etc/shellinaboxd.cfg

configuration file for the HTTP server daemon **shellinaboxd** which serves the application. See also **shellinaboxd(3)** for more information.

edrc/etc/nginx.shellinaboxd.cfg

configuration file for the HTTPS server daemon **nginx** which serves the application. The **shellinaboxd** service is a prerequisite for **nginx_shellinaboxd**. See also **nginx(3)** for more information.

edrc/etc/edrcinit.cfg

configuration file of the WA2L/edrc service handler. See also **edrcinit(1m)** for more information.

EXAMPLES

-

NAME

WA2L::Util – General WA2L/edrc Utility Functions Perl Module

SYNOPSIS

Initialize environment (see also: **perlenv**(3) for a description of how to initialize the environment and how to start a Perl program):

```
[ /home/fred ]
[ fred@acme-007 ][bash]: eval `~edrc/lib/perlenv`
```

Perl program using **WA2L::Util**:

```
#!/usr/bin/env perl

use WA2L::Util;
use File::Basename;

$ENV{EDRC_LOGFILE} = approot() . "/var/log/" .
    basename($0) . ".log";

# print message
#
msg( level => "INFO", txt => "start script" );

# create a log file entry
#
log( level => "INFO", txt => "start script" );

# print timestamp
#
print now() . "\n";

# check options
#
checkopt(
    used_opts=>"fv",
    truthtable => "
        fnv
        100
        101
        110
    "
) or die('Usage: ' . basename $0 . ' -f file [ -n | -v ]');
```

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is a collection of general WA2L/edrc utility functions to be used in Perl scripts or other Perl modules.

FUNCTIONS

msg(level => "LEVEL", txt => "text")

print a standardized message text to **stderr**.

See **msg(3)** for the message format.

log(level => "LEVEL", txt => "text")

write a standardized message text to the log file specified in the **\$EDRC_LOGFILE** environment variable. The session can be set in the **\$EDRC_SESSION**. If **\$EDRC_SESSION** is not set, the process ID of the calling Perl script is used as a ad-hoc session id.

See **log(3)** for the output format.

now()

return the current date and time in the military format **YYYY-MM-DD hh:mm:ss**.

approot()

return the root of the WA2L/edrc package installation. The output is identical to the **approot(3)** command.

checkopt(used_opts => "options", truthtable => "table")

check if a list of used *options* matches against a *table* of allowed option combinations. This command is intended to be used to efficiently parse arguments in a script.

The **checkopt** function returns **1** (=true) if *options* are correct, **0** (=false) if *options* are not correct.

See **checkopt(3)** for the detail description.

ENVIRONMENT

\$EDRC_SESSION

session name.

\$EDRC_LOGFILE

log file name and path.

EXIT STATUS

-

FILES

edrc/lib/perl/pm/perl*/vendor_perl/WA2L/Util.pm

this Perl module file.

NAME

watchdog – a watchdog to check a condition and react on it

SYNOPSIS

edrc/bin/watchdog [**-h**]

watchdog **-n** *name* **-c** *check_script* **-b** *bite_script* [**-i** *c_int* [, *b_int*]] [**-r** *l_int*]

watchdog **-s** *name*

watchdog **-l** | **-L** { [**start**] | **stop** }

AVAILABILITY

WA2L/edrc

DESCRIPTION

The intention of the **watchdog** command is to easily monitor a certain condition or service and react if the condition is not OK.

The states and terminology of the watchdog is adapted from the behavior of a real dog which checks, waits (between checks), bites (if something is not OK) and breaths (to recover between bites).

The different possible states of all running watchdogs are logged to a logfile.

The check script has to be written that way that a successful check returns an exit code of 0. An unsuccessful check has to return an exit code $\neq 0$. The interval between check script starts (= check interval) can be specified with the **-i** option.

The bite script (= reaction to an unsuccessful check) has to be written that way that a successful bite returns an exit code of 0. An unsuccessful bite should return an exit code $\neq 0$ to ensure a direct bite script restart. The interval between bite script restarts (= bite interval) can be specified with the **-i** option.

The bite script and the check script must exist on startup of a watchdog.

If a bite- or check script disappears during operation the number of retries can be configured in the configuration file **watchdog.cfg** with the **RETRIES_ON_MISSING_SCRIPT** setting.

The watchdog has the following states which are also recorded to the logfile:

check This is also the first state after the start of a watchdog. Execute the check script. If the check script returns an exit code of 0 goto state "wait", else goto state "bite".

To avoid logfile fill ups of subsequent "check" state recordings, the "check" state is logged in a bigger interval, which can be specified with the **-r** option if there is a need to deviate from the default of an hour.

| | |
|---------------|--|
| bite | Execute the bite script which hopefully can restart the service or recreate the proper condition. If the bite script returns an exit code of 0 goto state "check", else goto state "breath". |
| wait | Wait the duration of seconds specified as the <i>check_interval</i> , then goto state "check". |
| breath | Wait the duration of seconds specified as the <i>bite_interval</i> , then goto state "bite". |
| stop | The watchdog has been stopped with the -s option. |
| abort | The watchdog has been killed with the kill watchdog_process_id command (not recommended). |

OPTIONS

| | |
|------------------------|--|
| -h | usage message. |
| -n name | name of the watchdog. |
| -c check_script | script or single command that performs a check. If this script returns an exit code $\neq 0$ then the bite script specified with the -b option is started. |
| -b bite_script | script or single command that performs the reaction (bite) if the check script specified with the -c option returned an exit code $\neq 0$. |
| -i c_int | [, <i>b_int</i>] <i>c_int</i> check interval in seconds. Every <i>c_int</i> seconds the script specified in option -c is executed. If -i is not specified the default check interval of 500 seconds applies. <i>b_int</i> bite interval in seconds. This is the interval between the execution of the <i>bite_script</i> if the bite script returns an exit code $\neq 0$, that means between unsuccessful reactions (bites) of the script specified in option -b . If the <i>b_int</i> is not specified the default bite interval of 20 seconds applies. |
| -r l_int | minimal interval in seconds between logging of the check state message. If this option is not specified the default of 3600 seconds applies. |
| -s name | Stop a running watchdog with the name <i>name</i> . Users can only stop own started watchdogs. Be aware that a stop of a watchdog can be delayed by the duration of the check- or bite script run. You should not kill the watchdog with the kill command. |
| -l | list all running watchdogs. |

-L { [start] | stop }

list start/stop commands for all running watchdogs. This enables you to easily restart all currently running watchdogs with the related command options.

ENVIRONMENT

-

EXIT STATUS

- 0** no error.
- 1** the configuration file **edrc/etc/watchdog.cfg** does not exist.
- 2** operating system not supported, see **osid(3)**
- 3** cannot write to lock directory. The ability for all user to write to the lockdir is mandatory.
- 4** usage displayed.
- 5** a watchdog with the same name as specified in the **-n** option is already running.
- 6** the specified check script does not exist during watchdog startup.
- 7** the specified bite script does not exist during watchdog startup.
- 8** cannot write to logfile. The ability for all users to write to the logfile is mandatory.
- 9** unsuccessful attempt to stop a watchdog of an other user.
- 10** no watchdog is running while listing the started watchdogs with the **-l** or **-L** option.
- 11** temporary directory could not be claimed or created in **/var/tmp**. Check the system temporary directory **/var/tmp** if you get this error, it is an indicator of system intrusion.

FILES

edrc/etc/watchdog.cfg

configuration file of **watchdog**. See **watchdog.cfg(4)** for more information.

edrc/var/watchdog

default lockdir. This directory holds the lockfiles of watchdog. Do not edit them by hand. The lockdir can be configured in **watchdog.cfg**, see **watchdog.cfg(4)** for more information.

EXAMPLES

1) using watchdog to guard the AutoSYS event daemon

The AutoSYS event daemon is a program that is connected to a database and initiates job starts on remote systems. In some versions of AutoSYS the daemon tends to shut down after a startup. To ensure the permanent availability of the AutoSYS job scheduler the event daemon is guarded by a watchdog.

1.1) check script

The check script uses the AutoSYS command "chk_auto_up" to verify if the event daemon is up and running and returns 0 if this is true.

```
#!/bin/ksh
#
# eventor.check - check the event_daemon is running
#
# [00] 13.08.2004 CWa Initial Version
#
/bin/su - sys_asys -c "chk_auto_up"
if [ $? -eq 11 ]; then
    exit 0
else
    exit 1
fi
```

1.2) bite script

The bite script uses the AutoSYS command "eventor -q" to start the event daemon and the command "chk_auto_up" to verify if the start of the event daemon was successful. If the start was successful the script returns 0.

```
#!/bin/ksh
#
# eventor.bite - restart event_daemon if it not available
#
# [00] 13.08.2004 CWa Initial Version
#
/bin/su - sys_asys -c "eventor -q"
sleep 5

/bin/su - sys_asys -c "chk_auto_up"
if [ $? -eq 11 ]; then
    exit 0
else
    exit 1
fi
```

1.3) watchdog startup

This watchdog checks every 5 minutes if the event daemon is up and bites every 30 seconds if the event daemon start was not successful. Check states are logged to the logfile once approximately every 30 minutes.

```
watchdog -n event_daemon \  
-c /etc/cmcluster/asys_sv1_prod/eventor.check \  
-b /etc/cmcluster/asys_sv1_prod/eventor.bite \  
-i 300,30 \  
-r 1800
```

NAME

watchdog.cfg – configuration file for watchdog

SYNOPSIS

edrc/etc/watchdog.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **watchdog** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS

LOG Log output dir of **watchdog**. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation.

Example: LOG=/var/opt/edrc/log

Default: LOG=var/log

LOCKDIR

Lock dir of **watchdog**. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation. In General it is not recommended to set the lockdir within EDRC, locate it in a system own directory.

Example: LOCKDIR=/var/run/watchdog

Default: LOCKDIR=var/watchdog

DEFAULT_CHECK_INTERVAL

Default interval of watchdog checks. This setting applies if no interval is set on the command line.

Example: DEFAULT_CHECK_INTERVAL=500

Default: DEFAULT_CHECK_INTERVAL=600

DEFAULT_CHECKLOG_INTERVAL

Default minimal interval of logentries in check state. This setting applies if no interval is set on the command line. This setting should be an even multiple of DEFAULT_CHECK_INTERVAL.

Example: DEFAULT_CHECKLOG_INTERVAL=3600

Default: DEFAULT_CHECKLOG_INTERVAL=6000

DEFAULT_BITE_INTERVAL

Default interval of **watchdog** bites (=executes of the bite script). This setting applies if no interval is set on the command line.

Example: DEFAULT_BITE_INTERVAL=15

Default: DEFAULT_BITE_INTERVAL=5

EXEC_SHELL

Shell to execute the check_script and bite_script if they are not executable.

Example: EXEC_SHELL=/bin/ksh

Default: EXEC_SHELL=/bin/sh

RETRIES_ON_MISSING_SCRIPT

Number of retries if the check_script or bite_script is missing after startup. If the number of retries is reached the **watchdog** will end.

0 = retry for ever

Example: RETRIES_ON_MISSING_SCRIPT=10

Default: RETRIES_ON_MISSING_SCRIPT=0

NAME

Wget – The non-interactive network downloader.

SYNOPSIS

```
wget [option]... [URL]...
```

DESCRIPTION

GNU Wget is a free utility for non-interactive download of files from the Web. It supports HTTP, HTTPS, and FTP protocols, as well as retrieval through HTTP proxies.

Wget is non-interactive, meaning that it can work in the background, while the user is not logged on. This allows you to start a retrieval and disconnect from the system, letting Wget finish the work. By contrast, most of the Web browsers require constant user's presence, which can be a great hindrance when transferring a lot of data.

Wget can follow links in HTML and XHTML pages and create local versions of remote web sites, fully recreating the directory structure of the original site. This is sometimes referred to as “recursive downloading.” While doing that, Wget respects the Robot Exclusion Standard (*/robots.txt*). Wget can be instructed to convert the links in downloaded HTML files to the local files for offline viewing.

Wget has been designed for robustness over slow or unstable network connections; if a download fails due to a network problem, it will keep retrying until the whole file has been retrieved. If the server supports regetting, it will instruct the server to continue the download from where it left off.

OPTIONS**Option Syntax**

Since Wget uses GNU getopt to process command-line arguments, every option has a long form along with the short one. Long options are more convenient to remember, but take time to type. You may freely mix different option styles, or specify options after the command-line arguments. Thus you may write:

```
wget -r --tries=10 http://fly.srk.fer.hr/ -o log
```

The space between the option accepting an argument and the argument may be omitted. Instead **-o log** you can write **-olog**.

You may put several options that do not require arguments together, like:

```
wget -drc <URL>
```

This is a complete equivalent of:

```
wget -d -r -c <URL>
```

Since the options can be specified after the arguments, you may terminate them with **--**. So the following will try to download URL **-x**, reporting failure to *log*:

```
wget -o log -- -x
```

The options that accept comma-separated lists all respect the convention that specifying an empty list clears its value. This can be useful to clear the *.wgetrc* settings. For instance, if your *.wgetrc* sets *exclude_directories* to */cgi-bin*, the following example will first reset it, and then set it to exclude */nobody* and */somebody*. You can also clear the lists in *.wgetrc*.

```
wget -X '' -X /~nobody,/~somebody
```

Most options that do not accept arguments are *boolean* options, so named because their state can be captured with a yes-or-no (“boolean”) variable. For example, **—follow-ftp** tells Wget to follow FTP links from HTML files and, on the other hand, **—no-glob** tells it not to perform file globbing on FTP URLs. A boolean option is either *affirmative* or *negative* (beginning with **—no**). All such options share several properties.

Unless stated otherwise, it is assumed that the default behavior is the opposite of what the option

accomplishes. For example, the documented existence of **—follow-ftp** assumes that the default is to *not* follow FTP links from HTML pages.

Affirmative options can be negated by prepending the **—no-** to the option name; negative options can be negated by omitting the **—no-** prefix. This might seem superfluous---if the default for an affirmative option is to not do something, then why provide a way to explicitly turn it off? But the startup file may in fact change the default. For instance, using `follow_ftp = off` in `.wgetrc` makes Wget *not* follow FTP links by default, and using **—no-follow-ftp** is the only way to restore the factory default from the command line.

Basic Startup Options

-V

—version

Display the version of Wget.

-h

—help

Print a help message describing all of Wget's command-line options.

-b

—background

Go to background immediately after startup. If no output file is specified via the **-o**, output is redirected to `wget-log`.

-e command

—execute command

Execute *command* as if it were a part of `.wgetrc`. A command thus invoked will be executed *after* the commands in `.wgetrc`, thus taking precedence over them. If you need to specify more than one wgetrc command, use multiple instances of **-e**.

Logging and Input File Options

-o logfile

—output-file=logfile

Log all messages to *logfile*. The messages are normally reported to standard error.

-a logfile

—append-output=logfile

Append to *logfile*. This is the same as **-o**, only it appends to *logfile* instead of overwriting the old log file. If *logfile* does not exist, a new file is created.

-d

—debug

Turn on debug output, meaning various information important to the developers of Wget if it does not work properly. Your system administrator may have chosen to compile Wget without debug support, in which case **-d** will not work. Please note that compiling with debug support is always safe---Wget compiled with the debug support will *not* print any debug info unless requested with **-d**.

-q

—quiet

Turn off Wget's output.

-v

—verbose

Turn on verbose output, with all the available data. The default output is verbose.

-nv

—no-verbose

Turn off verbose without being completely quiet (use **-q** for that), which means that error messages and basic information still get printed.

-i file

—input-file=file

Read URLs from *file*. If *-* is specified as *file*, URLs are read from the standard input. (Use **-J-** to read from a file literally named *-*.)

If this function is used, no URLs need be present on the command line. If there are URLs both on the command line and in an input file, those on the command lines will be the first ones to be retrieved. The *file* need not be an HTML document (but no harm if it is)---it is enough if the URLs are just listed sequentially.

However, if you specify **—force-html**, the document will be regarded as **html**. In that case you may have problems with relative links, which you can solve either by adding `<base href="url">` to HTML, or to the documents or by specifying **—base=url** on the command line.

-F

—force-html

When input is read from a file, force it to be treated as an HTML file. This enables you to retrieve relative links from existing HTML files on your local disk, by adding `<base href="url">` to HTML, or using the **—base** command-line option.

-B URL

—base=URL

Prepends *URL* to relative links read from the file specified with the **-i** option.

Download Options

—bind-address=ADDRESS

When making client TCP/IP connections, bind to *ADDRESS* on the local machine. *ADDRESS* may be specified as a hostname or IP address. This option can be useful if your machine is bound to multiple IPs.

-t number

—tries=number

Set number of retries to *number*. Specify 0 or **inf** for infinite retrying. The default is to retry 20 times, with the exception of fatal errors like “connection refused” or “not found” (404), which are not retried.

-O file

—output-document=file

The documents will not be written to the appropriate files, but all will be concatenated together and written to *file*. If *-* is used as *file*, documents will be printed to standard output, disabling link conversion. (Use **-J-** to print to a file literally named *-*.)

Note that a combination with **-k** is only well-defined for downloading a single document.

-nc

—no-clobber

If a file is downloaded more than once in the same directory, Wget’s behavior depends on a few options, including **-nc**. In certain cases, the local file will be *clobbered*, or overwritten, upon repeated download. In other cases it will be preserved.

When running Wget without **-N**, **-nc**, or **-r**, downloading the same file in the same directory will result in the original copy of *file* being preserved and the second copy being named *file.1*. If that file is

downloaded yet again, the third copy will be named *file.2*, and so on. When **-nc** is specified, this behavior is suppressed, and Wget will refuse to download newer copies of *file*. Therefore, “no-clobber” is actually a misnomer in this mode—it’s not clobbering that’s prevented (as the numeric suffixes were already preventing clobbering), but rather the multiple version saving that’s prevented.

When running Wget with **-r**, but without **-N** or **-nc**, re-downloading a file will result in the new copy simply overwriting the old. Adding **-nc** will prevent this behavior, instead causing the original version to be preserved and any newer copies on the server to be ignored.

When running Wget with **-N**, with or without **-r**, the decision as to whether or not to download a newer copy of a file depends on the local and remote timestamp and size of the file. **-nc** may not be specified at the same time as **-N**.

Note that when **-nc** is specified, files with the suffixes **.html** or **.htm** will be loaded from the local disk and parsed as if they had been retrieved from the Web.

-c

—continue

Continue getting a partially-downloaded file. This is useful when you want to finish up a download started by a previous instance of Wget, or by another program. For instance:

```
wget -c ftp://sunsite.doc.ic.ac.uk/ls-lR.Z
```

If there is a file named *ls-lR.Z* in the current directory, Wget will assume that it is the first portion of the remote file, and will ask the server to continue the retrieval from an offset equal to the length of the local file.

Note that you don’t need to specify this option if you just want the current invocation of Wget to retry downloading a file should the connection be lost midway through. This is the default behavior. **-c** only affects resumption of downloads started *prior* to this invocation of Wget, and whose local files are still sitting around.

Without **-c**, the previous example would just download the remote file to *ls-lR.Z.1*, leaving the truncated *ls-lR.Z* file alone.

Beginning with Wget 1.7, if you use **-c** on a non-empty file, and it turns out that the server does not support continued downloading, Wget will refuse to start the download from scratch, which would effectively ruin existing contents. If you really want the download to start from scratch, remove the file.

Also beginning with Wget 1.7, if you use **-c** on a file which is of equal size as the one on the server, Wget will refuse to download the file and print an explanatory message. The same happens when the file is smaller on the server than locally (presumably because it was changed on the server since your last download attempt)—because “continuing” is not meaningful, no download occurs.

On the other side of the coin, while using **-c**, any file that’s bigger on the server than locally will be considered an incomplete download and only $(\text{length}(\text{remote}) - \text{length}(\text{local}))$ bytes will be downloaded and tacked onto the end of the local file. This behavior can be desirable in certain cases—for instance, you can use **wget -c** to download just the new portion that’s been appended to a data collection or log file.

However, if the file is bigger on the server because it’s been *changed*, as opposed to just *appended* to, you’ll end up with a garbled file. Wget has no way of verifying that the local file is really a valid prefix of the remote file. You need to be especially careful of this when using **-c** in conjunction with **-r**, since every file will be considered as an “incomplete download” candidate.

Another instance where you’ll get a garbled file if you try to use **-c** is if you have a lame HTTP proxy that inserts a “transfer interrupted” string into the local file. In the future a “rollback” option may be added to deal with this case.

Note that **-c** only works with FTP servers and with HTTP servers that support the Range header.

—progress=*type*

Select the type of the progress indicator you wish to use. Legal indicators are “dot” and “bar”.

The “bar” indicator is used by default. It draws an ASCII progress bar graphics (a.k.a “thermometer” display) indicating the status of retrieval. If the output is not a TTY, the “dot” bar will be used by default.

Use **—progress=dot** to switch to the “dot” display. It traces the retrieval by printing dots on the screen, each dot representing a fixed amount of downloaded data.

When using the dotted retrieval, you may also set the *style* by specifying the type as **dot:style**. Different styles assign different meaning to one dot. With the default style each dot represents 1K, there are ten dots in a cluster and 50 dots in a line. The binary style has a more “computer”-like orientation—8K dots, 16-dots clusters and 48 dots per line (which makes for 384K lines). The mega style is suitable for downloading very large files—each dot represents 64K retrieved, there are eight dots in a cluster, and 48 dots on each line (so each line contains 3M).

Note that you can set the default style using the `progress` command in `.wgetrc`. That setting may be overridden from the command line. The exception is that, when the output is not a TTY, the “dot” progress will be favored over “bar”. To force the bar output, use **—progress=bar:force**.

-N

—timestamping

Turn on time-stamping.

-S

—server-response

Print the headers sent by HTTP servers and responses sent by FTP servers.

—spider

When invoked with this option, Wget will behave as a Web *spider*, which means that it will not download the pages, just check that they are there. For example, you can use Wget to check your bookmarks:

```
wget --spider --force-html -i bookmarks.html
```

This feature needs much more work for Wget to get close to the functionality of real web spiders.

-T seconds

—timeout=*seconds*

Set the network timeout to *seconds* seconds. This is equivalent to specifying **—dns-timeout**, **—connect-timeout**, and **—read-timeout**, all at the same time.

When interacting with the network, Wget can check for timeout and abort the operation if it takes too long. This prevents anomalies like hanging reads and infinite connects. The only timeout enabled by default is a 900-second read timeout. Setting a timeout to 0 disables it altogether. Unless you know what you are doing, it is best not to change the default timeout settings.

All timeout-related options accept decimal values, as well as subsecond values. For example, **0.1** seconds is a legal (though unwise) choice of timeout. Subsecond timeouts are useful for checking server response times or for testing network latency.

—dns-timeout=*seconds*

Set the DNS lookup timeout to *seconds* seconds. DNS lookups that don’t complete within the specified time will fail. By default, there is no timeout on DNS lookups, other than that implemented by system libraries.

—connect-timeout=seconds

Set the connect timeout to *seconds* seconds. TCP connections that take longer to establish will be aborted. By default, there is no connect timeout, other than that implemented by system libraries.

—read-timeout=seconds

Set the read (and write) timeout to *seconds* seconds. The “time” of this timeout refers *idle time*: if, at any point in the download, no data is received for more than the specified number of seconds, reading fails and the download is restarted. This option does not directly affect the duration of the entire download.

Of course, the remote server may choose to terminate the connection sooner than this option requires. The default read timeout is 900 seconds.

—limit-rate=amount

Limit the download speed to *amount* bytes per second. Amount may be expressed in bytes, kilobytes with the **k** suffix, or megabytes with the **m** suffix. For example, **—limit-rate=20k** will limit the retrieval rate to 20KB/s. This is useful when, for whatever reason, you don’t want Wget to consume the entire available bandwidth.

This option allows the use of decimal numbers, usually in conjunction with power suffixes; for example, **—limit-rate=2.5k** is a legal value.

Note that Wget implements the limiting by sleeping the appropriate amount of time after a network read that took less time than specified by the rate. Eventually this strategy causes the TCP transfer to slow down to approximately the specified rate. However, it may take some time for this balance to be achieved, so don’t be surprised if limiting the rate doesn’t work well with very small files.

—w seconds**—wait=seconds**

Wait the specified number of seconds between the retrievals. Use of this option is recommended, as it lightens the server load by making the requests less frequent. Instead of in seconds, the time can be specified in minutes using the **m** suffix, in hours using **h** suffix, or in days using **d** suffix.

Specifying a large value for this option is useful if the network or the destination host is down, so that Wget can wait long enough to reasonably expect the network error to be fixed before the retry.

—waitretry=seconds

If you don’t want Wget to wait between *every* retrieval, but only between retries of failed downloads, you can use this option. Wget will use *linear backoff*, waiting 1 second after the first failure on a given file, then waiting 2 seconds after the second failure on that file, up to the maximum number of *seconds* you specify. Therefore, a value of 10 will actually make Wget wait up to $(1 + 2 + \dots + 10) = 55$ seconds per file.

Note that this option is turned on by default in the global *wgetrc* file.

—random-wait

Some web sites may perform log analysis to identify retrieval programs such as Wget by looking for statistically significant similarities in the time between requests. This option causes the time between requests to vary between 0 and $2 * \text{wait}$ seconds, where *wait* was specified using the **—wait** option, in order to mask Wget’s presence from such analysis.

A recent article in a publication devoted to development on a popular consumer platform provided code to perform this analysis on the fly. Its author suggested blocking at the class C address level to ensure automated retrieval programs were blocked despite changing DHCP-supplied addresses.

The **—random-wait** option was inspired by this ill-advised recommendation to block many unrelated users from a web site due to the actions of one.

—no-proxy

Don’t use proxies, even if the appropriate **_proxy* environment variable is defined.

For more information about the use of proxies with Wget,

-Q quota**—quota=quota**

Specify download quota for automatic retrievals. The value can be specified in bytes (default), kilobytes (with **k** suffix), or megabytes (with **m** suffix).

Note that quota will never affect downloading a single file. So if you specify **wget -Q10k ftp://wuarchive.wustl.edu/ls-lR.gz**, all of the *ls-lR.gz* will be downloaded. The same goes even when several URLs are specified on the command-line. However, quota is respected when retrieving either recursively, or from an input file. Thus you may safely type **wget -Q2m -i sites**—download will be aborted when the quota is exceeded.

Setting quota to 0 or to **inf** unlimits the download quota.

—no-dns-cache

Turn off caching of DNS lookups. Normally, Wget remembers the IP addresses it looked up from DNS so it doesn't have to repeatedly contact the DNS server for the same (typically small) set of hosts it retrieves from. This cache exists in memory only; a new Wget run will contact DNS again.

However, it has been reported that in some situations it is not desirable to cache host names, even for the duration of a short-running application like Wget. With this option Wget issues a new DNS lookup (more precisely, a new call to `gethostbyname` or `getaddrinfo`) each time it makes a new connection. Please note that this option will *not* affect caching that might be performed by the resolving library or by an external caching layer, such as NSCD.

If you don't understand exactly what this option does, you probably won't need it.

—restrict-file-names=mode

Change which characters found in remote URLs may show up in local file names generated from those URLs. Characters that are *restricted* by this option are escaped, i.e. replaced with **%HH**, where **HH** is the hexadecimal number that corresponds to the restricted character.

By default, Wget escapes the characters that are not valid as part of file names on your operating system, as well as control characters that are typically unprintable. This option is useful for changing these defaults, either because you are downloading to a non-native partition, or because you want to disable escaping of the control characters.

When mode is set to "unix", Wget escapes the character **/** and the control characters in the ranges 0—31 and 128—159. This is the default on Unix-like OS'es.

When mode is set to "windows", Wget escapes the characters ****, **|**, **/**, **:**, **?**, **"**, *****, **<**, **>**, and the control characters in the ranges 0—31 and 128—159. In addition to this, Wget in Windows mode uses **+** instead of **:** to separate host and port in local file names, and uses **@** instead of **?** to separate the query portion of the file name from the rest. Therefore, a URL that would be saved as **www.xemacs.org:4300/search.pl?input=blah** in Unix mode would be saved as **www.xemacs.org+4300/search.pl@input=blah** in Windows mode. This mode is the default on Windows.

If you append **,nocontrol** to the mode, as in **unix,nocontrol**, escaping of the control characters is also switched off. You can use **—restrict-file-names=nocontrol** to turn off escaping of control characters without affecting the choice of the OS to use as file name restriction mode.

-4**—inet4-only****-6****—inet6-only**

Force connecting to IPv4 or IPv6 addresses. With **—inet4-only** or **-4**, Wget will only connect to IPv4 hosts, ignoring AAAA records in DNS, and refusing to connect to IPv6 addresses specified in URLs. Conversely, with **—inet6-only** or **-6**, Wget will only connect to IPv6 hosts and ignore A records and IPv4 addresses.

Neither options should be needed normally. By default, an IPv6-aware Wget will use the address family specified by the host's DNS record. If the DNS responds with both IPv4 and IPv6 addresses, Wget will try them in sequence until it finds one it can connect to. (Also see `--prefer-family` option described below.)

These options can be used to deliberately force the use of IPv4 or IPv6 address families on dual family systems, usually to aid debugging or to deal with broken network configuration. Only one of **—inet6-only** and **—inet4-only** may be specified at the same time. Neither option is available in Wget compiled without IPv6 support.

—prefer-family=IPv4/IPv6/none

When given a choice of several addresses, connect to the addresses with specified address family first. IPv4 addresses are preferred by default.

This avoids spurious errors and connect attempts when accessing hosts that resolve to both IPv6 and IPv4 addresses from IPv4 networks. For example, **www.kame.net** resolves to **2001:200:0:8002:203:47ff:fea5:3085** and to **203.178.141.194**. When the preferred family is IPv4, the IPv4 address is used first; when the preferred family is IPv6, the IPv6 address is used first; if the specified value is `none`, the address order returned by DNS is used without change.

Unlike **-4** and **-6**, this option doesn't inhibit access to any address family, it only changes the *order* in which the addresses are accessed. Also note that the reordering performed by this option is *stable*—it doesn't affect order of addresses of the same family. That is, the relative order of all IPv4 addresses and of all IPv6 addresses remains intact in all cases.

—retry-connrefused

Consider “connection refused” a transient error and try again. Normally Wget gives up on a URL when it is unable to connect to the site because failure to connect is taken as a sign that the server is not running at all and that retries would not help. This option is for mirroring unreliable sites whose servers tend to disappear for short periods of time.

—user=*user*

—password=*password*

Specify the username *user* and password *password* for both FTP and HTTP file retrieval. These parameters can be overridden using the **—ftp-user** and **—ftp-password** options for FTP connections and the **—http-user** and **—http-password** options for HTTP connections.

Directory Options

—nd

—no-directories

Do not create a hierarchy of directories when retrieving recursively. With this option turned on, all files will get saved to the current directory, without clobbering (if a name shows up more than once, the filenames will get extensions **.n**).

—x

—force-directories

The opposite of **—nd**—create a hierarchy of directories, even if one would not have been created otherwise. E.g. **wget -x http://fly.srk.fer.hr/robots.txt** will save the downloaded file to *fly.srk.fer.hr/robots.txt*.

—nH

—no-host-directories

Disable generation of host-prefixed directories. By default, invoking Wget with **—r http://fly.srk.fer.hr/** will create a structure of directories beginning with *fly.srk.fer.hr/*. This option disables such behavior.

—protocol-directories

Use the protocol name as a directory component of local file names. For example, with this option, **wget -r http://host** will save to **http/host/...** rather than just to **host/...**

—cut-dirs=number

Ignore *number* directory components. This is useful for getting a fine-grained control over the directory where recursive retrieval will be saved.

Take, for example, the directory at **ftp://ftp.xemacs.org/pub/xemacs/**. If you retrieve it with **-r**, it will be saved locally under **ftp.xemacs.org/pub/xemacs/**. While the **-nH** option can remove the **ftp.xemacs.org/** part, you are still stuck with **pub/xemacs**. This is where **—cut-dirs** comes in handy; it makes Wget not “see” *number* remote directory components. Here are several examples of how **—cut-dirs** option works.

```

No options          -> ftp.xemacs.org/pub/xemacs/
-nH                 -> pub/xemacs/
-nH --cut-dirs=1    -> xemacs/
-nH --cut-dirs=2    -> .

--cut-dirs=1        -> ftp.xemacs.org/xemacs/
...

```

If you just want to get rid of the directory structure, this option is similar to a combination of **-nd** and **-P**. However, unlike **-nd**, **—cut-dirs** does not lose with subdirectories—for instance, with **-nH --cut-dirs=1**, a *beta/* subdirectory will be placed to *xemacs/beta*, as one would expect.

-P prefix**—directory-prefix=prefix**

Set directory prefix to *prefix*. The *directory prefix* is the directory where all other files and subdirectories will be saved to, i.e. the top of the retrieval tree. The default is **.** (the current directory).

HTTP Options**-E****—html-extension**

If a file of type **application/xhtml+xml** or **text/html** is downloaded and the URL does not end with the regexp **\[Hh][Tt][Mm][Ll]?**, this option will cause the suffix **.html** to be appended to the local filename. This is useful, for instance, when you’re mirroring a remote site that uses **.asp** pages, but you want the mirrored pages to be viewable on your stock Apache server. Another good use for this is when you’re downloading CGI-generated materials. A URL like **http://site.com/article.cgi?25** will be saved as *article.cgi?25.html*.

Note that filenames changed in this way will be re-downloaded every time you re-mirror a site, because Wget can’t tell that the local *X.html* file corresponds to remote URL *X* (since it doesn’t yet know that the URL produces output of type **text/html** or **application/xhtml+xml**). To prevent this re-downloading, you must use **-k** and **-K** so that the original version of the file will be saved as *X.orig*.

—http-user=user**—http-password=password**

Specify the username *user* and password *password* on an HTTP server. According to the type of the challenge, Wget will encode them using either the **basic** (insecure) or the **digest** authentication scheme.

Another way to specify username and password is in the URL itself. Either method reveals your password to anyone who bothers to run **ps**. To prevent the passwords from being seen, store them in *.wgetrc* or *.netrc*, and make sure to protect those files from other users with **chmod**. If the passwords are really important, do not leave them lying in those files either—edit the files and delete them after Wget has started the download.

—no-cache

Disable server-side cache. In this case, Wget will send the remote server an appropriate directive (**Pragma: no-cache**) to get the file from the remote service, rather than returning the cached version. This is especially useful for retrieving and flushing out-of-date documents on proxy servers.

Caching is allowed by default.

—no-cookies

Disable the use of cookies. Cookies are a mechanism for maintaining server-side state. The server sends the client a cookie using the `Set-Cookie` header, and the client responds with the same cookie upon further requests. Since cookies allow the server owners to keep track of visitors and for sites to exchange this information, some consider them a breach of privacy. The default is to use cookies; however, *storing* cookies is not on by default.

—load-cookies file

Load cookies from *file* before the first HTTP retrieval. *file* is a textual file in the format originally used by Netscape's *cookies.txt* file.

You will typically use this option when mirroring sites that require that you be logged in to access some or all of their content. The login process typically works by the web server issuing an HTTP cookie upon receiving and verifying your credentials. The cookie is then resent by the browser when accessing that part of the site, and so proves your identity.

Mirroring such a site requires Wget to send the same cookies your browser sends when communicating with the site. This is achieved by **—load-cookies**—simply point Wget to the location of the *cookies.txt* file, and it will send the same cookies your browser would send in the same situation. Different browsers keep textual cookie files in different locations:

Netscape 4.x.

The cookies are in *~/netscape/cookies.txt*.

Mozilla and Netscape 6.x.

Mozilla's cookie file is also named *cookies.txt*, located somewhere under *~/mozilla*, in the directory of your profile. The full path usually ends up looking somewhat like *~/mozilla/default/some-weird-string/cookies.txt*.

Internet Explorer.

You can produce a cookie file Wget can use by using the File menu, Import and Export, Export Cookies. This has been tested with Internet Explorer 5; it is not guaranteed to work with earlier versions.

Other browsers.

If you are using a different browser to create your cookies, **—load-cookies** will only work if you can locate or produce a cookie file in the Netscape format that Wget expects.

If you cannot use **—load-cookies**, there might still be an alternative. If your browser supports a “cookie manager”, you can use it to view the cookies used when accessing the site you're mirroring. Write down the name and value of the cookie, and manually instruct Wget to send those cookies, bypassing the “official” cookie support:

```
wget --no-cookies --header "Cookie: <name>=<value>"
```

—save-cookies file

Save cookies to *file* before exiting. This will not save cookies that have expired or that have no expiry time (so-called “session cookies”), but also see **—keep-session-cookies**.

—keep-session-cookies

When specified, causes **—save-cookies** to also save session cookies. Session cookies are normally not saved because they are meant to be kept in memory and forgotten when you exit the browser. Saving them is useful on sites that require you to log in or to visit the home page before you can access some pages. With this option, multiple Wget runs are considered a single browser session as far as the

site is concerned.

Since the cookie file format does not normally carry session cookies, Wget marks them with an expiry timestamp of 0. Wget's **—load-cookies** recognizes those as session cookies, but it might confuse other browsers. Also note that cookies so loaded will be treated as other session cookies, which means that if you want **—save-cookies** to preserve them again, you must use **—keep-session-cookies** again.

—ignore-length

Unfortunately, some HTTP servers (CGI programs, to be more precise) send out bogus `Content-Length` headers, which makes Wget go wild, as it thinks not all the document was retrieved. You can spot this syndrome if Wget retries getting the same document again and again, each time claiming that the (otherwise normal) connection has closed on the very same byte.

With this option, Wget will ignore the `Content-Length` header—as if it never existed.

—header=header-line

Send *header-line* along with the rest of the headers in each HTTP request. The supplied header is sent as-is, which means it must contain name and value separated by colon, and must not contain newlines.

You may define more than one additional header by specifying **—header** more than once.

```
wget --header='Accept-Charset: iso-8859-2' \
      --header='Accept-Language: hr' \
      http://fly.srk.fer.hr/
```

Specification of an empty string as the header value will clear all previous user-defined headers.

As of Wget 1.10, this option can be used to override headers otherwise generated automatically. This example instructs Wget to connect to localhost, but to specify **foo.bar** in the `Host` header:

```
wget --header="Host: foo.bar" http://localhost/
```

In versions of Wget prior to 1.10 such use of **—header** caused sending of duplicate headers.

—proxy-user=user

—proxy-password=password

Specify the username *user* and password *password* for authentication on a proxy server. Wget will encode them using the `basic` authentication scheme.

Security considerations similar to those with **—http-password** pertain here as well.

—referer=url

Include 'Referer: *url*' header in HTTP request. Useful for retrieving documents with server-side processing that assume they are always being retrieved by interactive web browsers and only come out properly when Referer is set to one of the pages that point to them.

—save-headers

Save the headers sent by the HTTP server to the file, preceding the actual contents, with an empty line as the separator.

—U agent-string

—user-agent=agent-string

Identify as *agent-string* to the HTTP server.

The HTTP protocol allows the clients to identify themselves using a `User-Agent` header field. This enables distinguishing the WWW software, usually for statistical purposes or for tracing of protocol violations. Wget normally identifies as **Wget/version**, *version* being the current version number of Wget.

However, some sites have been known to impose the policy of tailoring the output according to the `User-Agent`-supplied information. While this is not such a bad idea in theory, it has been abused by servers denying information to clients other than (historically) Netscape or, more frequently,

Microsoft Internet Explorer. This option allows you to change the `User-Agent` line issued by Wget. Use of this option is discouraged, unless you really know what you are doing.

Specifying empty user agent with `—user-agent=""` instructs Wget not to send the `User-Agent` header in HTTP requests.

—post-data=string

—post-file=file

Use POST as the method for all HTTP requests and send the specified data in the request body. `--post-data` sends *string* as data, whereas `--post-file` sends the contents of *file*. Other than that, they work in exactly the same way.

Please be aware that Wget needs to know the size of the POST data in advance. Therefore the argument to `--post-file` must be a regular file; specifying a FIFO or something like `/dev/stdin` won't work. It's not quite clear how to work around this limitation inherent in HTTP/1.0. Although HTTP/1.1 introduces *chunked* transfer that doesn't require knowing the request length in advance, a client can't use chunked unless it knows it's talking to an HTTP/1.1 server. And it can't know that until it receives a response, which in turn requires the request to have been completed — a chicken-and-egg problem.

Note: if Wget is redirected after the POST request is completed, it will not send the POST data to the redirected URL. This is because URLs that process POST often respond with a redirection to a regular page, which does not desire or accept POST. It is not completely clear that this behavior is optimal; if it doesn't work out, it might be changed in the future.

This example shows how to log to a server using POST and then proceed to download the desired pages, presumably only accessible to authorized users:

```
# Log in to the server. This can be done only once.
wget --save-cookies cookies.txt \
      --post-data 'user=foo&password=bar' \
      http://server.com/auth.php

# Now grab the page or pages we care about.
wget --load-cookies cookies.txt \
      -p http://server.com/interesting/article.php
```

If the server is using session cookies to track user authentication, the above will not work because **—save-cookies** will not save them (and neither will browsers) and the *cookies.txt* file will be empty. In that case use **—keep-session-cookies** along with **—save-cookies** to force saving of session cookies.

HTTPS (SSL/TLS) Options

To support encrypted HTTP (HTTPS) downloads, Wget must be compiled with an external SSL library, currently OpenSSL. If Wget is compiled without SSL support, none of these options are available.

—secure-protocol=protocol

Choose the secure protocol to be used. Legal values are **auto**, **SSLv2**, **SSLv3**, and **TLSv1**. If **auto** is used, the SSL library is given the liberty of choosing the appropriate protocol automatically, which is achieved by sending an SSLv2 greeting and announcing support for SSLv3 and TLSv1. This is the default.

Specifying **SSLv2**, **SSLv3**, or **TLSv1** forces the use of the corresponding protocol. This is useful when talking to old and buggy SSL server implementations that make it hard for OpenSSL to choose the correct protocol version. Fortunately, such servers are quite rare.

—no-check-certificate

Don't check the server certificate against the available certificate authorities. Also don't require the URL host name to match the common name presented by the certificate.

As of Wget 1.10, the default is to verify the server's certificate against the recognized certificate authorities, breaking the SSL handshake and aborting the download if the verification fails. Although this provides more secure downloads, it does break interoperability with some sites that worked with previous Wget versions, particularly those using self-signed, expired, or otherwise invalid certificates. This option forces an "insecure" mode of operation that turns the certificate verification errors into warnings and allows you to proceed.

If you encounter "certificate verification" errors or ones saying that "common name doesn't match requested host name", you can use this option to bypass the verification and proceed with the download. *Only use this option if you are otherwise convinced of the site's authenticity, or if you really don't care about the validity of its certificate.* It is almost always a bad idea not to check the certificates when transmitting confidential or important data.

—certificate=file

Use the client certificate stored in *file*. This is needed for servers that are configured to require certificates from the clients that connect to them. Normally a certificate is not required and this switch is optional.

—certificate-type=type

Specify the type of the client certificate. Legal values are **PEM** (assumed by default) and **DER**, also known as **ASN1**.

—private-key=file

Read the private key from *file*. This allows you to provide the private key in a file separate from the certificate.

—private-key-type=type

Specify the type of the private key. Accepted values are **PEM** (the default) and **DER**.

—ca-certificate=file

Use *file* as the file with the bundle of certificate authorities ("CA") to verify the peers. The certificates must be in PEM format.

Without this option Wget looks for CA certificates at the system-specified locations, chosen at OpenSSL installation time.

—ca-directory=directory

Specifies directory containing CA certificates in PEM format. Each file contains one CA certificate, and the file name is based on a hash value derived from the certificate. This is achieved by processing a certificate directory with the `c_rehash` utility supplied with OpenSSL. Using **—ca-directory** is more efficient than **—ca-certificate** when many certificates are installed because it allows Wget to fetch certificates on demand.

Without this option Wget looks for CA certificates at the system-specified locations, chosen at OpenSSL installation time.

—random-file=file

Use *file* as the source of random data for seeding the pseudo-random number generator on systems without `/dev/random`.

On such systems the SSL library needs an external source of randomness to initialize. Randomness may be provided by EGD (see **—egd-file** below) or read from an external source specified by the user. If this option is not specified, Wget looks for random data in `$RANDFILE` or, if that is unset, in `$HOME/.rnd`. If none of those are available, it is likely that SSL encryption will not be usable.

If you're getting the "Could not seed OpenSSL PRNG; disabling SSL." error, you should provide random data using some of the methods described above.

—egd-file=file

Use *file* as the EGD socket. EGD stands for *Entropy Gathering Daemon*, a user-space program that collects data from various unpredictable system sources and makes it available to other programs that might need it. Encryption software, such as the SSL library, needs sources of non-repeating

randomness to seed the random number generator used to produce cryptographically strong keys.

OpenSSL allows the user to specify his own source of entropy using the `RAND_FILE` environment variable. If this variable is unset, or if the specified file does not produce enough randomness, OpenSSL will read random data from EGD socket specified using this option.

If this option is not specified (and the equivalent startup command is not used), EGD is never contacted. EGD is not needed on modern Unix systems that support `/dev/random`.

FTP Options

— **ftp-user=***user*

— **ftp-password=***password*

Specify the username *user* and password *password* on an FTP server. Without this, or the corresponding startup option, the password defaults to `-wget@`, normally used for anonymous FTP.

Another way to specify username and password is in the URL itself. Either method reveals your password to anyone who bothers to run `ps`. To prevent the passwords from being seen, store them in `.wgetrc` or `.netrc`, and make sure to protect those files from other users with `chmod`. If the passwords are really important, do not leave them lying in those files either—edit the files and delete them after Wget has started the download.

— **no-remove-listing**

Don't remove the temporary `.listing` files generated by FTP retrievals. Normally, these files contain the raw directory listings received from FTP servers. Not removing them can be useful for debugging purposes, or when you want to be able to easily check on the contents of remote server directories (e.g. to verify that a mirror you're running is complete).

Note that even though Wget writes to a known filename for this file, this is not a security hole in the scenario of a user making `.listing` a symbolic link to `/etc/passwd` or something and asking `root` to run Wget in his or her directory. Depending on the options used, either Wget will refuse to write to `.listing`, making the globbing/recursion/time-stamping operation fail, or the symbolic link will be deleted and replaced with the actual `.listing` file, or the listing will be written to a `.listing.number` file.

Even though this situation isn't a problem, though, `root` should never run Wget in a non-trusted user's directory. A user could do something as simple as linking `index.html` to `/etc/passwd` and asking `root` to run Wget with `-N` or `-r` so the file will be overwritten.

— **no-glob**

Turn off FTP globbing. Globbing refers to the use of shell-like special characters (*wildcards*), like `*`, `?`, `[` and `]` to retrieve more than one file from the same directory at once, like:

```
wget ftp://gnjilux.srk.fer.hr/*.msg
```

By default, globbing will be turned on if the URL contains a globbing character. This option may be used to turn globbing on or off permanently.

You may have to quote the URL to protect it from being expanded by your shell. Globbing makes Wget look for a directory listing, which is system-specific. This is why it currently works only with Unix FTP servers (and the ones emulating Unix `ls` output).

— **no-passive-ftp**

Disable the use of the *passive* FTP transfer mode. Passive FTP mandates that the client connect to the server to establish the data connection rather than the other way around.

If the machine is connected to the Internet directly, both passive and active FTP should work equally well. Behind most firewall and NAT configurations passive FTP has a better chance of working. However, in some rare firewall configurations, active FTP actually works when passive FTP doesn't. If you suspect this to be the case, use this option, or set `passive_ftp=off` in your init file.

—retr-symlinks

Usually, when retrieving FTP directories recursively and a symbolic link is encountered, the linked-to file is not downloaded. Instead, a matching symbolic link is created on the local filesystem. The pointed-to file will not be downloaded unless this recursive retrieval would have encountered it separately and downloaded it anyway.

When **—retr-symlinks** is specified, however, symbolic links are traversed and the pointed-to files are retrieved. At this time, this option does not cause Wget to traverse symlinks to directories and recurse through them, but in the future it should be enhanced to do this.

Note that when retrieving a file (not a directory) because it was specified on the command-line, rather than because it was recursed to, this option has no effect. Symbolic links are always traversed in this case.

—no-http-keep-alive

Turn off the “keep-alive” feature for HTTP downloads. Normally, Wget asks the server to keep the connection open so that, when you download more than one document from the same server, they get transferred over the same TCP connection. This saves time and at the same time reduces the load on the server.

This option is useful when, for some reason, persistent (keep-alive) connections don’t work for you, for example due to a server bug or due to the inability of server-side scripts to cope with the connections.

Recursive Retrieval Options**—r****—recursive**

Turn on recursive retrieving.

—l *depth***—level=*depth***

Specify recursion maximum depth level *depth*. The default maximum depth is 5.

—delete-after

This option tells Wget to delete every single file it downloads, *after* having done so. It is useful for pre-fetching popular pages through a proxy, e.g.:

```
wget -r -nd --delete-after http://whatever.com/~popular/page/
```

The **—r** option is to retrieve recursively, and **—nd** to not create directories.

Note that **—delete-after** deletes files on the local machine. It does not issue the **DELE** command to remote FTP sites, for instance. Also note that when **—delete-after** is specified, **—convert-links** is ignored, so **.orig** files are simply not created in the first place.

—k**—convert-links**

After the download is complete, convert the links in the document to make them suitable for local viewing. This affects not only the visible hyperlinks, but any part of the document that links to external content, such as embedded images, links to style sheets, hyperlinks to non-HTML content, etc.

Each link will be changed in one of the two ways:

- The links to files that have been downloaded by Wget will be changed to refer to the file they point to as a relative link.

Example: if the downloaded file */foo/doc.html* links to */bar/img.gif*, also downloaded, then the link in *doc.html* will be modified to point to ***../bar/img.gif***. This kind of transformation works reliably for arbitrary combinations of directories.

- The links to files that have not been downloaded by Wget will be changed to include host name and absolute path of the location they point to.

Example: if the downloaded file */foo/doc.html* links to */bar/img.gif* (or to *../bar/img.gif*), then the link in *doc.html* will be modified to point to *http://hostname/bar/img.gif*.

Because of this, local browsing works reliably: if a linked file was downloaded, the link will refer to its local name; if it was not downloaded, the link will refer to its full Internet address rather than presenting a broken link. The fact that the former links are converted to relative links ensures that you can move the downloaded hierarchy to another directory.

Note that only at the end of the download can Wget know which links have been downloaded. Because of that, the work done by **-k** will be performed at the end of all the downloads.

-K

—backup-converted

When converting a file, back up the original version with a **.orig** suffix. Affects the behavior of **-N**.

-m

—mirror

Turn on options suitable for mirroring. This option turns on recursion and time-stamping, sets infinite recursion depth and keeps FTP directory listings. It is currently equivalent to **-r -N -l inf --no-remove-listing**.

-p

—page-requisites

This option causes Wget to download all the files that are necessary to properly display a given HTML page. This includes such things as inlined images, sounds, and referenced stylesheets.

Ordinarily, when downloading a single HTML page, any requisite documents that may be needed to display it properly are not downloaded. Using **-r** together with **-l** can help, but since Wget does not ordinarily distinguish between external and inlined documents, one is generally left with “leaf documents” that are missing their requisites.

For instance, say document *1.html* contains an **** tag referencing *1.gif* and an **<A>** tag pointing to external document *2.html*. Say that *2.html* is similar but that its image is *2.gif* and it links to *3.html*. Say this continues up to some arbitrarily high number.

If one executes the command:

```
wget -r -l 2 http://<site>/1.html
```

then *1.html*, *1.gif*, *2.html*, *2.gif*, and *3.html* will be downloaded. As you can see, *3.html* is without its requisite *3.gif* because Wget is simply counting the number of hops (up to 2) away from *1.html* in order to determine where to stop the recursion. However, with this command:

```
wget -r -l 2 -p http://<site>/1.html
```

all the above files *and* *3.html*'s requisite *3.gif* will be downloaded. Similarly,

```
wget -r -l 1 -p http://<site>/1.html
```

will cause *1.html*, *1.gif*, *2.html*, and *2.gif* to be downloaded. One might think that:

```
wget -r -l 0 -p http://<site>/1.html
```

would download just *1.html* and *1.gif*, but unfortunately this is not the case, because **-l 0** is equivalent to **-l inf**—that is, infinite recursion. To download a single HTML page (or a handful of them, all specified on the command-line or in a **-i** URL input file) and its (or their) requisites, simply leave off **-r** and **-l**:

```
wget -p http://<site>/1.html
```

Note that Wget will behave as if **-r** had been specified, but only that single page and its requisites will be downloaded. Links from that page to external documents will not be followed. Actually, to download a single page and all its requisites (even if they exist on separate websites), and make sure the lot displays properly locally, this author likes to use a few options in addition to **-p**:

```
wget -E -H -k -K -p http://<site>/<document>
```

To finish off this topic, it's worth knowing that Wget's idea of an external document link is any URL specified in an `<A>` tag, an `<AREA>` tag, or a `<LINK>` tag other than `<LINK REL="stylesheet">`.

—strict-comments

Turn on strict parsing of HTML comments. The default is to terminate comments at the first occurrence of `-->`.

According to specifications, HTML comments are expressed as SGML *declarations*. Declaration is special markup that begins with `<!--` and ends with `>`, such as `<!DOCTYPE ...>`, that may contain comments between a pair of `--` delimiters. HTML comments are “empty declarations”, SGML declarations without any non-comment text. Therefore, `<!--foo-->` is a valid comment, and so is `<!--one---two-->`, but `<!--1---2-->` is not.

On the other hand, most HTML writers don't perceive comments as anything other than text delimited with `<!--` and `-->`, which is not quite the same. For example, something like `<!------->` works as a valid comment as long as the number of dashes is a multiple of four (!). If not, the comment technically lasts until the next `--`, which may be at the other end of the document. Because of this, many popular browsers completely ignore the specification and implement what users have come to expect: comments delimited with `<!--` and `-->`.

Until version 1.9, Wget interpreted comments strictly, which resulted in missing links in many web pages that displayed fine in browsers, but had the misfortune of containing non-compliant comments. Beginning with version 1.9, Wget has joined the ranks of clients that implements “naive” comments, terminating each comment at the first occurrence of `-->`.

If, for whatever reason, you want strict comment parsing, use this option to turn it on.

Recursive Accept/Reject Options

-A *acclist* — **accept** *acclist*

-R *rejlist* — **reject** *rejlist*

Specify comma-separated lists of file name suffixes or patterns to accept or reject (@pxref{Types of Files} for more details).

-D *domain-list*

--domains=*domain-list*

Set domains to be followed. *domain-list* is a comma-separated list of domains. Note that it does *not* turn on **-H**.

--exclude-domains *domain-list*

Specify the domains that are *not* to be followed..

--follow-ftp

Follow FTP links from HTML documents. Without this option, Wget will ignore all the FTP links.

--follow-tags=*list*

Wget has an internal table of HTML tag / attribute pairs that it considers when looking for linked documents during a recursive retrieval. If a user wants only a subset of those tags to be considered, however, he or she should be specify such tags in a comma-separated *list* with this option.

—ignore-tags=*list*

This is the opposite of the **—follow-tags** option. To skip certain HTML tags when recursively looking for documents to download, specify them in a comma-separated *list*.

In the past, this option was the best bet for downloading a single page and its requisites, using a command-line like:

```
wget --ignore-tags=a,area -H -k -K -r http://<site>/<document>
```

However, the author of this option came across a page with tags like `<LINK REL="home" HREF="/ ">` and came to the realization that specifying tags to ignore was not enough. One can't just tell Wget to ignore `<LINK>`, because then stylesheets will not be downloaded. Now the best bet for downloading a single page and its requisites is the dedicated **—page-requisites** option.

-H**—span-hosts**

Enable spanning across hosts when doing recursive retrieving.

-L**—relative**

Follow relative links only. Useful for retrieving a specific home page without any distractions, not even those from the same hosts.

-I *list***—include-directories=*list***

Specify a comma-separated list of directories you wish to follow when downloading (@pxref{Directory-Based Limits} for more details.) Elements of *list* may contain wildcards.

-X *list***—exclude-directories=*list***

Specify a comma-separated list of directories you wish to exclude from download (@pxref{Directory-Based Limits} for more details.) Elements of *list* may contain wildcards.

-np**—no-parent**

Do not ever ascend to the parent directory when retrieving recursively. This is a useful option, since it guarantees that only the files *below* a certain hierarchy will be downloaded.

EXAMPLES

The examples are divided into three sections loosely based on their complexity.

Simple Usage

- Say you want to download a URL. Just type:

```
wget http://fly.srk.fer.hr/
```

- But what will happen if the connection is slow, and the file is lengthy? The connection will probably fail before the whole file is retrieved, more than once. In this case, Wget will try getting the file until it either gets the whole of it, or exceeds the default number of retries (this being 20). It is easy to change the number of tries to 45, to insure that the whole file will arrive safely:

```
wget --tries=45 http://fly.srk.fer.hr/jpg/flyweb.jpg
```

- Now let's leave Wget to work in the background, and write its progress to log file *log*. It is tiring to type **—tries**, so we shall use **-t**.

```
wget -t 45 -o log http://fly.srk.fer.hr/jpg/flyweb.jpg &
```

The ampersand at the end of the line makes sure that Wget works in the background. To unlimited the number of retries, use **-t inf**.

- The usage of FTP is as simple. Wget will take care of login and password.

```
wget ftp://gnjilux.srk.fer.hr/welcome.msg
```

- If you specify a directory, Wget will retrieve the directory listing, parse it and convert it to HTML. Try:

```
wget ftp://ftp.gnu.org/pub/gnu/
links index.html
```

Advanced Usage

- You have a file that contains the URLs you want to download? Use the **-i** switch:

```
wget -i <file>
```

If you specify - as file name, the URLs will be read from standard input.

- Create a five levels deep mirror image of the GNU web site, with the same directory structure the original has, with only one try per document, saving the log of the activities to *gnulog*:

```
wget -r http://www.gnu.org/ -o gnulog
```

- The same as the above, but convert the links in the HTML files to point to local files, so you can view the documents off-line:

```
wget --convert-links -r http://www.gnu.org/ -o gnulog
```

- Retrieve only one HTML page, but make sure that all the elements needed for the page to be displayed, such as inline images and external style sheets, are also downloaded. Also make sure the downloaded page references the downloaded links.

```
wget -p --convert-links http://www.server.com/dir/page.html
```

The HTML page will be saved to *www.server.com/dir/page.html*, and the images, stylesheets, etc., somewhere under *www.server.com/*, depending on where they were on the remote server.

- The same as the above, but without the *www.server.com/* directory. In fact, I don't want to have all those random server directories anyway---just save *all* those files under a *download/* subdirectory of the current directory.

```
wget -p --convert-links -nH -nd -Pdownload \
http://www.server.com/dir/page.html
```

- Retrieve the index.html of **www.lycos.com**, showing the original server headers:

```
wget -S http://www.lycos.com/
```

- Save the server headers with the file, perhaps for post-processing.

```
wget --save-headers http://www.lycos.com/
more index.html
```

- Retrieve the first two levels of **wuarchive.wustl.edu**, saving them to */tmp*.

```
wget -r -l2 -P/tmp ftp://wuarchive.wustl.edu/
```

- You want to download all the GIFs from a directory on an HTTP server. You tried **wget http://www.server.com/dir/*.gif**, but that didn't work because HTTP retrieval does not support globbing. In that case, use:

```
wget -r -l1 --no-parent -A.gif http://www.server.com/dir/
```

More verbose, but the effect is the same. **-r -l1** means to retrieve recursively, with maximum depth of 1. **--no-parent** means that references to the parent directory are ignored, and **-A.gif** means to download only the GIF files. **-A "*.gif"** would have worked too.

- Suppose you were in the middle of downloading, when Wget was interrupted. Now you do not want to clobber the files already present. It would be:

```
wget -nc -r http://www.gnu.org/
```

- If you want to encode your own username and password to HTTP or FTP, use the appropriate URL syntax.

```
wget ftp://hnksic:mypassword@unix.server.com/.emacs
```

Note, however, that this usage is not advisable on multi-user systems because it reveals your password to anyone who looks at the output of `ps`.

- You would like the output documents to go to standard output instead of to files?

```
wget -O - http://jagor.srce.hr/ http://www.srce.hr/
```

You can also combine the two options and make pipelines to retrieve the documents from remote hotlists:

```
wget -O - http://cool.list.com/ | wget --force-html -i -
```

Very Advanced Usage

- If you wish Wget to keep a mirror of a page (or FTP subdirectories), use **--mirror (-m)**, which is the shorthand for **-r -l inf -N**. You can put Wget in the crontab file asking it to recheck a site each Sunday:

```
crontab
0 0 * * 0 wget --mirror http://www.gnu.org/ -o /home/me/weeklog
```

- In addition to the above, you want the links to be converted for local viewing. But, after having read this manual, you know that link conversion doesn't play well with timestamping, so you also want Wget to back up the original HTML files before the conversion. Wget invocation would look like this:

```
wget --mirror --convert-links --backup-converted \
http://www.gnu.org/ -o /home/me/weeklog
```

- But you've also noticed that local viewing doesn't work all that well when HTML files are saved under extensions other than **.html**, perhaps because they were served as *index.cgi*. So you'd like Wget to rename all the files served with content-type **text/html** or **application/xhtml+xml** to *name.html*.

```
wget --mirror --convert-links --backup-converted \
    --html-extension -o /home/me/weeklog \
    http://www.gnu.org/
```

Or, with less typing:

```
wget -m -k -K -E http://www.gnu.org/ -o /home/me/weeklog
```

FILES

/usr/local/etc/wgetrc

Default location of the *global* startup file.

.wgetrc

User startup file.

BUGS

You are welcome to send bug reports about GNU Wget to **<bug-wget@gnu.org>**.

Before actually submitting a bug report, please try to follow a few simple guidelines.

1. Please try to ascertain that the behavior you see really is a bug. If Wget crashes, it's a bug. If Wget does not behave as documented, it's a bug. If things work strange, but you are not sure about the way they are supposed to work, it might well be a bug.
2. Try to repeat the bug in as simple circumstances as possible. E.g. if Wget crashes while downloading **wget -r10 -kKE -t5 -Y0 http://yoyodyne.com -o /tmp/log**, you should try to see if the crash is repeatable, and if will occur with a simpler set of options. You might even try to start the download at the page where the crash occurred to see if that page somehow triggered the crash.

Also, while I will probably be interested to know the contents of your *.wgetrc* file, just dumping it into the debug message is probably a bad idea. Instead, you should first try to see if the bug repeats with *.wgetrc* moved out of the way. Only if it turns out that *.wgetrc* settings affect the bug, mail me the relevant parts of the file.

3. Please start Wget with **-d** option and send us the resulting output (or relevant parts thereof). If Wget was compiled without debug support, recompile it—it is *much* easier to trace bugs with debug support on.

Note: please make sure to remove any potentially sensitive information from the debug log before sending it to the bug address. The **-d** won't go out of its way to collect sensitive information, but the log *will* contain a fairly complete transcript of Wget's communication with the server, which may include passwords and pieces of downloaded data. Since the bug address is publically archived, you may assume that all bug reports are visible to the public.

4. If Wget has crashed, try to run it in a debugger, e.g. `gdb `which wget` core` and type `where` to get the backtrace. This may not work if the system administrator has disabled core files, but it is safe to try.

NAME

whatis – search the whatis database for complete words

SYNOPSIS

edrc/bin/whatis *keyword* ...

AVAILABILITY

WA2L/edrc

DESCRIPTION

whatis searches a set of database files containing short descriptions of system commands for keywords and displays the result on the standard output. Only complete word matches are displayed.

OPTIONS

keyword keyword to be searched.

FILES

whatis whatis databases in the \$MANPATH.

SEE ALSO

edrcintro(1), **apropos(1)**, **edrcman(1)**, **man(1)**

NOTES

Parts of this manpage were extracted from the documentation of the whatis man page written by John W. Eaton and modified to fit into WA2L/edrc package.

BUGS

-

AUTHOR

whatis was developed by John W. Eaton, <jwe@che.utexas.edu>, Department of Chemical Engineering, The University of Texas at Austin, Austin Texas 78712 and integrated into WA2L/edrc by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net .

NAME

whereami – print server environment/system information

SYNOPSIS

edrc/bin/whereami [**-h**]

whereami [**-l**] [**-u** *username*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

print the server environment name and the name of the related customer where logged on.

In addition the structured user definition information of the current user can be printed.

This command is intended for interactive human information. Basically to display where logged on. To compute this information in other scripts, use the **server_environment**(3) and/or the **user_info**(3) command.

OPTIONS

-h usage message.

-l long output. The long output extends the normal output with the user account information details.

-u *username*
name of the user account whose detail information should be printed if the information of a user account that differs from the user that executes the **whereami** command.

ENVIRONMENT

-

EXIT STATUS

0 no error.

2 operating system is not supported, yet. See **osid**(3) if you get this error.

4 usage printed.

FILES

-

EXAMPLES

1) common usage

The following output is returned when logged on to a system that is used as part of the *PRODUCTION* environment for the customer *ACME*.

```
[ / ]  
[ jdoe@acme001 ][bash]: whereami
```

LOGGED ON TO SERVER ENVIRONMENT:

| | |
|-------------|--------------------------------------|
| Customer | : ACME |
| Environment | : PRODUCTION |
| Description | : ACME Corp. Production, Switzerland |

NAME

whoisin – list users that are logged in to remote systems

SYNOPSIS

edrc/bin/whoisin [**-h**] [*hostlist*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

print a list of users who are logged in on certain (remote) hosts.

The connect to the remote systems is performed using **ssh-exec** internally; the resolution of logged on users is done using **who**(1).

OPTIONS

-h usage message.

hostlist list of hosts to list the users.

The *hostlist* may contain *@HOSTGRPS* and normal *hostnames*.

If no *hostlist* is defined, the hosts to check are read from the **etc/whoisin.list** file.

ENVIRONMENT

-

EXIT STATUS

4 usage printed.

0 no error.

FILES

edrc/etc/whoisin.list

list of hosts to be checked when no *hostlist* is specified on the command line.

EXAMPLES

-

SEE ALSO

edrcintro(1), **hostlist(3)**, **resolve_targetlist(3)**, **ssh-exec(1)**, **who(1)**, **whoisin.list(4)**

NAME

whoisin.list – host list definition for whoisin

SYNOPSIS

edrc/etc/whoisin.list

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the target host definition for the **whoisin** command.

FILEFORMAT

The fileformat is a plain list of hostnames and hostgroups.

Rows starting with a **#** are considered as comments. Empty lines are allowed, too.

OPTIONS

-

EXAMPLES

```
#
# whoisin.list - configuration file for whoisin
#
# [00] 06.01.2000 CWa Initial Version
#

acme-004 acme-005 acme-006 @ACME.APPS
lab-001 lab-003 @TEST
```

SEE ALSO

edrcintro(1), **hostlist(4)**, **resolve_targetlist(3)**, **whoisin(1)**

NOTES

The entries specified in this configuration file are resolved by **resolve_targetlist(3)**.

BUGS

NAME

winexe – Winexe is a Remote Windows–command executor

SYNOPSIS

```
winexe [-h] [-V] [-U [DOMAIN/]USERNAME[%PASSWORD]] [-A FILE] [-N] [-k]
      [-d DEBUGLEVEL] [--uninstall] [--reinstall] [--runas [DOMAIN/]USERNAME[%PASSWORD]]
      [--runas-file FILE] [--interactive [0|1]] [--ostype [0|1]]
```

DESCRIPTION

This tool is part of the **samba**(7) suite.

The winexe allows remote command execution on native Windows operating systems.

OPTIONS

-?|--help
Print a summary of command line options.

-V|--version
Prints the program version number.

-U|--user=username[%password]
Sets the SMB username or username and password.

If %password is not specified, the user will be prompted. The client will first check the **USER** environment variable, then the **LOGNAME** variable and if either exists, the string is uppercased. If these environmental variables are not found, the username **GUEST** is used.

A third option is to use a credentials file which contains the plaintext of the username and password. This option is mainly provided for scripts where the admin does not wish to pass the credentials on the command line or via environment variables. If this method is used, make certain that the permissions on the file restrict access from unwanted users. See the **-A** for more details.

Be cautious about including passwords in scripts. Also, on many systems the command line of a running process may be seen via the ps command. To be safe always allow rpcclient to prompt for a password and type it in directly.

-A|--authentication-file=filename
This option allows you to specify a file from which to read the username and password used in the connection. The format of the file is

```
username = <value>
password = <value>
domain   = <value>
```

Make certain that the permissions on the file restrict access from unwanted users.

-N|--no-pass
If specified, this parameter suppresses the normal password prompt from the client to the user. This is useful when accessing a service that does not require a password.

Unless a password is specified on the command line or this parameter is specified, the client will request a password.

If a password is specified on the command line and this option is also defined the password on the command line will be silently ignored and no password will be used.

-k|--kerberos
Try to authenticate with kerberos. Only useful in an Active Directory environment.

-d|--debuglevel=level

level is an integer from 0 to 10. The default value if this parameter is not specified is 1.

The higher this value, the more detail will be logged to the log files about the activities of the server. At level 0, only critical errors and serious warnings will be logged. Level 1 is a reasonable level for day-to-day running – it generates a small amount of information about operations carried out.

Levels above 1 will generate considerable amounts of log data, and should only be used when investigating a problem. Levels above 3 are designed for use only by developers and generate HUGE amounts of log data, most of which is extremely cryptic.

Note that specifying this parameter here will override the **log level** parameter in the smb.conf file.

--uninstall

Uninstall winexe service after remote execution.

--reinstall

Reinstall winexe service before remote execution.

--runas [DOMAIN/]USERNAME[%PASSWORD]]

Run as the given user (BEWARE: this password is sent in cleartext over the network!)

--runas-file FILE

Run as user options defined in a file.

--interactive [0|1]

Desktop interaction.

There are two options:

- 0 – disallow
- 1 – allow. If allow, also use the **---system** switch (Windows requirement). Vista does not support this option.

--ostype [0|1|2]

Determines which version (32-bit or 64-bit) of service will be installed.

There are three options:

- 0 – 32-bit
- 1 – 64-bit
- 2 – winexe will decide

EXIT STATUS

The winexe program returns 0 if the operation succeeded, or 1 if the operation failed.

VERSION

This man page is part of version 4.13.2 of the Samba suite.

AUTHOR

The original Samba software and related utilities were created by Andrew Tridgell. Samba is now developed by the Samba Team as an Open Source project similar to the way the Linux kernel is developed.

The winexe and its native Windows counterpart were written by Andrzej Hajda. The Samba client tool winexe was later rewritten by Volker Lendecke.

This manpage was written by Guenther Deschner.

[ --leak-report-full ] [ -R | --name-resolve NAME-RESOLVE-ORDER ] [ -O | --socket-options SOCKETOPTIONS ]
[ -n | --netbiosname name NETBIOSNAME ] [ -W | --workgroup WORKGROUP ]
[ --realm=REALM ] [ -i | --scope SCOPE ] [ -m | --maxprotocol MAXPROTOCOL ] [ -U | --user [DOMAIN]USERNAME[%PASSWORD] ]
[ -N | --no-pass ] [ --password=STRING ] [ -A | --authentication-file FILE ] [ -S | --signing on|off|required ] [ -P | --machine-pass ] [ --simple-bind-dn=STRING ]
[ -k | --kerberos STRING ] [ --use-security-mechanisms=STRING ] [ -V | --version ] [ --namespace=STRING ] //host query
```

EXAMPLE

Example: wmic -U [domain/]adminuser%password //host "select * from Win32_ComputerSystem"

DESCRIPTION

--namespace=STRING

WMI namespace, default to root\cimv2

Help options:

-?, --help

Show this help message

--usage

Display brief usage message

Common samba options:

-d, --debuglevel=DEBUGLEVEL

Set debug level

--debug-stderr

Send debug output to STDERR

-s, --configfile=CONFIGFILE

Use alternative configuration file

--option=name=value

Set smb.conf option from command line

-l, --log-basename=LOGFILEBASE

Basename for log/debug files

--leak-report

enable talloc leak reporting on exit

--leak-report-full

enable full talloc leak reporting on exit

Connection options:

-R, --name-resolve=NAME-RESOLVE-ORDER

Use these name resolution services only

-O, --socket-options=SOCKETOPTIONS

socket options to use

-n, --netbiosname=NETBIOSNAME

Primary netbios name

-W, --workgroup=WORKGROUP

Set the workgroup name

- realm=REALM**
Set the realm name
- i, --scope=SCOPE**
Use this Netbios scope
- m, --maxprotocol=MAXPROTOCOL**
Set max protocol level

Authentication options:

- U, --user=[DOMAIN]USERNAME[%PASSWORD]**
Set the network username
- N, --no-pass**
Don't ask for a password
- password=STRING**
Password
- A, --authentication-file=FILE**
Get the credentials from a file
- S, --signing=on|off|required**
Set the client signing state
- P, --machine-pass**
Use stored machine account password (implies **-k**)
- simple-bind-dn=STRING**
DN to use for a simple bind
- k, --kerberos=STRING**
Use Kerberos
- use-security-mechanisms=STRING**
Restricted list of authentication mechanisms available for use with this authentication

Common samba options:

- V, --version**
Print version

EXAMPLE

```
wmic -U [domain/]adminuser%password //host "select * from Win32_ComputerSystem"
```

NAME

woist – Search a Path For a File

SYNOPSIS

edrc/bin/woist [**-a**] [**-xdfhrs**] [**-p** *directory-list*] *file*

AVAILABILITY

WA2L/edrc

DESCRIPTION

does what whereis should have done. It examines a list of directories and looks for a file whose attributes match the corresponding arguments. The default is to look on \$PATH for executable files, but any of the standard arguments to **test** may be given, so that it is possible to look for a readable file, a writable file, or a non-empty file on any arbitrary path. If the file is found in one of directories in the path, the files path is printed to stdout.

If the file name contains a slash ("/"), the directory-list is ignored. The specified file is checked according to the conditions; if it exists and matches, its path is printed to stdout.

OPTIONS

-a All - list all instances found in all directories on the path. Otherwise only print the first one found.

-dfhrsx **test** argument. Only one may be specified. Options are:

-d Directory

-f Existing File of Any Type

-h Symbolic Link

-r Readable file

-s Non-Empty File

-w Writable File

-x Executable File (default)

-p '*directory-list*'

List of directories to examine. Default is \$PATH, but any colon separated list of directories may be used. The list is echoed by csh(1), to ensure that tilde-username in a directory have been properly resolved.

file File to be found.

EXIT STATUS

| | |
|----------|--------------------------------|
| 0 | file found |
| 1 | error |
| 4 | usage listed or file not found |

NAME

xlog – write stdin to log with a timestamp

SYNOPSIS

edrc/bin/xlog [**-h**]

xlog [**-t tag**] **-f logfile**

AVAILABILITY

WA2L/edrc

DESCRIPTION

write data from **stdin** to a *logfile*.

Each line is preceded with a date, time, sequence and tag entry.

A common use might be in crontab instead of piping outputs to **/dev/null**.

Example:

```
a_command 2>&1 | xlog -t a_cmd -f /var/adm/log/a_command.log
```

OPTIONS

-h usage message.

-t tag tag to be added to the log file.

-f logfile log file name.

ENVIRONMENT

-

EXIT STATUS

0 no error.

1 cannot write to *logfile*.

2 operating system not supported.

4 usage printed.

NAME**SYNOPSIS**

edrc/lib/xml2csv [**-h**]

xml2csv [{ **-l** *fieldname* | **-k** *fieldlist* | **-i** *fieldlist* | **-e** *emptydata* | **-s** *separator* }] (*sourcefile* | *URL*) *destinationfile*

AVAILABILITY

WA2L/edrc

DESCRIPTION

Command line XML to CSV converter.

xml2csv is command line tool for converting data from XML schema to CSV. The tool has many command line options. The software is platform independent and was written in Java language.

Features:

- Converts XML schema to CSV file
- Can deal with filenames and urls
- Automatically detects loops (repeated elements) in XML used for splitting data to rows
- Allows to override name of the loop/repeated field
- Allows to keep only specific tags/fields
- Allows to ignore specific tags/fields
- Allows to set values for empty data and CSV separator
- Supports distinct option
- Platform Independent

OPTIONS

-h usage message.

-l *fieldname* set the name of the field that repeats in XML schema.

-k *fieldlist* comma separated list of fields to be kept.

-i *fieldlist* comma separated list of fields to be ignored.

-e *emptydata* data to be used for empty fields.

-s *separator*
field separator in **CSV** file.

sourcefile | *URL*
file or url to read the **XML** data from.

destinationfile
CSV file to write the data to.

ENVIRONMENT

-

EXIT STATUS

0 always.

FILES

-

EXAMPLES

Example usage of the **xml2csv** command:

```
xml2csv -l field -i city,country -d -s "," data.xml data.csv
xml2csv -k "name, surname" data.xml data.csv
xml2csv http://www.example.com/data.xml data.csv
xml2csv data.xml data.csv
```

NAME

xpid – select proccmd from process list (enhanced ps -ef | grep pattern)

SYNOPSIS

edrc/bin/xpid [*proccmd-pattern*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

select processes from the process command part of the process list.

This is a convenience command to the **pslist**(1) command.

Internally the **xpid** command calls currently **pslist -l -c '.*selection.*'** .

The **xpid** command is intended for manual command line use only, for script use the **pslist** command should be used because the output of the **xpid** command is not intended for further processing and might be changed.

OPTIONS

proccmd-pattern

regular expression to select only from the proccmd column of the process list.

ENVIRONMENT

-

EXIT STATUS

x exit status of **pslist**.

FILES

-

EXAMPLES

-

NAME

xtee – tee with timestamp output to file

SYNOPSIS

edrc/bin/xtee

xtee *file*

AVAILABILITY

WA2L/edrc

DESCRIPTION

xtee(1) an enhanced version of the standard **tee** command.

This one appends the standard output with extra data and session columns to the logfile.

OPTIONS

usage message.

file file to append the data received thru **stdin**.

ENVIRONMENT

-

EXIT STATUS

4 usage printed.

0 no error.

FILES

-

EXAMPLES

-

SEE ALSO

edrcintro(1), **edrc(1m)**, **tscat(1)**, **tee(1)**

NOTES

-

BUGS

The **xtee(1)** command causes a SIGSEGV signal on HP-UX 11.00 in some circumstances. Therefore it is currently not used in the **edrc** command. To save the output to the logfiles **tee(1)** is used as long as this issue is not resolved completely. On Linux and Solaris this behavior was not discovered so far.

NAME

xz, **unxz**, **xzcat**, **lzma**, **unlzma**, **lzcat** – Compress or decompress **.xz** and **.lzma** files

SYNOPSIS

xz [*option...*] [*file...*]

COMMAND ALIASES

unxz is equivalent to **xz --decompress**.

xzcat is equivalent to **xz --decompress --stdout**.

lzma is equivalent to **xz --format=lzma**.

unlzma is equivalent to **xz --format=lzma --decompress**.

lzcat is equivalent to **xz --format=lzma --decompress --stdout**.

When writing scripts that need to decompress files, it is recommended to always use the name **xz** with appropriate arguments (**xz -d** or **xz -dc**) instead of the names **unxz** and **xzcat**.

DESCRIPTION

xz is a general-purpose data compression tool with command line syntax similar to **gzip(1)** and **bzip2(1)**. The native file format is the **.xz** format, but the legacy **.lzma** format used by LZMA Utils and raw compressed streams with no container format headers are also supported.

xz compresses or decompresses each *file* according to the selected operation mode. If no *files* are given or *file* is **-**, **xz** reads from standard input and writes the processed data to standard output. **xz** will refuse (display an error and skip the *file*) to write compressed data to standard output if it is a terminal. Similarly, **xz** will refuse to read compressed data from standard input if it is a terminal.

Unless **--stdout** is specified, *files* other than **-** are written to a new file whose name is derived from the source *file* name:

- When compressing, the suffix of the target file format (**.xz** or **.lzma**) is appended to the source filename to get the target filename.
- When decompressing, the **.xz** or **.lzma** suffix is removed from the filename to get the target filename. **xz** also recognizes the suffixes **.txz** and **.tlz**, and replaces them with the **.tar** suffix.

If the target file already exists, an error is displayed and the *file* is skipped.

Unless writing to standard output, **xz** will display a warning and skip the *file* if any of the following applies:

- *File* is not a regular file. Symbolic links are not followed, and thus they are not considered to be regular files.
- *File* has more than one hard link.
- *File* has **setuid**, **setgid**, or sticky bit set.
- The operation mode is set to compress and the *file* already has a suffix of the target file format (**.xz** or **.txz** when compressing to the **.xz** format, and **.lzma** or **.tlz** when compressing to the **.lzma** format).
- The operation mode is set to decompress and the *file* doesn't have a suffix of any of the supported file formats (**.xz**, **.txz**, **.lzma**, or **.tlz**).

After successfully compressing or decompressing the *file*, **xz** copies the owner, group, permissions, access time, and modification time from the source *file* to the target file. If copying the group fails, the permissions are modified so that the target file doesn't become accessible to users who didn't have permission to access the source *file*. **xz** doesn't support copying other metadata like access control lists or extended attributes yet.

Once the target file has been successfully closed, the source *file* is removed unless **--keep** was specified. The source *file* is never removed if the output is written to standard output.

Sending **SIGINFO** or **SIGUSR1** to the **xz** process makes it print progress information to standard error. This has only limited use since when standard error is a terminal, using **--verbose** will display an automatically updating progress indicator.

Memory usage

The memory usage of **xz** varies from a few hundred kilobytes to several gigabytes depending on the compression settings. The settings used when compressing a file determine the memory requirements of the decompressor. Typically the decompressor needs 5 % to 20 % of the amount of memory that the compressor needed when creating the file. For example, decompressing a file created with **xz -9** currently requires 65 MiB of memory. Still, it is possible to have **.xz** files that require several gigabytes of memory to decompress.

Especially users of older systems may find the possibility of very large memory usage annoying. To prevent uncomfortable surprises, **xz** has a built-in memory usage limiter, which is disabled by default. While some operating systems provide ways to limit the memory usage of processes, relying on it wasn't deemed to be flexible enough (e.g. using **ulimit(1)** to limit virtual memory tends to cripple **mmap(2)**).

The memory usage limiter can be enabled with the command line option **--memlimit=limit**. Often it is more convenient to enable the limiter by default by setting the environment variable **XZ_DEFAULTS**, e.g. **XZ_DEFAULTS=--memlimit=150MiB**. It is possible to set the limits separately for compression and decompression by using **--memlimit-compress=limit** and **--memlimit-decompress=limit**. Using these two options outside **XZ_DEFAULTS** is rarely useful because a single run of **xz** cannot do both compression and decompression and **--memlimit=limit** (or **-M limit**) is shorter to type on the command line.

If the specified memory usage limit is exceeded when decompressing, **xz** will display an error and decompressing the file will fail. If the limit is exceeded when compressing, **xz** will try to scale the settings down so that the limit is no longer exceeded (except when using **--format=raw** or **--no-adjust**). This way the operation won't fail unless the limit is very small. The scaling of the settings is done in steps that don't match the compression level presets, e.g. if the limit is only slightly less than the amount required for **xz -9**, the settings will be scaled down only a little, not all the way down to **xz -8**.

Concatenation and padding with .xz files

It is possible to concatenate **.xz** files as is. **xz** will decompress such files as if they were a single **.xz** file.

It is possible to insert padding between the concatenated parts or after the last part. The padding must consist of null bytes and the size of the padding must be a multiple of four bytes. This can be useful e.g. if the **.xz** file is stored on a medium that measures file sizes in 512-byte blocks.

Concatenation and padding are not allowed with **.lzma** files or raw streams.

OPTIONS

Integer suffixes and special values

In most places where an integer argument is expected, an optional suffix is supported to easily indicate large integers. There must be no space between the integer and the suffix.

KiB Multiply the integer by 1,024 (2^{10}). **Ki**, **k**, **kB**, **K**, and **KB** are accepted as synonyms for **KiB**.

MiB Multiply the integer by 1,048,576 (2^{20}). **Mi**, **m**, **M**, and **MB** are accepted as synonyms for **MiB**.

GiB Multiply the integer by 1,073,741,824 (2^{30}). **Gi**, **g**, **G**, and **GB** are accepted as synonyms for **GiB**.

The special value **max** can be used to indicate the maximum integer value supported by the option.

Operation mode

If multiple operation mode options are given, the last one takes effect.

-z, --compress

Compress. This is the default operation mode when no operation mode option is specified and no other operation mode is implied from the command name (for example, **unxz** implies **--decompress**).

-d, --decompress, --uncompress

Decompress.

-t, --test

Test the integrity of compressed *files*. This option is equivalent to **--decompress --stdout** except that the decompressed data is discarded instead of being written to standard output. No files are created or removed.

-l, --list

Print information about compressed *files*. No uncompressed output is produced, and no files are created or removed. In list mode, the program cannot read the compressed data from standard input or from other unseekable sources.

The default listing shows basic information about *files*, one file per line. To get more detailed information, use also the **--verbose** option. For even more information, use **--verbose** twice, but note that this may be slow, because getting all the extra information requires many seeks. The width of verbose output exceeds 80 characters, so piping the output to e.g. **less -S** may be convenient if the terminal isn't wide enough.

The exact output may vary between **xz** versions and different locales. For machine-readable output, **--robot --list** should be used.

Operation modifiers**-k, --keep**

Don't delete the input files.

-f, --force

This option has several effects:

- If the target file already exists, delete it before compressing or decompressing.
- Compress or decompress even if the input is a symbolic link to a regular file, has more than one hard link, or has the setuid, setgid, or sticky bit set. The setuid, setgid, and sticky bits are not copied to the target file.
- When used with **--decompress --stdout** and **xz** cannot recognize the type of the source file, copy the source file as is to standard output. This allows **xzcat --force** to be used like **cat(1)** for files that have not been compressed with **xz**. Note that in future, **xz** might support new compressed file formats, which may make **xz** decompress more types of files instead of copying them as is to standard output. **--format=format** can be used to restrict **xz** to decompress only a single file format.

-c, --stdout, --to-stdout

Write the compressed or decompressed data to standard output instead of a file. This implies **--keep**.

--single-stream

Decompress only the first **.xz** stream, and silently ignore possible remaining input data following the stream. Normally such trailing garbage makes **xz** display an error.

xz never decompresses more than one stream from **.lzma** files or raw streams, but this option still makes **xz** ignore the possible trailing data after the **.lzma** file or raw stream.

This option has no effect if the operation mode is not **--decompress** or **--test**.

--no-sparse

Disable creation of sparse files. By default, if decompressing into a regular file, **xz** tries to make the file sparse if the decompressed data contains long sequences of binary zeros. It also works when writing to standard output as long as standard output is connected to a regular file and certain additional conditions are met to make it safe. Creating sparse files may save disk space and speed up the decompression by reducing the amount of disk I/O.

-S .suf, --suffix=.suf

When compressing, use *.suf* as the suffix for the target file instead of **.xz** or **.lzma**. If not writing to standard output and the source file already has the suffix *.suf*, a warning is displayed and the file is skipped.

When decompressing, recognize files with the suffix *.suf* in addition to files with the **.xz**, **.txz**, **.lzma**, or **.tlz** suffix. If the source file has the suffix *.suf*, the suffix is removed to get the target filename.

When compressing or decompressing raw streams (**--format=raw**), the suffix must always be specified unless writing to standard output, because there is no default suffix for raw streams.

--files[=*file*]

Read the filenames to process from *file*; if *file* is omitted, filenames are read from standard input. Filenames must be terminated with the newline character. A dash (-) is taken as a regular filename; it doesn't mean standard input. If filenames are given also as command line arguments, they are processed before the filenames read from *file*.

--files0[=*file*]

This is identical to **--files[=*file*]** except that each filename must be terminated with the null character.

Basic file format and compression options

-F *format*, --format=*format*

Specify the file *format* to compress or decompress:

auto This is the default. When compressing, **auto** is equivalent to **xz**. When decompressing, the format of the input file is automatically detected. Note that raw streams (created with **--format=raw**) cannot be auto-detected.

xz Compress to the **.xz** file format, or accept only **.xz** files when decompressing.

lzma, alone

Compress to the legacy **.lzma** file format, or accept only **.lzma** files when decompressing. The alternative name **alone** is provided for backwards compatibility with LZMA Utils.

raw Compress or uncompress a raw stream (no headers). This is meant for advanced users only. To decode raw streams, you need use **--format=raw** and explicitly specify the filter chain, which normally would have been stored in the container headers.

-C *check*, --check=*check*

Specify the type of the integrity check. The check is calculated from the uncompressed data and stored in the **.xz** file. This option has an effect only when compressing into the **.xz** format; the **.lzma** format doesn't support integrity checks. The integrity check (if any) is verified when the **.xz** file is decompressed.

Supported *check* types:

none Don't calculate an integrity check at all. This is usually a bad idea. This can be useful when integrity of the data is verified by other means anyway.

crc32 Calculate CRC32 using the polynomial from IEEE-802.3 (Ethernet).

crc64 Calculate CRC64 using the polynomial from ECMA-182. This is the default, since it is slightly better than CRC32 at detecting damaged files and the speed difference is negligible.

sha256 Calculate SHA-256. This is somewhat slower than CRC32 and CRC64.

Integrity of the **.xz** headers is always verified with CRC32. It is not possible to change or disable it.

--ignore-check

Don't verify the integrity check of the compressed data when decompressing. The CRC32 values in the **.xz** headers will still be verified normally.

Do not use this option unless you know what you are doing. Possible reasons to use this option:

- Trying to recover data from a corrupt .xz file.
- Speeding up decompression. This matters mostly with SHA-256 or with files that have compressed extremely well. It's recommended to not use this option for this purpose unless the file integrity is verified externally in some other way.

-0 ... -9

Select a compression preset level. The default is **-6**. If multiple preset levels are specified, the last one takes effect. If a custom filter chain was already specified, setting a compression preset level clears the custom filter chain.

The differences between the presets are more significant than with **gzip(1)** and **bzip2(1)**. The selected compression settings determine the memory requirements of the decompressor, thus using a too high preset level might make it painful to decompress the file on an old system with little RAM. Specifically, **it's not a good idea to blindly use -9 for everything** like it often is with **gzip(1)** and **bzip2(1)**.

-0 ... -3

These are somewhat fast presets. **-0** is sometimes faster than **gzip -9** while compressing much better. The higher ones often have speed comparable to **bzip2(1)** with comparable or better compression ratio, although the results depend a lot on the type of data being compressed.

-4 ... -6

Good to very good compression while keeping decompressor memory usage reasonable even for old systems. **-6** is the default, which is usually a good choice e.g. for distributing files that need to be decompressible even on systems with only 16 MiB RAM. (**-5e** or **-6e** may be worth considering too. See **--extreme**.)

-7 ... -9

These are like **-6** but with higher compressor and decompressor memory requirements. These are useful only when compressing files bigger than 8 MiB, 16 MiB, and 32 MiB, respectively.

On the same hardware, the decompression speed is approximately a constant number of bytes of compressed data per second. In other words, the better the compression, the faster the decompression will usually be. This also means that the amount of uncompressed output produced per second can vary a lot.

The following table summarises the features of the presets:

| Preset | DictSize | CompCPU | CompMem | DecMem |
|--------|----------|---------|---------|--------|
| -0 | 256 KiB | 0 | 3 MiB | 1 MiB |
| -1 | 1 MiB | 1 | 9 MiB | 2 MiB |
| -2 | 2 MiB | 2 | 17 MiB | 3 MiB |
| -3 | 4 MiB | 3 | 32 MiB | 5 MiB |
| -4 | 4 MiB | 4 | 48 MiB | 5 MiB |
| -5 | 8 MiB | 5 | 94 MiB | 9 MiB |
| -6 | 8 MiB | 6 | 94 MiB | 9 MiB |
| -7 | 16 MiB | 6 | 186 MiB | 17 MiB |
| -8 | 32 MiB | 6 | 370 MiB | 33 MiB |
| -9 | 64 MiB | 6 | 674 MiB | 65 MiB |

Column descriptions:

- DictSize is the LZMA2 dictionary size. It is waste of memory to use a dictionary bigger than the size of the uncompressed file. This is why it is good to avoid using the presets **-7 ... -9** when there's no real need for them. At **-6** and lower, the amount of memory wasted is usually low enough to not matter.
- CompCPU is a simplified representation of the LZMA2 settings that affect compression speed. The dictionary size affects speed too, so while CompCPU is the same for levels **-6 ... -9**,

higher levels still tend to be a little slower. To get even slower and thus possibly better compression, see **--extreme**.

- CompMem contains the compressor memory requirements in the single-threaded mode. It may vary slightly between **xz** versions. Memory requirements of some of the future multi-threaded modes may be dramatically higher than that of the single-threaded mode.
- DecMem contains the decompressor memory requirements. That is, the compression settings determine the memory requirements of the decompressor. The exact decompressor memory usage is slightly more than the LZMA2 dictionary size, but the values in the table have been rounded up to the next full MiB.

-e, --extreme

Use a slower variant of the selected compression preset level (**-0 ... -9**) to hopefully get a little bit better compression ratio, but with bad luck this can also make it worse. Decompressor memory usage is not affected, but compressor memory usage increases a little at preset levels **-0 ... -3**.

Since there are two presets with dictionary sizes 4 MiB and 8 MiB, the presets **-3e** and **-5e** use slightly faster settings (lower CompCPU) than **-4e** and **-6e**, respectively. That way no two presets are identical.

| Preset | DictSize | CompCPU | CompMem | DecMem |
|------------|----------|---------|---------|--------|
| -0e | 256 KiB | 8 | 4 MiB | 1 MiB |
| -1e | 1 MiB | 8 | 13 MiB | 2 MiB |
| -2e | 2 MiB | 8 | 25 MiB | 3 MiB |
| -3e | 4 MiB | 7 | 48 MiB | 5 MiB |
| -4e | 4 MiB | 8 | 48 MiB | 5 MiB |
| -5e | 8 MiB | 7 | 94 MiB | 9 MiB |
| -6e | 8 MiB | 8 | 94 MiB | 9 MiB |
| -7e | 16 MiB | 8 | 186 MiB | 17 MiB |
| -8e | 32 MiB | 8 | 370 MiB | 33 MiB |
| -9e | 64 MiB | 8 | 674 MiB | 65 MiB |

For example, there are a total of four presets that use 8 MiB dictionary, whose order from the fastest to the slowest is **-5**, **-6**, **-5e**, and **-6e**.

--fast

--best These are somewhat misleading aliases for **-0** and **-9**, respectively. These are provided only for backwards compatibility with LZMA Utils. Avoid using these options.

--block-size=size

When compressing to the **.xz** format, split the input data into blocks of *size* bytes. The blocks are compressed independently from each other, which helps with multi-threading and makes limited random-access decompression possible. This option is typically used to override the default block size in multi-threaded mode, but this option can be used in single-threaded mode too.

In multi-threaded mode about three times *size* bytes will be allocated in each thread for buffering input and output. The default *size* is three times the LZMA2 dictionary size or 1 MiB, whichever is more. Typically a good value is 2–4 times the size of the LZMA2 dictionary or at least 1 MiB. Using *size* less than the LZMA2 dictionary size is waste of RAM because then the LZMA2 dictionary buffer will never get fully used. The sizes of the blocks are stored in the block headers, which a future version of **xz** will use for multi-threaded decompression.

In single-threaded mode no block splitting is done by default. Setting this option doesn't affect memory usage. No size information is stored in block headers, thus files created in single-threaded mode won't be identical to files created in multi-threaded mode. The lack of size information also means that a future version of **xz** won't be able to decompress the files in multi-threaded mode.

--block-list=sizes

When compressing to the **.xz** format, start a new block after the given intervals of uncompressed data.

The uncompressed *sizes* of the blocks are specified as a comma-separated list. Omitting a size (two or more consecutive commas) is a shorthand to use the size of the previous block.

If the input file is bigger than the sum of *sizes*, the last value in *sizes* is repeated until the end of the file. A special value of **0** may be used as the last value to indicate that the rest of the file should be encoded as a single block.

If one specifies *sizes* that exceed the encoder's block size (either the default value in threaded mode or the value specified with **--block-size=size**), the encoder will create additional blocks while keeping the boundaries specified in *sizes*. For example, if one specifies **--block-size=10MiB --block-list=5MiB,10MiB,8MiB,12MiB,24MiB** and the input file is 80 MiB, one will get 11 blocks: 5, 10, 8, 10, 2, 10, 10, 4, 10, 10, and 1 MiB.

In multi-threaded mode the sizes of the blocks are stored in the block headers. This isn't done in single-threaded mode, so the encoded output won't be identical to that of the multi-threaded mode.

--flush-timeout=timeout

When compressing, if more than *timeout* milliseconds (a positive integer) has passed since the previous flush and reading more input would block, all the pending input data is flushed from the encoder and made available in the output stream. This can be useful if **xz** is used to compress data that is streamed over a network. Small *timeout* values make the data available at the receiving end with a small delay, but large *timeout* values give better compression ratio.

This feature is disabled by default. If this option is specified more than once, the last one takes effect. The special *timeout* value of **0** can be used to explicitly disable this feature.

This feature is not available on non-POSIX systems.

This feature is still experimental. Currently **xz** is unsuitable for decompressing the stream in real time due to how **xz** does buffering.

--memlimit-compress=limit

Set a memory usage limit for compression. If this option is specified multiple times, the last one takes effect.

If the compression settings exceed the *limit*, **xz** will adjust the settings downwards so that the limit is no longer exceeded and display a notice that automatic adjustment was done. Such adjustments are not made when compressing with **--format=raw** or if **--no-adjust** has been specified. In those cases, an error is displayed and **xz** will exit with exit status 1.

The *limit* can be specified in multiple ways:

- The *limit* can be an absolute value in bytes. Using an integer suffix like **MiB** can be useful. Example: **--memlimit-compress=80MiB**
- The *limit* can be specified as a percentage of total physical memory (RAM). This can be useful especially when setting the **XZ_DEFAULTS** environment variable in a shell initialization script that is shared between different computers. That way the limit is automatically bigger on systems with more memory. Example: **--memlimit-compress=70%**
- The *limit* can be reset back to its default value by setting it to **0**. This is currently equivalent to setting the *limit* to **max** (no memory usage limit). Once multithreading support has been implemented, there may be a difference between **0** and **max** for the multithreaded case, so it is recommended to use **0** instead of **max** until the details have been decided.

See also the section **Memory usage**.

--memlimit-decompress=limit

Set a memory usage limit for decompression. This also affects the **--list** mode. If the operation is not possible without exceeding the *limit*, **xz** will display an error and decompressing the file will

fail. See `--memlimit-compress=limit` for possible ways to specify the *limit*.

-M *limit*, `--memlimit=limit`, `--memory=limit`

This is equivalent to specifying `--memlimit-compress=limit --memlimit-decompress=limit`.

`--no-adjust`

Display an error and exit if the compression settings exceed the memory usage limit. The default is to adjust the settings downwards so that the memory usage limit is not exceeded. Automatic adjusting is always disabled when creating raw streams (`--format=raw`).

-T *threads*, `--threads=threads`

Specify the number of worker threads to use. Setting *threads* to a special value **0** makes **xz** use as many threads as there are CPU cores on the system. The actual number of threads can be less than *threads* if the input file is not big enough for threading with the given settings or if using more threads would exceed the memory usage limit.

Currently the only threading method is to split the input into blocks and compress them independently from each other. The default block size depends on the compression level and can be overridden with the `--block-size=size` option.

Threaded decompression hasn't been implemented yet. It will only work on files that contain multiple blocks with size information in block headers. All files compressed in multi-threaded mode meet this condition, but files compressed in single-threaded mode don't even if `--block-size=size` is used.

Custom compressor filter chains

A custom filter chain allows specifying the compression settings in detail instead of relying on the settings associated to the presets. When a custom filter chain is specified, preset options (`-0 ... -9` and `--extreme`) earlier on the command line are forgotten. If a preset option is specified after one or more custom filter chain options, the new preset takes effect and the custom filter chain options specified earlier are forgotten.

A filter chain is comparable to piping on the command line. When compressing, the uncompressed input goes to the first filter, whose output goes to the next filter (if any). The output of the last filter gets written to the compressed file. The maximum number of filters in the chain is four, but typically a filter chain has only one or two filters.

Many filters have limitations on where they can be in the filter chain: some filters can work only as the last filter in the chain, some only as a non-last filter, and some work in any position in the chain. Depending on the filter, this limitation is either inherent to the filter design or exists to prevent security issues.

A custom filter chain is specified by using one or more filter options in the order they are wanted in the filter chain. That is, the order of filter options is significant! When decoding raw streams (`--format=raw`), the filter chain is specified in the same order as it was specified when compressing.

Filters take filter-specific *options* as a comma-separated list. Extra commas in *options* are ignored. Every option has a default value, so you need to specify only those you want to change.

To see the whole filter chain and *options*, use **xz -vv** (that is, use `--verbose` twice). This works also for viewing the filter chain options used by presets.

`--lzma1[=options]`

`--lzma2[=options]`

Add LZMA1 or LZMA2 filter to the filter chain. These filters can be used only as the last filter in the chain.

LZMA1 is a legacy filter, which is supported almost solely due to the legacy **.lzma** file format, which supports only LZMA1. LZMA2 is an updated version of LZMA1 to fix some practical issues of LZMA1. The **.xz** format uses LZMA2 and doesn't support LZMA1 at all. Compression speed and ratios of LZMA1 and LZMA2 are practically the same.

LZMA1 and LZMA2 share the same set of *options*:

preset=*preset*

Reset all LZMA1 or LZMA2 *options* to *preset*. *Preset* consist of an integer, which may be followed by single-letter preset modifiers. The integer can be from **0** to **9**, matching the command line options **-0** ... **-9**. The only supported modifier is currently **e**, which matches **--extreme**. If no **preset** is specified, the default values of LZMA1 or LZMA2 *options* are taken from the preset **6**.

dict=*size*

Dictionary (history buffer) *size* indicates how many bytes of the recently processed uncompressed data is kept in memory. The algorithm tries to find repeating byte sequences (matches) in the uncompressed data, and replace them with references to the data currently in the dictionary. The bigger the dictionary, the higher is the chance to find a match. Thus, increasing dictionary *size* usually improves compression ratio, but a dictionary bigger than the uncompressed file is waste of memory.

Typical dictionary *size* is from 64 KiB to 64 MiB. The minimum is 4 KiB. The maximum for compression is currently 1.5 GiB (1536 MiB). The decompressor already supports dictionaries up to one byte less than 4 GiB, which is the maximum for the LZMA1 and LZMA2 stream formats.

Dictionary *size* and match finder (*mf*) together determine the memory usage of the LZMA1 or LZMA2 encoder. The same (or bigger) dictionary *size* is required for decompressing that was used when compressing, thus the memory usage of the decoder is determined by the dictionary size used when compressing. The **.xz** headers store the dictionary *size* either as 2^n or $2^n + 2^{(n-1)}$, so these *sizes* are somewhat preferred for compression. Other *sizes* will get rounded up when stored in the **.xz** headers.

lc=*lc* Specify the number of literal context bits. The minimum is 0 and the maximum is 4; the default is 3. In addition, the sum of *lc* and *lp* must not exceed 4.

All bytes that cannot be encoded as matches are encoded as literals. That is, literals are simply 8-bit bytes that are encoded one at a time.

The literal coding makes an assumption that the highest *lc* bits of the previous uncompressed byte correlate with the next byte. E.g. in typical English text, an upper-case letter is often followed by a lower-case letter, and a lower-case letter is usually followed by another lower-case letter. In the US-ASCII character set, the highest three bits are 010 for upper-case letters and 011 for lower-case letters. When *lc* is at least 3, the literal coding can take advantage of this property in the uncompressed data.

The default value (3) is usually good. If you want maximum compression, test **lc=4**. Sometimes it helps a little, and sometimes it makes compression worse. If it makes it worse, test e.g. **lc=2** too.

lp=*lp* Specify the number of literal position bits. The minimum is 0 and the maximum is 4; the default is 0.

Lp affects what kind of alignment in the uncompressed data is assumed when encoding literals. See *pb* below for more information about alignment.

pb=*pb* Specify the number of position bits. The minimum is 0 and the maximum is 4; the default is 2.

Pb affects what kind of alignment in the uncompressed data is assumed in general. The default means four-byte alignment ($2^{pb}=2^2=4$), which is often a good choice when there's no better guess.

When the alignment is known, setting *pb* accordingly may reduce the file size a little. E.g. with text files having one-byte alignment (US-ASCII, ISO-8859-*, UTF-8), setting **pb=0** can improve compression slightly. For UTF-16 text, **pb=1** is a good choice. If the alignment is an odd number like 3 bytes, **pb=0** might be the best choice.

Even though the assumed alignment can be adjusted with *pb* and *lp*, LZMA1 and LZMA2 still slightly favor 16-byte alignment. It might be worth taking into account when designing file formats that are likely to be often compressed with LZMA1 or LZMA2.

mf=mf Match finder has a major effect on encoder speed, memory usage, and compression ratio. Usually Hash Chain match finders are faster than Binary Tree match finders. The default depends on the *preset*: 0 uses **hc3**, 1–3 use **hc4**, and the rest use **bt4**.

The following match finders are supported. The memory usage formulas below are rough approximations, which are closest to the reality when *dict* is a power of two.

- hc3** Hash Chain with 2- and 3-byte hashing
Minimum value for *nice*: 3
Memory usage:
dict * 7.5 (if *dict* ≤ 16 MiB);
dict * 5.5 + 64 MiB (if *dict* > 16 MiB)
- hc4** Hash Chain with 2-, 3-, and 4-byte hashing
Minimum value for *nice*: 4
Memory usage:
dict * 7.5 (if *dict* ≤ 32 MiB);
dict * 6.5 (if *dict* > 32 MiB)
- bt2** Binary Tree with 2-byte hashing
Minimum value for *nice*: 2
Memory usage: *dict* * 9.5
- bt3** Binary Tree with 2- and 3-byte hashing
Minimum value for *nice*: 3
Memory usage:
dict * 11.5 (if *dict* ≤ 16 MiB);
dict * 9.5 + 64 MiB (if *dict* > 16 MiB)
- bt4** Binary Tree with 2-, 3-, and 4-byte hashing
Minimum value for *nice*: 4
Memory usage:
dict * 11.5 (if *dict* ≤ 32 MiB);
dict * 10.5 (if *dict* > 32 MiB)

mode=mode

Compression *mode* specifies the method to analyze the data produced by the match finder. Supported *modes* are **fast** and **normal**. The default is **fast** for *presets* 0–3 and **normal** for *presets* 4–9.

Usually **fast** is used with Hash Chain match finders and **normal** with Binary Tree match finders. This is also what the *presets* do.

nice=nice

Specify what is considered to be a nice length for a match. Once a match of at least *nice* bytes is found, the algorithm stops looking for possibly better matches.

Nice can be 2–273 bytes. Higher values tend to give better compression ratio at the expense of speed. The default depends on the *preset*.

depth=depth

Specify the maximum search depth in the match finder. The default is the special value of 0, which makes the compressor determine a reasonable *depth* from *mf* and *nice*.

Reasonable *depth* for Hash Chains is 4–100 and 16–1000 for Binary Trees. Using very high values for *depth* can make the encoder extremely slow with some files. Avoid setting the *depth* over 1000 unless you are prepared to interrupt the compression in case it is

taking far too long.

When decoding raw streams (**--format=raw**), LZMA2 needs only the dictionary *size*. LZMA1 needs also *lc*, *lp*, and *pb*.

--x86[=*options*]
--powerpc[=*options*]
--ia64[=*options*]
--arm[=*options*]
--armthumb[=*options*]
--sparc[=*options*]

Add a branch/call/jump (BCJ) filter to the filter chain. These filters can be used only as a non-last filter in the filter chain.

A BCJ filter converts relative addresses in the machine code to their absolute counterparts. This doesn't change the size of the data, but it increases redundancy, which can help LZMA2 to produce 0–15 % smaller **.xz** file. The BCJ filters are always reversible, so using a BCJ filter for wrong type of data doesn't cause any data loss, although it may make the compression ratio slightly worse.

It is fine to apply a BCJ filter on a whole executable; there's no need to apply it only on the executable section. Applying a BCJ filter on an archive that contains both executable and non-executable files may or may not give good results, so it generally isn't good to blindly apply a BCJ filter when compressing binary packages for distribution.

These BCJ filters are very fast and use insignificant amount of memory. If a BCJ filter improves compression ratio of a file, it can improve decompression speed at the same time. This is because, on the same hardware, the decompression speed of LZMA2 is roughly a fixed number of bytes of compressed data per second.

These BCJ filters have known problems related to the compression ratio:

- Some types of files containing executable code (e.g. object files, static libraries, and Linux kernel modules) have the addresses in the instructions filled with filler values. These BCJ filters will still do the address conversion, which will make the compression worse with these files.
- Applying a BCJ filter on an archive containing multiple similar executables can make the compression ratio worse than not using a BCJ filter. This is because the BCJ filter doesn't detect the boundaries of the executable files, and doesn't reset the address conversion counter for each executable.

Both of the above problems will be fixed in the future in a new filter. The old BCJ filters will still be useful in embedded systems, because the decoder of the new filter will be bigger and use more memory.

Different instruction sets have have different alignment:

| Filter | Alignment | Notes |
|-----------|-----------|----------------------|
| x86 | 1 | 32-bit or 64-bit x86 |
| PowerPC | 4 | Big endian only |
| ARM | 4 | Little endian only |
| ARM-Thumb | 2 | Little endian only |
| IA-64 | 16 | Big or little endian |
| SPARC | 4 | Big or little endian |

Since the BCJ-filtered data is usually compressed with LZMA2, the compression ratio may be improved slightly if the LZMA2 options are set to match the alignment of the selected BCJ filter. For example, with the IA-64 filter, it's good to set **pb=4** with LZMA2 ($2^4=16$). The x86 filter is an exception; it's usually good to stick to LZMA2's default four-byte alignment when compressing x86 executables.

All BCJ filters support the same *options*:

start=offset

Specify the start *offset* that is used when converting between relative and absolute addresses. The *offset* must be a multiple of the alignment of the filter (see the table above). The default is zero. In practice, the default is good; specifying a custom *offset* is almost never useful.

--delta[=options]

Add the Delta filter to the filter chain. The Delta filter can be only used as a non-last filter in the filter chain.

Currently only simple byte-wise delta calculation is supported. It can be useful when compressing e.g. uncompressed bitmap images or uncompressed PCM audio. However, special purpose algorithms may give significantly better results than Delta + LZMA2. This is true especially with audio, which compresses faster and better e.g. with **flac**(1).

Supported *options*:

dist=distance

Specify the *distance* of the delta calculation in bytes. *distance* must be 1–256. The default is 1.

For example, with **dist=2** and eight-byte input A1 B1 A2 B3 A3 B5 A4 B7, the output will be A1 B1 01 02 01 02 01 02.

Other options

-q, --quiet

Suppress warnings and notices. Specify this twice to suppress errors too. This option has no effect on the exit status. That is, even if a warning was suppressed, the exit status to indicate a warning is still used.

-v, --verbose

Be verbose. If standard error is connected to a terminal, **xz** will display a progress indicator. Specifying **--verbose** twice will give even more verbose output.

The progress indicator shows the following information:

- Completion percentage is shown if the size of the input file is known. That is, the percentage cannot be shown in pipes.
- Amount of compressed data produced (compressing) or consumed (decompressing).
- Amount of uncompressed data consumed (compressing) or produced (decompressing).
- Compression ratio, which is calculated by dividing the amount of compressed data processed so far by the amount of uncompressed data processed so far.
- Compression or decompression speed. This is measured as the amount of uncompressed data consumed (compression) or produced (decompression) per second. It is shown after a few seconds have passed since **xz** started processing the file.
- Elapsed time in the format M:SS or H:MM:SS.
- Estimated remaining time is shown only when the size of the input file is known and a couple of seconds have already passed since **xz** started processing the file. The time is shown in a less precise format which never has any colons, e.g. 2 min 30 s.

When standard error is not a terminal, **--verbose** will make **xz** print the filename, compressed size, uncompressed size, compression ratio, and possibly also the speed and elapsed time on a single line to standard error after compressing or decompressing the file. The speed and elapsed time are included only when the operation took at least a few seconds. If the operation didn't finish, e.g. due to user interruption, also the completion percentage is printed if the size of the input file is known.

-Q, --no-warn

Don't set the exit status to 2 even if a condition worth a warning was detected. This option doesn't affect the verbosity level, thus both **--quiet** and **--no-warn** have to be used to not display warnings and to not alter the exit status.

--robot

Print messages in a machine-parsable format. This is intended to ease writing frontends that want to use **xz** instead of liblzma, which may be the case with various scripts. The output with this option enabled is meant to be stable across **xz** releases. See the section **ROBOT MODE** for details.

--info-memory

Display, in human-readable format, how much physical memory (RAM) **xz** thinks the system has and the memory usage limits for compression and decompression, and exit successfully.

-h, --help

Display a help message describing the most commonly used options, and exit successfully.

-H, --long-help

Display a help message describing all features of **xz**, and exit successfully

-V, --version

Display the version number of **xz** and liblzma in human readable format. To get machine-parsable output, specify **--robot** before **--version**.

ROBOT MODE

The robot mode is activated with the **--robot** option. It makes the output of **xz** easier to parse by other programs. Currently **--robot** is supported only together with **--version**, **--info-memory**, and **--list**. It will be supported for compression and decompression in the future.

Version

xz --robot --version will print the version number of **xz** and liblzma in the following format:

XZ_VERSION=YYYYZZZS

LIBLZMA_VERSION=YYYYZZZS

X Major version.

YYY Minor version. Even numbers are stable. Odd numbers are alpha or beta versions.

ZZZ Patch level for stable releases or just a counter for development releases.

S Stability. 0 is alpha, 1 is beta, and 2 is stable. **S** should be always 2 when **YYY** is even.

YYYYZZZS are the same on both lines if **xz** and liblzma are from the same XZ Utils release.

Examples: 4.999.9beta is **49990091** and 5.0.0 is **50000002**.

Memory limit information

xz --robot --info-memory prints a single line with three tab-separated columns:

1. Total amount of physical memory (RAM) in bytes
2. Memory usage limit for compression in bytes. A special value of zero indicates the default setting, which for single-threaded mode is the same as no limit.
3. Memory usage limit for decompression in bytes. A special value of zero indicates the default setting, which for single-threaded mode is the same as no limit.

In the future, the output of **xz --robot --info-memory** may have more columns, but never more than a single line.

List mode

xz --robot --list uses tab-separated output. The first column of every line has a string that indicates the type of the information found on that line:

- name** This is always the first line when starting to list a file. The second column on the line is the file-name.
- file** This line contains overall information about the **.xz** file. This line is always printed after the **name** line.
- stream** This line type is used only when **--verbose** was specified. There are as many **stream** lines as there are streams in the **.xz** file.
- block** This line type is used only when **--verbose** was specified. There are as many **block** lines as there are blocks in the **.xz** file. The **block** lines are shown after all the **stream** lines; different line types are not interleaved.

summary

This line type is used only when **--verbose** was specified twice. This line is printed after all **block** lines. Like the **file** line, the **summary** line contains overall information about the **.xz** file.

- totals** This line is always the very last line of the list output. It shows the total counts and sizes.

The columns of the **file** lines:

2. Number of streams in the file
3. Total number of blocks in the stream(s)
4. Compressed size of the file
5. Uncompressed size of the file
6. Compression ratio, for example **0.123**. If ratio is over 9.999, three dashes (---) are displayed instead of the ratio.
7. Comma-separated list of integrity check names. The following strings are used for the known check types: **None**, **CRC32**, **CRC64**, and **SHA-256**. For unknown check types, **Unknown-N** is used, where *N* is the Check ID as a decimal number (one or two digits).
8. Total size of stream padding in the file

The columns of the **stream** lines:

2. Stream number (the first stream is 1)
3. Number of blocks in the stream
4. Compressed start offset
5. Uncompressed start offset
6. Compressed size (does not include stream padding)
7. Uncompressed size
8. Compression ratio
9. Name of the integrity check
10. Size of stream padding

The columns of the **block** lines:

2. Number of the stream containing this block
3. Block number relative to the beginning of the stream (the first block is 1)
4. Block number relative to the beginning of the file
5. Compressed start offset relative to the beginning of the file
6. Uncompressed start offset relative to the beginning of the file
7. Total compressed size of the block (includes headers)
8. Uncompressed size
9. Compression ratio
10. Name of the integrity check

If **--verbose** was specified twice, additional columns are included on the **block** lines. These are not displayed with a single **--verbose**, because getting this information requires many seeks and can thus be slow:

11. Value of the integrity check in hexadecimal
12. Block header size
13. Block flags: **c** indicates that compressed size is present, and **u** indicates that uncompressed size is present. If the flag is not set, a dash (-) is shown instead to keep the string length

- fixed. New flags may be added to the end of the string in the future.
14. Size of the actual compressed data in the block (this excludes the block header, block padding, and check fields)
 15. Amount of memory (in bytes) required to decompress this block with this **xz** version
 16. Filter chain. Note that most of the options used at compression time cannot be known, because only the options that are needed for decompression are stored in the **.xz** headers.

The columns of the **summary** lines:

2. Amount of memory (in bytes) required to decompress this file with this **xz** version
3. **yes** or **no** indicating if all block headers have both compressed size and uncompressed size stored in them

Since **xz 5.1.2alpha**:

4. Minimum **xz** version required to decompress the file

The columns of the **totals** line:

2. Number of streams
3. Number of blocks
4. Compressed size
5. Uncompressed size
6. Average compression ratio
7. Comma-separated list of integrity check names that were present in the files
8. Stream padding size
9. Number of files. This is here to keep the order of the earlier columns the same as on **file** lines.

If **--verbose** was specified twice, additional columns are included on the **totals** line:

10. Maximum amount of memory (in bytes) required to decompress the files with this **xz** version
11. **yes** or **no** indicating if all block headers have both compressed size and uncompressed size stored in them

Since **xz 5.1.2alpha**:

12. Minimum **xz** version required to decompress the file

Future versions may add new line types and new columns can be added to the existing line types, but the existing columns won't be changed.

EXIT STATUS

- | | |
|----------|--|
| 0 | All is good. |
| 1 | An error occurred. |
| 2 | Something worth a warning occurred, but no actual errors occurred. |

Notices (not warnings or errors) printed on standard error don't affect the exit status.

ENVIRONMENT

xz parses space-separated lists of options from the environment variables **XZ_DEFAULTS** and **XZ_OPT**, in this order, before parsing the options from the command line. Note that only options are parsed from the environment variables; all non-options are silently ignored. Parsing is done with **getopt_long(3)** which is used also for the command line arguments.

XZ_DEFAULTS

User-specific or system-wide default options. Typically this is set in a shell initialization script to enable **xz**'s memory usage limiter by default. Excluding shell initialization scripts and similar special cases, scripts must never set or unset **XZ_DEFAULTS**.

XZ_OPT

This is for passing options to **xz** when it is not possible to set the options directly on the **xz** command line. This is the case e.g. when **xz** is run by a script or tool, e.g. GNU **tar(1)**:

```
XZ_OPT=-2v tar caf foo.tar.xz foo
```

Scripts may use **XZ_OPT** e.g. to set script-specific default compression options. It is still recommended to allow users to override **XZ_OPT** if that is reasonable, e.g. in **sh**(1) scripts one may use something like this:

```
XZ_OPT=${XZ_OPT:-"-7e"}
export XZ_OPT
```

LZMA UTILS COMPATIBILITY

The command line syntax of **xz** is practically a superset of **lzma**, **unlzma**, and **lzcat** as found from LZMA Utils 4.32.x. In most cases, it is possible to replace LZMA Utils with XZ Utils without breaking existing scripts. There are some incompatibilities though, which may sometimes cause problems.

Compression preset levels

The numbering of the compression level presets is not identical in **xz** and LZMA Utils. The most important difference is how dictionary sizes are mapped to different presets. Dictionary size is roughly equal to the decompressor memory usage.

| Level | xz | LZMA Utils |
|-------|---------|------------|
| -0 | 256 KiB | N/A |
| -1 | 1 MiB | 64 KiB |
| -2 | 2 MiB | 1 MiB |
| -3 | 4 MiB | 512 KiB |
| -4 | 4 MiB | 1 MiB |
| -5 | 8 MiB | 2 MiB |
| -6 | 8 MiB | 4 MiB |
| -7 | 16 MiB | 8 MiB |
| -8 | 32 MiB | 16 MiB |
| -9 | 64 MiB | 32 MiB |

The dictionary size differences affect the compressor memory usage too, but there are some other differences between LZMA Utils and XZ Utils, which make the difference even bigger:

| Level | xz | LZMA Utils 4.32.x |
|-------|---------|-------------------|
| -0 | 3 MiB | N/A |
| -1 | 9 MiB | 2 MiB |
| -2 | 17 MiB | 12 MiB |
| -3 | 32 MiB | 12 MiB |
| -4 | 48 MiB | 16 MiB |
| -5 | 94 MiB | 26 MiB |
| -6 | 94 MiB | 45 MiB |
| -7 | 186 MiB | 83 MiB |
| -8 | 370 MiB | 159 MiB |
| -9 | 674 MiB | 311 MiB |

The default preset level in LZMA Utils is **-7** while in XZ Utils it is **-6**, so both use an 8 MiB dictionary by default.

Streamed vs. non-streamed .lzma files

The uncompressed size of the file can be stored in the **.lzma** header. LZMA Utils does that when compressing regular files. The alternative is to mark that uncompressed size is unknown and use end-of-payload marker to indicate where the decompressor should stop. LZMA Utils uses this method when uncompressed size isn't known, which is the case for example in pipes.

xz supports decompressing **.lzma** files with or without end-of-payload marker, but all **.lzma** files created by **xz** will use end-of-payload marker and have uncompressed size marked as unknown in the **.lzma** header. This may be a problem in some uncommon situations. For example, a **.lzma** decompressor in an embedded device might work only with files that have known uncompressed size. If you hit this problem, you need to use LZMA Utils or LZMA SDK to create **.lzma** files with known uncompressed size.

Unsupported .lzma files

The **.lzma** format allows *lc* values up to 8, and *lp* values up to 4. LZMA Utils can decompress files with any *lc* and *lp*, but always creates files with **lc=3** and **lp=0**. Creating files with other *lc* and *lp* is possible with **xz** and with LZMA SDK.

The implementation of the LZMA1 filter in liblzma requires that the sum of *lc* and *lp* must not exceed 4. Thus, **.lzma** files, which exceed this limitation, cannot be decompressed with **xz**.

LZMA Utils creates only **.lzma** files which have a dictionary size of 2^n (a power of 2) but accepts files with any dictionary size. liblzma accepts only **.lzma** files which have a dictionary size of 2^n or $2^n + 2^{(n-1)}$. This is to decrease false positives when detecting **.lzma** files.

These limitations shouldn't be a problem in practice, since practically all **.lzma** files have been compressed with settings that liblzma will accept.

Trailing garbage

When decompressing, LZMA Utils silently ignore everything after the first **.lzma** stream. In most situations, this is a bug. This also means that LZMA Utils don't support decompressing concatenated **.lzma** files.

If there is data left after the first **.lzma** stream, **xz** considers the file to be corrupt unless **--single-stream** was used. This may break obscure scripts which have assumed that trailing garbage is ignored.

NOTES

Compressed output may vary

The exact compressed output produced from the same uncompressed input file may vary between XZ Utils versions even if compression options are identical. This is because the encoder can be improved (faster or better compression) without affecting the file format. The output can vary even between different builds of the same XZ Utils version, if different build options are used.

The above means that once **--rsyncable** has been implemented, the resulting files won't necessarily be rsyncable unless both old and new files have been compressed with the same xz version. This problem can be fixed if a part of the encoder implementation is frozen to keep rsyncable output stable across xz versions.

Embedded .xz decompressors

Embedded **.xz** decompressor implementations like XZ Embedded don't necessarily support files created with integrity *check* types other than **none** and **crc32**. Since the default is **--check=crc64**, you must use **--check=none** or **--check=crc32** when creating files for embedded systems.

Outside embedded systems, all **.xz** format decompressors support all the *check* types, or at least are able to decompress the file without verifying the integrity check if the particular *check* is not supported.

XZ Embedded supports BCJ filters, but only with the default start offset.

EXAMPLES

Basics

Compress the file *foo* into *foo.xz* using the default compression level (**-6**), and remove *foo* if compression is successful:

```
xz foo
```

Decompress *bar.xz* into *bar* and don't remove *bar.xz* even if decompression is successful:

```
xz -dk bar.xz
```

Create *baz.tar.xz* with the preset **-4e** (**-4 --extreme**), which is slower than e.g. the default **-6**, but needs less memory for compression and decompression (48 MiB and 5 MiB, respectively):

```
tar cf - baz | xz -4e > baz.tar.xz
```

A mix of compressed and uncompressed files can be decompressed to standard output with a single command:

```
xz -dcf a.txt b.txt.xz c.txt d.txt.lzma > abcd.txt
```

Parallel compression of many files

On GNU and *BSD, **find**(1) and **xargs**(1) can be used to parallelize compression of many files:

```
find . -type f \! -name '*.xz' -print0 \
| xargs -0r -P4 -n16 xz -T1
```

The **-P** option to **xargs**(1) sets the number of parallel **xz** processes. The best value for the **-n** option depends on how many files there are to be compressed. If there are only a couple of files, the value should probably be 1; with tens of thousands of files, 100 or even more may be appropriate to reduce the number of **xz** processes that **xargs**(1) will eventually create.

The option **-T1** for **xz** is there to force it to single-threaded mode, because **xargs**(1) is used to control the amount of parallelization.

Robot mode

Calculate how many bytes have been saved in total after compressing multiple files:

```
xz --robot --list *.xz | awk '/^totals/{print $5-$4}'
```

A script may want to know that it is using new enough **xz**. The following **sh**(1) script checks that the version number of the **xz** tool is at least 5.0.0. This method is compatible with old beta versions, which didn't support the **--robot** option:

```
if ! eval "$(xz --robot --version 2> /dev/null)" ||
[ "$XZ_VERSION" -lt 50000002 ]; then
    echo "Your xz is too old."
fi
unset XZ_VERSION LIBLZMA_VERSION
```

Set a memory usage limit for decompression using **XZ_OPT**, but if a limit has already been set, don't increase it:

```
NEWLIM=$((123 << 20)) # 123 MiB
OLDLIM=$(xz --robot --info-memory | cut -f3)
if [ $OLDLIM -eq 0 -o $OLDLIM -gt $NEWLIM ]; then
    XZ_OPT="$XZ_OPT --memlimit-decompress=$NEWLIM"
    export XZ_OPT
fi
```

Custom compressor filter chains

The simplest use for custom filter chains is customizing a LZMA2 preset. This can be useful, because the presets cover only a subset of the potentially useful combinations of compression settings.

The CompCPU columns of the tables from the descriptions of the options **-0 ... -9** and **--extreme** are useful when customizing LZMA2 presets. Here are the relevant parts collected from those two tables:

| Preset | CompCPU |
|--------|---------|
| -0 | 0 |
| -1 | 1 |
| -2 | 2 |
| -3 | 3 |
| -4 | 4 |
| -5 | 5 |
| -6 | 6 |
| -5e | 7 |
| -6e | 8 |

If you know that a file requires somewhat big dictionary (e.g. 32 MiB) to compress well, but you want to compress it quicker than **xz -8** would do, a preset with a low CompCPU value (e.g. 1) can be modified to use a bigger dictionary:

```
xz --lzma2=preset=1,dict=32MiB foo.tar
```

With certain files, the above command may be faster than **xz -6** while compressing significantly better. However, it must be emphasized that only some files benefit from a big dictionary while keeping the ComCPU value low. The most obvious situation, where a big dictionary can help a lot, is an archive containing very similar files of at least a few megabytes each. The dictionary size has to be significantly bigger than any individual file to allow LZMA2 to take full advantage of the similarities between consecutive files.

If very high compressor and decompressor memory usage is fine, and the file being compressed is at least several hundred megabytes, it may be useful to use an even bigger dictionary than the 64 MiB that **xz -9** would use:

```
xz -vv --lzma2=dict=192MiB big_foo.tar
```

Using **-vv** (**--verbose --verbose**) like in the above example can be useful to see the memory requirements of the compressor and decompressor. Remember that using a dictionary bigger than the size of the uncompressed file is waste of memory, so the above command isn't useful for small files.

Sometimes the compression time doesn't matter, but the decompressor memory usage has to be kept low e.g. to make it possible to decompress the file on an embedded system. The following command uses **-6e** (**-6 --extreme**) as a base and sets the dictionary to only 64 KiB. The resulting file can be decompressed with XZ Embedded (that's why there is **--check=crc32**) using about 100 KiB of memory.

```
xz --check=crc32 --lzma2=preset=6e,dict=64KiB foo
```

If you want to squeeze out as many bytes as possible, adjusting the number of literal context bits (*lc*) and number of position bits (*pb*) can sometimes help. Adjusting the number of literal position bits (*lp*) might help too, but usually *lc* and *pb* are more important. E.g. a source code archive contains mostly US-ASCII text, so something like the following might give slightly (like 0.1 %) smaller file than **xz -6e** (try also without **lc=4**):

```
xz --lzma2=preset=6e,pb=0,lc=4 source_code.tar
```

Using another filter together with LZMA2 can improve compression with certain file types. E.g. to compress a x86-32 or x86-64 shared library using the x86 BCJ filter:

```
xz --x86 --lzma2 libfoo.so
```

Note that the order of the filter options is significant. If **--x86** is specified after **--lzma2**, **xz** will give an error, because there cannot be any filter after LZMA2, and also because the x86 BCJ filter cannot be used as the last filter in the chain.

The Delta filter together with LZMA2 can give good results with bitmap images. It should usually beat PNG, which has a few more advanced filters than simple delta but uses Deflate for the actual compression.

The image has to be saved in uncompressed format, e.g. as uncompressed TIFF. The distance parameter of the Delta filter is set to match the number of bytes per pixel in the image. E.g. 24-bit RGB bitmap needs **dist=3**, and it is also good to pass **pb=0** to LZMA2 to accommodate the three-byte alignment:

```
xz --delta=dist=3 --lzma2=pb=0 foo.tiff
```

If multiple images have been put into a single archive (e.g. **.tar**), the Delta filter will work on that too as long as all images have the same number of bytes per pixel.

NAME

yesterday – return the date of yesterday

SYNOPSIS

edrc/lib/yesterday [**-h**]

yesterday ["*date_format*"]

AVAILABILITY

WA2L/edrc

DESCRIPTION

return the date of yesterday. By default the date is returned in the format *YYYY-MM-DD*.

OPTIONS

-h print usage message.

"*date_format*"

date format as known from the **date**(1) command.

The following format place holders are the most compatible ones:

%Y year (1970...)

%y last two digits of year (00..99)

%m month (01..12)

%d day of month (01..31)

%H hour (00..23)

%M minute (00..59)

%S second (00..60)

%w day of week (0..6); 0 represents Sunday

ENVIRONMENT

\$TZ Timezone setting.

EXIT STATUS

0 no error.

yesterday(3)

Library Commands

yesterday(3)

2 date could not be resolved.

4 usage message printed.

NAME

ypxfr_all – transfer all maps from a NIS master server

SYNOPSIS

edrc/bin/ypxfr_all [-h]

ypxfr_all [-t]

AVAILABILITY

WA2L/edrc

DESCRIPTION

force a transfer of all NIS maps from a NIS master server to the NIS slave server where logged on.

This command is to completely refresh the maps on the NIS slave server independent of the automatic synchronization mechanism.

OPTIONS

- h** usage message.
- t** transfer the following maps from the NIS master server: **auto.apl**, **auto.apl_std**, **auto.dat**, **auto.home**, **auto.master**, **auto.wwr**, **bootparams**, **ethers.byaddr**, **ethers.byname**, **group.bygid**, **group.byname**, **hosts.byaddr**, **hosts.byname**, **mail.aliases**, **mail.byaddr**, **netgroup.byhost**, **netgroup.byuser**, **netgroup**, **netmasks.byaddr**, **networks.byaddr**, **networks.byname**, **passwd.byname**, **passwd.byuid**, **protocols.byname**, **protocols.bynumber**, **restr.byname**, **restr.byuid**, **rpc.bynumber**, **services.byname**, **timezone.byname** and **ypservers**.

ENVIRONMENT

-

EXIT STATUS

- 0** no error.
- 1** the **ypxfr_all** command was not started as user **root** or it was not started on a NIS slave server.
- 4** usage printed.

NAME

gzip, *gunzip*, *zcat* – compress or expand files

SYNOPSIS

gzip [**-acdfhlLnNrtvV19**] [**-S suffix**] [*name ...*]

gunzip [**-acfhllNrtvV**] [**-S suffix**] [*name ...*]

zcat [**-fhLV**] [*name ...*]

DESCRIPTION

Gzip reduces the size of the named files using Lempel-Ziv coding (LZ77). Whenever possible, each file is replaced by one with the extension **.gz**, while keeping the same ownership modes, access and modification times. (The default extension is **-gz** for VMS, **z** for MSDOS, OS/2 FAT, Windows NT FAT and Atari.) If no files are specified, or if a file name is "-", the standard input is compressed to the standard output. *Gzip* will only attempt to compress regular files. In particular, it will ignore symbolic links.

If the compressed file name is too long for its file system, *gzip* truncates it. *Gzip* attempts to truncate only the parts of the file name longer than 3 characters. (A part is delimited by dots.) If the name consists of small parts only, the longest parts are truncated. For example, if file names are limited to 14 characters, *gzip.msdos.exe* is compressed to *gzi.msd.exe.gz*. Names are not truncated on systems which do not have a limit on file name length.

By default, *gzip* keeps the original file name and timestamp in the compressed file. These are used when decompressing the file with the **-N** option. This is useful when the compressed file name was truncated or when the time stamp was not preserved after a file transfer.

Compressed files can be restored to their original form using *gzip -d* or *gunzip* or *zcat*. If the original name saved in the compressed file is not suitable for its file system, a new name is constructed from the original one to make it legal.

gunzip takes a list of files on its command line and replaces each file whose name ends with **.gz**, **-gz**, **.z**, **-z**, **_z** or **.Z** and which begins with the correct magic number with an uncompressed file without the original extension. *gunzip* also recognizes the special extensions **.tgz** and **.taz** as shorthands for **.tar.gz** and **.tar.Z** respectively. When compressing, *gzip* uses the **.tgz** extension if necessary instead of truncating a file with a **.tar** extension.

gunzip can currently decompress files created by *gzip*, *zip*, *compress*, *compress -H* or *pack*. The detection of the input format is automatic. When using the first two formats, *gunzip* checks a 32 bit CRC. For *pack*, *gunzip* checks the uncompressed length. The standard *compress* format was not designed to allow consistency checks. However *gunzip* is sometimes able to detect a bad **.Z** file. If you get an error when uncompressing a **.Z** file, do not assume that the **.Z** file is correct simply because the standard *uncompress* does not complain. This generally means that the standard *uncompress* does not check its input, and happily generates garbage output. The SCO *compress -H* format (lzh compression method) does not include a CRC but also allows some consistency checks.

Files created by *zip* can be uncompressed by *gzip* only if they have a single member compressed with the 'deflation' method. This feature is only intended to help conversion of *tar.zip* files to the *tar.gz* format. To extract a *zip* file with a single member, use a command like *gunzip <foo.zip* or *gunzip -S .zip foo.zip*. To extract *zip* files with several members, use *unzip* instead of *gunzip*.

zcat is identical to *gunzip -c*. (On some systems, *zcat* may be installed as *gzcat* to preserve the original link to *compress*.) *zcat* uncompresses either a list of files on the command line or its standard input and writes the uncompressed data on standard output. *zcat* will uncompress files that have the correct magic number whether they have a **.gz** suffix or not.

Gzip uses the Lempel-Ziv algorithm used in *zip* and PKZIP. The amount of compression obtained depends on the size of the input and the distribution of common substrings. Typically, text such as source code or English is reduced by 60–70%. Compression is generally much better than that achieved by LZW (as used in *compress*), Huffman coding (as used in *pack*), or adaptive Huffman coding (*compact*).

Compression is always performed, even if the compressed file is slightly larger than the original. The worst case expansion is a few bytes for the *gzip* file header, plus 5 bytes every 32K block, or an expansion ratio of

0.015% for large files. Note that the actual number of used disk blocks almost never increases. *gzip* preserves the mode, ownership and timestamps of files when compressing or decompressing.

The *gzip* file format is specified in P. Deutsch, GZIP file format specification version 4.3, <ftp://ftp.isi.edu/in-notes/rfc1952.txt>, Internet RFC 1952 (May 1996). The *zip* deflation format is specified in P. Deutsch, DEFLATE Compressed Data Format Specification version 1.3, <ftp://ftp.isi.edu/in-notes/rfc1951.txt>, Internet RFC 1951 (May 1996).

OPTIONS

-a --ascii

Ascii text mode: convert end-of-lines using local conventions. This option is supported only on some non-Unix systems. For MSDOS, CR LF is converted to LF when compressing, and LF is converted to CR LF when decompressing.

-c --stdout --to-stdout

Write output on standard output; keep original files unchanged. If there are several input files, the output consists of a sequence of independently compressed members. To obtain better compression, concatenate all input files before compressing them.

-d --decompress --uncompress

Decompress.

-f --force

Force compression or decompression even if the file has multiple links or the corresponding file already exists, or if the compressed data is read from or written to a terminal. If the input data is not in a format recognized by *gzip*, and if the option *--stdout* is also given, copy the input data without change to the standard output: let *zcat* behave as *cat*. If *-f* is not given, and when not running in the background, *gzip* prompts to verify whether an existing file should be overwritten.

-h --help

Display a help screen and quit.

-l --list For each compressed file, list the following fields:

compressed size: size of the compressed file
 uncompressed size: size of the uncompressed file
 ratio: compression ratio (0.0% if unknown)
 uncompressed_name: name of the uncompressed file

The uncompressed size is given as -1 for files not in gzip format, such as compressed .Z files. To get the uncompressed size for such a file, you can use:

```
zcat file.Z | wc -c
```

In combination with the *--verbose* option, the following fields are also displayed:

method: compression method
 crc: the 32-bit CRC of the uncompressed data
 date & time: time stamp for the uncompressed file

The compression methods currently supported are deflate, compress, lzh (SCO compress -H) and pack. The crc is given as ffffffff for a file not in gzip format.

With *--name*, the uncompressed name, date and time are those stored within the compress file if present.

With *--verbose*, the size totals and compression ratio for all files is also displayed, unless some sizes are unknown. With *--quiet*, the title and totals lines are not displayed.

-L --license

Display the *gzip* license and quit.

-n --no-name

When compressing, do not save the original file name and time stamp by default. (The original name is always saved if the name had to be truncated.) When decompressing, do not restore the original file name if present (remove only the *gzip* suffix from the compressed file name) and do not restore the original time stamp if present (copy it from the compressed file). This option is the default when decompressing.

-N --name

When compressing, always save the original file name and time stamp; this is the default. When decompressing, restore the original file name and time stamp if present. This option is useful on systems which have a limit on file name length or when the time stamp has been lost after a file transfer.

-q --quiet

Suppress all warnings.

-r --recursive

Travel the directory structure recursively. If any of the file names specified on the command line are directories, *gzip* will descend into the directory and compress all the files it finds there (or decompress them in the case of *gunzip*).

-S .suf --suffix .suf

Use suffix *.suf* instead of *.gz*. Any suffix can be given, but suffixes other than *.z* and *.gz* should be avoided to avoid confusion when files are transferred to other systems. A null suffix forces *gunzip* to try decompression on all given files regardless of suffix, as in:

```
gunzip -S "" *      (*. * for MSDOS)
```

Previous versions of *gzip* used the *.z* suffix. This was changed to avoid a conflict with *pack(1)*.

-t --test

Test. Check the compressed file integrity.

-v --verbose

Verbose. Display the name and percentage reduction for each file compressed or decompressed.

-V --version

Version. Display the version number and compilation options then quit.

-# --fast --best

Regulate the speed of compression using the specified digit #, where **-1** or **--fast** indicates the fastest compression method (less compression) and **-9** or **--best** indicates the slowest compression method (best compression). The default compression level is **-6** (that is, biased towards high compression at expense of speed).

ADVANCED USAGE

Multiple compressed files can be concatenated. In this case, *gunzip* will extract all members at once. For example:

```
gzip -c file1 > foo.gz
gzip -c file2 >> foo.gz
```

Then

```
gunzip -c foo
```

is equivalent to

```
cat file1 file2
```

In case of damage to one member of a .gz file, other members can still be recovered (if the damaged member is removed). However, you can get better compression by compressing all members at once:

```
cat file1 file2 | gzip > foo.gz
```

compresses better than

```
gzip -c file1 file2 > foo.gz
```

If you want to recompress concatenated files to get better compression, do:

```
gzip -cd old.gz | gzip > new.gz
```

If a compressed file consists of several members, the uncompressed size and CRC reported by the --list option applies to the last member only. If you need the uncompressed size for all members, you can use:

```
gzip -cd file.gz | wc -c
```

If you wish to create a single archive file with multiple members so that members can later be extracted independently, use an archiver such as tar or zip. GNU tar supports the -z option to invoke gzip transparently. gzip is designed as a complement to tar, not as a replacement.

ENVIRONMENT

The environment variable **GZIP** can hold a set of default options for *gzip*. These options are interpreted first and can be overwritten by explicit command line parameters. For example:

for sh: `GZIP="-8v --name"; export GZIP`

for csh: `setenv GZIP "-8v --name"`

for MSDOS: `set GZIP=-8v --name`

On Vax/VMS, the name of the environment variable is GZIP_OPT, to avoid a conflict with the symbol set for invocation of the program.

SEE ALSO

znew(1), zcmp(1), zmore(1), zforce(1), gzexe(1), zip(1), unzip(1), compress(1), pack(1), compact(1)

The *gzip* file format is specified in P. Deutsch, GZIP file format specification version 4.3, <<ftp://ftp.isi.edu/in-notes/rfc1952.txt>>, Internet RFC 1952 (May 1996). The *zip* deflation format is specified in P. Deutsch, DEFLATE Compressed Data Format Specification version 1.3, <<ftp://ftp.isi.edu/in-notes/rfc1951.txt>>, Internet RFC 1951 (May 1996).

DIAGNOSTICS

Exit status is normally 0; if an error occurs, exit status is 1. If a warning occurs, exit status is 2.

Usage: `gzip [-cdfhLnNrtvV19] [-S suffix] [file ...]`

Invalid options were specified on the command line.

file: not in gzip format

The file specified to *gunzip* has not been compressed.

file: Corrupt input. Use zcat to recover some data.

The compressed file has been damaged. The data up to the point of failure can be recovered using

```
zcat file > recover
```

file: compressed with *xx* bits, can only handle *yy* bits

File was compressed (using LZW) by a program that could deal with more *bits* than the decompress code on this machine. Recompress the file with gzip, which compresses better and uses less

memory.

file: already has .gz suffix -- no change

The file is assumed to be already compressed. Rename the file and try again.

file already exists; do you wish to overwrite (y or n)?

Respond "y" if you want the output file to be replaced; "n" if not.

gunzip: corrupt input

A SIGSEGV violation was detected which usually means that the input file has been corrupted.

xx.x% Percentage of the input saved by compression.

(Relevant only for **-v** and **-l**.)

-- not a regular file or directory: ignored

When the input file is not a regular file or directory, (e.g. a symbolic link, socket, FIFO, device file), it is left unaltered.

-- has *xx* other links: unchanged

The input file has links; it is left unchanged. See *ln(1)* for more information. Use the **-f** flag to force compression of multiply-linked files.

CAVEATS

When writing compressed data to a tape, it is generally necessary to pad the output with zeroes up to a block boundary. When the data is read and the whole block is passed to *gunzip* for decompression, *gunzip* detects that there is extra trailing garbage after the compressed data and emits a warning by default. You have to use the **--quiet** option to suppress the warning. This option can be set in the **GZIP** environment variable as in:

```
for sh: GZIP="-q" tar -xfz --block-compress /dev/rst0
```

```
for csh: (setenv GZIP -q; tar -xfz --block-compr /dev/rst0
```

In the above example, *gzip* is invoked implicitly by the **-z** option of GNU *tar*. Make sure that the same block size (**-b** option of *tar*) is used for reading and writing compressed data on tapes. (This example assumes you are using the GNU version of *tar*.)

BUGS

The *gzip* format represents the input size modulo 2^{32} , so the **--list** option reports incorrect uncompressed sizes and compression ratios for uncompressed files 4 GB and larger. To work around this problem, you can use the following command to discover a large uncompressed file's true size:

```
zcat file.gz | wc -c
```

The **--list** option reports sizes as **-1** and **crc** as **ffffff** if the compressed file is on a non seekable media.

In some rare cases, the **--best** option gives worse compression than the default compression level (**-6**). On some highly redundant files, *compress* compresses better than *gzip*.

NAME

zcmp, **zdiff** – compare compressed files

SYNOPSIS

zcmp [cmp_options] file1 [file2]

zdiff [diff_options] file1 [file2]

DESCRIPTION

Zcmp and *zdiff* are used to invoke the *cmp* or the *diff* program on files compressed via *gzip*. All options specified are passed directly to *cmp* or *diff*. If only 1 file is specified, then the files compared are *file1* and an uncompressed *file1.gz*. If two files are specified, then they are uncompressed if necessary and fed to *cmp* or *diff*. The exit status from *cmp* or *diff* is preserved.

SEE ALSO

cmp(1), *diff*(1), *zmore*(1), *zgrep*(1), *znew*(1), *zforce*(1), *gzip*(1), *gzexe*(1)

BUGS

Messages from the *cmp* or *diff* programs refer to temporary filenames instead of those specified.

NAME

zgrep – search possibly compressed files for a regular expression

SYNOPSIS

zgrep [*grep_options*] [**-e**] *pattern filename...*

DESCRIPTION

Zgrep invokes *grep* on compressed or gzipped files. All options specified are passed directly to *grep*. If no file is specified, then the standard input is decompressed if necessary and fed to *grep*. Otherwise the given files are uncompressed if necessary and fed to *grep*.

If the GREP environment variable is set, *zgrep* uses it as the *grep* program to be invoked.

NAME

zip – package and compress (archive) files

SYNOPSIS

zip [-aABcdDeEffghjklLmoqrRSTuvVwXyz!@\$] [--longoption ...] [-b path] [-n suffixes] [-t date] [-tt date] [*zipfile* [*file* ...]] [-xi list]

zipcloak (see separate man page)

zipnote (see separate man page)

zipsplit (see separate man page)

Note: Command line processing in *zip* has been changed to support long options and handle all options and arguments more consistently. Some old command lines that depend on command line inconsistencies may no longer work.

DESCRIPTION

zip is a compression and file packaging utility for Unix, VMS, MSDOS, OS/2, Windows 9x/NT/XP, Minix, Atari, Macintosh, Amiga, and Acorn RISC OS. It is analogous to a combination of the Unix commands *tar*(1) and *compress*(1) and is compatible with PKZIP (Phil Katz's ZIP for MSDOS systems).

A companion program (*unzip*(1L)) unpacks *zip* archives. The *zip* and *unzip*(1L) programs can work with archives produced by PKZIP (supporting most PKZIP features up to PKZIP version 4.6), and PKZIP and PKUNZIP can work with archives produced by *zip* (with some exceptions, notably streamed archives, but recent changes in the *zip* file standard may facilitate better compatibility). *zip* version 3.0 is compatible with PKZIP 2.04 and also supports the Zip64 extensions of PKZIP 4.5 which allow archives as well as files to exceed the previous 2 GB limit (4 GB in some cases). *zip* also now supports **bzip2** compression if the **bzip2** library is included when *zip* is compiled. Note that PKUNZIP 1.10 cannot extract files produced by PKZIP 2.04 or *zip* 3.0. You must use PKUNZIP 2.04g or *unzip* 5.0p1 (or later versions) to extract them.

See the **EXAMPLES** section at the bottom of this page for examples of some typical uses of *zip*.

Large Archives and Zip64. *zip* automatically uses the Zip64 extensions when files larger than 4 GB are added to an archive, an archive containing Zip64 entries is updated (if the resulting archive still needs Zip64), the size of the archive will exceed 4 GB, or when the number of entries in the archive will exceed about 64K. Zip64 is also used for archives streamed from standard input as the size of such archives are not known in advance, but the option **-fz-** can be used to force *zip* to create PKZIP 2 compatible archives (as long as Zip64 extensions are not needed). You must use a PKZIP 4.5 compatible *unzip*, such as *unzip* 6.0 or later, to extract files using the Zip64 extensions.

In addition, streamed archives, entries encrypted with standard encryption, or split archives created with the pause option may not be compatible with PKZIP as data descriptors are used and PKZIP at the time of this writing does not support data descriptors (but recent changes in the PKWare published *zip* standard now include some support for the data descriptor format *zip* uses).

Mac OS X. Though previous Mac versions had their own *zip* port, *zip* supports Mac OS X as part of the Unix port and most Unix features apply. References to "MacOS" below generally refer to MacOS versions older than OS X. Support for some Mac OS features in the Unix Mac OS X port, such as resource forks, is expected in the next *zip* release.

For a brief help on *zip* and *unzip*, run each without specifying any parameters on the command line.

USE

The program is useful for packaging a set of files for distribution; for archiving files; and for saving disk space by temporarily compressing unused files or directories.

The *zip* program puts one or more compressed files into a single *zip* archive, along with information about the files (name, path, date, time of last modification, protection, and check information to verify file integrity). An entire directory structure can be packed into a *zip* archive with a single command.

Compression ratios of 2:1 to 3:1 are common for text files. *zip* has one compression method (deflation) and can also store files without compression. (If **bzip2** support is added, *zip* can also compress using **bzip2** compression, but such entries require a reasonably modern unzip to decompress. When **bzip2** compression is selected, it replaces deflation as the default method.) *zip* automatically chooses the better of the two (deflation or store or, if **bzip2** is selected, **bzip2** or store) for each file to be compressed.

Command format. The basic command format is

```
zip options archive inpath inpath ...
```

where **archive** is a new or existing *zip* archive and **inpath** is a directory or file path optionally including wildcards. When given the name of an existing *zip* archive, *zip* will replace identically named entries in the *zip* archive (matching the relative names as stored in the archive) or add entries for new names. For example, if *foo.zip* exists and contains *foo/file1* and *foo/file2*, and the directory *foo* contains the files *foo/file1* and *foo/file3*, then:

```
zip -r foo.zip foo
```

or more concisely

```
zip -r foo foo
```

will replace *foo/file1* in *foo.zip* and add *foo/file3* to *foo.zip*. After this, *foo.zip* contains *foo/file1*, *foo/file2*, and *foo/file3*, with *foo/file2* unchanged from before.

So if before the *zip* command is executed *foo.zip* has:

```
foo/file1 foo/file2
```

and directory *foo* has:

```
file1 file3
```

then *foo.zip* will have:

```
foo/file1 foo/file2 foo/file3
```

where *foo/file1* is replaced and *foo/file3* is new.

-@ file lists. If a file list is specified as **-@** [Not on MacOS], *zip* takes the list of input files from standard input instead of from the command line. For example,

```
zip -@ foo
```

will store the files listed one per line on stdin in *foo.zip*.

Under Unix, this option can be used to powerful effect in conjunction with the *find* (1) command. For example, to archive all the C source files in the current directory and its subdirectories:

```
find . -name "*.c" -print | zip source -@
```

(note that the pattern must be quoted to keep the shell from expanding it).

Streaming input and output. *zip* will also accept a single dash ("-") as the *zip* file name, in which case it will write the *zip* file to standard output, allowing the output to be piped to another program. For example:

```
zip -r - . | dd of=/dev/nrst0 obs=16k
```

would write the *zip* output directly to a tape with the specified block size for the purpose of backing up the current directory.

zip also accepts a single dash ("-") as the name of a file to be compressed, in which case it will read the file from standard input, allowing *zip* to take input from another program. For example:

```
tar cf - . | zip backup -
```

would compress the output of the *tar* command for the purpose of backing up the current directory. This generally produces better compression than the previous example using the **-r** option because *zip* can take advantage of redundancy between files. The backup can be restored using the command

```
unzip -p backup | tar xf -
```

When no *zip* file name is given and stdout is not a terminal, *zip* acts as a filter, compressing standard input to standard output. For example,

```
tar cf - . | zip | dd of=/dev/nrst0 obs=16k
```

is equivalent to

```
tar cf - . | zip - - | dd of=/dev/nrst0 obs=16k
```

zip archives created in this manner can be extracted with the program *funzip* which is provided in the *unzip* package, or by *gunzip* which is provided in the *gzip* package (but some *gunzip* may not support this if *zip* used the Zip64 extensions). For example:

```
dd if=/dev/nrst0 ibs=16k | funzip | tar xvf -
```

The stream can also be saved to a file and *unzip* used.

If Zip64 support for large files and archives is enabled and *zip* is used as a filter, *zip* creates a Zip64 archive that requires a PKZIP 4.5 or later compatible unzip to read it. This is to avoid ambiguities in the zip file structure as defined in the current zip standard (PKWARE AppNote) where the decision to use Zip64 needs to be made before data is written for the entry, but for a stream the size of the data is not known at that point. If the data is known to be smaller than 4 GB, the option **-fz-** can be used to prevent use of Zip64, but *zip* will exit with an error if Zip64 was in fact needed. *zip* 3 and *unzip* 6 and later can read archives with Zip64 entries. Also, *zip* removes the Zip64 extensions if not needed when archive entries are copied (see the **-U** (**--copy**) option).

When directing the output to another file, note that all options should be before the redirection including **-x**. For example:

```
zip archive "*.h" "*.c" -x donotinclude.h orthis.h > tofile
```

Zip files. When changing an existing *zip* archive, *zip* will write a temporary file with the new contents, and only replace the old one when the process of creating the new version has been completed without error.

If the name of the *zip* archive does not contain an extension, the extension **.zip** is added. If the name already contains an extension other than **.zip**, the existing extension is kept unchanged. However, split archives (archives split over multiple files) require the **.zip** extension on the last split.

Scanning and reading files. When *zip* starts, it scans for files to process (if needed). If this scan takes longer than about 5 seconds, *zip* will display a "Scanning files" message and start displaying progress dots every 2 seconds or every so many entries processed, whichever takes longer. If there is more than 2 seconds between dots it could indicate that finding each file is taking time and could mean a slow network connection for example. (Actually the initial file scan is a two-step process where the directory scan is followed by a sort and these two steps are separated with a space in the dots. If updating an existing archive, a space also appears between the existing file scan and the new file scan.) The scanning files dots are not controlled by the **-ds** dot size option, but the dots are turned off by the **-q** quiet option. The **-sf** show files option can be used to scan for files and get the list of files scanned without actually processing them.

If *zip* is not able to read a file, it issues a warning but continues. See the **-MM** option below for more on how *zip* handles patterns that are not matched and files that are not readable. If some files were skipped, a warning is issued at the end of the zip operation noting how many files were read and how many skipped.

Command modes. *zip* now supports two distinct types of command modes, **external** and **internal**. The **external** modes (add, update, and freshen) read files from the file system (as well as from an existing archive) while the **internal** modes (delete and copy) operate exclusively on entries in an existing archive.

add

Update existing entries and add new files. If the archive does not exist create it. This is the default mode.

update (-u)

Update existing entries if newer on the file system and add new files. If the archive does not exist issue warning then create a new archive.

freshen (-f)

Update existing entries of an archive if newer on the file system. Does not add new files to the archive.

delete (-d)

Select entries in an existing archive and delete them.

copy (-U)

Select entries in an existing archive and copy them to a new archive. This new mode is similar to **update** but command line patterns select entries in the existing archive rather than files from the file system and it uses the **--out** option to write the resulting archive to a new file rather than update the existing archive, leaving the original archive unchanged.

The new File Sync option (**-FS**) is also considered a new mode, though it is similar to **update**. This mode synchronizes the archive with the files on the OS, only replacing files in the archive if the file time or size of the OS file is different, adding new files, and deleting entries from the archive where there is no matching file. As this mode can delete entries from the archive, consider making a backup copy of the archive.

Also see **-DF** for creating difference archives.

See each option description below for details and the **EXAMPLES** section below for examples.

Split archives. *zip* version 3.0 and later can create split archives. A **split archive** is a standard zip archive split over multiple files. (Note that split archives are not just archives split in to pieces, as the offsets of entries are now based on the start of each split. Concatenating the pieces together will invalidate these offsets, but *unzip* can usually deal with it. *zip* will usually refuse to process such a spliced archive unless the **-FF** fix option is used to fix the offsets.)

One use of split archives is storing a large archive on multiple removable media. For a split archive with 20 split files the files are typically named (replace ARCHIVE with the name of your archive) ARCHIVE.z01, ARCHIVE.z02, ..., ARCHIVE.z19, ARCHIVE.zip. Note that the last file is the **.zip** file. In contrast, **spanned archives** are the original multi-disk archive generally requiring floppy disks and using volume labels to store disk numbers. *zip* supports split archives but not spanned archives, though a procedure exists for converting split archives of the right size to spanned archives. The reverse is also true, where each file of a spanned archive can be copied in order to files with the above names to create a split archive.

Use **-s** to set the split size and create a split archive. The size is given as a number followed optionally by one of k (kB), m (MB), g (GB), or t (TB) (the default is m). The **-sp** option can be used to pause *zip* between splits to allow changing removable media, for example, but read the descriptions and warnings for both **-s** and **-sp** below.

Though *zip* does not update split archives, *zip* provides the new option **-O** (**--output-file** or **--out**) to allow split archives to be updated and saved in a new archive. For example,

```
zip inarchive.zip foo.c bar.c --out outarchive.zip
```

reads archive **inarchive.zip**, even if split, adds the files **foo.c** and **bar.c**, and writes the resulting archive to **outarchive.zip**. If **inarchive.zip** is split then **outarchive.zip** defaults to the same split size. Be aware that if **outarchive.zip** and any split files that are created with it already exist, these are always overwritten as needed without warning. This may be changed in the future.

Unicode. Though the zip standard requires storing paths in an archive using a specific character set, in practice zips have stored paths in archives in whatever the local character set is. This creates problems when an archive is created or updated on a system using one character set and then extracted on another system using a different character set. When compiled with Unicode support enabled on platforms that support wide characters, *zip* now stores, in addition to the standard local path for backward compatibility, the UTF-8 translation of the path. This provides a common universal character set for storing paths that allows these paths to be fully extracted on other systems that support Unicode and to match as close as possible on systems that don't.

On Win32 systems where paths are internally stored as Unicode but represented in the local character set, it's possible that some paths will be skipped during a local character set directory scan. *zip* with Unicode support now can read and store these paths. Note that Win 9x systems and FAT file systems don't fully support Unicode.

Be aware that console windows on Win32 and Unix, for example, sometimes don't accurately show all characters due to how each operating system switches in character sets for display. However, directory navigation tools should show the correct paths if the needed fonts are loaded.

Command line format. This version of *zip* has updated command line processing and support for long options.

Short options take the form

```
-s[-][s[-]...] [value] [=value] [ value]
```

where *s* is a one or two character short option. A short option that takes a value is last in an argument and anything after it is taken as the value. If the option can be negated and "-" immediately follows the option, the option is negated. Short options can also be given as separate arguments

```
-s[-] [value] [=value] [ value] -s[-] [value] [=value] [ value] ...
```

Short options in general take values either as part of the same argument or as the following argument. An optional = is also supported. So

```
-ttmmddyyyy
```

and

```
-tt=mmddyyyy
```

and

```
-tt mmddyyyy
```

all work. The **-x** and **-i** options accept lists of values and use a slightly different format described below. See the **-x** and **-i** options.

Long options take the form

```
--longoption[-] [=value] [ value]
```

where the option starts with --, has a multicharacter name, can include a trailing dash to negate the option (if the option supports it), and can have a value (option argument) specified by preceeding it with = (no spaces). Values can also follow the argument. So

```
--before-date=mmddyyyy
```

and

```
--before-date mmddyyyy
```

both work.

Long option names can be shortened to the shortest unique abbreviation. See the option descriptions below for which support long options. To avoid confusion, avoid abbreviating a negatable option with an embedded dash ("-") at the dash if you plan to negate it (the parser would consider a trailing dash, such as for the option **--some-option** using **--some-** as the option, as part of the name rather than a negating dash). This may be changed to force the last dash in **--some-** to be negating in the future.

OPTIONS

-a

--ascii [Systems using EBCDIC] Translate file to ASCII format.

-A

--adjust-sfx

Adjust self-extracting executable archive. A self-extracting executable archive is created by prepending the SFX stub to an existing archive. The **-A** option tells *zip* to adjust the entry offsets stored in the archive to take into account this "preamble" data.

Note: self-extracting archives for the Amiga are a special case. At present, only the Amiga port of *zip* is capable of adjusting or updating these without corrupting them. **-J** can be used to remove the SFX stub if other updates need to be made.

-AC**--archive-clear**

[WIN32] Once archive is created (and tested if **-T** is used, which is recommended), clear the archive bits of files processed. WARNING: Once the bits are cleared they are cleared. You may want to use the **-sf** show files option to store the list of files processed in case the archive operation must be repeated. Also consider using the **-MM** must match option. Be sure to check out **-DF** as a possibly better way to do incremental backups.

-AS**--archive-set**

[WIN32] Only include files that have the archive bit set. Directories are not stored when **-AS** is used, though by default the paths of entries, including directories, are stored as usual and can be used by most unzips to recreate directories.

The archive bit is set by the operating system when a file is modified and, if used with **-AC**, **-AS** can provide an incremental backup capability. However, other applications can modify the archive bit and it may not be a reliable indicator of which files have changed since the last archive operation. Alternative ways to create incremental backups are using **-t** to use file dates, though this won't catch old files copied to directories being archived, and **-DF** to create a differential archive.

-B**--binary**

[VM/CMS and MVS] force file to be read binary (default is text).

-Bn

[TANDEM] set Edit/Enscribe formatting options with *n* defined as
 bit 0: Don't add delimiter (Edit/Enscribe)
 bit 1: Use LF rather than CR/LF as delimiter (Edit/Enscribe)
 bit 2: Space fill record to maximum record length (Enscribe)
 bit 3: Trim trailing space (Enscribe)
 bit 8: Force 30K (Expand) large read for unstructured files

-b path**--temp-path path**

Use the specified *path* for the temporary *zip* archive. For example:

```
zip -b /tmp stuff *
```

will put the temporary *zip* archive in the directory */tmp*, copying over *stuff.zip* to the current directory when done. This option is useful when updating an existing archive and the file system containing this old archive does not have enough space to hold both old and new archives at the same time. It may also be useful when streaming in some cases to avoid the need for data descriptors. Note that using this option may require *zip* take additional time to copy the archive file when done to the destination file system.

-c**--entry-comments**

Add one-line comments for each file. File operations (adding, updating) are done first, and the user is then prompted for a one-line comment for each file. Enter the comment followed by return, or just return for no comment.

-C**--preserve-case**

[VMS] Preserve case all on VMS. Negating this option (**-C-**) downcases.

-C2**--preserve-case-2**

[VMS] Preserve case ODS2 on VMS. Negating this option (**-C2-**) downcases.

-C5**--preserve-case-5**

[VMS] Preserve case ODS5 on VMS. Negating this option (**-C5-**) downcases.

-d**--delete**

Remove (delete) entries from a *zip* archive. For example:

```
zip -d foo foo/tom/junk foo/harry/\* \*.o
```

will remove the entry *foo/tom/junk*, all of the files that start with *foo/harry/*, and all of the files that end with *.o* (in any path). Note that shell pathname expansion has been inhibited with backslashes, so that *zip* can see the asterisks, enabling *zip* to match on the contents of the *zip* archive instead of the contents of the current directory. (The backslashes are not used on MSDOS-based platforms.) Can also use quotes to escape the asterisks as in

```
zip -d foo foo/tom/junk "foo/harry/*" "*.o"
```

Not escaping the asterisks on a system where the shell expands wildcards could result in the asterisks being converted to a list of files in the current directory and that list used to delete entries from the archive.

Under MSDOS, **-d** is case sensitive when it matches names in the *zip* archive. This requires that file names be entered in upper case if they were zipped by PKZIP on an MSDOS system. (We considered making this case insensitive on systems where paths were case insensitive, but it is possible the archive came from a system where case does matter and the archive could include both **Bar** and **bar** as separate files in the archive.) But see the new option **-ic** to ignore case in the archive.

-db**--display-bytes**

Display running byte counts showing the bytes zipped and the bytes to go.

-dc**--display-counts**

Display running count of entries zipped and entries to go.

-dd**--display-dots**

Display dots while each entry is zipped (except on ports that have their own progress indicator). See **-ds** below for setting dot size. The default is a dot every 10 MB of input file processed. The

-v option also displays dots (previously at a much higher rate than this but now **-v** also defaults to 10 MB) and this rate is also controlled by **-ds**.

-df

--datafork

[MacOS] Include only data-fork of files zipped into the archive. Good for exporting files to foreign operating-systems. Resource-forks will be ignored at all.

-dg

--display-globaldots

Display progress dots for the archive instead of for each file. The command

```
zip -qdgds 10m
```

will turn off most output except dots every 10 MB.

-ds size

--dot-size size

Set amount of input file processed for each dot displayed. See **-dd** to enable displaying dots. Setting this option implies **-dd**. Size is in the format nm where n is a number and m is a multiplier. Currently m can be k (KB), m (MB), g (GB), or t (TB), so if n is 100 and m is k, size would be 100k which is 100 KB. The default is 10 MB.

The **-v** option also displays dots and now defaults to 10 MB also. This rate is also controlled by this option. A size of 0 turns dots off.

This option does not control the dots from the "Scanning files" message as *zip* scans for input files. The dot size for that is fixed at 2 seconds or a fixed number of entries, whichever is longer.

-du

--display-usize

Display the uncompressed size of each entry.

-dv

--display-volume

Display the volume (disk) number each entry is being read from, if reading an existing archive, and being written to.

-D

--no-dir-entries

Do not create entries in the *zip* archive for directories. Directory entries are created by default so that their attributes can be saved in the zip archive. The environment variable ZIPOPT can be used to change the default options. For example under Unix with sh:

```
ZILOPT="-D"; export ZIPOPT
```

(The variable ZIPOPT can be used for any option, including **-i** and **-x** using a new option format detailed below, and can include several options.) The option **-D** is a shorthand for **-x "*/"** but the latter previously could not be set as default in the ZIPOPT environment variable as the contents of ZIPOPT gets inserted near the beginning of the command line and the file list had to end at the end of the line.

This version of *zip* does allow **-x** and **-i** options in ZIPOPT if the form

```
-x file file ... @
```

is used, where the @ (an argument that is just @) terminates the list.

-DF

--difference-archive

Create an archive that contains all new and changed files since the original archive was created. For this to work, the input file list and current directory must be the same as during the original *zip* operation.

For example, if the existing archive was created using

```
zip -r foofull .
```

from the *bar* directory, then the command

```
zip -r foofull . -DF --out foonew
```

also from the *bar* directory creates the archive *foonew* with just the files not in *foofull* and the files where the size or file time of the files do not match those in *foofull*.

Note that the timezone environment variable TZ should be set according to the local timezone in order for this option to work correctly. A change in timezone since the original archive was created could result in no times matching and all files being included.

A possible approach to backing up a directory might be to create a normal archive of the contents of the directory as a full backup, then use this option to create incremental backups.

-e

--encrypt

Encrypt the contents of the *zip* archive using a password which is entered on the terminal in response to a prompt (this will not be echoed; if standard error is not a tty, *zip* will exit with an error). The password prompt is repeated to save the user from typing errors.

-E

--longnames

[OS/2] Use the .LONGNAME Extended Attribute (if found) as filename.

-f

--freshen

Replace (freshen) an existing entry in the *zip* archive only if it has been modified more recently than the version already in the *zip* archive; unlike the update option (**-u**) this will not add files that are not already in the *zip* archive. For example:

```
zip -f foo
```

This command should be run from the same directory from which the original *zip* command was run, since paths stored in *zip* archives are always relative.

Note that the timezone environment variable TZ should be set according to the local timezone in order for the **-f**, **-u** and **-o** options to work correctly.

The reasons behind this are somewhat subtle but have to do with the differences between the Unix-format file times (always in GMT) and most of the other operating systems (always local time) and the necessity to compare the two. A typical TZ value is "MET-IMEST" (Middle European time with automatic adjustment for "summertime" or Daylight Savings Time).

The format is TTThhDDD, where TTT is the time zone such as MET, hh is the difference between GMT and local time such as -1 above, and DDD is the time zone when daylight savings time is in effect. Leave off the DDD if there is no daylight savings time. For the US Eastern time zone EST5EDT.

-F
--fix
-FF
--fixfix

Fix the *zip* archive. The **-F** option can be used if some portions of the archive are missing, but requires a reasonably intact central directory. The input archive is scanned as usual, but *zip* will ignore some problems. The resulting archive should be valid, but any inconsistent entries will be left out.

When doubled as in **-FF**, the archive is scanned from the beginning and *zip* scans for special signatures to identify the limits between the archive members. The single **-F** is more reliable if the archive is not too much damaged, so try this option first.

If the archive is too damaged or the end has been truncated, you must use **-FF**. This is a change from *zip* 2.32, where the **-F** option is able to read a truncated archive. The **-F** option now more reliably fixes archives with minor damage and the **-FF** option is needed to fix archives where **-F** might have been sufficient before.

Neither option will recover archives that have been incorrectly transferred in ascii mode instead of binary. After the repair, the **-t** option of *unzip* may show that some files have a bad CRC. Such files cannot be recovered; you can remove them from the archive using the **-d** option of *zip*.

Note that **-FF** may have trouble fixing archives that include an embedded zip archive that was stored (without compression) in the archive and, depending on the damage, it may find the entries in the embedded archive rather than the archive itself. Try **-F** first as it does not have this problem.

The format of the fix commands have changed. For example, to fix the damaged archive *foo.zip*,

```
zip -F foo --out foofix
```

tries to read the entries normally, copying good entries to the new archive *foofix.zip*. If this doesn't work, as when the archive is truncated, or if some entries you know are in the archive are missed, then try

```
zip -FF foo --out foofixfix
```

and compare the resulting archive to the archive created by **-F**. The **-FF** option may create an inconsistent archive. Depending on what is damaged, you can then use the **-F** option to fix that archive.

A split archive with missing split files can be fixed using **-F** if you have the last split of the archive (the **.zip** file). If this file is missing, you must use **-FF** to fix the archive, which will prompt you for the splits you have.

Currently the fix options can't recover entries that have a bad checksum or are otherwise damaged.

-FI

--fifo [Unix] Normally *zip* skips reading any FIFOs (named pipes) encountered, as *zip* can hang if the FIFO is not being fed. This option tells *zip* to read the contents of any FIFO it finds.

-FS

--filesync

Synchronize the contents of an archive with the files on the OS. Normally when an archive is updated, new files are added and changed files are updated but files that no longer exist on the OS are not deleted from the archive. This option enables a new mode that checks entries in the archive against the file system. If the file time and file size of the entry matches that of the OS file, the entry is copied from the old archive instead of being read from the file system and compressed. If the OS file has changed, the entry is read and compressed as usual. If the entry in the archive does not match a file on the OS, the entry is deleted. Enabling this option should create archives

that are the same as new archives, but since existing entries are copied instead of compressed, updating an existing archive with **-FS** can be much faster than creating a new archive. Also consider using **-u** for updating an archive.

For this option to work, the archive should be updated from the same directory it was created in so the relative paths match. If few files are being copied from the old archive, it may be faster to create a new archive instead.

Note that the timezone environment variable **TZ** should be set according to the local timezone in order for this option to work correctly. A change in timezone since the original archive was created could result in no times matching and recompression of all files.

This option deletes files from the archive. If you need to preserve the original archive, make a copy of the archive first or use the **--out** option to output the updated archive to a new file. Even though it may be slower, creating a new archive with a new archive name is safer, avoids mismatches between archive and OS paths, and is preferred.

-g

--grow

Grow (append to) the specified *zip* archive, instead of creating a new one. If this operation fails, *zip* attempts to restore the archive to its original state. If the restoration fails, the archive might become corrupted. This option is ignored when there's no existing archive or when at least one archive member must be updated or deleted.

-h

-?

--help

Display the *zip* help information (this also appears if *zip* is run with no arguments).

-h2

--more-help

Display extended help including more on command line format, pattern matching, and more obscure options.

-i files

--include files

Include only the specified files, as in:

```
zip -r foo . -i \*.c
```

which will include only the files that end in *.c* in the current directory and its subdirectories. (Note for PKZIP users: the equivalent command is

```
pkzip -rP foo *.c
```

PKZIP does not allow recursion in directories other than the current one.) The backslash avoids the shell filename substitution, so that the name matching is performed by *zip* at all directory levels. [This is for Unix and other systems where ** escapes the next character. For other systems where the shell does not process *** do not use ** and the above is

```
zip -r foo . -i *.c
```

Examples are for Unix unless otherwise specified.] So to include *dir*, a directory directly under the current directory, use

```
zip -r foo . -i dir/\*
```

or

```
zip -r foo . -i "dir/*"
```

to match paths such as `dir/a` and `dir/b/file.c` [on ports without wildcard expansion in the shell such as MSDOS and Windows]

```
zip -r foo . -i dir/*
```

is used.] Note that currently the trailing `/` is needed for directories (as in

```
zip -r foo . -i dir/
```

to include directory `dir`).

The long option form of the first example is

```
zip -r foo . --include \*.c
```

and does the same thing as the short option form.

Though the command syntax used to require **-i** at the end of the command line, this version actually allows **-i** (or **--include**) anywhere. The list of files terminates at the next argument starting with `-`, the end of the command line, or the list terminator `@` (an argument that is just `@`). So the above can be given as

```
zip -i \*.c @ -r foo .
```

for example. There must be a space between the option and the first file of a list. For just one file you can use the single value form

```
zip -i \*.c -r foo .
```

(no space between option and value) or

```
zip --include=\*.c -r foo .
```

as additional examples. The single value forms are not recommended because they can be confusing and, in particular, the **-ifile** format can cause problems if the first letter of **file** combines with **i** to form a two-letter option starting with **i**. Use **-sc** to see how your command line will be parsed.

Also possible:

```
zip -r foo . -i@include.lst
```

which will only include the files in the current directory and its subdirectories that match the patterns in the file `include.lst`.

Files to **-i** and **-x** are patterns matching internal archive paths. See **-R** for more on patterns.

-I

--no-image

[Acorn RISC OS] Don't scan through Image files. When used, *zip* will not consider Image files (eg. DOS partitions or Spark archives when SparkFS is loaded) as directories but will store them as single files.

For example, if you have SparkFS loaded, zipping a Spark archive will result in a zipfile containing a directory (and its content) while using the **'I'** option will result in a zipfile containing a Spark archive. Obviously this second case will also be obtained (without the **'I'** option) if SparkFS isn't loaded.

-ic

--ignore-case

[VMS, WIN32] Ignore case when matching archive entries. This option is only available on systems where the case of files is ignored. On systems with case-insensitive file systems, case is normally ignored when matching files on the file system but is not ignored for **-f** (freshen), **-d** (delete), **-U** (copy), and similar modes when matching against archive entries (currently **-f** ignores case on

VMS) because archive entries can be from systems where case does matter and names that are the same except for case can exist in an archive. The **-ic** option makes all matching case insensitive. This can result in multiple archive entries matching a command line pattern.

-j

--junk-paths

Store just the name of a saved file (junk the path), and do not store directory names. By default, *zip* will store the full path (relative to the current directory).

-jj

--absolute-path

[MacOS] record Fullpath (+ Volname). The complete path including volume will be stored. By default the relative path will be stored.

-J

--junk-sfx

Strip any prepended data (e.g. a SFX stub) from the archive.

-k

--DOS-names

Attempt to convert the names and paths to conform to MSDOS, store only the MSDOS attribute (just the user write attribute from Unix), and mark the entry as made under MSDOS (even though it was not); for compatibility with PKUNZIP under MSDOS which cannot handle certain names such as those with two dots.

-l

--to-crlf

Translate the Unix end-of-line character LF into the MSDOS convention CR LF. This option should not be used on binary files. This option can be used on Unix if the zip file is intended for PKUNZIP under MSDOS. If the input files already contain CR LF, this option adds an extra CR. This is to ensure that **unzip -a** on Unix will get back an exact copy of the original file, to undo the effect of **zip -l**. See **-ll** for how binary files are handled.

-la

--log-append

Append to existing logfile. Default is to overwrite.

-lf logfilepath

--logfile-path logfilepath

Open a logfile at the given path. By default any existing file at that location is overwritten, but the **-la** option will result in an existing file being opened and the new log information appended to any existing information. Only warnings and errors are written to the log unless the **-li** option is also given, then all information messages are also written to the log.

-li

--log-info

Include information messages, such as file names being zipped, in the log. The default is to only include the command line, any warnings and errors, and the final status.

-ll

--from-crlf

Translate the MSDOS end-of-line CR LF into Unix LF. This option should not be used on binary files. This option can be used on MSDOS if the zip file is intended for unzip under Unix. If the file is converted and the file is later determined to be binary a warning is issued and the file is probably corrupted. In this release if **-ll** detects binary in the first buffer read from a file, *zip* now issues a warning and skips line end conversion on the file. This check seems to catch all binary files tested, but the original check remains and if a converted file is later determined to be binary

that warning is still issued. A new algorithm is now being used for binary detection that should allow line end conversion of text files in **UTF-8** and similar encodings.

-L

--license

Display the *zip* license.

-m

--move

Move the specified files into the *zip* archive; actually, this deletes the target directories/files after making the specified *zip* archive. If a directory becomes empty after removal of the files, the directory is also removed. No deletions are done until *zip* has created the archive without error. This is useful for conserving disk space, but is potentially dangerous so it is recommended to use it in combination with **-T** to test the archive before removing all input files.

-MM

--must-match

All input patterns must match at least one file and all input files found must be readable. Normally when an input pattern does not match a file the "name not matched" warning is issued and when an input file has been found but later is missing or not readable a missing or not readable warning is issued. In either case *zip* continues creating the archive, with missing or unreadable new files being skipped and files already in the archive remaining unchanged. After the archive is created, if any files were not readable *zip* returns the OPEN error code (18 on most systems) instead of the normal success return (0 on most systems). With **-MM** set, *zip* exits as soon as an input pattern is not matched (whenever the "name not matched" warning would be issued) or when an input file is not readable. In either case *zip* exits with an OPEN error and no archive is created.

This option is useful when a known list of files is to be zipped so any missing or unreadable files will result in an error. It is less useful when used with wildcards, but *zip* will still exit with an error if any input pattern doesn't match at least one file and if any matched files are unreadable. If you want to create the archive anyway and only need to know if files were skipped, don't use **-MM** and just check the return code. Also **-If** could be useful.

-n suffixes

--suffixes suffixes

Do not attempt to compress files named with the given **suffixes**. Such files are simply stored (0% compression) in the output zip file, so that *zip* doesn't waste its time trying to compress them. The suffixes are separated by either colons or semicolons. For example:

```
zip -rn .Z:.zip:.tiff:.gif:.snd foo foo
```

will copy everything from *foo* into *foo.zip*, but will store any files that end in *.Z*, *.zip*, *.tiff*, *.gif*, or *.snd* without trying to compress them (image and sound files often have their own specialized compression methods). By default, *zip* does not compress files with extensions in the list *.Z:.zip:.zoo:.arc:.lzh:.arj*. Such files are stored directly in the output archive. The environment variable **ZIPOPT** can be used to change the default options. For example under Unix with *csh*:

```
setenv ZIPOPT "-n .gif:.zip"
```

To attempt compression on all files, use:

```
zip -n : foo
```

The maximum compression option **-9** also attempts compression on all files regardless of extension.

On Acorn RISC OS systems the suffixes are actually filetypes (3 hex digit format). By default, *zip* does not compress files with filetypes in the list *DDC:D96:68E* (i.e. Archives, CFS files and Pack-Dir files).

-nw

--no-wild

Do not perform internal wildcard processing (shell processing of wildcards is still done by the shell unless the arguments are escaped). Useful if a list of paths is being read and no wildcard substitution is desired.

-N**--notes**

[Amiga, MacOS] Save Amiga or MacOS filenotes as zipfile comments. They can be restored by using the -N option of *unzip*. If -c is used also, you are prompted for comments only for those files that do not have filenotes.

-o**--latest-time**

Set the "last modified" time of the *zip* archive to the latest (oldest) "last modified" time found among the entries in the *zip* archive. This can be used without any other operations, if desired. For example:

```
zip -o foo
```

will change the last modified time of **foo.zip** to the latest time of the entries in **foo.zip**.

-O output-file**--output-file output-file**

Process the archive changes as usual, but instead of updating the existing archive, output the new archive to output-file. Useful for updating an archive without changing the existing archive and the input archive must be a different file than the output archive.

This option can be used to create updated split archives. It can also be used with **-U** to copy entries from an existing archive to a new archive. See the **EXAMPLES** section below.

Another use is converting *zip* files from one split size to another. For instance, to convert an archive with 700 MB CD splits to one with 2 GB DVD splits, can use:

```
zip -s 2g cd-split.zip --out dvd-split.zip
```

which uses copy mode. See **-U** below. Also:

```
zip -s 0 split.zip --out unsplit.zip
```

will convert a split archive to a single-file archive.

Copy mode will convert stream entries (using data descriptors and which should be compatible with most unzips) to normal entries (which should be compatible with all unzips), except if standard encryption was used. For archives with encrypted entries, *zipcloak* will decrypt the entries and convert them to normal entries.

-p**--paths**

Include relative file paths as part of the names of files stored in the archive. This is the default. The **-j** option junks the paths and just stores the names of the files.

-P password**--password password**

Use *password* to encrypt zipfile entries (if any). **THIS IS INSECURE!** Many multi-user operating systems provide ways for any user to see the current command line of any other user; even on stand-alone systems there is always the threat of over-the-shoulder peeking. Storing the plaintext password as part of a command line in an automated script is even worse. Whenever possible, use the non-echoing, interactive prompt to enter passwords. (And where security is truly important, use strong encryption such as Pretty Good Privacy instead of the relatively weak standard encryption provided by zipfile utilities.)

-q**--quiet**

Quiet mode; eliminate informational messages and comment prompts. (Useful, for example, in shell scripts and background tasks).

-Qn**--Q-flag n**

[QDOS] store information about the file in the file header with *n* defined as

bit 0: Don't add headers for any file

bit 1: Add headers for all files

bit 2: Don't wait for interactive key press on exit

-r**--recurse-paths**

Travel the directory structure recursively; for example:

```
zip -r foo.zip foo
```

or more concisely

```
zip -r foo foo
```

In this case, all the files and directories in **foo** are saved in a *zip* archive named **foo.zip**, including files with names starting with ".", since the recursion does not use the shell's file-name substitution mechanism. If you wish to include only a specific subset of the files in directory **foo** and its subdirectories, use the **-i** option to specify the pattern of files to be included. You should not use **-r** with the name ".*", since that matches "." which will attempt to zip up the parent directory (probably not what was intended).

Multiple source directories are allowed as in

```
zip -r foo foo1 foo2
```

which first zips up **foo1** and then **foo2**, going down each directory.

Note that while wildcards to **-r** are typically resolved while recursing down directories in the file system, any **-R**, **-x**, and **-i** wildcards are applied to internal archive pathnames once the directories are scanned. To have wildcards apply to files in subdirectories when recursing on Unix and similar systems where the shell does wildcard substitution, either escape all wildcards or put all arguments with wildcards in quotes. This lets *zip* see the wildcards and match files in subdirectories using them as it recurses.

-R**--recurse-patterns**

Travel the directory structure recursively starting at the current directory; for example:

```
zip -R foo "*.c"
```

In this case, all the files matching ***.c** in the tree starting at the current directory are stored into a *zip* archive named **foo.zip**. Note that ***.c** will match **file.c**, **a/file.c** and **a/b/c**. More than one pattern can be listed as separate arguments. Note for PKZIP users: the equivalent command is

```
pkzip -rP foo *.c
```

Patterns are relative file paths as they appear in the archive, or will after zipping, and can have optional wildcards in them. For example, given the current directory is **foo** and under it are directories **foo1** and **foo2** and in **foo1** is the file **bar.c**,

```
zip -R foo/*
```

will zip up **foo**, **foo/foo1**, **foo/foo1/bar.c**, and **foo/foo2**.

```
zip -R */bar.c
```

will zip up **foo/foo1/bar.c**. See the note for **-r** on escaping wildcards.

-RE**--regex**

[WIN32] Before *zip* 3.0, regular expression list matching was enabled by default on Windows platforms. Because of confusion resulting from the need to escape "[" and "]" in names, it is now off by default for Windows so "[" and "]" are just normal characters in names. This option enables [] matching again.

-s splitsize**--split-size** splitsize

Enable creating a split archive and set the split size. A split archive is an archive that could be split over many files. As the archive is created, if the size of the archive reaches the specified split size, that split is closed and the next split opened. In general all splits but the last will be the split size and the last will be whatever is left. If the entire archive is smaller than the split size a single-file archive is created.

Split archives are stored in numbered files. For example, if the output archive is named **archive** and three splits are required, the resulting archive will be in the three files **archive.z01**, **archive.z02**, and **archive.zip**. Do not change the numbering of these files or the archive will not be readable as these are used to determine the order the splits are read.

Split size is a number optionally followed by a multiplier. Currently the number must be an integer. The multiplier can currently be one of **k** (kilobytes), **m** (megabytes), **g** (gigabytes), or **t** (terabytes). As 64k is the minimum split size, numbers without multipliers default to megabytes. For example, to create a split archive called **foo** with the contents of the **bar** directory with splits of 670 MB that might be useful for burning on CDs, the command:

```
zip -s 670m -r foo bar
```

could be used.

Currently the old splits of a split archive are not excluded from a new archive, but they can be specifically excluded. If possible, keep the input and output archives out of the path being zipped when creating split archives.

Using **-s** without **-sp** as above creates all the splits where **foo** is being written, in this case the current directory. This split mode updates the splits as the archive is being created, requiring all splits to remain writable, but creates split archives that are readable by any unzip that supports split archives. See **-sp** below for enabling split pause mode which allows splits to be written directly to removable media.

The option **-sv** can be used to enable verbose splitting and provide details of how the splitting is being done. The **-sb** option can be used to ring the bell when *zip* pauses for the next split destination.

Split archives cannot be updated, but see the **-O** (**--out**) option for how a split archive can be updated as it is copied to a new archive. A split archive can also be converted into a single-file archive using a split size of 0 or negating the **-s** option:

```
zip -s 0 split.zip --out single.zip
```

Also see **-U** (**--copy**) for more on using copy mode.

-sb**--split-bell**

If splitting and using split pause mode, ring the bell when *zip* pauses for each split destination.

-sc

--show-command

Show the command line starting *zip* as processed and exit. The new command parser permutes the arguments, putting all options and any values associated with them before any non-option arguments. This allows an option to appear anywhere in the command line as long as any values that go with the option go with it. This option displays the command line as *zip* sees it, including any arguments from the environment such as from the **ZIPOPT** variable. Where allowed, options later in the command line can override options earlier in the command line.

-sf**--show-files**

Show the files that would be operated on, then exit. For instance, if creating a new archive, this will list the files that would be added. If the option is negated, **-sf-**, output only to an open log file. Screen display is not recommended for large lists.

-so**--show-options**

Show all available options supported by *zip* as compiled on the current system. As this command reads the option table, it should include all options. Each line includes the short option (if defined), the long option (if defined), the format of any value that goes with the option, if the option can be negated, and a small description. The value format can be no value, required value, optional value, single character value, number value, or a list of values. The output of this option is not intended to show how to use any option but only show what options are available.

-sp**--split-pause**

If splitting is enabled with **-s**, enable split pause mode. This creates split archives as **-s** does, but stream writing is used so each split can be closed as soon as it is written and *zip* will pause between each split to allow changing split destination or media.

Though this split mode allows writing splits directly to removable media, it uses stream archive format that may not be readable by some unzips. Before relying on splits created with **-sp**, test a split archive with the unzip you will be using.

To convert a stream split archive (created with **-sp**) to a standard archive see the **--out** option.

-su**--show-unicode**

As **-sf**, but also show Unicode version of the path if exists.

-sU**--show-just-unicode**

As **-sf**, but only show Unicode version of the path if exists, otherwise show the standard version of the path.

-sv**--split-verbose**

Enable various verbose messages while splitting, showing how the splitting is being done.

-S**--system-hidden**

[MSDOS, OS/2, WIN32 and ATARI] Include system and hidden files.

[MacOS] Includes finder invisible files, which are ignored otherwise.

-t mmddyyyy**--from-date mmddyyyy**

Do not operate on files modified prior to the specified date, where **mm** is the month (00-12), **dd** is the day of the month (01-31), and **yyyy** is the year. The *ISO 8601* date format **yyyy-mm-dd** is also accepted. For example:

```
zip -rt 12071991 infamy foo
```

```
zip -rt 1991-12-07 infamy foo
```

will add all the files in **foo** and its subdirectories that were last modified on or after 7 December 1991, to the *zip* archive **infamy.zip**.

-tt mmddyyyy

--before-date mmddyyyy

Do not operate on files modified after or at the specified date, where **mm** is the month (00-12), **dd** is the day of the month (01-31), and **yyyy** is the year. The *ISO 8601* date format **yyyy-mm-dd** is also accepted. For example:

```
zip -rtt 11301995 infamy foo
```

```
zip -rtt 1995-11-30 infamy foo
```

will add all the files in **foo** and its subdirectories that were last modified before 30 November 1995, to the *zip* archive **infamy.zip**.

-T

--test

Test the integrity of the new zip file. If the check fails, the old zip file is unchanged and (with the **-m** option) no input files are removed.

-TT cmd

--unzip-command cmd

Use command *cmd* instead of 'unzip -tqq' to test an archive when the **-T** option is used. On Unix, to use a copy of unzip in the current directory instead of the standard system unzip, could use:

```
zip archive file1 file2 -T -TT "./unzip -tqq"
```

In *cmd*, { } is replaced by the name of the temporary archive, otherwise the name of the archive is appended to the end of the command. The return code is checked for success (0 on Unix).

-u

--update

Replace (update) an existing entry in the *zip* archive only if it has been modified more recently than the version already in the *zip* archive. For example:

```
zip -u stuff *
```

will add any new files in the current directory, and update any files which have been modified since the *zip* archive *stuff.zip* was last created/modified (note that *zip* will not try to pack *stuff.zip* into itself when you do this).

Note that the **-u** option with no input file arguments acts like the **-f** (freshen) option.

-U

--copy-entries

Copy entries from one archive to another. Requires the **--out** option to specify a different output file than the input archive. Copy mode is the reverse of **-d** delete. When delete is being used with **--out**, the selected entries are deleted from the archive and all other entries are copied to the new archive, while copy mode selects the files to include in the new archive. Unlike **-u** update, input patterns on the command line are matched against archive entries only and not the file system files. For instance,

```
zip inarchive "*.c" --copy --out outarchive
```

copies entries with names ending in **.c** from **inarchive** to **outarchive**. The wildcard must be escaped on some systems to prevent the shell from substituting names of files from the file system which may have no relevance to the entries in the archive.

If no input files appear on the command line and **--out** is used, copy mode is assumed:

```
zip inarchive --out outarchive
```

This is useful for changing split size for instance. Encrypting and decrypting entries is not yet supported using copy mode. Use *zipcloak* for that.

-UN v

--unicode v

Determine what *zip* should do with Unicode file names. *zip 3.0*, in addition to the standard file path, now includes the UTF-8 translation of the path if the entry path is not entirely 7-bit ASCII. When an entry is missing the Unicode path, *zip* reverts back to the standard file path. The problem with using the standard path is this path is in the local character set of the *zip* that created the entry, which may contain characters that are not valid in the character set being used by the *unzip*. When *zip* is reading an archive, if an entry also has a Unicode path, *zip* now defaults to using the Unicode path to recreate the standard path using the current local character set.

This option can be used to determine what *zip* should do with this path if there is a mismatch between the stored standard path and the stored UTF-8 path (which can happen if the standard path was updated). In all cases, if there is a mismatch it is assumed that the standard path is more current and *zip* uses that. Values for **v** are

- q – quit if paths do not match
- w – warn, continue with standard path
- i – ignore, continue with standard path
- n – no Unicode, do not use Unicode paths

The default is to warn and continue.

Characters that are not valid in the current character set are escaped as **#Uxxxx** and **#Lxxxxxx**, where **x** is an ASCII character for a hex digit. The first is used if a 16-bit character number is sufficient to represent the Unicode character and the second if the character needs more than 16 bits to represent its Unicode character code. Setting **-UN** to

e – escape

as in

```
zip archive -sU -UN=e
```

forces *zip* to escape all characters that are not printable 7-bit ASCII.

Normally *zip* stores UTF-8 directly in the standard path field on systems where UTF-8 is the current character set and stores the UTF-8 in the new extra fields otherwise. The option

u – UTF-8

as in

```
zip archive dir -r -UN=UTF8
```

forces *zip* to store UTF-8 as native in the archive. Note that storing UTF-8 directly is the default on Unix systems that support it. This option could be useful on Windows systems where the escaped path is too large to be a valid path and the UTF-8 version of the path is smaller, but native UTF-8 is not backward compatible on Windows systems.

-v

--verbose

Verbose mode or print diagnostic version info.

Normally, when applied to real operations, this option enables the display of a progress indicator during compression (see **-dd** for more on dots) and requests verbose diagnostic info about zipfile structure oddities.

However, when **-v** is the only command line argument a diagnostic screen is printed instead. This should now work even if stdout is redirected to a file, allowing easy saving of the information for sending with bug reports to Info-ZIP. The version screen provides the help screen header with program name, version, and release date, some pointers to the Info-ZIP home and distribution sites, and shows information about the target environment (compiler type and version, OS version, compilation date and the enabled optional features used to create the *zip* executable).

-V

--VMS-portable

[VMS] Save VMS file attributes. (Files are truncated at EOF.) When a **-V** archive is unpacked on a non-VMS system, some file types (notably Stream_LF text files and pure binary files like fixed-512) should be extracted intact. Indexed files and file types with embedded record sizes (notably variable-length record types) will probably be seen as corrupt elsewhere.

-VV

--VMS-specific

[VMS] Save VMS file attributes, and all allocated blocks in a file, including any data beyond EOF. Useful for moving ill-formed files among VMS systems. When a **-VV** archive is unpacked on a non-VMS system, almost all files will appear corrupt.

-w

--VMS-versions

[VMS] Append the version number of the files to the name, including multiple versions of files. Default is to use only the most recent version of a specified file.

-ww

--VMS-dot-versions

[VMS] Append the version number of the files to the name, including multiple versions of files, using the .nnn format. Default is to use only the most recent version of a specified file.

-ws

--wild-stop-dirs

Wildcards match only at a directory level. Normally *zip* handles paths as strings and given the paths

`/foo/bar/dir/file1.c`

`/foo/bar/file2.c`

an input pattern such as

`/foo/bar/*`

normally would match both paths, the ***** matching **dir/file1.c** and **file2.c**. Note that in the first case a directory boundary (*/*) was crossed in the match. With **-ws** no directory bounds will be included in the match, making wildcards local to a specific directory level. So, with **-ws** enabled, only the second path would be matched.

When using **-ws**, use ****** to match across directory boundaries as ***** does normally.

-x files

--exclude files

Explicitly exclude the specified files, as in:

`zip -r foo foo -x *.o`

which will include the contents of **foo** in **foo.zip** while excluding all the files that end in **.o**. The backslash avoids the shell filename substitution, so that the name matching is performed by *zip* at all directory levels.

Also possible:

```
zip -r foo foo -x@exclude.lst
```

which will include the contents of **foo** in **foo.zip** while excluding all the files that match the patterns in the file **exclude.lst**.

The long option forms of the above are

```
zip -r foo foo --exclude \*.o
```

and

```
zip -r foo foo --exclude @exclude.lst
```

Multiple patterns can be specified, as in:

```
zip -r foo foo -x \*.o \*.c
```

If there is no space between **-x** and the pattern, just one value is assumed (no list):

```
zip -r foo foo -x\*.o
```

See **-i** for more on include and exclude.

-X

--no-extra

Do not save extra file attributes (Extended Attributes on OS/2, uid/gid and file times on Unix). The zip format uses extra fields to include additional information for each entry. Some extra fields are specific to particular systems while others are applicable to all systems. Normally when *zip* reads entries from an existing archive, it reads the extra fields it knows, strips the rest, and adds the extra fields applicable to that system. With **-X**, *zip* strips all old fields and only includes the Unicode and Zip64 extra fields (currently these two extra fields cannot be disabled).

Negating this option, **-X-**, includes all the default extra fields, but also copies over any unrecognized extra fields.

-y

--symlinks

For UNIX and VMS (V8.3 and later), store symbolic links as such in the *zip* archive, instead of compressing and storing the file referred to by the link. This can avoid multiple copies of files being included in the archive as *zip* recurses the directory trees and accesses files directly and by links.

-z

--archive-comment

Prompt for a multi-line comment for the entire *zip* archive. The comment is ended by a line containing just a period, or an end of file condition (^D on Unix, ^Z on MSDOS, OS/2, and VMS). The comment can be taken from a file:

```
zip -z foo < foowhat
```

-Z cm

--compression-method cm

Set the default compression method. Currently the main methods supported by *zip* are **store** and **deflate**. Compression method can be set to:

store – Setting the compression method to **store** forces *zip* to store entries with no compression. This is generally faster than compressing entries, but results in no space savings. This is the same as using **-0** (compression level zero).

deflate – This is the default method for *zip*. If *zip* determines that storing is better than deflation, the entry will be stored instead.

bzip2 – If **bzip2** support is compiled in, this compression method also becomes available. Only some modern unzips currently support the **bzip2** compression method, so test the unzip you will be using before relying on archives using this method (compression method 12).

For example, to add **bar.c** to archive **foo** using **bzip2** compression:

```
zip -Z bzip2 foo bar.c
```

The compression method can be abbreviated:

```
zip -Zb foo bar.c
```

-#

(-0, -1, -2, -3, -4, -5, -6, -7, -8, -9)

Regulate the speed of compression using the specified digit #, where **-0** indicates no compression (store all files), **-1** indicates the fastest compression speed (less compression) and **-9** indicates the slowest compression speed (optimal compression, ignores the suffix list). The default compression level is **-6**.

Though still being worked, the intention is this setting will control compression speed for all compression methods. Currently only deflation is controlled.

#!

--use-privileges

[WIN32] Use privileges (if granted) to obtain all aspects of WinNT security.

--@

--names-stdin

Take the list of input files from standard input. Only one filename per line.

-\$

--volume-label

[MSDOS, OS/2, WIN32] Include the volume label for the drive holding the first file to be compressed. If you want to include only the volume label or to force a specific drive, use the drive name as first file name, as in:

```
zip -$ foo a: c:bar
```

EXAMPLES

The simplest example:

```
zip stuff *
```

creates the archive *stuff.zip* (assuming it does not exist) and puts all the files in the current directory in it, in compressed form (the **.zip** suffix is added automatically, unless the archive name contains a dot already; this allows the explicit specification of other suffixes).

Because of the way the shell on Unix does filename substitution, files starting with "." are not included; to include these as well:

```
zip stuff .* *
```

Even this will not include any subdirectories from the current directory.

To zip up an entire directory, the command:

```
zip -r foo foo
```

creates the archive *foo.zip*, containing all the files and directories in the directory *foo* that is contained within the current directory.

You may want to make a *zip* archive that contains the files in *foo*, without recording the directory name, *foo*. You can use the **-j** option to leave off the paths, as in:

```
zip -j foo foo/*
```

If you are short on disk space, you might not have enough room to hold both the original directory and the corresponding compressed *zip* archive. In this case, you can create the archive in steps using the **-m** option. If *foo* contains the subdirectories *tom*, *dick*, and *harry*, you can:

```
zip -rm foo foo/tom
zip -rm foo foo/dick
zip -rm foo foo/harry
```

where the first command creates *foo.zip*, and the next two add to it. At the completion of each *zip* command, the last created archive is deleted, making room for the next *zip* command to function.

Use **-s** to set the split size and create a split archive. The size is given as a number followed optionally by one of k (kB), m (MB), g (GB), or t (TB). The command

```
zip -s 2g -r split.zip foo
```

creates a split archive of the directory *foo* with splits no bigger than 2 GB each. If *foo* contained 5 GB of contents and the contents were stored in the split archive without compression (to make this example simple), this would create three splits, *split.z01* at 2 GB, *split.z02* at 2 GB, and *split.zip* at a little over 1 GB.

The **-sp** option can be used to pause *zip* between splits to allow changing removable media, for example, but read the descriptions and warnings for both **-s** and **-sp** below.

Though *zip* does not update split archives, *zip* provides the new option **-O** (**--output-file**) to allow split archives to be updated and saved in a new archive. For example,

```
zip inarchive.zip foo.c bar.c --out outarchive.zip
```

reads archive **inarchive.zip**, even if split, adds the files **foo.c** and **bar.c**, and writes the resulting archive to **outarchive.zip**. If **inarchive.zip** is split then **outarchive.zip** defaults to the same split size. Be aware that **outarchive.zip** and any split files that are created with it are always overwritten without warning. This may be changed in the future.

PATTERN MATCHING

This section applies only to Unix. Watch this space for details on MSDOS and VMS operation. However, the special wildcard characters ***** and **[]** below apply to at least MSDOS also.

The Unix shells (*sh*, *csh*, *bash*, and others) normally do filename substitution (also called "globbing") on command arguments. Generally the special characters are:

- ?** match any single character
- *** match any number of characters (including none)
- []** match any character in the range indicated within the brackets (example: [a-f], [0-9]). This form of wildcard matching allows a user to specify a list of characters between square brackets and if any of the characters match the expression matches. For example:

```
zip archive "*. [hc] "
```

would archive all files in the current directory that end in **.h** or **.c**.

Ranges of characters are supported:

```
zip archive "[a-f] *"
```

would add to the archive all files starting with "a" through "f".

Negation is also supported, where any character in that position not in the list matches. Negation is supported by adding `!` or `^` to the beginning of the list:

```
zip archive "*. [!o]"
```

matches files that don't end in ".o".

On WIN32, `[]` matching needs to be turned on with the `-RE` option to avoid the confusion that names with `[` or `]` have caused.

When these characters are encountered (without being escaped with a backslash or quotes), the shell will look for files relative to the current path that match the pattern, and replace the argument with a list of the names that matched.

The *zip* program can do the same matching on names that are in the *zip* archive being modified or, in the case of the `-x` (exclude) or `-i` (include) options, on the list of files to be operated on, by using backslashes or quotes to tell the shell not to do the name expansion. In general, when *zip* encounters a name in the list of files to do, it first looks for the name in the file system. If it finds it, it then adds it to the list of files to do. If it does not find it, it looks for the name in the *zip* archive being modified (if it exists), using the pattern matching characters described above, if present. For each match, it will add that name to the list of files to be processed, unless this name matches one given with the `-x` option, or does not match any name given with the `-i` option.

The pattern matching includes the path, and so patterns like `*.o` match names that end in ".o", no matter what the path prefix is. Note that the backslash must precede every special character (i.e. `?*[]`), or the entire argument must be enclosed in double quotes (`"`).

In general, use backslashes or double quotes for paths that have wildcards to make *zip* do the pattern matching for file paths, and always for paths and strings that have spaces or wildcards for `-i`, `-x`, `-R`, `-d`, and `-U` and anywhere *zip* needs to process the wildcards.

ENVIRONMENT

The following environment variables are read and used by *zip* as described.

ZIPOPT

contains default options that will be used when running *zip*. The contents of this environment variable will get added to the command line just after the **zip** command.

ZIP [Not on RISC OS and VMS] see ZIPOPT

Zip\$Options

[RISC OS] see ZIPOPT

Zip\$Exts

[RISC OS] contains extensions separated by a `:` that will cause native filenames with one of the specified extensions to be added to the zip file with basename and extension swapped.

ZIP_OPTS

[VMS] see ZIPOPT

SEE ALSO

compress(1), shar(1L), tar(1), unzip(1L), gzip(1L)

DIAGNOSTICS

The exit status (or error level) approximates the exit codes defined by PKWARE and takes on the following values, except under VMS:

- 0 normal; no errors or warnings detected.
- 2 unexpected end of zip file.
- 3 a generic error in the zipfile format was detected. Processing may have completed successfully anyway; some broken zipfiles created by other archivers have simple work-arounds.

- 4 *zip* was unable to allocate memory for one or more buffers during program initialization.
- 5 a severe error in the zipfile format was detected. Processing probably failed immediately.
- 6 entry too large to be processed (such as input files larger than 2 GB when not using Zip64 or trying to read an existing archive that is too large) or entry too large to be split with *zipsplit*
- 7 invalid comment format
- 8 *zip -T* failed or out of memory
- 9 the user aborted *zip* prematurely with control-C (or similar)
- 10 *zip* encountered an error while using a temp file
- 11 read or seek error
- 12 *zip* has nothing to do
- 13 missing or empty zip file
- 14 error writing to a file
- 15 *zip* was unable to create a file to write to
- 16 bad command line parameters
- 18 *zip* could not open a specified file to read
- 19 *zip* was compiled with options not supported on this system

VMS interprets standard Unix (or PC) return values as other, scarier-looking things, so *zip* instead maps them into VMS-style status codes. In general, *zip* sets VMS Facility = 1955 (0x07A3), Code = 2* Unix_status, and an appropriate Severity (as specified in ziperr.h). More details are included in the VMS-specific documentation. See [.vms]NOTES.TXT and [.vms]vms_msg_gen.c.

BUGS

zip 3.0 is not compatible with PKUNZIP 1.10. Use *zip* 1.1 to produce *zip* files which can be extracted by PKUNZIP 1.10.

zip files produced by *zip* 3.0 must not be *updated* by *zip* 1.1 or PKZIP 1.10, if they contain encrypted members or if they have been produced in a pipe or on a non-seekable device. The old versions of *zip* or PKZIP would create an archive with an incorrect format. The old versions can list the contents of the zip file but cannot extract it anyway (because of the new compression algorithm). If you do not use encryption and use regular disk files, you do not have to care about this problem.

Under VMS, not all of the odd file formats are treated properly. Only stream-LF format *zip* files are expected to work with *zip*. Others can be converted using Rahul Dhesi's BILF program. This version of *zip* handles some of the conversion internally. When using Kermit to transfer zip files from VMS to MSDOS, type "set file type block" on VMS. When transferring from MSDOS to VMS, type "set file type fixed" on VMS. In both cases, type "set file type binary" on MSDOS.

Under some older VMS versions, *zip* may hang for file specifications that use DECnet syntax *foo::*.**.

On OS/2, *zip* cannot match some names, such as those including an exclamation mark or a hash sign. This is a bug in OS/2 itself: the 32-bit DosFindFirst/Next don't find such names. Other programs such as GNU tar are also affected by this bug.

Under OS/2, the amount of Extended Attributes displayed by DIR is (for compatibility) the amount returned by the 16-bit version of DosQueryPathInfo(). Otherwise OS/2 1.3 and 2.0 would report different EA sizes when DIRing a file. However, the structure layout returned by the 32-bit DosQueryPathInfo() is a bit different, it uses extra padding bytes and link pointers (it's a linked list) to have all fields on 4-byte boundaries for portability to future RISC OS/2 versions. Therefore the value reported by *zip* (which uses this 32-bit-mode size) differs from that reported by DIR. *zip* stores the 32-bit format for portability, even the 16-bit MS-C-compiled version running on OS/2 1.3, so even this one shows the 32-bit-mode size.

ACKNOWLEDGEMENTS

Thanks to R. P. Byrne for his *Shrink.Pas* program, which inspired this project, and from which the shrink algorithm was stolen; to Phil Katz for placing in the public domain the *zip* file format, compression format, and .ZIP filename extension, and for accepting minor changes to the file format; to Steve Burg for clarifications on the deflate format; to Haruhiko Okumura and Leonid Broukhis for providing some useful ideas for the compression algorithm; to Keith Petersen, Rich Wales, Hunter Goatley and Mark Adler for providing a mailing list and *ftp* site for the Info-ZIP group to use; and most importantly, to the Info-ZIP group itself (listed in the file *infozip.who*) without whose tireless testing and bug-fixing efforts a portable *zip* would not have been possible. Finally we should thank (blame) the first Info-ZIP moderator, David Kirschbaum, for getting us into this mess in the first place. The manual page was rewritten for Unix by R. P. C. Rodgers and updated by E. Gordon for *zip* 3.0.

NAME

zless – file perusal filter for crt viewing of compressed text

SYNOPSIS

zless [name ...]

DESCRIPTION

Zless is a filter which allows examination of compressed or plain text files one screenful at a time on a soft-copy terminal. It is the equivalent of setting the environment variable LESSOPEN to '|gzip -cdfq -- %s', and the environment variable LESSMETACHARS to and then running *less*. However, enough people seem to think that having the command *zless* available is important to be worth providing it.

SEE ALSO

zmore(1), *less*(1)

BUGS

Zless does not work with compressed data that is piped to it via standard input; it requires that input files be specified as arguments.

NAME

zmore – file perusal filter for crt viewing of compressed text

SYNOPSIS

zmore [name ...]

DESCRIPTION

Zmore is a filter which allows examination of compressed or plain text files one screenful at a time on a soft-copy terminal. *zmore* works on files compressed with *compress*, *pack* or *gzip*, and also on uncompressed files. If a file does not exist, *zmore* looks for a file of the same name with the addition of a .gz, .z or .Z suffix.

Zmore normally pauses after each screenful, printing --More-- at the bottom of the screen. If the user then types a carriage return, one more line is displayed. If the user hits a space, another screenful is displayed. Other possibilities are enumerated later.

Zmore looks in the file */etc/termcap* to determine terminal characteristics, and to determine the default window size. On a terminal capable of displaying 24 lines, the default window size is 22 lines. To use a pager other than the default *more*, set environment variable *PAGER* to the name of the desired program, such as *less*.

Other sequences which may be typed when *zmore* pauses, and their effects, are as follows (*i* is an optional integer argument, defaulting to 1) :

- i*<space> display *i* more lines, (or another screenful if no argument is given)
- ^D display 11 more lines (a “scroll”). If *i* is given, then the scroll size is set to *i*.
- d same as ^D (control-D)
- iz* same as typing a space except that *i*, if present, becomes the new window size. Note that the window size reverts back to the default at the end of the current file.
- is* skip *i* lines and print a screenful of lines
- if* skip *i* screenfuls and print a screenful of lines
- q or Q quit reading the current file; go on to the next (if any)
- e or q When the prompt --More--(Next file: *file*) is printed, this command causes *zmore* to exit.
- s When the prompt --More--(Next file: *file*) is printed, this command causes *zmore* to skip the next file and continue.
- = Display the current line number.
- i*/expr search for the *i*-th occurrence of the regular expression *expr*. If the pattern is not found, *zmore* goes on to the next file (if any). Otherwise, a screenful is displayed, starting two lines before the place where the expression was found. The user's erase and kill characters may be used to edit the regular expression. Erasing back past the first column cancels the search command.
- in* search for the *i*-th occurrence of the last regular expression entered.
- !command invoke a shell with *command*. The character '!' in "command" is replaced with the previous shell command. The sequence "\!" is replaced by "!".
- :q or :Q quit reading the current file; go on to the next (if any) (same as q or Q).
- . (dot) repeat the previous command.

The commands take effect immediately, i.e., it is not necessary to type a carriage return. Up to the time when the command character itself is given, the user may hit the line kill character to cancel the numerical argument being formed. In addition, the user may hit the erase character to redisplay the --More-- message.

At any time when output is being sent to the terminal, the user can hit the quit key (normally control-\\).

Zmore will stop sending output, and will display the usual --More-- prompt. The user may then enter one of the above commands in the normal manner. Unfortunately, some output is lost when this is done, due to the fact that any characters waiting in the terminal's output queue are flushed when the quit signal occurs.

The terminal is set to *noecho* mode by this program so that the output can be continuous. What you type will thus not show on your terminal, except for the / and ! commands.

If the standard output is not a teletype, then *zmore* acts just like *zcat*, except that a header is printed before each file.

NAME

zstd – zstd, zstdmt, unzstd, zstdcat – Compress or decompress .zst files

SYNOPSIS

zstd [*OPTIONS*] [-*INPUT-FILE*] [-o *OUTPUT-FILE*]

zstdmt is equivalent to **zstd -T0**

unzstd is equivalent to **zstd -d**

zstdcat is equivalent to **zstd -dcf**

DESCRIPTION

zstd is a fast lossless compression algorithm and data compression tool, with command line syntax similar to **gzip** (1) and **xz** (1). It is based on the **LZ77** family, with further FSE & huff0 entropy stages. **zstd** offers highly configurable compression speed, with fast modes at > 200 MB/s per core, and strong modes nearing lzma compression ratios. It also features a very fast decoder, with speeds > 500 MB/s per core.

zstd command line syntax is generally similar to gzip, but features the following differences :

- Source files are preserved by default. It's possible to remove them automatically by using the **--rm** command.
- When compressing a single file, **zstd** displays progress notifications and result summary by default. Use **-q** to turn them off.
- **zstd** does not accept input from console, but it properly accepts **stdin** when it's not the console.
- **zstd** displays a short help page when command line is an error. Use **-q** to turn it off.

zstd compresses or decompresses each *file* according to the selected operation mode. If no *files* are given or *file* is -, **zstd** reads from standard input and writes the processed data to standard output. **zstd** will refuse to write compressed data to standard output if it is a terminal : it will display an error message and skip the *file*. Similarly, **zstd** will refuse to read compressed data from standard input if it is a terminal.

Unless **--stdout** or **-o** is specified, *files* are written to a new file whose name is derived from the source *file* name:

- When compressing, the suffix **.zst** is appended to the source filename to get the target filename.
- When decompressing, the **.zst** suffix is removed from the source filename to get the target filename

Concatenation with .zst files

It is possible to concatenate **.zst** files as is. **zstd** will decompress such files as if they were a single **.zst** file.

OPTIONS**Integer suffixes and special values**

In most places where an integer argument is expected, an optional suffix is supported to easily indicate large integers. There must be no space between the integer and the suffix.

KiB Multiply the integer by 1,024 (2¹⁰). **Ki**, **K**, and **KB** are accepted as synonyms for **KiB**.

MiB Multiply the integer by 1,048,576 (2²⁰). **Mi**, **M**, and **MB** are accepted as synonyms for **MiB**.

Operation mode

If multiple operation mode options are given, the last one takes effect.

-z, --compress

Compress. This is the default operation mode when no operation mode option is specified and no other operation mode is implied from the command name (for example, **unzstd** implies **--decompress**).

-d, --decompress, --uncompress

Decompress.

-t, --test

Test the integrity of compressed *files*. This option is equivalent to **--decompress --stdout** except that the decompressed data is discarded instead of being written to standard output. No files are created or removed.

-b# Benchmark file(s) using compression level #

--train FILES

Use FILES as a training set to create a dictionary. The training set should contain a lot of small files (> 100).

-l, --list

Display information related to a zstd compressed file, such as size, ratio, and checksum. Some of these fields may not be available. This command can be augmented with the **-v** modifier.

Operation modifiers

- **-#**: # compression level [1–19] (default: 3)
- **--ultra**: unlocks high compression levels 20+ (maximum 22), using a lot more memory. Note that decompression will also require more memory when using these levels.
- **--fast[=#]**: switch to ultra-fast compression levels. If **=#** is not present, it defaults to **1**. The higher the value, the faster the compression speed, at the cost of some compression ratio. This setting overwrites compression level if one was set previously. Similarly, if a compression level is set after **--fast**, it overrides it.
- **-T#**, **--threads=#**: Compress using # working threads (default: 1). If # is 0, attempt to detect and use the number of physical CPU cores. In all cases, the nb of threads is capped to **ZSTDMT_NBWORKERS_MAX**, which is either 64 in 32-bit mode, or 256 for 64-bit environments. This modifier does nothing if **zstd** is compiled without multithread support.
- **--single-thread**: Does not spawn a thread for compression, use a single thread for both I/O and compression. In this mode, compression is serialized with I/O, which is slightly slower. (This is different from **-T1**, which spawns 1 compression thread in parallel of I/O). This mode is the only one available when multithread support is disabled. Single-thread mode features lower memory usage. Final compressed result is slightly different from **-T1**.
- **--adapt[=min=#,max=#]** : **zstd** will dynamically adapt compression level to perceived I/O conditions. Compression level adaptation can be observed live by using command **-v**. Adaptation can be constrained between supplied **min** and **max** levels. The feature works when combined with multi-threading and **--long** mode. It does not work with **--single-thread**. It sets window size to 8 MB by default (can be changed manually, see **wlog**). Due to the chaotic nature of dynamic adaptation, compressed result is not reproducible. *note* : at the time of this writing, **--adapt** can remain stuck at low speed when combined with multiple worker threads (>=2).
- **--long[=#]**: enables long distance matching with # **windowLog**, if not # is not present it defaults to **27**. This increases the window size (**windowLog**) and memory usage for both the compressor and decompressor. This setting is designed to improve the compression ratio for files with long matches at a large distance.

Note: If **windowLog** is set to larger than 27, **--long=windowLog** or **--memory=windowSize** needs to be passed to the decompressor.

- **-D DICT**: use **DICT** as Dictionary to compress or decompress FILE(s)
- **--patch-from FILE**: Specify the file to be used as a reference point for zstd's diff engine. This is effectively dictionary compression with some convenient parameter selection, namely that window-Size > srcSize.

Note: cannot use both this and `-D` together Note: `--long` mode will be automatically activated if `chainLog < fileLog` (`fileLog` being the `windowLog` required to cover the whole file). You can also manually force it. Note: for all levels, you can use `--patch-from` in `--single-thread` mode to improve compression ratio at the cost of speed Note: for level 19, you can get increased compression ratio at the cost of speed by specifying `--zstd=targetLength=` to be something large (i.e 4096), and by setting a large `--zstd=chainLog=`

- `--rsyncable` : `zstd` will periodically synchronize the compression state to make the compressed file more rsync-friendly. There is a negligible impact to compression ratio, and the faster compression levels will see a small compression speed hit. This feature does not work with `--single-thread`. You probably don't want to use it with long range mode, since it will decrease the effectiveness of the synchronization points, but your mileage may vary.
- `-C`, `--[no-]check`: add integrity check computed from uncompressed data (default: enabled)
- `--[no-]content-size`: enable / disable whether or not the original size of the file is placed in the header of the compressed file. The default option is `--content-size` (meaning that the original size will be placed in the header).
- `--no-dictID`: do not store dictionary ID within frame header (dictionary compression). The decoder will have to rely on implicit knowledge about which dictionary to use, it won't be able to check if it's correct.
- `-M#`, `--memory=#`: Set a memory usage limit. By default, Zstandard uses 128 MB for decompression as the maximum amount of memory the decompressor is allowed to use, but you can override this manually if need be in either direction (ie. you can increase or decrease it).

This is also used during compression when using with `--patch-from=`. In this case, this parameter overrides that maximum size allowed for a dictionary. (128 MB).

- `--stream-size=#` : Sets the pledged source size of input coming from a stream. This value must be exact, as it will be included in the produced frame header. Incorrect stream sizes will cause an error. This information will be used to better optimize compression parameters, resulting in better and potentially faster compression, especially for smaller source sizes.
- `--size-hint=#`: When handling input from a stream, `zstd` must guess how large the source size will be when optimizing compression parameters. If the stream size is relatively small, this guess may be a poor one, resulting in a higher compression ratio than expected. This feature allows for controlling the guess when needed. Exact guesses result in better compression ratios. Overestimates result in slightly degraded compression ratios, while underestimates may result in significant degradation.
- `-o FILE`: save result into **FILE**
- `-f`, `--force`: disable input and output checks. Allows overwriting existing files, input from console, output to stdout, operating on links, block devices, etc.
- `-c`, `--stdout`: force write to standard output, even if it is the console
- `--[no-]sparse`: enable / disable sparse FS support, to make files with many zeroes smaller on disk. Creating sparse files may save disk space and speed up decompression by reducing the amount of disk I/O. default: enabled when output is into a file, and disabled when output is stdout. This setting overrides default and can force sparse mode over stdout.
- `--rm`: remove source file(s) after successful compression or decompression. If used in combination with `-o`, will trigger a confirmation prompt (which can be silenced with `-f`), as this is a destructive operation.
- `-k`, `--keep`: keep source file(s) after successful compression or decompression. This is the default behavior.
- `-r`: operate recursively on directories
- `--filelist FILE` read a list of files to process as content from **FILE**. Format is compatible with `ls` output, with one file per line.

- **--output-dir-flat DIR**: resulting files are stored into target **DIR** directory, instead of same directory as origin file. Be aware that this command can introduce name collision issues, if multiple files, from different directories, end up having the same name. Collision resolution ensures first file with a given name will be present in **DIR**, while in combination with **-f**, the last file will be present instead.
- **--output-dir-mirror DIR**: similar to **--output-dir-flat**, the output files are stored underneath target **DIR** directory, but this option will replicate input directory hierarchy into output **DIR**.
If input directory contains ".", the files in this directory will be ignored. If input directory is an absolute directory (i.e. "/var/tmp/abc"), it will be stored into the "output-dir/var/tmp/abc". If there are multiple input files or directories, name collision resolution will follow the same rules as **--output-dir-flat**.
- **--format=FORMAT**: compress and decompress in other formats. If compiled with support, zstd can compress to or decompress from other compression algorithm formats. Possibly available options are **zstd**, **gzip**, **xz**, **lzma**, and **lz4**. If no such format is provided, **zstd** is the default.
- **-h/-H, --help**: display help/long help and exit
- **-V, --version**: display version number and exit. Advanced : **-vV** also displays supported formats. **-vvV** also displays POSIX support. **-q** will only display the version number, suitable for machine reading.
- **-v, --verbose**: verbose mode, display more information
- **-q, --quiet**: suppress warnings, interactivity, and notifications. specify twice to suppress errors too.
- **--no-progress**: do not display the progress bar, but keep all other messages.
- **--show-default-cparams**: Shows the default compression parameters that will be used for a particular src file. If the provided src file is not a regular file (eg. named pipe), the cli will just output the default parameters. That is, the parameters that are used when the src size is unknown.
- **--**: All arguments after **--** are treated as files

Restricted usage of Environment Variables

Using environment variables to set parameters has security implications. Therefore, this avenue is intentionally restricted. Only **ZSTD_CLEVEL** and **ZSTD_NBTHREADS** are currently supported. They set the compression level and number of threads to use during compression, respectively.

ZSTD_CLEVEL can be used to set the level between 1 and 19 (the "normal" range). If the value of **ZSTD_CLEVEL** is not a valid integer, it will be ignored with a warning message. **ZSTD_CLEVEL** just replaces the default compression level (3).

ZSTD_NBTHREADS can be used to set the number of threads **zstd** will attempt to use during compression. If the value of **ZSTD_NBTHREADS** is not a valid unsigned integer, it will be ignored with a warning message. **ZSTD_NBTHREADS** has a default value of (1), and is capped at **ZSTDMT_NBWORKERS_MAX==200**. **zstd** must be compiled with multithread support for this to have any effect.

They can both be overridden by corresponding command line arguments: **-#** for compression level and **-T#** for number of compression threads.

Parallel Zstd OPTIONS

Additional options for the pzstd utility

- **-p, --processes**
number of threads to use for (de)compression (default:4)

DICTIONARY BUILDER

zstd offers *dictionary* compression, which greatly improves efficiency on small files and messages. It's possible to train **zstd** with a set of samples, the result of which is saved into a file called a **dictionary**. Then during compression and decompression, reference the same dictionary, using command **-D dictionaryFileName**. Compression of small files similar to the sample set will be greatly improved.

--train FILES

Use FILES as training set to create a dictionary. The training set should contain a lot of small files (> 100), and weight typically 100x the target dictionary size (for example, 10 MB for a 100 KB dictionary).

Supports multithreading if **zstd** is compiled with threading support. Additional parameters can be specified with **--train-fastcover**. The legacy dictionary builder can be accessed with **--train-legacy**. The cover dictionary builder can be accessed with **--train-cover**. Equivalent to **--train-fastcover=d=8,steps=4**.

-o file Dictionary saved into **file** (default name: dictionary).

--maxdict=#

Limit dictionary to specified size (default: 112640).

-# Use # compression level during training (optional). Will generate statistics more tuned for selected compression level, resulting in a *small* compression ratio improvement for this level.

-B# Split input files in blocks of size # (default: no split)

--dictID=#

A dictionary ID is a locally unique ID that a decoder can use to verify it is using the right dictionary. By default, zstd will create a 4-bytes random number ID. It's possible to give a precise number instead. Short numbers have an advantage : an ID < 256 will only need 1 byte in the compressed frame header, and an ID < 65536 will only need 2 bytes. This compares favorably to 4 bytes default. However, it's up to the dictionary manager to not assign twice the same ID to 2 different dictionaries.

---train-cover=[k=#,d=#,steps=#,split=#,shrink=[#]]

Select parameters for the default dictionary builder algorithm named cover. If *d* is not specified, then it tries *d* = 6 and *d* = 8. If *k* is not specified, then it tries *steps* values in the range [50, 2000]. If *steps* is not specified, then the default value of 40 is used. If *split* is not specified or *split* <= 0, then the default value of 100 is used. Requires that *d* <= *k*. If *shrink* flag is not used, then the default value for *shrinkDict* of 0 is used. If *shrink* is not specified, then the default value for *shrinkDictMaxRegression* of 1 is used.

Selects segments of size *k* with highest score to put in the dictionary. The score of a segment is computed by the sum of the frequencies of all the subsegments of size *d*. Generally *d* should be in the range [6, 8], occasionally up to 16, but the algorithm will run faster with *d* <= 8. Good values for *k* vary widely based on the input data, but a safe range is [2 * *d*, 2000]. If *split* is 100, all input samples are used for both training and testing to find optimal *d* and *k* to build dictionary. Supports multithreading if **zstd** is compiled with threading support. Having *shrink* enabled takes a truncated dictionary of minimum size and doubles in size until compression ratio of the truncated dictionary is at most *shrinkDictMaxRegression*% worse than the compression ratio of the largest dictionary.

Examples:

zstd --train-cover FILES

zstd --train-cover=k=50,d=8 FILES

zstd --train-cover=d=8,steps=500 FILES

zstd --train-cover=k=50 FILES

zstd --train-cover=k=50,split=60 FILES

zstd --train-cover=shrink FILES

zstd --train-cover=shrink=2 FILES

---train-fastcover=[k=#,d=#,f=#,steps=#,split=#,accel=#]

Same as cover but with extra parameters *f* and *accel* and different default value of *split*. If *split* is not specified, then it tries *split* = 75. If *f* is not specified, then it tries *f* = 20. Requires that 0 < *f* < 32. If *accel* is not specified, then it tries *accel* = 1. Requires that 0 < *accel* <= 10. Requires that *d* =

6 or $d = 8$.

f is log of size of array that keeps track of frequency of subsegments of size d . The subsegment is hashed to an index in the range $[0, 2^f - 1]$. It is possible that 2 different subsegments are hashed to the same index, and they are considered as the same subsegment when computing frequency. Using a higher f reduces collision but takes longer.

Examples:

zstd --train-fastcover FILEs

zstd --train-fastcover=d=8,f=15,accel=2 FILEs

--train-legacy[=selectivity=#]

Use legacy dictionary builder algorithm with the given dictionary *selectivity* (default: 9). The smaller the *selectivity* value, the denser the dictionary, improving its efficiency but reducing its possible maximum size. **--train-legacy=s=#** is also accepted.

Examples:

zstd --train-legacy FILEs

zstd --train-legacy=selectivity=8 FILEs

BENCHMARK

-b# benchmark file(s) using compression level #

-e# benchmark file(s) using multiple compression levels, from **-b#** to **-e#** (inclusive)

-i# minimum evaluation time, in seconds (default: 3s), benchmark mode only

-B#, --block-size=#

cut file(s) into independent blocks of size # (default: no block)

--priority=rt

set process priority to real-time

Output Format: CompressionLevel#Filename : InputSize -> OutputSize (CompressionRatio), CompressionSpeed, DecompressionSpeed

Methodology: For both compression and decompression speed, the entire input is compressed/decompressed in-memory to measure speed. A run lasts at least 1 sec, so when files are small, they are compressed/decompressed several times per run, in order to improve measurement accuracy.

ADVANCED COMPRESSION OPTIONS

-B#:

Select the size of each compression job. This parameter is only available when multi-threading is enabled. Each compression job is run in parallel, so this value indirectly impacts the nb of active threads. Default job size varies depending on compression level (generally $4 * \text{windowSize}$). **-B#** makes it possible to manually select a custom size. Note that job size must respect a minimum value which is enforced transparently. This minimum is either 512 KB, or **overlapSize**, whichever is largest. Different job sizes will lead to (slightly) different compressed frames.

--zstd[=options]:

zstd provides 22 predefined compression levels. The selected or default predefined compression level can be changed with advanced compression options. The *options* are provided as a comma-separated list. You may specify only the options you want to change and the rest will be taken from the selected or default compression level. The list of available *options*:

strategy=*strat*, **strat=***strat*

Specify a strategy used by a match finder.

There are 9 strategies numbered from 1 to 9, from faster to stronger: 1=ZSTD_fast, 2=ZSTD_dfast, 3=ZSTD_greedy, 4=ZSTD_lazy, 5=ZSTD_lazy2, 6=ZSTD_btlazy2, 7=ZSTD_btopt, 8=ZSTD_btultra, 9=ZSTD_btultra2.

windowLog=wlog, wlog=wlog

Specify the maximum number of bits for a match distance.

The higher number of increases the chance to find a match which usually improves compression ratio. It also increases memory requirements for the compressor and decompressor. The minimum *wlog* is 10 (1 KiB) and the maximum is 30 (1 GiB) on 32-bit platforms and 31 (2 GiB) on 64-bit platforms.

Note: If **windowLog** is set to larger than 27, **--long=windowLog** or **--memory=windowSize** needs to be passed to the decompressor.

hashLog=hlog, hlog=hlog

Specify the maximum number of bits for a hash table.

Bigger hash tables cause less collisions which usually makes compression faster, but requires more memory during compression.

The minimum *hlog* is 6 (64 B) and the maximum is 30 (1 GiB).

chainLog=clog, clog=clog

Specify the maximum number of bits for a hash chain or a binary tree.

Higher numbers of bits increases the chance to find a match which usually improves compression ratio. It also slows down compression speed and increases memory requirements for compression. This option is ignored for the ZSTD_fast strategy.

The minimum *clog* is 6 (64 B) and the maximum is 29 (524 Mib) on 32-bit platforms and 30 (1 Gib) on 64-bit platforms.

searchLog=slog, slog=slog

Specify the maximum number of searches in a hash chain or a binary tree using logarithmic scale.

More searches increases the chance to find a match which usually increases compression ratio but decreases compression speed.

The minimum *slog* is 1 and the maximum is 'windowLog' - 1.

minMatch=mml, mml=mml

Specify the minimum searched length of a match in a hash table.

Larger search lengths usually decrease compression ratio but improve decompression speed.

The minimum *mml* is 3 and the maximum is 7.

targetLength=tlen, tlen=tlen

The impact of this field vary depending on selected strategy.

For ZSTD_btopt, ZSTD_btultra and ZSTD_btultra2, it specifies the minimum match length that causes match finder to stop searching. A larger **targetLength** usually improves compression ratio but decreases compression speed. For ZSTD_fast, it triggers ultra-fast mode when > 0. The value represents the amount of data skipped between match sampling. Impact is reversed : a larger **targetLength** increases compression speed but decreases compression ratio.

For all other strategies, this field has no impact.

The minimum *tlen* is 0 and the maximum is 128 Kib.

overlapLog=ovlog, ovlog=ovlog

Determine **overlapSize**, amount of data reloaded from previous job. This parameter is only available when multithreading is enabled. Reloading more data improves compression ratio, but decreases speed.

The minimum *ovlog* is 0, and the maximum is 9. 1 means "no overlap", hence completely independent jobs. 9 means "full overlap", meaning up to **windowSize** is reloaded from previous job. Reducing *ovlog* by 1 reduces the reloaded amount by a factor 2. For example, 8 means "windowSize/2", and 6 means "windowSize/8". Value 0 is special and means "default" : *ovlog* is

automatically determined by **zstd**. In which case, *ovlog* will range from 6 to 9, depending on selected *strat*.

IdmHashLog=*lhlog*, lhlog=*lhlog*

Specify the maximum size for a hash table used for long distance matching.

This option is ignored unless long distance matching is enabled.

Bigger hash tables usually improve compression ratio at the expense of more memory during compression and a decrease in compression speed.

The minimum *lhlog* is 6 and the maximum is 30 (default: 20).

IdmMinMatch=*lmml*, lmml=*lmml*

Specify the minimum searched length of a match for long distance matching.

This option is ignored unless long distance matching is enabled.

Larger/very small values usually decrease compression ratio.

The minimum *lmml* is 4 and the maximum is 4096 (default: 64).

IdmBucketSizeLog=*lblog*, lblog=*lblog*

Specify the size of each bucket for the hash table used for long distance matching.

This option is ignored unless long distance matching is enabled.

Larger bucket sizes improve collision resolution but decrease compression speed.

The minimum *lblog* is 1 and the maximum is 8 (default: 3).

IdmHashRateLog=*lhrlog*, lhrlog=*lhrlog*

Specify the frequency of inserting entries into the long distance matching hash table.

This option is ignored unless long distance matching is enabled.

Larger values will improve compression speed. Deviating far from the default value will likely result in a decrease in compression ratio.

The default value is **wlog – lhlog**.

Example

The following parameters sets advanced compression options to something similar to predefined level 19 for files bigger than 256 KB:

--zstd=wlog=23,clog=23,hlog=22,slog=6,mml=3,tlen=48,strat=6

NAME

edrcrevision – revision history of WA2L/edrc

AVAILABILITY

WA2L/edrc

DESCRIPTION

This manpage gives you an overview of changes between the different releases of WA2L/edrc.

For an explanation of the revision number system see section **RELEASE-NUMBERS** and for an explanation of used shortcuts in the **REVISION-HISTORY** see section **SHORTCUTS**.

RELEASE-NUMBERS

The release number format is: <major>.<update>.<patch_level> .

If the <major> part changes, major design changes were applied, therefore you have to upgrade your installation.

If the <update> part changes, important bugfixes were applied, the config file might have changed, therefore you should upgrade your WA2L/edrc installation to the current version.

If the <patch_level> part changes, minor changes or bugfixes were applied, the configuration file format did not change, therefore it is not urgent to upgrade your installation, but recommended.

SHORTCUTS**OBJECT**

| | |

new new function, configuration parameter, option, behavior

chg change

fix bugfix

cor correction of descriptions, comments, logfile output, typing errors

REVISION-HISTORY

1.5.57

Sun Dec 22 22:22:22 CEST 2024 release

MAIN IMPROVEMENTS:

- obj/act *: several minor corrections and improvements.
- cmd/new lgcheckd: more efficient and leaner log check daemon to replace the logcheckd.

ALL CHANGES:

- cfg/chg edrcrevision.cfg: new release 1.5.57 (Sat May 25 20:19:00 CEST 2024)
- cfg/chg syslog.Linux-64: significant enhancement of pattern file.
- cfg/chg ..name_index: . to document the current directory added in many directories.
- cfg/chg edrcman.map: many more man pages and elements mapped to manual pages to enable looking up as most files as possible.
- cfg/chg logcheckd.cfg: new setting USE_LEGACY_COMMAND to transparently relay to new log check daemon lgcheckd.
- cfg/chg edrcinit.cfg: new setting nginx_shellinaboxd.
- cfg/chg edrcinit.cfg: new setting batteryalert.
- cfg/chg binprobe.dat: add md5string.
- cfg/new edrcinit/WA2Ledrc.batteryalert: edrcinit service handler for batteryalert.
- cmd/chg vsav: save file versions compressed.
- cmd/chg edrcman: the OS in -o OS manpage is not case sensitive.
- cmd/chg pack: react on \$EDRC_DEBUG_PACK_EXCLUDE to debug the EXCLUDE_LIST of the pack.cfg file.
- cmd/chg pack: add the pack.cfg file at the beginning of the package file to be more error resilient.
- cmd/chg patchinstall: repeat file installation and symlink property adjustment after corpse removal on cpio extract error.
- cmd/chg lua, luac: moved from edrc/lib/ to edrc/bin/.
- cmd/chg job, joblog, jobwatch, joblog: new option -V to print program version.
- cmd/chg job, jobwatch: state in job list is colored on terminal.
- cmd/chg perlenv: new -n option to avoid export VARIABLE output.
- cmd/chg shlib: new -n option to avoid export VARIABLE output.
- cmd/chg joblog: new -q option to tail always the current running job log.
- cmd/chg www/report/cgi/vsdfml: display vsdfml files in WA2L/edrc:report portal.
- cmd/chg www/report/cgi/md: display markdown files in WA2L/edrc:report portal.
- cmd/chg www/report/cgi/man: display man files in WA2L/edrc:report portal.
- cmd/chg www/report/cgi/edoc: display files formatted with contrib.doc syntax in WA2L/edrc:report portal.
- cmd/chg www/report/cgi/doc: enhancement to display vsdfml, md, man, doc and compressed files in WA2L/edrc:report portal.
- cmd/chg select_columns: enable to display CSV files with an initial sep=... line properly.
- cmd/chg lgcpattern: add -i option to only print [IGNORED] lines.
- cmd/chg lgcpattern: add -p option to print a regular expression based on logfile entries.
- cmd/chg batteryalert: add -a option to query alert state.
- cmd/chg csvcat: enable to display CSV files with an initial sep=... line properly.
- cmd/new cpanm: get, unpack build and install modules from CPAN.
- cmd/new luarocks: Lua package installation program.
- cmd/new luaversion: print lua version.
- cmd/new .lua_wrapper: lua wrapper.

- cmd/new luaenv: print environment for lua.
- cmd/new pip: Python package manager to handle python packages distributed with WA2L/edrc.
- cmd/new pythonversion: print major.minor python version.
- cmd/new name: handle also files started thru .python_wrapper.
- cmd/chg edrcman: add -i option to display internet based man pages.
- cmd/chg edrcman: add/chg -l (sys|os) option to list available local and internet based man page sources.
- cmd/chg cmdlist: handle also python scripts started thru .python_wrapper.
- cmd/chg .python_wrapper: wrap python commands.
- cmd/new pythonenv: print environment needed for external python commands or recovery scripts written in python to profit from WA2L/edrc distributed packages.
- cmd/chg contrib/scriptinstall: avoid error message on empty scripts dir. cmd/chg csv: skip empty and commented lines at input begin for w2s, t2s, ct2 commands.
- cmd/chg vls: list last (terminal page) of saved versions, whereas vlist lists all saved versions (unchanged).
- cmd/chg name: avoid read permission error messages.
- cmd/chg name: read '.' entry in directory/..name_index to print directory description.
- cmd/chg tpl: \$TPL_CFG can hold an additional configuration file for tpl.
- cmd/chg www/report/cgi/statistics: more accurate image alignment.
- cmd/chg www/report/cgi/users.list: timestamp format corrected.
- cmd/chg www/report/cgi/users.add: timestamp format corrected.
- cmd/chg www/report/cgi/users.*: use post in forms instead of get.
- cmd/chg sqlite: upgrade to version 3.46.0 for Linux.64/2.27/.
- cmd/chg sqlite: upgrade to version 3.46.0 for Linux.64/2.22/.
- cmd/chg job: last targets the last job enqueued by the user, now.
- cmd/chg pmdesc: new option -d for csv output, set default width of module name output to 52 characters.
- cmd/new lgcheckd: more efficient and leaner log check daemon to replace the logcheckd.
- cmd/chg csv: option cat:lgcheckd.cfg added.
- cmd/chg pstree: use long output of process list on Linux and limit output width on a TTY. Non-TTY output is not limited.
- cmd/chg jobstart: new option logswitch to switch logfile.
- cmd/chg pstree: exit code 5 on abort.
- cmd/chg pstree: new option -r to print process-ids in reverse order.
- cmd/chg logview: new option -h to print program usage.
- cmd/chg logtail: new option -h to print program usage, -c and -C to colorize tailed output based on pattern files.
- cmd/chg logtail: new option -t to add a high resolution timestamp to the output.
- cmd/chg jobstart: add DOCREF column to jobstart list output.
- cmd/new batteryalert: monitor battery charge level and alert.
- cmd/chg job: -c option to print commands fo job.
- cmd/chg job: remove job improved.
- cmd/chg lgcpattern: check a log check pattern file definition.
- cmd/new eterm: start an application in a separate X-terminal.
- cmd/chg job: state change (run/done/stab/abort/removed) are now also logged to the log file of the job to have the information also available when using joblog -j jobid.
- cmd/chg edrcinit: new options cfg-([un])(activate|guard)) to set the related configuration settings in the configuration file thru the command line.
- cmd/new md5string: calculate MD5 checksum for strings line by line.
- cmd/chg job: FUNCTIONs to be used in jobs: JOBBANNER, JOBTITLE, JOBSUBTITLE, JOBSUBSUBTITLE, JOBTAG, JOBCOMPLETED.
- cmd/chg job: -a option to print job run statistics for accounting purposes.
- cmd/chg job: print TAG when using job -p jobid.
- cmd/chg jobstart: cache file timestamp is no longer changed if no related logfile is changed.
- cmd/chg jobstart: avoid error message if no cache file was created yet.
- cmd/chg logviewer: increase resilience to filesystem shortage on report generation.

- cmd/chg name: enable handling files and directories with spaces in the file- or directory-name.
- cmd/chg cfg2html: new version 7.1.2.1 for Linux and Linux-64.
- cmd/chg lscomp: handle .whl, .rock files.
- cmd/chg llcomp: handle .whl, .rock files.
- cmd/chg catcomp: handle .whl, .rock files.
- man/chg *: *: formatting correction of many manual pages.
- man/chg pack.1m: description of \$EDRC_DEBUG_PACK_EXCLUDE to debug the EXCLUDE_LIST of the pack.cfg file.
- man/chg perlenv.3: description of -n option to avoid export output.
- man/chg shlib.3: description of -n option to avoid export output.
- man/chg joblog.1: description of -q option to tail always the current run log file.
- man/chg pkgdir.4: replace man command call with edrcman command call.
- man/chg pkgdir.4: add PIP package handling.
- man/chg tpl.1: environment variable \$TPL_CFG description.
- man/chg shell.cfg.4: environment variable \$TPL_CFG description.
- man/chg utility.h.3: synopsis corrected.
- man/chg strings.h.3: include file now located in edrc/lib/\$OSID/includes/.
- man/chg utility.h.3: include file now located in edrc/lib/\$OSID/includes/.
- man/chg program.h.3: include file now located in edrc/lib/\$OSID/includes/.
- man/chg checkopt.h.3: include file now located in edrc/lib/\$OSID/includes/.
- man/chg job.1: adjust description of last, add .job.last file description.
- man/chg pmdesc.1: description of -d option added, manual page formatting changed.
- man/new cpanm.1
- man/new luarocks.1
- man/new luarocks.cfg.4
- man/new luaenv.3
- man/new luaversion.3
- man/new lua_wrapper.1
- man/new lua_wrapper.cfg.4
- man/new lgcheckd.1m
- man/new lgcheckd.cfg.4
- man/new logcheckd.pattern.4: adjustments to cover also lgcheckd.
- man/new logcheckd.interface.4: new environment variables \$APPROOT, \$SERVER_ENVIRONMENT_NAME, \$SERVER_ENVIRONMENT_CUSTOMER, \$SERVER_ENVIRONMENT_DESCRIPTION that can be used in interfaces.
- man/new logcheckd.interface.3: adjustments to cover also lgcheckd.
- man/new logcheckd.1m: hint to lgcheckd.
- man/new lgcheckd.state.db.4: description of the state.db structure.
- man/new python_wrapper.1
- man/new pythonversion.3
- man/new pythonenv.3
- man/chg csv.3: description of csv cat:lgcheckd.cfg option.
- man/chg jobstart.1: description of logswitch option.
- man/chg pstree.1: description of exit code 5.
- man/chg pstree.1: description of -r option to print process-ids in reverse order.
- man/chg logview.1: description of -h option to print the program usage.
- man/chg logtail.1: description of -h option to print the program usage, -c and -C to colorize output.
- man/chg logtail.1: description of -t to add a high resolution to the output.
- man/chg jobstart.1m: description of DOCREF column in jobstart list output.
- man/new batteryalert.1: description of batteryalert command.
- man/chg job.1: description of -c option.
- man/new lgcpattern.3
- man/new wa2ledrc_shellinaboxd.1

- man/chg EDRC.1: add eterm.1, pythonenv.1, python_wrapper.1, pip.1.
- man/chg edrcintro.1: add eterm.1.
- man/new eterm.1
- man/chg edrcinit.1m: description of new options cfg-([un](activate|guard)).
- man/new md5string.1
- man/chg job.1: description of -a option and job FUNCTIONS.
- man/chg lspm.1: add SEE ALSO section.
- man/new pip.1
- man/new pip3.1
- man/new pip3-check.1
- man/new pip3-wheel.1
- man/new pip3-uninstall.1
- man/new pip3-show.1
- man/new pip3-search.1
- man/new pip3-list.1
- man/new pip3-install.1
- man/new pip3-help.1
- man/new pip3-hash.1
- man/new pip3-freeze.1
- man/new pip3-download.1
- doc/cor WA2Ledrc:report/help: typing errors.
- doc/chg www/report/html/help.html: description of handling of certain file extensions added
- dir/new lib/python/: storage for python scripts within WA2L/edrc started thru .python_wrapper.
- dir/new lib/python/pym/: location of python modules in a virtual environment (venv) within WA2L/edrc started thru .python_wrapper.

1.5.56

Fri May 24 22:08:13 CEST 2024 release

MAIN IMPROVEMENTS:

- cmd/chg tpl: select and print template file.
- cmd/chg csv: many improvements.
- cmd/chg hostlist: allow output of Ansible inventory in ini-, json- and yaml file format.
- cmd/chg www/foswiki: Foswiki is no longer distributed with WA2L/edrc.
- cmd/new jobstart: run jobs thru a simple interface.

ALL CHANGES:

- cfg/chg edrcrevision.cfg: new release 1.5.56 (Thu Oct 21 21:42:36 METDST 2021)
- cfg/chg edrc*.cfg: fallback to linux -> vt220, if TERM=terminal does not exist.
- cfg/chg job.cfg: new setting COLORIZE to switch off colorizing output on terminal.
- cfg/chg binprobe.dat: special probe command for bzmre on Ubuntu, more descriptive output of special probe commands on certain preconditions.
- cmd/chg tpl: select and print template file.
- cmd/chg csv: new option variable to print a record as initialize-able variables.
- cmd/chg csv: new option row to return a row by linenumber.
- cmd/chg csv: new option wherenot and wherenot:ignorecase for inverse data select.
- cmd/chg csv: new option where:ignorecase for non case sensitive data select.
- cmd/chg csv: new option cat:authorized_keys for .ssh/authorized_keys files.
- cmd/chg csv: new option cat:known_hosts for .ssh/known_hosts files.
- cmd/chg csv: new option comm, comm:both, comm:stdin, comm:file to compare CSV data.
- cmd/chg csv: new option addcol to add a column.
- cmd/chg csv: new option order to reorder the columns.
- cmd/chg csv: new option transpose to transpose a csv file.
- cmd/chg csv: new option renamecol to rename columns.
- cmd/chg csv: new option sed to sed on data rows.
- cmd/chg csv: new option t2s to convert tab separations to semicolon separations.

- cmd/chg csv: new option w2s to convert white-space separations to semicolon separations.
- cmd/chg csv: new option avtar to create CSV from Avamar avtar output.
- cmd/chg csv: new option mccli to create CSV from Avamar mccli output.
- cmd/chg csv: new option cat:list to create CSV from csv list output.
- cmd/chg csv: new option diff to diff CSV stream with file.
- cmd/chg csv: new option unselect to de-select columns.
- cmd/chg csv: new option list:nocount to for list output without counter line.
- cmd/chg csv: new option list:*.nocount to for list output without counter line.
- cmd/chg csv: new option cat:mailcap for '/etc/mailcap' format.
- cmd/chg contrib/scriptdocbook: create a single-file menu (accessible thru index.htm) to enable serving a ScriptDocBook from servers blocking JavaScript files.
- cmd/chg shell: if WA2L/edrc is not installed on remote system a normal ssh connection without shell is established.
- cmd/new contrib/find: search text in recovery scripts header and documentation.
- cmd/fix edrcman: man compute MAN_PATH as ordered in edrcman.cfg file setting.
- cmd/chg edrcman: possibility to query in bundled OS native manual pages.
- cmd/chg www/report/cgi/doc: correct size listing of symlinked files.
- cmd/new contrib/scriptdocbook: in PATH= of the scriptdocbook.bib file now also files with spaces are possible and when the path begins with "/" it is relative to the recovery script tree.
- cmd/chg hostlist: allow output of Ansible inventory in ini-, json- and yaml file format.
- cmd/fix contrib/search: syntax error on search in scriptcode eliminated.
- cmd/chg httpd: compiled for GLIBC 2.31 (ubuntu).
- cmd/chg WA2L::Util: new function checkopt() to parse options in Perl programs.
- cmd/chg www/foswiki: Foswiki is no longer distributed with WA2L/edrc. The last full distribution which contains Foswiki (version 1.1.8) is WA2L/edrc version 1.5.55. However, it is not actively removed to prevent data loss. To cleanup Foswiki files, remove by hand: edrc/var/www/foswiki/, edrc/etc/*.foswiki.cfg, edrc/lib/edrcinit/WA2Ledrc.foswiki and eliminate the foswiki entries in edrc/etc/edrcinit.cfg.
- cmd/chg remote_shell: new option -N to prevent 'su' to the user given in -s username prior to the connection.
- cmd/chg edrc: the \$EDRC_SCRIPTS_BASEDIR variable is now also available in the file editor and viewer.
- cmd/chg edrc: 'getcwd: cannot access parent dir' error corrected when invoking quit command after distribute -> full.
- cmd/chg tpl: reads also the \$EDRC_SCRIPTS_BASEDIR/tpl.cfg file.
- cmd/chg loggrep: argument parsing improved.
- cmd/chg loggrep: now th first 211 lines are probed for timestamps.
- cmd/chg loggrep, lgrep: performance improvements (on long files).
- cmd/chg loggrep, lgrep: new -NUM option to only analyse the last NUM lines instead of the whole file.
- cmd/chg loggrep, lgrep, logcat, lcat: output when using -M option goes now to fd3 and no longer to stderr.
- cmd/chg binprobe: internal improvements.
- cmd/chg shell: does not any more loose the tty resizing information when connecting to a remote system. Therefore using vi on remote systems is more convenient, now.
- cmd/fix csvcat: no longer remove whitespaces in fields when not before or after field separator.
- cmd/new nc: version 1.89 for Linux/glibc 2.22.
- cmd/chg filedist: print ego message also to stderr to allow better command embedding.
- cmd/new screen: version 4.0.4 for Linux/glibc 2.22.
- cmd/new screen: version 4.0.3 for Linux/glibc 2.27.
- cmd/chg shell: set terminal title when using shell hostname.
- cmd/new purgetemp: purge temporary directories.
- cmd/chg name: now also lists directories that are listed in the ..name_index file.
- cmd/chg logcat: cat log files with time stamps.
- cmd/chg name: also process files with spaces in filename.

- cmd/chg revision: also process files with spaces in filename.
- cmd/chg remote_shell: exit code of ssh/rsh is passed to caller.
- cmd/chg remote_copy: exit code of scp/rcp is passed to caller.
- cmd/chg remote_copy: new option -N to omit su to connection user.
- cmd/chg name: avoid shell interpreting wildcards in file description.
- cmd/new csvq: query csv files with SQL for Linux and Linux-64.
- cmd/chg remote_copy: can now also handle files with spaces.
- cmd/chg remote_copy: new option -v for verbose output.
- cmd/chg contrib/pwsafe: reduce multiple white spaces to a space on output.
- cmd/new uuencode: encode files, compiled for Linux-64/GLIBC 2.27.
- cmd/new decode: decode uuencoded files, compiled for Linux-64/GLIBC 2.27.
- cmd/chg h2: version 2.1.214.
- cmd/chg csv2worksheet: version 2.0.09 use the new POI Java library poi-poi-5.2.2.
- cmd/chg csv2worksheet: very large worksheet support.
- cmd/chg csv2worksheet: support of old *.xls files discontinued.
- cmd/new fit: alias for fit2width.
- cmd/new contrib/scriptinstall: install a script tree package generated using the scriptpack contributed command.
- cmd/new lua: lua language interpreter, compiled for Linux-64, glibc 2.27.
- cmd/new luac: lua language compiler, compiled for Linux-64, glibc 2.27.
- cmd/chg logview: improvement in program abort handling.
- cmd/chg logtail: improvement in program abort handling.
- cmd/chg edrcman: check if man command exists on the system.
- cmd/chg pscount: allow reading list of processes also from file.
- cmd/chg pscount: Performance improvement.
- cmd/chg pscount: no longer react on PRINT_FIT2WIDTH environment variable.
- cmd/chg pscount: spaces at the end of list outputs are eliminated, now.
- cmd/chg pslist: remove additional pslist processes from process list.
- cmd/chg pslist: support very long process lists, now.
- cmd/chg sys2html: create 'System Documentation' HTML reports of remote systems.
- cmd/chg vsav: versioned file save.
- cmd/chg vmore: more saved file version.
- cmd/chg vcat: cat saved file version.
- cmd/chg vgrep: grep pattern in saved file version.
- cmd/chg vdiff: diff to saved file version.
- cmd/chg vlist: list saved file versions.
- cmd/chg vls: list saved file versions.
- cmd/chg vrestore: restore saved file version.
- cmd/new locate: query locate database.
- cmd/new updatedb: update locate database.
- cmd/chg loggrep/logcat: new option -s num to set the number of lines used to resolve the timestamp.
- cmd/chg loggrep/logcat: new option -T id to set the used timestamp id manually.
- cmd/chg stat: new option -L to follow symlinks.
- cmd/chg contrib/scriptpack: extra packed files are now saved to .sav/scriptpack/ of the generated script tree package.
- cmd/new crond: cron daemon.
- cmd/new ecrontab: edit crontab entries for crond.
- cmd/new ecrontab: show next scheduled jobs of crond.
- cmd/new gs: Ghostscript.
- cmd/new fnmatch: match a stream with a wildcard.
- cmd/chg scriptgrep: internally now egrep is used to allow extended regular expressions.
- cmd/chg scriptgrep: matches are colored red on Linux.
- cmd/chg abc, abcd: output of \$e, \$f, \$g, \$TODAY added.

- cmd/chg e, f, g: setting of additional working variables \$e, \$f, \$g.
- cmd/new cde, cdf, cdg: jump to working variables dirs \$e, \$f, \$g.
- cmd/chg pstree: no longer limit output to console width.
- cmd/chg pstree: now also accepts a process name as start point of the process tree.
- cmd/new jobstart: run jobs thru a simple interface.
- cmd/chg timer: date and time options to calculate seconds since epoch for
- cmd/new ps2pdf: PostScript to PDF file conversion.
- cmd/chg .daemon_wrapper: change of CWD to root can be avoided when PWDPRESERVE=daemon_command is set in the daemon_command.
- cmd/chg job: preserve current working directory.
- cmd/chg joblog: now also a log file of a job can be monitored.
- cmd/chg edrcman: output of -l extended by number of man PAGES per operating system.
- cmd/chg job/jobwatch/joblog: now reads the config file job.cfg where the SPOOLBASEDIR can be set.
- cmd/chg .os_wrapper: binary resolution improved. On Linux on missing files sometimes directories with executable permissions set were selected.
- cmd/chg edrcman: more portable checking if man command is installed on the operating system.
- cmd/new lib/man: the man command from mandoc is bundled to provide a man command (called by edrcman and edrc->doc) on systems where the man command is missing.
- cmd/chg woist: do not search a directory twice for a command.
- cmd/chg manvi: uses vsav instead of sav prior to file editing.
- cmd/chg llcomp: support for cpio.xz files added.
- cmd/chg lscomp: support for cpio.xz files added.
- cmd/chg catcomp: support for cpio.xz files added.
- cmd/chg WA2L/edrc:report: statistics simplified and performance increase.
- cmd/chg job: representation of enqueued jobs without observation.
- cmd/chg csv: performance improvement in 'csv header'.
- cmd/chg print_index: now also non-fixed column width is possible.
- cmd/fix edrcinit: services stopped using 'edrcinit stop' are no longer guarded and remain stopped until 'edrcinit start [name]' is invoked.
- cmd/chg edrcinit: new option checknow to force an immediate service check.
- cmd/chg edrcinit: when 'edrcinit unguard' is used, the services remain unguarded until 'edrcinit guard' is used. Therefore the service guarding is no longer influenced by other options.
- cmd/new zstd: compress and uncompress files.
- cmd/new unzstd: uncompress files.
- cmd/new unczst: uncompress zstd-compressed cpio files.
- cmd/new unczstd: uncompress zstd-compressed cpio files.
- cmd/new untzst: uncompress zstd-compressed tar files.
- cmd/new untzstd: uncompress zstd-compressed tar files.
- cmd/chg catcomp can now also handle zstd-compressed cpio and tar files.
- cmd/chg lscomp can now also handle zstd-compressed cpio and tar files.
- cmd/chg llcomp can now also handle zstd-compressed cpio and tar files.
- cmd/chg unrpm can now also handle rpm packages that contain a .cpio.zst archive.
- cmd/chg cfg2html: new version 7.0.1.1 for Linux and Linux-64.
- cmd/chg tomorrow, yesterday: more stable return value.
- cmd/new tscat: filter to add a timestamp and filename to a stream.
- cmd/chg job: enable -f to force to stab a running job with running processes.
- cmd/chg job: add DURATION to output of job -p.
- cmd/fix pstree: no process output when given process id does not exist.
- cmd/fix pstree: message prefix corrected to pstree.
- cmd/new md2html: convert markdown file to html.
- cmd/chg print_index: new option to eliminate trailing spaces in output.
- cmd/chg cmdlist: startmode direct/daemon added, output of commands started thru the .os_wrapper improved.

- cmd/chg revision: now where possible revision of target file is listed for wrapped commands (not the revision of the wrapper).
- cmd/chg name: now where possible name of target file is listed for wrapped commands (not the name of the wrapper).
- cmd/new pod2html: convert POD to html.
- cmd/new cdrpt: cd var/www/report/rpt.
- cmd/new kalc: RPN calculator.
- cmd/new contrib/kalc: RPN calculator as contributed command in edrc.
- cmd/chg rssh: -l option to list and select from past connections.
- cmd/chg patchinstall: -i option to list installed patches.
- cmd/new contrib/bc: bc calculator as contributed command in edrc.
- cmd/new vvi: versioned file editor.
- dir/new var/samples/templates/: templates to be used with the tpl command.
- dir/new var/vsav/files/: storage for vsav.
- man/new tpl.1
- man/new tpl.cfg.1
- man/chg job.cfg.4.1: description of COLORIZE setting to control coloring job list output.
- man/chg compatibility.1: add tpl.
- man/chg compatibility.1: add YSCR for python scripts.
- man/chg edrcports.4: add SMTP, enhance port requirement documentation.
- man/chg csv.3: description of wherenot, wherenot:ignorecase, where:ignorecase, cat:authorized_keys, and cat:known_hosts option added.
- man/new ascii.3
- man/new charsets.3
- man/new utf-8.3
- man/chg shell: description of host connection when WA2L/edrc is not installed.
- man/chg shell: EXIT STATUS descriptions enhanced.
- man/chg manpages.4: description to .PP to end indent in list.
- man/chg edrcman.1: add description of man/OS/<OSID>/ directory.
- man/new OpenSUSE, Ubuntu, OpenSolaris: native manual pages bundled with WA2L/edrc.
- man/chg contrib.edrc.1m: description of the changed PATH= settings.
- man/chg hostlist.3: description of the Ansible inventory ini- and yaml file format output options.
- man/new wa2ledrc_edrcapi.1: description of WA2L/edrc:edrcapi.
- man/chg wa2ledrc_report.1: add documentation of https using nginx.
- man/chg wa2l_util.3: documentation of checkopt() function.
- man/chg edrcports.4: add edrcapi.
- man/chg remote_shell.1: documentation of the new -N option.
- man/chg tpl.1: documentation of \$EDRC_SCRIPTS_BASEDIR/tpl.cfg.
- man/chg loggrep.1: description of -NUM option.
- man/chg loggrep.1: description of -M option which output goes to fd3 now.
- man/chg remote_shell.3: description of exit code 1##.
- man/chg remote_copy.3: description of exit code 1##.
- man/chg remote_copy.3: description of -N option.
- man/new TLDP: version 5.13 of TLDP (The Linux Documentation Project) manual pages included.
- man/new csvq.3: short description for csvq.
- man/chg remote_copy.3: description of -v option.
- man/new uuencode.1
- man/new uuencode.4
- man/new uuencode.1
- man/new lua.3
- man/new luac.3
- man/chg pscount.3: description of -f option.
- man/chg pscount.3: \$PRINT_FIT2WIDTH removed.

- man/new sys2html.1m
- man/chg edrcintro.1: sys2html added
- man/new vsav.1: manual page for vsav, vcat, vmore, vdiff, vlist, vrestore.
- man/new locate.1
- man/new updatedb.1
- man/new locatedb.4
- man/chg contrib.edrc.1m: description of the directory where extra files are packed to using scriptpack.
- man/new crond.3
- man/new ecrontab.1
- man/new ecrontab.4
- man/new gs.3
- man/new fnmatch.3
- man/chg pstree.1: description of processname.
- man/new jobstart.1
- man/new ps2pdf.3
- man/chg daemon_wrapper.1: documentation of PWDPRESERVE=command.
- man/chg joblog.1: documentation of new -j id option.
- man/new job.cfg.4
- man/chg llcomp.1: support for cpio.xz.
- man/chg lscomp.1: support for cpio.xz.
- man/chg catcomp.1: support for cpio.xz.
- man/chg edrcinit.1m: improved.
- man/new pkgdir.4: directory of package/software handling commands.
- man/new tscat.3
- man/new md2html.3
- man/chg print_index.3: description of new nospace option.
- man/chg cmdlist.1m: description of daemon start mode added.
- man/chg job.1: purpose description of the job state files.
- man/new pod2html.3
- man/new perlpod.4
- man/new kalc.1
- man/chg rssh.1: -l option to list and select from past connections.
- man/chg patchinstall.1m: -l option to list installed patches.
- man/new edrclicense.4: GNU General Public License for WA2L/edrc.
- man/new vvi.1: versioned file edit.
- doc/chg WA2Ledrc:report/help: provide access to local- and sourceforge-manuals.
- doc/chg WA2Ledrc:report/doc: new DESCRIPTION column for report sub-folders whereas the description is also provided thru a ..du_index file owned by edrc in the related folder.

1.5.55

Sun Oct 10 22:23:55 METDST 2021 release

MAIN IMPROVEMENTS:

- cmd/chg tinydns, tinydns-data, dnscache, djbdns: removed from WA2L/edrc because it does not support IPV4 and IPV6, probably YADIFA will be integrated.
- cmd/new rosid: resolve osid of a remote system.
- cmd/new rcat: display (cat) remote- or local file(s).
- cmd/new rdif: display differences (diff) of remote- or local file(s).
- cmd/new rcomm: compare (comm) remote- or local file(s).
- cmd/new loggrep: (aka. lgrep) grep selected time range in log files.
- cmd/new contrib/clock: a clock in military format.
- cmd/new contrib/search: search text in recovery scripts.
- cmd/chg exiftool: upgraded to version 12.26.
- man/new many

ALL CHANGES:

- cfg/chg edrcrevision.cfg: new release 1.5.55 (Sat Nov 14 19:11:54 MET 2020)
- cfg/chg www/report/.meta/VERSION: 1.0.20.
- cfg/new lynx.lss: color configuration file for lynx.
- cfg/chg kshrc: set ls colors for .xcf.
- cfg/chg kshrc: save directory stack on shell exit to enable ret on re-entry.
- cmd/chg whoisin: now uses ssh-exec internally and no longer rlogin.
- cmd/new wmic: for Linux-64, running on GLIBC 2.27.
- cmd/new wmic: for Linux-64, running on GLIBC 2.8.
- cmd/new winexe: for Linux-64, running on GLIBC 2.8.
- cmd/chg tinydns, tinydns-data, dnscache, djbdns: removed from WA2L/edrc because it does not support IPV4 and IPV6, probably YADIFA will be integrated.
- cmd/new scriptmenupath: return script menu path in form 'menu -> submenu -> subsubmenu -> menu-point'.
- cmd/new rosid: resolve osid of a remote system.
- cmd/chg .os_wrapper: more save internal glibc.version resolution.
- cmd/new contrib/clock: a clock in military format.
- cmd/chg scriptsequence: log to var/log/scriptsequence.log.
- cmd/new csv: filter to process CSV data.
- cmd/chg contrib/doc: avoid code output on first line before .SS.
- cmd/chg edrc: WARNING on removed menu when invoking a contributed command.
- cmd/chg ssh-exec: mode of executing commands changed to avoid problems with quotes.
- cmd/chg ssh-exec: it is now possible to start the command as user different from the START_USER setting in ssh-exec.cfg as long as the local user specified in the -l option is equal to the user's ID.
- cmd/chg ssh-exec: -b option to avoid remote banner output.
- cmd/fix ssh-exec: usage parsing.
- cmd/chg www/report/js/report.js: formatting of the 'leaving web server message' changed.
- cmd/chg lynx: version 2.8.9rel.1 (glibc 2.17) compiled with ssl (HTTPS) and bundled for Linux-64.
- cmd/chg lynx: version 2.8.9rel.1 (glibc 2.8) compiled with ssl (HTTPS) and bundled for Linux-64.
- cmd/new shell: grep is an alias for grep --color on *Linux* to colorize matching patterns.
- cmd/new shell: egrep is an alias for egrep --color on *Linux* to colorize matching patterns.
- cmd/chg shell: prints README contents to stderr when doing a 'cd' to a directory where a README file exists.
- cmd/chg scriptextract: no longer use the portable cpio format (-c switch) to extract the distribution file for Linux-64.
- cmd/new rcat: display (cat) remote- or local file(s).
- cmd/new rdiff: display differences (diff) of remote- or local file(s).
- cmd/new rcomm: compare (comm) remote- or local file(s).
- cmd/chg contrib/logviewer: can now include additional extra log files.
- cmd/new loggrep: grep selected time range in log files.
- cmd/new textblock: format a stream into a justified text block with an optional hanging first line.
- cmd/chg xmore: now catches Ctrl+C and cleanly aborts to avoid a mangled terminal. This had mostly an impact when using vsdfml in a recovery script and the user pressed Ctrl+C while still viewing the file.
- cmd/new ansi2txt: convert ANSI color codes to text.
- cmd/new ansi2txt: compiled for Linux/GLIBC 2.8.
- cmd/new contrib/search: search text in recovery scripts.
- cmd/chg tcpdump: version 3.9.9 (GLIBC 2.8) bundled for Linux-64.
- cmd/chg edrcman: on SuSE 12.3 and 12.5 with man versions 2.63 or 2.6.6 manual pages residing in directories having a dash in it could not be found. The edrcman command now is resistant to this and regardless can displays the manual page.
- cmd/fix contrib/doc: do not compute '-' and '/' in O: sections any more.
- cmd/fix resolve_targets: correctly handle when an empty targetlist in -t option is given.
- cmd/chg contrib/edrcupgrade: repeat target input query when an empty target list is given.

- cmd/chg mc, mcview, mcedit: version 4.6.28 compiled for Linux-64/GLIBC 2.27.
- cmd/chg many: cleanup of old, inactive binaries.
- cmd/chg contrib/scriptdocbook: new special reference [----] to add a horizontal line allowing some structuring of entries.
- cmd/chg contrib/scriptdocbook: bibliography fields output order changed to scientific standard.
- cmd/new sortv: sort -V for operating systems where sort lacks this functionality.
- cmd/chg logtail: sort log files by version.
- cmd/chg logtail: beside 'Ctrl+C' abort also when entering '0'.
- cmd/chg logview: sort log files by version.
- cmd/chg logview: beside 'Ctrl+C' abort also when entering '0'.
- cmd/chg contrib/logs: a global search option allows to search in all log files.
- cmd/new xml2json: convert XML file to JSON.
- cmd/new cmdlist: list all available WA2L/edrc commands.
- cmd/chg logtail: allows to select a subset of all logfiles.
- cmd/chg logview: allows to select a subset of all logfiles.
- cmd/chg vsdfml: format text by default as manual page and load it into man. The previous default terminal output is available as TTY output format now.
- cmd/chg exiftool: upgraded to version 12.26.
- cmd/chg vsdfml: avoid big indent of body text in MAN mode.
- cmd/chg csv: convert dos to unix files when using "csv cat".
- cmd/chg is_up: IPv6 support added.
- cmd/chg pmdesc: avoid "cannot stat" errors on non existing include directories.
- cmd/new is_user: check if command is started using the correct user.
- cmd/new rssh: direct or interactive remote ssh invocation.
- cmd/chg edrcinit: no longer use the upstart method on Linux (as seen on Ubuntu) because it is now deprecated.
- cmd/chg edrcinit: write actions and config settings to log file.
- cmd/new contrib/motd: print system wide message of the day.
- cmd/chg input: new TTY option to read/write from/to tty.
- dir/chg edrc/var/dns/djbdns/: remove the djbdns directory by hand because the patchinstall cannot remove it due to the fact that it sits in the protected (STATIC) directory edrc/var/dns/.
- lib/new perlmodules: version 5.16.2 (glibc 2.17) compiled and bundled for Linux-64.
- man/chg ini.1: shell usage examples.
- man/new vadsp.1
- man/new whoisin.1
- man/new whoisin.list.4
- man/new tzdump.3
- man/new job.1
- man/new jobwatch.1
- man/new joblog.1
- man/new logcheckd.interface.3
- man/new dbrep.1
- man/new dbrep.cfg.4
- man/new passwdsyncd_apply.3
- man/new remote_shell.3
- man/new remote_copy.3
- man/chg perlversion.3: command has no option.
- man/new role_option.1
- man/new role_option.cfg.4
- man/new scriptextract.cfg.4
- man/new winexe.1
- man/new passwdcombine.1
- man/new edrcscripts.1m

- man/new hostlist.dat.4
- man/new scriptmenupath.3
- man/chg scripttitle.3: exit status 1 documented.
- man/chg edrcintro.1m: documentation of scriptmenupath.
- man/chg edrcintro.1m: documentation of rcac, rdif, rcomm.
- man/new rosid.3
- man/chg contrib.edrc.1m: contrib.clock.1m added.
- man/chg scriptsequence.1: log to scriptsequence.log.
- man/new csv.3
- man/new mandir.4: directory of online man page resources.
- man/new rcac.1
- man/new rcomm.1
- man/new rdif.1
- man/new loggrep.1
- man/new textblock.3
- man/new ansi2txt.1
- man/chg man/Linux-64/man1/lynx.1: for version lynx version 2.8.9rel.1 (08 Jul 2018).
- man/chg ssh-exec.cfg.4: START_USER description changed.
- man/chg contrib.edrc.1m: documentation to include extra log files in contrib.logviewer.
- man/new awk.1
- man/new awk-bsd.1: BSD version man page included (not linked, not used in HTML, PDF).
- man/new bash.1: GNU 3.2 version included.
- man/new gawk.1: Free Software Foundation version included.
- man/new sh.1: Heirloom Bourne Shell version man page (from <https://sourceforge.net/projects/heirloom/files/heirloom-sh/050706/>) included.
- man/new sh-bsd.1: BSD version man page included (not linked, not used in HTML, PDF).
- man/new ksh.1: RDS Standard version included.
- man/chg compatibility.1: add Linux-64.
- man/new xml2json.3
- man/new cmdlist.1m
- man/new edrcports.4
- man/chg perlenv.3: description of how to write perl scripts that live outside of WA2L/edrc, but profit from all perl modules bundled with WA2L/edrc.
- doc/chg doc/.man/bin/*: cleanup of old unused files.

1.5.54

Sun Nov 1 00:01:00 METDST 2020 release

MAIN IMPROVEMENTS:

- cmd/new scriptsequence: check if scripts are started in sequence and inform or abort if not. This command can be used in an _env file or in a recovery script.
- cmd/chg binprobe: probe (compiled) executables if they are able to start on the current operating system.
- cmd/chg many: compiled for Linux-64/GLIBC 2.8.
- lib/chg expect: elimination of extra start script in lib/<OSID>/.
- man/new many

ALL CHANGES:

- cfg/chg edrcrevision.cfg: new release 1.5.54 (Thu Sept 22 20:42:00 METDST 2020)
- cfg/chg kshrc: cdsw can jump to a subdirectory now.
- cfg/chg os_wrapper/timer.cfg: probe options corrected.
- cfg/chg contrib.edrc.countdown.cfg: use COUNTDOWN_COUNTER_CHARACTER="c" to set the character used to display the countdown.
- cmd/chg thttpd: resolve glibc version.
- cmd/chg msmtpt: compiled for Linux-64/GLIBC 2.8.
- cmd/chg thttpd: compiled for Linux-64/GLIBC 2.8.
- cmd/chg pl: compiled for Linux-64/GLIBC 2.8.

- cmd/chg glibc.version: compiled for Linux/GLIBC 2.8.
- cmd/chg sqlite: compiled for Linux-64/GLIBC 2.8.
- cmd/chg nano: version 2.5.1 compiled for Linux-64/GLIBC 2.8.
- cmd/chg os_wrapper: more controlled abort on 'FATAL: Kernel too old' condition.
- cmd/chg shell: many cd* aliases accept a subdir now.
- cmd/chg shell: the ret command jumps back thru the whole cd spur not only between the two last directories (for this use cd -).
- cmd/new xml2csv: convert XML schema to CSV.
- cmd/chg cfg2html: new version 6.41 for Linux-64.
- cmd/chg cfg2html: new version 6.41 for Linux.
- cmd/chg jq: version 1.5 for Linux.
- cmd/chg os_wrapper: allow multiple switches in EXEC_PROBE_OPTION.
- cmd/chg contrib/edrcupgrade: show patch installation step also in terminal window title.
- cmd/chg contrib/doc: allow to use .SS in O: without loosing the preformatted text output mode.
- cmd/fix contrib/doc: no longer extra lines are printed in HTML output (=ScriptDocBook) when empty lines are present between <pre> ... </pre>.
- cmd/chg contrib/scriptdocbook: css support including TOC and Index buttons as known from the new HTML manual pages added.
- cmd/chg LogViewer: possibility to choose if the Index pane is at top or bottom.
- cmd/chg LogViewer: help page added.
- cmd/chg name: resolve also SVG- and empty files.
- cmd/chg revision: resolve also SVG- and empty files.
- cmd/chg outex: correct logfile resolution when called interactively without specifying a logfile as option.
- cmd/new scriptsequence: check if scripts are started in sequence and inform or abort if not. This command can be used in an _env file or in a recovery script.
- cmd/chg contrib/logviewer: description not is not optional any more.
- cmd/chg edrc: script tempfile also removed when _env file is actively exited using the exit command.
- cmd/chg ssh-exec: internal code improvements.
- cmd/chg binprobe: probe (compiled) executables if they are able to start on the current operating system.
- cmd/fix bget: syntax error on un-escaped braces.
- cmd/new sshpass: a utility designed for running ssh using the mode referred to as "keyboard-interactive" password authentication, but in non-interactive mode.
- cmd/chg contrib/scriptdocbook: URL in *.bib file.
- cmd/fix lbanner: argument parsing improved.
- cmd/fix mail_file: more reliable mail sending configuration when using msmtplib as MAIL_CLIENT.
- cmd/fix contrib/scriptdocbook: mail sending.
- cmd/chg contrib/scriptdocbook: it is now possible to protect the ScriptDocBook archive with a password.
- cmd/chg contrib/scriptdocbook, contrib/logviewer, contrib/scriptpack: more error tolerant email address input.
- cmd/chg contrib/scriptdocbook, contrib/scriptpack: can now also produce password protected archives.
- cmd/chg resolve_targetlist: typing error in usage corrected.
- cmd/new contrib/scriptsequence: (remote)-control the behaviour of the scriptsequence program.
- lib/chg Linux/libs: libraries moved from libs/ to 0.0/ and symlinked.
- lib/chg Linux-64/libs: libraries moved from libs/ to 0.0/ and symlinked.
- lib/chg expect: elimination of extra start script in lib/<OSID>/.
- man/chg os_wrapper.3: added libs/ directory for a specific glibc version.
- man/chg manpages.4: description on how to build the documentation using make.
- man/new scripttitle.3
- man/new scriptsequence.3
- man/new sshpass.1
- man/new portscan.3
- man/new is_writeable.3
- man/new is_existing.3

- man/new filewatch.3
- man/new scriptrevision.3
- man/new outex.1
- man/new perlversion.3
- man/new lbanner.3
- man/new locations.1
- man/new locations.cfg.4
- man/new xtee.1
- man/new xpid.1
- man/new xmore.1
- man/new ssh-keyadd.cfg.4
- man/new ssh-keyadd.pub.4
- man/new streamcat.3
- man/new ksh_wrapper.cfg.4
- man/new perl_wrapper.cfg.4
- man/new xlog.1
- man/new xml2csv.1
- man/chg manpages.4: review.
- man/new is_permitted.3
- man/new manvi.1
- man/new manvi.cfg.4
- man/new repeat.3
- man/new rel2abs.3
- man/new sortc.3
- man/new sectioncat.3
- man/new filelink.1
- man/new hwinventory.1
- man/new is_running.3
- man/new java_wrapper.cfg.4
- man/new rl.1
- man/new log_files.cfg.4
- man/new fields2swvi.3
- man/new usage.list.4
- man/new epub2pdf.1
- man/new passwdsort.1
- man/new resolve_targetlist.3
- man/new pdfscissors.1
- man/new pdfmetaedit.1
- man/new ypxfr_all.1
- man/new java.1
- man/new sw_report.1
- man/new java_wrapper.1
- man/new kshrc.4
- man/new exrc.4
- man/new readline.3
- man/new rsat.1
- man/new rsat.cfg.4
- man/new shell.cfg.4
- man/new sysdiff.1
- man/new pkg_hostname.cfg.4
- man/new edrcinit.handler.3
- man/new sw_inventory.4
- man/new untrash.1

- man/new ini.1
- man/new ini.cfg.4
- man/new env.4
- man/new timezone.dat.4

1.5.53

Sun Sep 20 07:47:12 METDST 2020 release

MAIN IMPROVEMENTS:

- cmd/chg os_wrapper: can handle different glibc versions.

ALL CHANGES:

- cfg/chg edrcrevision.cfg: new release 1.5.53 (Mon August 24 11:08:00 METDST 2020)
- cfg/chg edrcman.map: mappings of shell added.
- cmd/chg exiftool: upgraded to version 12.00.
- cmd/chg shell: view alias changed from view to vi -R.
- cmd/chg edrc: probes on *Linux* if HISTORY_BROWSE is supported and only in this case it is enabled.
- cmd/chg os_wrapper: can handle different glibc versions.
- dir/chg edrc/lib/Linux-64: now supports binaries for different glibc versions.
- dir/chg edrc/bin/Linux-64: now supports binaries for different glibc versions.
- dir/chg edrc/src: cleanup of code fragments.
- lib/new perlmodules: version 5.26.1 (glibc 2.27) compiled and bundled for Linux.
- lib/new perlmodules: version 5.10.0 (glibc 2.11.2) compiled and bundled for Linux.
- lib/chg perlmodules: beginning with version 5.26.1 the install directory structure in edrc/lib/perl/pm/perl5/<version> and the build process to bundle perl modules has been significantly simplified. As long as the .perl_wrapper is used to start perl programs, no change in the perl program is needed.
- man/chg os_wrapper.1: description of the GLIBC version dependent binary location.

1.5.52

Sun Jul 26 18:46:40 METDST 2020 release

MAIN IMPROVEMENTS:

- cmd/chg edrc: new environment variable \$EDRC_TMP_DIR_SESSION that points to a secure temporary directory to be used to save temporary data that is used multiple times throughout an edrc session.
- cmd/chg contrib/pwsafe: remember the entered master password between queries.
- cmd/chg csv2worksheet: now can also load data into xlsx files.
- cmd/new ssh-exec: execute commands provided thru stdin on remote system using ssh.

ALL CHANGES:

- cfg/chg edrcrevision.cfg: new release 1.5.52 (Sat May 9 14:29:34 METDST 2020)
- cmd/chg contrib/logs: use vi -R instead of view (which sometimes is not a read only vi) to view files.
- cmd/chg contrib/logs: also output and query MENUPOINT.
- cmd/chg contrib/pwsafe: remember the entered master password between queries.
- cmd/chg contrib/pwsafe: allow pwsafe to be called to query password for user@system directly in recovery script (=direct query).
- cmd/chg edrc: use vi -R instead of view (which sometimes is not a read only vi) to view files.
- cmd/chg input: on LOG_STARS also log stars for default input.
- cmd/chg edrc: new environment variable \$EDRC_TMP_DIR_SESSION that points to a secure temporary directory to be used to save temporary data that is used multiple times throughout an edrc session.
- cmd/chg edrc: log also menu point to log files.
- cmd/chg edrcenv: print also \$EDRC_TMP_DIR_SESSION.
- cmd/chg WA2LDocBrowser: let the menu width resize.
- cmd/new ssh-exec: execute commands provided thru stdin on remote system using ssh.
- cmd/chg ssh-keyadd: set correct file permissions if authorized_keys file does not exist in a users home.
- cmd/chg csv2worksheet: now can also load data into xlsx files.
- cmd/new scripttitle: print recovery script title (menupoint and description). This command is intended to be called from a recovery script or _env file to give the user more awareness which menu point

- he started.
- cmd/new shell: cda, cdb, cdc, cdd, cdp to cd to the directory saved in the related working variables \$a, \$b, \$c, \$d, \$p.
- cmd/chg install: print correct path when adjusting permissions.
- cmd/chg contrib/doc: improvement on the remembering of the last doc invocation.
- cmd/chg ccrypt: version 1.11 provided as statically linked executable to avoid missing libraries errors.
- cmd/new contrib/logviewer: create a browseable LogViewer HTML archive containing all log files between two selected dates.
- cmd/chg contrib/scriptdocbook: correct handling of sender address when sending the archive by email.
- cmd/new outex: produce # O: prepended output of a given logfile to be used within recovery scripts in contrib.doc.
- cmd/chg edrcman: suppress the multiple manpage suggestion dialog as observed on SuSE 11.1 Linux.
- cmd/new contrib/tail: to tail -f a file from within edrc.
- cmd/chg edrc: after editing a file no longer provide [n] as default choice to "not to save" the file, now an explicit input is needed.
- cmd/chg choice: lesser number of space between prompt and colon when no default key is given.
- cmd/chg edrc: allow using the cursor keys in edrc prompt to access the history.
- cmd/chg contrib/doc: new T: tag to document the DURATION of a script run.
- cmd/chg edrcman: mapfile to map certain manual pages.
- cmd/new jq: a JSON processor.
- cmd/chg contrib/pwsafe: now also supports semicolons, spaces and tabs in passwords.
- man/chg edrc.1m: document the usage of the \$EDRC_TMP_DIR_SESSION variable.
- man/chg contrib.edrc.1m: document direct query functionality of pwsafe.
- man/chg edrcintro.1: document ssh-exec.
- man/chg EDRC.1: add ssh-exec, ssh-exec.cfg.
- man/new ssh-exec
- man/chg wintoolsintro.1: short description of outex.
- man/chg wintoolsintro.1: short description of jq.
- man/chg contrib.doc.1m: hint to outex usage.
- man/chg contrib.doc.1m: documentation of doc tag T: (DURATION).
- man/new js.3: JSON processor.
- doc/chg doc: directory structure in doc/ cleaned up. If you linked manual pages as for example in *.bib files, as: PATH=doc/edrc_manpages-1.5.51/edrc.html this must be changed to PATH=doc/manuals/man1m/edrc.1m.html.

1.5.51

Tue May 5 07:59:42 METDST 2020 release

MAIN IMPROVEMENTS:

- cmd/chg contrib/*: simplify implementations by the use of \$EDRC_TMP_DIR as temporary directory instead of handling it within the contributed command.

ALL CHANGES:

- cfg/chg edrcrevision.cfg: new release 1.5.51 (Tue Mar 17 00:36:28 CET 2015)
- cfg/chg kshrc: add cdtmp alias.
- cfg/chg lotsctl: use \$EDRC_TMP_DIR as temporary directory in all scripts where applicable in entire script tree.
- cfg/chg sys: use \$EDRC_TMP_DIR as temporary directory in all scripts where applicable in entire script tree.
- cfg/chg shell.cfg: new setting USER_DROPBOX_DIR.
- cfg/chg lib/os_wrapper/wget.cfg: EXEC_PRIORITY=OS.
- man/chg shell.1: description of cdtmp command.
- man/chg edrcintro.1: hint to other WA2L projects in NOTES section.
- man/fix edrcsetup.1m: created package in step 6 from edrc_WA21 to edrc_ACME.
- man/chg vsdfml.3: use #!/usr/bin/env vsdfml instead of #!/bin/sh vsdfml as magic key.
- man/chg shell.1: add description of pid command.

- man/cor syspoll.cfg.4: description of LOCK_TIMEOUT.
- man/chg logview.1: only files that can be read by the user are listed.
- man/chg logtail.1: only files that can be read by the user are listed.
- man/chg lsof.1: version 4.88 for Linux.
- man/cor syspoll.1m: correct date format from %Y%d%m to %Y%m%d in examples.
- man/chg syspoll.1m: description that -t option now also accepts hostgroups directly.
- man/chg shell.1: document edrcdebug to compute also a lists of commands.
- man/chg edrcinit.1m: documentation of the enable and disable options.
- man/cor edrcintro.1: short description of cmswitch command.
- man/ch edrcintro.1: short description of untxz command.
- man/new untxz.1
- cmd/fix ux2dos: no error message when '-' is given as input file.
- cmd/fix dos2ux: no error message when '-' is given as input file.
- cmd/chg name: process also release-numbered files as present in edrc/lib/daemon/.
- cmd/chg name: now process the first 20 instead of 10 lines for header information.
- cmd/chg filewatch: avoid error message when file to watch does not exist (yet).
- cmd/chg filewatch: hide cursor and no longer print command.
- cmd/chg filewatch: allow also a process been referenced by process id.
- cmd/chg edrcenv: add output of \$EDRC_TMP_DIR, \$EDRC_CONTRIB_VARDIR.
- cmd/new cdtmp: cd to \$EDRC_TMP_DIR or /tmp if the \$EDRC_TMP_DIR is not set.
- cmd/chg edrc: assign tempdirs created for scripts, contrib commands and shell to edrc to list it active when calling listtemp.
- cmd/chg contrib/dirwatch: use \$EDRC_TMP_DIR as temporary directory, now.
- cmd/chg contrib/logs: use \$EDRC_TMP_DIR as temporary directory, now.
- cmd/chg contrib/scriptdocbook: use \$EDRC_TMP_DIR as temporary directory, now.
- cmd/chg contrib/scriptpack: use \$EDRC_TMP_DIR as temporary directory, now.
- cmd/chg contrib/clonemenu: use \$EDRC_TMP_DIR as temporary directory, now.
- cmd/chg contrib/doc: use \$EDRC_TMP_DIR as temporary directory, now.
- cmd/chg contrib/edrcupgrade: new default URL for download is <https://master.dl.sourceforge.net/project/wa2l-edrc/edrc-patch>.
- cmd/new cdbx: change to user's DropBox directory.
- cmd/new cdrel: change to release control folder (for edrc developer).
- cmd/chg logtail: when calling as non-root users only list the files that the user is permitted to read.
- cmd/chg logview: when calling as non-root users only list the files that the user is permitted to read.
- cmd/chg lsof: version 4.88 for Linux.
- cmd/chg h2: version 1.4.187.
- cmd/chg edrcupgrade: read environment file to set http_proxy, no longer switch to root user.
- cmd/chg hwinventory: improvement in resolving the OSDISTRIBUTION field.
- cmd/chg syspoll: also accept hostgroups (@HOSTGROUP) as target specification in the -t option.
- cmd/chg tsize: use stty internally also on Linux due to SIGTSTP signals received on Ubuntu calling /usr/bin/resize.
- cmd/chg edrcdebug: now more then one command can be specified with one call to edrcdebug supplying a space separated list.
- cmd/chg manvi: exclude .ps and .html files from selection list.
- cmd/chg edrcinit: disable option to disable services startup thru edrc, enable to enable disabled startup again.
- cmd/chg contrib/countdown: allow countdown calculation based on 'Planned End Time'.
- cmd/chg contrib/countdown: more precise output prioritisation on terminal height reduction.
- cmd/chg contrib/countdown: internal design improvements.
- cmd/chg manvi: menu point to quit the command.
- cmd/chg osid: return a 'binary incompatible' error message to stderr if the test run of <osid>.probe is not successful.
- cmd/chg edrcenv: output of environment variables \$OSID_PROBE, \$PRINT_FIT2WIDTH, \$SYSPOLL_CONFIGFILE, \$LOTS_CONFIGFILE, \$LOTS_IDENTITYIES,

\$SYSCONFIG_ROOTDIR, \$SYSCONFIG_FORCE when set.

- cmd/new untxz: uncompressed a *.tar.xz file.
- cmd/chg lscomp, llcomp, catcomp: process *.tar.xz files.
- cmd/chg collectd: removed from package.
- cmd/chg lscomp, llcomp, catcomp: process *.epub files.

1.5.50

Sun Mar 15 19:30:33 CET 2015 release

MAIN IMPROVEMENTS:

- cmd/chg edrc: provide a temporary directory \$EDRC_TMP_DIR during execution of recovery script, contributed command and the shell command.
- cmd/new ux2dos: convert ASCII fileformat between UNIX and DOS formats.
- cmd/new dos2ux: convert ASCII fileformat between UNIX and DOS formats.

ALL CHANGES:

- cfg/chg edrcrevision.cfg: new release 1.5.50 (Tue Feb 26 21:54:09 CET 2015)
- cfg/chg kshrc: set ls colors for .css, .js, .awk, Makefile, Makefile.var and COPYING.
- cfg/chg shell.cfg: add LC_TIME=C.
- man/chg edrcintro: add description of edrc/var/manvi/.
- man/chg shell.1: add descriptions of files in FILE section.
- man/chg edrcintro.1: add kshell description.
- man/chg EDRC.1: add kshell.
- man/chg compatibility.1: add kshell.
- man/chg syspoll.1: add csv2worksheet (3) to SEE ALSO.
- man/new dos2ux.3
- man/new ux2dos.3
- man/chg: edrc.1m: description of the \$EDRC_TMP_DIR environment variable.
- cmd/new kshell: print path of Korn- or Bourne Again Shell.
- cmd/chg scripthheadersync: be more error tolerant on files containing spaces.
- cmd/chg lsmv: quote all file names to support also file names with spaces.
- cmd/chg lscp: quote all file names to support also file names with spaces.
- cmd/new ux2dos: convert ASCII fileformat between UNIX and DOS formats.
- cmd/new dos2ux: convert ASCII fileformat between UNIX and DOS formats.
- cmd/chg mail_file: improve portability thru the use of ux2dos instead of native command.
- cmd/chg contrib/edrcupgrade: allow cancel in select patchfile to install dialog.
- cmd/chg edrc: provide a temporary directory \$EDRC_TMP_DIR during execution of recovery script, contributed command and the shell command.
- cmd/chg manvi: provide man page templates.
- cmd/cor syspoll: correct usage output of '-s set' option.

1.5.49

Mon Feb 23 23:16:08 CET 2015 release

MAIN IMPROVEMENTS:

- cmd/new syspoll: poll systems for actions and execute queries.
- opt/new lots: -a list_session to list all lots sessions.
- cmd/new wmic: client to use the Windows Management Instrumentation from Linux.
- cmd/new winexe: client to execute commands remote on Windows.

ALL CHANGES:

- cfg/chg edrcrevision.cfg: new release 1.5.49 (Sun Nov 16 23:47:04 CET 2014)
- cfg/new manvi.cfg: configuration file for manvi.
- man/chg edrcrevision.cfg.4: add apprevision(3) to SEE ALSO.
- man/chg edrcintro.1: manvi description added.
- man/chg EDRC.1: manvi(1), manvi.cfg(4) added.
- man/chg indent.3: allow output channel setting of leading indent.
- man/new syspoll.1
- man/chg edrcintro.1: sectioncat description added.

- man/chg edrcintro.1: syspoll description added.
- man/chg compatibility.1: syspoll and sectioncat added.
- man/chg sav.1: add */lib/syspoll/protocols/* to special sav handling.
- man/chg daemon_wrapper.1: add documentation of exit code 103 (permission denied to start command).
- man/chg os_wrapper.1: add documentation of exit code 103 (permission denied to start command).
- man/chg perl_wrapper.1: add documentation of exit code 103 (permission denied to start command).
- man/chg ksh_wrapper.1: add documentation of exit code 103 (permission denied to start command).
- man/new undeb.1
- man/new syspoll.cfg.4
- cmd/new manvi: edit WA2L/edrc manual pages.
- cmd/chg edrcman: error output on missing man page.
- cmd/chg indent: allow output channel setting of leading indent.
- cmd/chg xpid: option parsing changed. If no dash option is given select query string from command list, else parse options as given.
- cmd/new sectioncat: cat a section ([SECTION]) of a (config) file.
- cmd/new syspoll: poll systems for actions and execute queries.
- cmd/fix ssh-keyadd: removed unwanted key output that included an egrep error message when adding keys.
- cmd/chg sav: */lib/syspoll/protocols/* added for special sav handling.
- cmd/chg .daemon_wrapper: check if calling user has the permissions to execute/access started file.
- cmd/chg .ksh_wrapper: check if calling user has the permissions to execute/access started file.
- cmd/chg .os_wrapper: check if calling user has the permissions to execute/access started file.
- cmd/chg .perl_wrapper: check if calling user has the permissions to execute/access started file.
- cmd/chg edrcman: output when there is no manpage for a WA2L/edrc command available.
- cmd/new wmic: client to use the Windows Management Instrumentation from Linux.
- cmd/new winexe: client to execute commands remote on Windows. from Linux.
- cmd/new undeb: uncompress deb (Debian package) files.
- cmd/cor watchdog: typing error in usage message corrected.
- opt/new lots: -a list_session to list all lots sessions.
- lib/new Text::Aspell: perl module for spell checking using aspell.
- lib/new Net::SNMP, Crypt::DES, Crypt::Rijndael, Digest::SHA1: modules for SNMP queries.

1.5.48

Sun Nov 16 20:27:45 CET 2014 release

MAIN IMPROVEMENTS:

- man/chg many manpages: documentation enhancements.
- cmd/chg sqlite, h2: version upgrades.
- lib/chg libpng, libz: version upgrades.
- lib/new Tk: integration of Tk::* perl modules for graphical programming in perl.

ALL CHANGES:

- cfg/chg edrcrevision.cfg: new release 1.5.48 (Sun Oct 26 02:05:03 CEST 2014)
- cfg/new nginx.doc.cfg: provide nginx configuration to serve var/www/doc.
- man/new scriptgrep.1
- man/new filegrep.1
- man/new histlist.1
- man/chg EDRC.1: add scriptgrep (1), filegrep (1), histlist (3).
- man/chg compatibility.1: edrcinit specification.
- man/chg compatibility.1: table format modernized.
- man/chg edrcman.1: add description when a missing *(PK man page is requested).
- man/new edrcinit.1m
- man/chg manpages.4: elimination of dq (double quote) and aq (single quote) macros to improve output of generated html files.
- man/chg histlist.3 fssum.cfg.4 title.1 fmatch.3 WA2L::Util.3 manpages.4 edrcrevision.1 edrcintro.1 perlenv.3 perl_modules.3: avoid the use of the ad and dq man macros to improve output of generated html files.

- man/chg edrc.1m: var/tmp directory description added.
- man/new edrcinit.cfg.4
- man/chg sav.1: add /etc/default/ for special save file handling.
- man/chg EDRC.1: title page layout changed.
- cmd/chg edrcinit: change ownership of rc script on selected operating systems.
- cmd/chg edrcinit: support rcinstall on upstart Linux systems, rcinstall simplified.
- cmd/chg edrcman: a suggestion to invoke 'edrcman manpage' is printed, when a currently non existent WA2L/edrc man page is requested.
- cmd/chg sav: /etc/default/ added for special file save handling.
- cmd/chg h2: new version 1.4.182 (2014-10-17).
- cmd/new filewatch: watch the progress of file size.
- cmd/chg sqlite: new SQLite version 3.8.7.1.
- cmd/chg WA2LDocBrowser: menu and foot line formatting changes.
- dir/new var/tmp/: to store temp files in a more controlled environment.
- lib/chg lib/perl/pm: eliminate world writable files and directories.
- lib/chg libpng: new version 1.6.14.
- lib/chg libz: new version 1.2.8.
- lib/new Tk: integration of Tk::* perl modules for graphical programming in perl.

1.5.47

Sat Oct 25 23:16:48 CEST 2014 release

MAIN IMPROVEMENTS:

- man/chg many manpages: documentation enhancements.
- cmd/chg many commands: improved portability.

ALL CHANGES:

- cfg/chg edrcrevision.cfg: new release 1.5.47 (Wed Mar 26 22:50:27 CET 2014)
- cfg/chg foswiki/.../LocalSite.cfg: also handle DefaultUriHost in edrcinit/WA2Ledrc.foswiki handler.
- man/chg edrcsetup.1m: formulation in NOTES section enhanced.
- man/chg busy.1: add description of \$BUSY_ANIMATION.
- man/cor os_wrapper.1: path in example corrected.
- man/cor edrcsetup.1m: comment in example hostlist.dat file output corrected from hostlistdat2cfg -a dat to (...) -a list_dat.
- man/cor ssh-keyadd.1m: SEE ALSO ssh-keygen.
- man/chg perl_modules.3: reduce perl modules list to modules used by distributed commands written in perl.
- man/chg edrcintro.1: add lotsctl as example configurations in sat(1) explanation.
- man/chg edrc.1m: documentation of 'usage' command as alias to 'help'.
- man/chg pf_wrapper.1m: description of sudoers example enhanced.
- man/cor edrcsetup.1m: sudoers example configuration file corrected.
- man/chg shell.1: description of manvi added.
- man/new eshell.1
- man/chg perl_modules.3: documentation of how to compile and install bundled Perl modules if needed.
- man/chg compatibility.1: compatibility table format changed.
- man/chg edrcsetup.1m: add Ubuntu 14.04 as additional development operating system.
- man/chg perl_modules.3: change pack example to use the standard software location edrc/var/sw for package output.
- cmd/chg contrib/countdown: print halted and stopped state in banner to allow status view from distance.
- cmd/chg busy: can now print also different animations then the classic rotating slash by setting the BUSY_ANIMATION environment variable.
- cmd/new lbanner: print a large ASCII banner.
- cmd/chg leo: output formatting.
- cmd/chg contrib/leo: input method.
- cmd/new pdfmetaedit: GUI to edit PDF file meta data.
- cmd/new pdfscissors: GUI to crop PDF file for eBook reader.

- cmd/chg edrc: command 'usage' as alias to 'help'.
- cmd/fix apply2sw_inventory calc choice cltrash cmmon countdown crfile doc drvstat edrcman envpasswd-strip filedist filelink filesize freespace fssum histlist hwinventory input is_config_byhand job listtemp locations logcheckd logs lots mail_file maketemp makeuser omnimon omnistat omniutil passwdsyncd passwdsyncd_apply pscount pslist rcmd remote_copy remote_shell removetemp resolve_targetlist role_option rsat scriptheadersync scriptstats server_environment sessions ssh-keyadd swvi trash untrash user_info watchdog whereami: set absolute path to echo binary for Linux.
- cmd/fix pack: correct un-terminated quoted string used in input command options.
- cmd/chg symlink: error handling if change directory to directory where the symlink should be created is not possible.
- cmd/chg edrcinit: also support rc*.d directories as located on Ubuntu Linux systems.
- cmd/new lsof: lsof_4.87_3.13.0-37-generic for Ubuntu.
- cmd/chg lscomp: debian package (*.deb) support.
- cmd/chg llcomp: debian package (*.deb) support.
- cmd/chg catcomp: debian package (*.deb) support.
- lib/new Text::vCard: a package to edit and create a single vCard (RFC 2426).

1.5.46

Tue Mar 25 01:53:42 CET 2014 release

MAIN IMPROVEMENTS:

- cmd/new shellinaboxd: publish command line shell through AJAX interface.
- cmd/new leo: command line interface to dict.leo.org.
- doc/new toc: Table of Contents with page numbers in PDF document.

ALL CHANGES:

- cfg/chg edrcrevision.cfg: new release 1.5.46 (Fri Mar 7 08:36:34 CET 2014)
- cfg/chg kshrc: change vi/vim startup to also allow editing of files having spaces.
- man/cor symlink.1: the link is removed, not the original.
- man/new leo.1
- man/chg contrib.edrc.1m: description of contrib.leo.1m added.
- man/chg pid.1: add pslist(3) and xpid(1) to see also.
- man/cor vsdfml.3: troff formatting to view section MARKUP TAGS at the right position.
- man/new shellinaboxd.3: publish command line shell through AJAX interface.
- man/chg edrcsetup.1m: give hint to edrcupgrade command for patch download and install.
- man/chg edrcsetup.1m: add description of pbin directory to ease up startup of commands thru sudo or pfexec.
- man/cor busy.1: description grammar.
- doc/new toc: Table of Contents with page numbers in PDF document.
- cmd/chg hostlistdat2cfg: accept the XGRPS_PREF=str option in -m, as documented in the man page and in the commands usage message. The actually implemented option XGRPS_PREFIX=str is also still accepted (and will not be removed in the future) for backward compatibility to ensure users using that option can continue to use the command without change.
- cmd/fix symlink: setting and querying of symlink ownership when not called by root.
- cmd/new leo: command line interface to dict.leo.org.
- cmd/new contrib/leo: access to leo in edrc.
- cmd/chg edrc: check prompt input for allowed characters.
- cmd/new shellinaboxd: publish command line shell through AJAX interface.
- cmd/new xpid: convenience function to pslist and enhanced version to the pid command.
- cmd/chg contrib/countdown: avoid flicker on output.
- cmd/chg lib/edrcinit/WA2L.*: add EDRC_DEBUG_* facility, from now on the edrcdebug command can be used to debug those service handlers.
- cmd/fix days: parsing of date format YYYY-MM-DD.
- cmd/fix tsize: check if resize command does not exist.

1.5.45

Thu Mar 6 23:23:01 CET 2014 release

MAIN IMPROVEMENTS:

- cmd/chg symlink: setting of symlink ownership based on replaced link or original file.
- cmd/new exiftool: to edit/view meta information in files.
- cmd/new epub2pdf: convert EPUB files to PDF.
- cmd/chg contrib/countdown: visual and functional improvements.
- cmd/chg h2: integration of version 1.3.175.
- cmd/chg cfg2html: integration of version 5.31 for HP-11, HP-11i, HP-11ia.
- man/chg *: documentation enhancements.

ALL CHANGES:

- cfg/chg edrcrevision.cfg: new release 1.5.45 (Sat Aug 24 12:00:49 CEST 2013)
- cfg/chg usage.list: nmap, nping, h2 added.
- cfg/chg edrcinit.cfg: entry for sshd_system added.
- cfg/chg kshrc: .ico files added.
- cfg/fix kshrc: save working variables \$a, \$b, \$c, \$d, \$p with quotes to enable settings containing spaces to be loaded correctly.
- man/new csvcat.1
- man/chg pf_wrapper.1: description of exit state 107.
- man/chg contrib.edrc.1m: the scriptpack.fl file should be located in the \$EDRC_SCRIPTS_BASEDIR and not in \$EDRC_ENTRY_DIR for contrib.scriptdocbook(1m).
- man/chg tty_columns.3: tty_variable is used internally.
- man/chg contrib.edrc.1m: configuration of countdown in the optional config file etc/contrib.edrc.countdown.cfg.
- man/chg edrcintro.1: add epub2pdf short description.
- man/chg edrcintro.1: add eshell short description.
- man/chg edrcintro.1: add tput_examples short description.
- man/chg edrcintro.1: remove all perl modules from TOC.
- man/chg EDRC.1: add epub2pdf.
- man/chg EDRC.1: add eshell.
- man/chg EDRC.1: remove all perl modules from TOC, link in HTML output will go via perl_modules.1 man page.
- man/chg compatibility.1: add epub2pdf.
- man/chg compatibility.1: add eshell.
- man/cor perl_modules.3: formatting.
- man/new tput_examples.3: examples of tput(1) usage.
- man/chg textcolor.3: add tput_examples(3) to SEE ALSO.
- man/chg symlink.1: document also setting of owner:group setting of created symlinks.
- man/chg contrib.edrc.1m: add short description of contrib.edrcenv.1m.
- man/chg edrcsetup.1: remove the hostlist.cfg "inline" example of configuring hostgroups and lists within the hostlist.cfg.
- man/new exiftool.1
- doc/chg doc/.man/sourceforge.net/project-web/WA2Ledrc.html: hyperlink cleanup and new DOWNLOADS chapter added.
- doc/new h2-1.3.175.html: HTML and PDF documentation of H" database engine.
- doc/chg edrc_manpages-*.pdf: add date to title page.
- cmd/chg .pf_wrapper: avoid direct call of .pf_wrapper.
- cmd/chg contrib/scripttree: handle symlinks that are broken.
- cmd/chg contrib/scriptpack: ensure proper directory permissions of copied files when packing config files and files listed in scriptpack.fl.
- cmd/chg contrib/scriptdocbook: read scriptpack.fl when located in \$EDRC_SCRIPTS_BASEDIR instead of \$EDRC_ENTRY_DIR.
- cmd/chg contrib/scriptdocbook: do not follow symlinked menus.

- cmd/chg contrib/checklist: do not follow symlinked menus.
- cmd/new lib/edrcinit/WA2Ledrc.sshd: service handler for sshd to be used on systems where sshd is not automatically started.
- cmd/chg contrib/edrcupgrade: allow cancel also when specifying a patchfile to install.
- cmd/cor contrib/countdown: typing error in prompt.
- cmd/chg contrib/countdown: output of help/usage message.
- cmd/chg contrib/countdown: countdown output.
- cmd/chg contrib/countdown: countdown handling streamlined.
- cmd/chg contrib/countdown: output of large countdowns also in large letters displayed correctly.
- cmd/chg contrib/countdown: reads color definitions from optional config file etc/contrib.edrc.countdown.cfg.
- cmd/fix edrcman: always write cache content in language setting 'C' to avoid re-evaluation of cache when the system language differs from 'C'.
- cmd/new epub2pdf: convert EPUB files to PDF.
- cmd/chg h2: new version 1.3.175.
- cmd/new pbin/eshell: normal start of bin/shell.
- cmd/fix a, b, c, d, abc, abcd: save working variables with quotes to enable settings containing spaces to be loaded correctly.
- cmd/fix edrc: \$TODAY is now also exported to the contributed commands.
- cmd/chg symlink: symlink also sets the owner and group permissions of the created symlink whenever possible.
- cmd/new contrib/edrcenv: display official WA2L/edrc environment variables, as the edrcenv command in the shell.
- cmd/chg HP-11ia/cfg2html: new version 5.31.
- cmd/chg HP-11i/cfg2html: new version 5.31.
- cmd/chg HP-11/cfg2html: new version 5.31.
- cmd/new exiftool: view/edit file meta information.

1.5.44

Sat Aug 24 00:11:06 CEST 2013 release

MAIN IMPROVEMENTS:

- cmd/chg www/foswiki: integration of Foswiki-1.1.8 with more flexible file structure and enhanced startup handling thru edrcinit.
- dir/new edrc/pbin: start commands thru RBAC or sudo transparently. User only has to add ~edrc/pbin to \$PATH.
- cmd/new h2: integration of H2 database engine.

ALL CHANGES:

- cfg/chg edrcrevision.cfg: new release 1.5.44 (Wed Apr 17 21:54:49 CEST 2013)
- cfg/chg www/report/.meta/VERSION: 1.0.19.
- cfg/chg kshrc: color *.bib and *.fl as config file.
- cfg/chg kshrc: remove mv2dsav alias.
- cfg/chg edrcman.cfg: LC_ALL to ensure proper special character display. If not set, but \$LANG on system is set, LC_ALL is set to \$LANG. If \$LANG also is not defined, the "C" locale is set as default.
- cfg/new h2.cfg: configuration file for H2 database engine.
- cfg/chg edrc.cfg: EDRC_HOSTPROMPT to display the host name after the @ sign in the prompt in full length (long) or to display only the host name part (short).
- man/chg EDRC.1: no longer include the PostScript manpage file.
- man/chg contrib.edrc.1m: add description of checklist to section of contrib.scriptdocbook(1m).
- man/chg WA2Ledrc:report.1: documentation of initial password of the user "admin" in the portal.
- man/chg Linux/banner.3: Copyright to 2013.
- man/new hostlistdat2cfg.3
- man/chg edrcman.1: add description of \$LANG and \$LC_ALL environment variable.
- man/cor *: PDF file of all man pages no longer contains empty pages.

- man/chg name.1: add description of etc/name.index file.
- man/chg edrcrevision.1: add bundled perl modules to lib/* section.
- man/chg shell.1: add cdwww.
- man/new h2.1
- man/new pf_wrapper.1
- man/chg shell.1: description of cdpbin command.
- man/new nping.1
- man/new nmap.1
- doc/chg edrc_manpages<version>.pdf: add graphical titlepage.
- doc/chg edrc_manpages<version>.ps: no longer include the PostScript file into the release. PostScript is still used to create the pdf file.
- cmd/chg www/report/main/help.html: correct logos.my to mylogos and change formatting of file paths.
- doc/new h2-1.3.172.html: HTML and PDF documentation of H" database engine.
- cmd/chg sys/1:patchinstall: enable startup of edrcupgrade contrib command from within that menu point.
- cmd/fix contrib/edrcupgrade: also accept 'c' to cancel in step 'list contents of patchfile'.
- cmd/chg DocBrowser: footer line.
- cmd/chg www/report/cgi/statistics: do not count number of lines in hour statistics.
- cmd/fix lotsctl/e:edit_lotsctl_settings: edit lotsctl.cfg file that as defined in the topmost _env file.
- cmd/chg contrib/scriptdocbook: also add checklist as produced by the contrib.checklist(1m) command to the ScriptDocBook. Permission related to this functionality is contrib.scriptdocbook.checklist.
- cmd/chg contrib/scriptdocbook: read also settings from optional config file
\$EDRC_SCRIPTS_BASEDIR/scriptdocbook.cfg to specify some defaults script tree specific.
- cmd/chg contrib/scriptdocbook: no default on 'create ScriptDocBook' dialog to avoid runaway cancel.
- cmd/chg contrib/scriptdocbook: formatting and style of index page.
- cmd/chg contrib/checklist: all informational output goes to stderr now, to allow contrib.scripttree(1m) to process the output.
- cmd/chg httpd: only list applications that also have a corresponding config file edrc/etc/htthpd.<app>.cfg.
- cmd/chg edrcman: set LC_ALL to ensure proper special character display.
- cmd/chg name: when the description of a file cannot be resolved from file header and ..name_index the global etc/name.index file is consulted.
- cmd/new cdwww: alias to go to var/www.
- cmd/chg DocBrowser: add a favicon icon.
- cmd/chg sysconfig: avoid backing up files multiple times. This was the case when a file has been listed multiple times in the backup file.
- cmd/new h2: H2 database engine console.
- cmd/new .pf_wrapper: start WA2L/edrc commands thru sudo or pfexec.
- cmd/new cdpbin: cd to edrc/pbin.
- cmd/chg edrc: dynamic number of columns on output when invoking edrcperm command.
- cmd/chg edrc: host name prompt part is configurable using the EDRC_HOSTPROMPT setting in edrc.cfg.
- cmd/chg www/foswiki: integration of Foswiki-1.1.8 and change of structure.
- dir/new pbin: location of command symlinks started thru .pf_wrapper.
- lib/new version, Module::Module-Metadata, Perl::Perl-OSType, CPAN::CPAN-Meta-Requirements, CPAN::CPAN-Meta-YAML, JSON::JSON-PP, Parse::Parse-CPAN-Meta, CPAN::CPAN-Meta, Locale::Locale-Maketext, Params::Params-Check, Module::Module-Corelist, Module::Module-Load, Module::Module-Load-Conditional, CPAN::CPAN-Meta, IPC::IPC-Cmd, ExtU-tils::ExtUtils-CBuilder, CPAN::CPAN-Meta-YAML, Parse::Parse-CPAN-Meta, Perl::Perl-OSType, Module::Module-Build, Try::Try-Tiny, Test::Test-Fatal, HTML::HTML-Tree

1.5.43

Fri Apr 12 21:41:54 CEST 2013 release

MAIN IMPROVEMENTS:

- cmd/new hostlistdat2cfg: generate the hostlist.cfg structure based on a simple csv list in hostlist.dat. The use of this command in hostlist.cfg reduces the configuration effort of hostlists and hostgroups significantly.

- cmd/new contrib/edrcupgrade: provide download of WA2L/edrc patches from sourceforge.net, deployment and installation in a contributed edrc command.
- cmd/new lotsctl: a "recovery" script tree to control lots (long term data save).
- cmd/new nginx: the small and portable proxy server is bundled with WA2L/edrc now. The start/stop/reload is handled thru edrcinit.
- cmd/new djbdns: the small and portable DNS server and cache is bundled with WA2L/edrc now. The start/stop/reload is handled thru edrcinit.
- cmd/chg syscp: now allows also to copy a system file to the repository if it is not already present in it.
- cmd/chg WA2L/report: several functional and stability enhancements.
- man/chg edrcsetup.1m: complete review of the WA2L/edrc "Quick Installation Guide".
- man/chg *: many documentation enhancements and corrections.

ALL CHANGES:

- cfg/chg edrcrevision.cfg: new release 1.5.43 (Thu Nov 1 22:24:38 CET 2012)
- cfg/new edrc.lotsctl.cfg: configuration for lots control menu (edrc short start lotsctl).
- cfg/new lotsctl.cfg: general configuration for lots control menu (edrc short start lotsctl).
- cfg/chg www/report/.meta/VERSION: 1.0.18.
- cfg/chg bin/usage.list: add lotsctl, screen.
- cfg/chg edrcman.cfg: add legacy linux man page directories.
- cfg/chg kshrc: only print warning when calling "m" when shell is started within "edrc".
- cfg/chg: edrc.cfg: new setting SCRIPTS_SHELLFALLBACKS to define fallback shells for recovery scripts.
- cfg/chg thttpd.report.cfg: no longer check referer urlpat, to be able to serve the page without many host-name restrictions.
- cfg/chg lib/usage.list: add nc, fcreate, tzdump.
- cfg/new lib/os_wrapper/lsof.cfg
- cfg/chg kshrc: cdsw alias performance.
- cfg/fix kshrc: ensure that termsize always sets the terminal size on initial command start.
- cfg/chg thttpd.report.cfg: change logfile from var/log/thttpd_access.log to var/log/thttpd_report_access.log.
- cfg/new tinydns.cfg: config file for tinydns startup via edrcinit.
- cfg/new tinydns.dat: DNS source data file for tinydns startup via edrcinit.
- man/chg EDRC.1: add lotsctl (1).
- man/chg EDRC.1: add WA2Ledrc:report (1).
- man/chg EDRC.1: add thttpd.report.cfg (4).
- man/chg EDRC.1: add textcolor (3), perlversion (3).
- man/chg edrcintro.1: add lotsctl short description.
- man/chg edrcintro.1: add textcolor short description.
- man/chg edrcrevision.1: definition of patchlevel change in RELEASE-NUMBERS section.
- man/chg edrcman.1: description of the -s option.
- man/new WA2Ledrc:report.1: description of the operating system report portal.
- man/chg edrcintro.1: add WA2Ledrc:report.
- man/chg edrcintro.1: add thttpd.report.cfg (4) in SEE ALSO section.
- man/new pscount.3
- man/new pscount.4
- man/new ssh-keyadd.1m
- man/chg regexintro.4: portability hint in POSIX CHARACTER CLASSES section.
- man/chg edrcintro.1: change email addresses @eds.com to @hp.com, remove email address of Reimund Mueller.
- man/chg edrcintro.1: add hint to Sourceforge.
- man/chg lsof.1: version 4.87 for Linux.
- man/chg edrcrevision.1: new object 'lib'.
- man/chg sav.1: add manual page and *.d directories to special handled dirs.
- man/new cmswitch.1m

- man/new cmmn.1m
- man/new title.1
- man/chg edrc.1m: add validation of magic key of executable recovery scripts.
- man/chg edrc.cfg.4: describe the SCRIPTS_SHELLFALLBACKS setting used to define the magic key shell fall-backs.
- man/new fcreate.3
- man/new textcolor.3
- man/chg contrib.edrc.1m: add the description of the possible deny functionalities of the contrib.count-down command.
- man/chg compatibility.1: add textcolor, nginx, csvcat commands.
- man/new tsize.3
- man/new random.3
- man/chg contrib.edrc.1m: contrib.scriptpack section.
- man/fix contrib.edrc.1m: contrib.scriptdocbook section.
- man/chg edrcintro.1: add untbz, untbz2, uncbz, uncbz2, perlversion short descriptions.
- man/chg edrcintro.1: add hostlistdat2cfg short descriptions.
- man/new uncbz.1
- man/new uncbz2.1
- man/new untbz.1
- man/new untbz2.1
- man/chg patchinstall.1m: description of the -m and -l options.
- man/chg uncgz.1: add references to uncbz, uncbz2, untbz, untbz2 to SEE ALSO.
- man/chg untgz.1: add references to uncbz, uncbz2, untbz, untbz2 to SEE ALSO.
- man/chg unrpm.1: add references to uncbz, uncbz2, untbz, untbz2 to SEE ALSO.
- man/chg unczip.1: add references to uncbz, uncbz2, untbz, untbz2 to SEE ALSO.
- man/chg edrcman.1: add description of influence of config file etc/perl_wrapper.cfg.
- man/chg perlenv.3: add description of directory structure in edrc/lib/perl/pm/ and include an extract of the mode how perl accesses modules of different versions from cpan.org.
- man/new nginx.3
- man/chg nginx.3: use more portable man macros.
- man/chg perl_modules.3: add URI perl module.
- man/chg logtail.1: add description of \$APPROOT resolution in logfile definition.
- man/chg logview.1: add description of \$APPROOT resolution in logfile definition.
- man/chg contrib.edrc.1m: add description of the optional config file contrib.edrc.scriptdocbook.cfg.
- man/chg contrib.edrc.1m: add description of the optional config file contrib.edrc.scriptpack.cfg.
- man/chg edrcsetup.1m: complete review.
- man/chg syscp.1: description of the checking of replacement tags in repository files.
- man/chg man/all/man*/*: add section title to header.
- man/chg syscp.1: add description of adding new files to a repository. Enhance EXAMPLES.
- man/chg shell.1: description of lscolors command.
- man/cor fmatch.3: change double quote macro use to increase man page display portability.
- man/new ipcalc.1
- man/chg perl modules: no longer distribute the manpages of bundled perl modules in the edrc/man/all/man3/ directory. The manpages of the bundled perl modules are only located in the edrc/lib/perl/pm/perl5/share/ directory.
- man/chg hostlist.3: add hostlistdat2cfg (3) to SEE ALSO section.
- man/chg hostlist.cfg.4: add hostlistdat2cfg (3), hostlist.dat (4) to SEE ALSO section.
- man/chg name.1: add description of ..name.index file.
- man/new strace.1:
- man/chg duvi.1: add exrc to FILES section.
- man/chg swvi.1: add exrc to FILES section.
- man/chg logview.1: add exrc to FILES section.
- man/chg sysvi.1: add exrc to FILES section.

- man/chg rcmd.1: add exrc to FILES section.
- man/chg mail_file.cfg.4: documentation of the options MAIL_SERVER_PORT, MAIL_SERVER_NAME, MAIL_CLIENT_OPTS, MAIL_CLIENT.
- doc/chg doc/*-current*: no longer create, maintain and distribute the symlinks to the current documents.
The most recent documents can be accessed always thru the DocBrowser.
- cmd/fix .perl_wrapper: also check if the executable found as a shell is a file.
- cmd/fix .ksh_wrapper: also check if the executable found as a shell is a file. cmd/new lotsctl: symlink to sat to provide a shortstart for the lots control menu.
- cmd/fix www/report/cgi/users.modify: avoid that a non admin user can modify the user account.
- cmd/new www/report/cgi/settings: dynamic settings menu which displays menu points based on user role.
- cmd/new www/report/cgi/settings.list: display the portal settings.
- cmd/chg www/report/cgi/reports: display the customers logo in header if it exists.
- cmd/chg www/report/cgi/doc: display the customers logo in header if it exists.
- cmd/chg www/report/cgi/doc: only list files, that have the correct permissions to be served (file=r.., directory=r.x).
- cmd/chg www/report/cgi/cgi.inc: add get_logo to library.
- cmd/chg www/report/cgi/logo: move get_logo to library.
- cmd/chg www/report/cgi/about: copyright date to 2012.
- cmd/chg www/report/cgi/statistics: back-links to dynamic home menu.
- cmd/chg www/report/cgi/users.*: back-links to dynamic user administration menu.
- cmd/chg www/report/cgi/logo.gallery: back-links to dynamic home menu.
- cmd/new www/report/cgi/home: dynamic home menu which displays menu points based on user role.
- cmd/new www/report/cgi/users: dynamic user administration menu which displays menu points based on user role.
- cmd/chg www/report/*: change all hyperlinks from absolute to relative.
- cmd/chg www/report/main/menu.html: provide a running clock.
- cmd/fix www/report/cgi/*: no longer check \$HTTP_REFERER in cgi scripts.
- cmd/fix www/report/cgi/statistics: calculation of user access and selection of http server accesses.
- cmd/chg www/report/cgi/statistics: new statistics of accesses per hour of the day only.
- cmd/chg uniqpath: eliminate repetitive colons (::) in output.
- cmd/fix contrib/doc: internal call of edrcman instead of man to display the documentation menu points to ensure that the documentation display is more reliable.
- cmd/fix ssh-keygen: correct authorized_keys writing in header and usage.
- cmd/chg contrib/countdown: output screen adjusted, implementation of halt and continue functionality to temporarily suspend the countdown.
- cmd/chg contrib/countdown: provides now the functionalities init, start, stop, resume, display to be used in edrcperm.
- cmd/chg HP-11ia/cfg2html: new version 5.27.
- cmd/chg HP-11i/cfg2html: new version 5.27.
- cmd/chg HP-11/cfg2html: new version 5.27.
- cmd/chg Solaris/cfg2html: new version 1.7.0.
- cmd/chg Solaris-x86/cfg2html: new version 1.7.0.
- cmd/chg Linux/lsof: new version 4.87.
- cmd/chg sav: handle files in man directories special.
- cmd/chg sav: more flexible and more general special directory handling.
- cmd/chg cmswitch: logfile when not using within edrc is edrc/var/log/cmswitch.log.
- cmd/chg edrc: copyright 2012 added. Validate if the interpreter for the recovery script exists and only start it if it does.
- cmd/chg edrc: reset windows title after recovery script and contributed command start or abort.
- cmd/chg edrc: if the shell in the magic key of a recovery script does not exist, a fallback mechanism tries to resolve alternate shell locations and alternate shells to ensure a script start. Script that do not have execute permissions are no longer started simply using the ksh shell, here also the fallback mechanism that resolves the magic key and the alternate shells, applies.

- cmd/chg edrc: output of recovery scripts and contributed commands to sdterr are now saved to the log files, too.
- cmd/new textcolor: to set the terminal text color.
- cmd/chg shar.setup: add information to transfer the package in binary mode to header.
- cmd/chg contrib/license: copyright 2003-2013.
- cmd/chg contrib/scriptpack: now it is also possible to select to save all config files and a list of other files to the script package, not only the related edrc.cfg file.
- cmd/new untbz: unzip a b2zipped tar file.
- cmd/new untbz2: unzip a b2zipped tar file.
- cmd/new uncbz: unzip a b2zipped cpio file.
- cmd/new uncbz2: unzip a b2zipped cpio file.
- cmd/chg .perl_wrapper,perlenv: PERLLIB resolution improved. With MODULE_DIR in perl_wrapper.cfg the location of the perl modules can be set (intended for testing purposes).
- cmd/chg edrcman: display also man pages of bundled Perl modules. To achieve this, also the MODULE_DIR setting of perl_wrapper.cfg is read.
- cmd/chg lib/perl/pm: compiled all bundled Perl modules for perl 5.14.3 and the x86_64-linux-thread-multi architecture.
- cmd/new lib/perl/pm: new module URI, Schedule::Cron, Time::DaysInMonth, Time::ParseDate, Time::CTime, Time::Timezone, Time::JulianDay.
- cmd/new nginx: HTTP and reverse proxy server, mail proxy server.
- cmd/chg name: when file header does not provide an entry for a symlinked file, display the header description of the original file. When file is a saved file, also resolve file header.
- cmd/chg name: if the description cannot be resolved from the file header, consult also the ..name.index file for a description.
- cmd/fix edrcinit: usage message corrected.
- cmd/chg edrcinit: rcinstall improved.
- cmd/chg edrcinit: status output includes also the guarded information, now.
- cmd/new lib/edrcinit/WA2Ledrc.nginx: new handler for edrcinit.
- cmd/cor histlist: file header.
- cmd/chg logview: resolve \$APPROOT (=‘approot’) environment variable in logfile definition.
- cmd/chg logtail: resolve \$APPROOT (=‘approot’) environment variable in logfile definition.
- cmd/chg histlist: suppress output of last column having undefined column.
- cmd/chg contrib/scriptdocbook: save the persistent input data now in a single file.
- cmd/chg syscp: check for replacement tags @[-_A-Z]+@ of differing files in the repository and display a warning to inform.
- cmd/chg syscp: can now also add new files to repositories.
- cmd/new lscolors: toggle ls color display in shell between true and false.
- cmd/chg is_running: remove s-bit, due to the fact it never worked really.
- cmd/chg patchinstall: avoid blocks output when printing meta data or list files of patch.
- chg/cmd contrib.logs: performance improvement on cache file handling.
- chg/cmd bin/Linux*/lsof: do a more fine os check.
- chg/cmd .os_wrapper: export \$OSID. This enables to act operating system specific in the lib/os_wrapper/<cmd>.cfg files.
- cmd/new perlversion: print resolved perl interpreter version.
- cmd/chg contrib/cmswitch: add startup prompt.
- cmd/chg contrib/dirwatch: add startup prompt.
- cmd/chg contrib/drvstat: add startup prompt.
- cmd/chg contrib/logtail: add startup prompt.
- cmd/chg contrib/oerr: add startup prompt.
- cmd/chg contrib/omnimon: add startup prompt.
- cmd/chg contrib/omnistat: add startup prompt.
- cmd/chg contrib/pid: add startup prompt.
- cmd/chg contrib/pstree: add startup prompt.

- cmd/chg contrib/scriptdocbook: add startup prompt.
- cmd/chg contrib/scriptpack: add startup prompt.
- cmd/chg contrib/scripttree: add startup prompt.
- cmd/chg .perl_wrapper: header.
- cmd/chg .ksh_wrapper: header.
- cmd/chg .os_wrapper: header.
- cmd/chg .java_wrapper: header.
- cmd/chg perlenv: header.
- cmd/chg edrcman: order of man pages reorganized.
- cmd/chg Linux-ia/cfg2html: new version 2.66.
- cmd/chg Linux/cfg2html: new version 2.66.
- cmd/chg HP-11/cfg2html: new version 5.30.
- cmd/chg HP-11ia/cfg2html: new version 5.30.
- cmd/chg HP-11i/cfg2html: new version 5.30.
- cmd/chg hwinventory: for Linux return SERVERNAME without domain.
- cmd/fix www/report/js/report.js: pad hours with leading zeros when hour is smaller than 10.
- cmd/chg edrcman: cache settings.
- cmd/new hostlistdat2cfg: to generate the hostlist.cfg config file out of a csv structure definition in a hostlist.dat file.
- cmd/fix hostlist: escape dot (.) in groups specified on the command line to ensure correct group resolution. Therefore e.g.: @ACME.ORG is not any longer resolved identically as @ACMECORP.
- cmd/chg hostlist: print the hostgroup prefix (@) in the output of the hostgroup names. Before the hostgroup was printed without the prefix.
- cmd/chg contrib/pwsafe: use vi settings from edrc/etc/exrc for the vi editor in pwsafe.
- cmd/new appendpdf: append a PDF file to another and write concatenated file to stdout or to an output file.
- cmd/new ipcalc: an IP address subnet calculator.
- cmd/new tinydns: a tiny, fast and secure DNS server.
- cmd/new tinydns-data: create the data file for tinydns.
- cmd/new Linux/strace: trace system calls. This command is called if truss is invoked on Linux.
- cmd/new Linux-ia/strace: trace system calls. This command is called if truss is invoked on Linux.
- cmd/new dnscache: DNS cache.
- cmd/new csvcat: clean a csv file or stream for further processing.
- cmd/chg rcmd: use the settings in exrc and prepare the terminal size before starting the vi editor.
- cmd/chg sysvi: prepare the terminal size before starting the vi editor.
- cmd/fix sysvi: correct missing file type resolution when multiple refiles exist which resulted in a "cannot edit" error.
- cmd/chg sysvi: also allow editing of repository files, if there is currently no active file on the system.
- cmd/chg logview: use the settings in exrc and prepare the terminal size before starting the vi editor.
- cmd/chg swvi: use the settings in exrc and prepare the terminal size before starting the vi editor.
- cmd/chg duvi: use the settings in exrc and prepare the terminal size before starting the vi editor.
- cmd/new contrib/edrcupgrade: install and upgrade an WA2L/edrc installation.
- opt/new patchinstall: -m to print the meta-data of the patch only.
- opt/new patchinstall: -l to list the logfiles of the patch only.
- opt/new edrcman: new option -s to display the used \$MANSECT, resolve of the /etc/man_db.config for the MANSECT setting.
- opt/new input: HHH:MM and HHH:MM:SS that allows time inputs, where the hours are not limited to 24 hours as in HH:MM and HH:MM:SS.
- dir/new var/www/report/var/mylogos: to save own factory logos that are not touched by application patch updates.
- lib/new Linux/libs/libext2fs.so.2: used by mc, mcedit, mcview.
- lib/new Linux/libs/libgpm.so.1: used by mc, mcedit, mcview.
- lib/new Linux/libs/libcom_err.so.2.1: used by mc, mcedit, mcview.

1.5.42

Tue Jan 12 00:11:06 CEST 2012 release

- cfg/chg edrcrevision.cfg: new release 1.5.42 (Mon May 23 19:03:12 CEST 2011)
- cfg/chg lots.cfg: remove unresolved options from config file.
- cfg/chg usage.list: add ftps.
- cfg/chg lib/os_wrapper/mc.cfg: ensure that on HP-UX the midnight commander is started instead of the media changer manipulation utility is started.
- man/chg lots.1m: add description of DATA_PURGE_LAG.
- man/chg lots.cfg.4: add description of DATA_PURGE_LAG and remove hint to unresolved options.
- man/chg EDRC.1: add ftps (1).
- man/chg edrcintro.1: add ftps short description.
- man/chg compatibility.1: add ftps.
- man/new ftps: based on README provided by the application.
- man/fix ksh_wrapper.3: correct step 2) description to "install the ksh script in the edrc/lib/ksh/directory"
- cmd/chg edrcman: revert stderr redirection of man command to /dev/null, this caused that on Unix only 1st manpage has been displayed.
- cmd/chg hwinventory: new fields DNSDOMAIN and IPADDRESS.
- cmd/fix maketemp: more restrictive fallback to internal emulation of mktempdir if the system own command does not succeeds.
- cmd/new ftps: secure FTP for SSL connections to the server.
- cmd/chg www/report/cgi/users.remove: support Firefox password manager.
- cmd/chg www/report/cgi/users.passwd: support Firefox password manager.
- cmd/new www/report/cgi/users.modify: modify an existing user account.
- cmd/chg www/report/cgi/users.add: support Firefox password manager.
- cmd/chg www/report/cgi/statistics: sorting order, also show counts of removed users.
- cmd/chg www/report/cgi/cgi.inc: sort list_users by NAME and not by timestamp.
- cmd/chg lots: add DATA_PURGE_LAG functionality.
- cmd/chg lots: add error checking during data purge.
- cmd/chg lots: remove processing of unresolved options.
- cmd/chg lots: print settings of \$LOTS_CONFIGFILE and \$LOTS_IDENTITIES in usage.
- cmd/chg .java_wrapper: support startup links, whose name is not equal to the class name using the edrc/lib/java/<scriptname>.javaopt file.
- cmd/new lib/logcheckd/interface/OVMail: send mails as in HP Openview.
- cmd/fix bin/HP-11ia/bzip2-1.0.5/bin/bunzip2: add symlink to provide the bunzip2 command.
- cmd/chg Linux/cfg2html: new version 2.25.
- cmd/chg Linux-ia/cfg2html: new version 2.25.
- cmd/chg HP-11ia/cfg2html: new version 2.50.
- cmd/chg HP-11i/cfg2html: new version 2.50.
- cmd/chg HP-11/cfg2html: new version 2.50.
- dir/chg lib/lots: remove directory and contents from application.

1.5.41

Mon May 16 18:56:29 CEST 2011 release

- cfg/chg edrcrevision.cfg: new release 1.5.41 (Sat Jan 15 15:38:31 CET 2011)
- cfg/chg os_wrapper/mc.cfg: EXEC_PRIORITY=OS.
- cfg/chg os_wrapper/mcview.cfg: EXEC_PRIORITY=OS.
- cfg/chg os_wrapper/mccedit.cfg: EXEC_PRIORITY=OS.
- cfg/chg osid.dat.WA2L: DISABLE_REGEX option to disable regular expression resolution.
- man/chg osid.3: -e and -h option and EXIT STATUS.
- man/chg osid.cfg.4: description of DISABLE_REGEX.
- man/chg osid.dat.4: description of the regex behaviour in WA2L format.
- man/chg name.1: add EXIT STATUS section.
- man/new osid.probe.3
- man/chg stat.3: -t option.

- man/chg stat.3: -s type option.
- man/chg patchinstall.1m: symlink timestamp update.
- cmd/fix www/report/cgi/statistics: correct statistics output in month December.
- cmd/chg is_osid: print \$EDRC_SCRIPTNAME if -s is not specified.
- cmd/fix logcheckd: correct logcheckd symlink from logcheckd.41 to logcheckd.42.
- cmd/chg HP-11/cfg2html: new version 4.84.
- cmd/chg HP-11ia/cfg2html: new version 4.84.
- cmd/chg lots: save the state of the actions collect, save, lock, purge also to the job file. Data of unsuccessful save actions is not locked and remains in the lock phase until cleared. The new fields COLLECTSTATE, SAVESTATE, LOCKSTATE and PURGESTATE are listed when invoking the -a print_job and -a list_jobs options.
- cmd/chg title: enhance os compatibility.
- cmd/fix whereami: print 'OS not supported message' to stderr.
- cmd/chg name: OS not supported on unknown operating systems.
- cmd/chg HP-11ia/cpio: recompiled without the /usr/local libraries. Version 2.10 is saved as 2.10a to enable patch installation of identical version.
- cmd/chg osid: osid entries can be defined as regular expression if OSID_DAT_FORMAT is set to WA2L and DISABLE_REGEX is not set to True.
- cmd/chg edrc: print copyright to 2011 in banner.
- cmd/chg edrcman: redirect stderr or man command to /dev/null.
- cmd/fix contrib/scripttree: correct handling of symlink-ed menus and menu points.
- cmd/chg pack: filelist is added to the sadm file.
- cmd/chg patchinstall: adjust timestamps of symlinks that are installed. This feature is only supported on operating systems whose kernel supports changing the timestamp of symlinks.
- cmd/chg www/report/js/report.js: formatting of the pop-up menus.
- opt/new osid: -e to list the entry to be added to osid.dat.
- opt/new osid: -h to print usage.
- opt/new stat: -t option to print CSV header.
- opt/chg stat: -t type option to print file type.

1.5.40

Sat Sep 25 02:35:19 CEST 2010 release

- cfg/chg edrcrevision.cfg: new release 1.5.40 (Fri Sep 24 02:51:11 CEST 2010)
- cfg/chg timezone.dat: Linux-ia added.
- man/chg compatibility.1: screen added.
- man/chg EDRC.1: screen added.
- man/chg edrcintro.1: description of screen.
- man/new screen.1
- cmd/fix logcheckd: avoid df "No such file or directory" error.
- cmd/new screen: screen manager with VT100/ANSI terminal emulation.
- cmd/chg shell: use /bin/bash as interactive shell whenever it is available on the system.
- cmd/fix contrib/scriptdocbook: handle symlinks within menu structure correctly.
- cmd/cor www/report/cgi/customers: html tag alignment.
- cmd/cor www/report/cgi/reports: html tag alignment.

1.5.39

Tue Sep 21 21:49:46 CEST 2010 release

- cfg/chg edrcrevision.cfg: new release 1.5.39 (Wed Sep 8 19:52:01 CEST 2010)
- cfg/new ssh-keyadd.cfg: config file for ssh-keyadd.
- cfg/new ssh-keyadd.pub: global key file for ssh-keyadd.
- man/chg edrcintro.1: short description of ssh-keygen.
- man/chg EDRC.1: ssh-keyadd added.
- man/chg compatibility.1: ssh-keyadd and sqlite added.
- man/chg apply2file.1: description of -s.
- cmd/new HP-11ia/gethostbyname: compiled for HP-11ia

- cmd/chg Linux/gzip: new version 1.4.
- cmd/chg www/report/cgi/logo.gallery: generate correct table html syntax.
- cmd/chg www/report/cgi/logo.gallery: add copyright and trademark hints.
- cmd/chg www/report/cgi/about: generate correct html syntax.
- cmd/chg www/report/cgi/customers: generate correct list html syntax.
- cmd/chg www/report/cgi/users.add: generate correct span html syntax.
- cmd/chg www/report/cgi/reports: generate correct list html syntax.
- cmd/chg www/report/cgi/reports: resolve en: text of ..du_index file located in report directories and add it as description to the report list.
- cmd/chg www/report/cgi/reports: list only report directories that have at least the permissions 005.
- cmd/chg www/report/cgi/statistics: count only report directories that have at least the permissions 005.
- cmd/chg hwinventory: avoid command hangs, when evaluating the system serial number from the EEPROM using sneep internally on Solaris.
- cmd/chg hwinventory: trim white-spaces out of csv output, remove trailing white-spaces from record output.
- cmd/cor crfile: units in usage.
- cmd/new ssh-keyadd: add SSH public keys to a users authorized_keys file(s) and modify the SSH daemon configuration file to setup the needed ssh trusts to connect.
- opt/new apply2file: -s to save a file prior of applying the data stream.

1.5.38

Wed Sep 8 10:57:33 CEST 2010 release

- cfg/chg edrcrevision.cfg: new release 1.5.38 (Tue Aug 31 21:46:05 CEST 2010)
- cfg/chg lib/usage.list: add osid.probe.
- man/new unczp.1
- man/chg EDRC.1: add unczp.1, unrpm.1.
- man/chg edrcintro.1: short description of unczp.
- man/chg unczg.1: add unczp and unrpm to SEE ALSO section.
- man/chg untgz.1: add unczp and unrpm to SEE ALSO section.
- man/new unrpm.1
- cmd/chg HP-11/cpio-2.10: adjust library binding in binary from static to dynamic.
- cmd/chg contrib/scriptdocbook: table in title page to 100% of page width.
- cmd/chg contrib/scriptdocbook: use apprevision to resolve WA2L/edrc version.
- cmd/chg contrib/scriptdocbook: unset environment variables, that influence the creation of the scriptdocbook archive file.
- cmd/chg contrib/scriptpack: unset environment variables, that influence the creation of the scriptdocbook archive file.
- cmd/chg lscomp: unset environment variables, that influence the listing of the compressed archive files.
- cmd/chg llcomp: unset environment variables, that influence the listing of the compressed archive files.
- cmd/chg catcomp: unset environment variables, that influence the display of the compressed archive files.
- cmd/new apprevision: return version of WA2L/edrc, the output is identical to the sat -V respectively edrc -V call, but faster.
- cmd/chg www/report/cgi/about: use apprevision to resolve WA2L/edrc version.
- cmd/chg www/report/cgi/links: allow '---' to add a separator between references.
- cmd/chg hwinventory: use apprevision to resolve WA2L/edrc version.
- cmd/fix histlist: correct begin timestamp output (???-??-??) when history file does not exist.
- cmd/fix histlist: eliminate empty lines.
- cmd/fix sysdiff: no empty file name output.
- cmd/new unczp: extract files of a zipped cpio file.
- cmd/new unrpm: extract files of a rpm file.
- cmd/chg patchinstall: umask setting for HP-* osid's to ensure correct directory permissions.
- cmd/chg sysconfig: umask setting for HP-* osid's to ensure correct directory permissions.

1.5.37

Tue Aug 31 13:57:59 CEST 2010 release

- cfg/chg edrcrevision.cfg: new release 1.5.37 (Sun Aug 15 13:45:29 CEST 2010)
- cfg/new osid.dat.WA2L: new osid Solaris-x86.
- cfg/fix os_wrapper/pl.cfg: make it sh compliant.
- cfg/chg osid.cfg: setting PROBE_BINARY to set the use of the osid.probe command.
- man/chg osid.3: description of the -n and -s options.
- man/chg compatibility.1: Solaris-x86 added.
- man/new man/Solaris-x86: man pages.
- man/chg tthttpd.3: remove manpage that explains -now option.
- man/chg edrcrevision.1: description of osid.probe.
- man/chg osid.cfg.4: description of PROBE_BINARY.
- man/chg stat.3: description of atimel, ctimel, mtimel and -f - option.
- cmd/chg tthttpd report: minor improvements, version 1.0.01.
- cmd/new many: compiled Solaris-x86 commands.
- cmd/chg: osid: probes if the OSID is correct to execute binaries. This is done via lib/OSID/osid.probe.
- cmd/new: lib/<OSID>/osid.probe: probe if it is possible to start a binary related to the chosen osid.
- cmd/opt tthttpd: remove -now option again
- cmd/fix contrib/newscripttree: _title is no longer empty.
- cmd/chg edrcinit: support of chkconfig when calling 'edrcinit rcinstall' on Linux.
- cmd/chg stat: can now also print atime, mtime and ctime in local time representation, not only as timer since the epoch. The all field also includes the local time representation fields.
- cmd/chg stat: can now read a list of files provided thru stdin.
- cmd/chg histlist: significant performance increase (real 1m47.090s -> real 0m2.521s). The jumping point is no longer needed.
- cmd/fix hwinventory: avoid error outputs, check for sneep on Solaris, if serial number is 0, return empty serial number.
- opt/new osid: -p and -s to print the definitions.

1.5.36

Fri Aug 13 13:46:32 CEST 2010 release

- cfg/chg edrcrevision.cfg: new release 1.5.36 (Tue Aug 10 23:05:00 CEST 2010)
- cfg/new osid.dat.WA2L: new osid Linux-ia.
- cfg/chg kshrc: display .WA2L files in the color of config files.
- man/chg tthttpd.3: only Linux shows the -now option in the man page.
- man/chg compatibility.1: Linux-ia added.
- cmd/chg tthttpd report: major improvements, version 1.0.00.
- cmd/new many: compiled Linux-ia commands.

1.5.35

Mon Aug 9 21:08:35 CEST 2010 release

- cfg/chg edrcrevision.cfg: new release 1.5.35 (Mon Jul 19 23:13:01 CEST 2010)
- man/chg contrib.edrc.1m: description of contrib.newscripttree.
- man/chg tthttpd.3: copy to man/Solaris, man/Linux.
- cmd/fix contrib/scriptdocbook: mail subject, mailing of the created file.
- cmd/chg contrib/scriptdocbook: user dialog.
- cmd/fix contrib/scriptpack: mail subject, mailing of the created file.
- cmd/chg contrib/scriptdocbook: user dialog.
- cmd/chg edrc: cleaner output of edrcperm output.
- cmd/new contrib/newscripttree: create a new script tree based on a template.
- cmd/chg syscp, sysvi, sysdiff: can now handle symlinks, directories and files.
- cmd/chg tthttpd report: improvements, version 0.0.02.
- cmd/chg bin/<OSID>/cfg2html: preparation to dynamically create a temporary systeminfo file containing the output of the hwinventory command.

1.5.34

Mon Jul 5 20:33:57 CEST 2010 release

- cfg/chg edrcrevision.cfg: new release 1.5.34 (Wed May 5 14:52:06 CEST 2010)

- cfg/new timezone.dat: map file for timezone setting on Linux.
- man/new banner.3
- man/chg pstree.1: -p option description.
- man/chg contrib.edrc.1m: enhance description of contrib.scriptpack.1m.
- man/chg contrib.edrc.1m: enhance description of contrib.scriptdocbook.1m.
- man/chg timezone.3: add -v and timezone.dat description.
- man/chg tthtpd.3: move to man/all.
- man/chg tthtpd.3: fix: nosymlinkcheck/symlinkcheck configfile option to nosymlink/symlink.
- man/chg tthtpd.3: description of the -now (nowworldreadable) feature.
- man/chg fssum.1: SYNOPSIS.
- cmd/fix lots: setting of the access time for files.
- cmd/fix lots: output of 'Configfile:' when \$LOTS_CONFIGFILE environment variable is set.
- cmd/chg contrib/sessions: forced kill of edrc sessions and cleanup of remaining session sub-processes when cleaning up inactive sessions.
- cmd/chg contrib/scriptdocbook: allow ~user in FILEPATH of scriptdocbook.bib.
- cmd/chg contrib/scriptdocbook: includes a (printable) 'Table Of Contents' page.
- cmd/chg contrib/scriptdocbook: formatting of 'HEADER', 'BIBLIOGRAPHY' and 'TABLE OF CONTENTS' pages adjusted.
- cmd/chg Linux/cfg2html: version 1.74.
- cmd/chg HP-11*/cfg2html: version 4.65.
- cmd/chg sysvi,sysdiff,syscp,svi: ensure that only the basic (without acl) permissions are compared.
- cmd/chg sysconfig: ensure that only the basic (without acl) permissions are compared.
- cmd/chg contrib/scriptpack: allow to choose between saving or mailing the generated script tree package.
- cmd/chg contrib/scriptdocbook: allow to choose between saving or mailing the generated script tree package.
- cmd/chg tsiz: set maximal columns for vi on SunOS (Solaris) versions prior to Solaris 10.
- cmd/new tzdump: dump contents of a zoneinfo file.
- cmd/chg timezone: has a map file (timezone.dat) to correct TZ on Linux if needed.
- cmd/chg fssum: no longer use cmviewcl to resolve packages.
- cmd/opt tthtpd: -now to disable the checking if the served file is world-readable.
- cmd/cor shell: message, when OS-ID is unknown points to the correct file, now.
- cmd/chg contrib/pwsafe: when displaying passwords using the s) or h) options, print the output directly to /dev/tty to ensure not logging the output. Be aware, that the pwsafe.nolog is still needed to ensure, that e) is not logged.
- cmd/fix fssum: argument parsing, now -t [-v] is working.
- cmd/chg fssum: if FREE + USED > KBYTES, the KBYTES output is FREE + USED. This corrects the behaviour as seen on Solaris, where KBYTES is reported as 0, when the file system is on ZFS.
- cmd/chg fssum: also report EXCLUDE lines when running in verbose (-v) mode.
- cmd/cor fssum: usage message output.
- opt/new pstree: -p to print a process-id list of the process tree only.

1.5.33

Thu Mar 25 22:52:08 CET 2010 release

- cfg/chg edrcrevision.cfg: new release 1.5.33 (Wed Jan 27 22:53:10 CET 2010)
- man/fix lots.cfg.4: SYNOPSIS.
- man/chg contrib.edrc.1m: contrib.scriptdocbook description.
- man/cor contrib.edrc.1m: grammar in contrib.scriptpack(1m) short description.
- man/new Linux/dmidecode.3: for dmidecode version 2.9.
- man/chg edrcintro.1: description of dmidecode.
- man/chg edrcintro.1: description of scriptrevision.
- man/chg compatibility.1: dmidecode added.
- man/chg compatibility.1: scriptrevision added.
- man/chg EDRC.1: dmidecode added.
- man/chg EDRC.1: scriptrevision added.

- man/new os_wrapper.1
- man/chg ksh_wrapper: SYNOPSIS precised.
- man/chg perl_wrapper: SYNOPSIS precised.
- cmd/chg contrib/scriptdocbook: a BIBLIOGRAPHY section can be added to the ScriptDocBook when a scriptdocbook.bib file is created in the related \$EDRC_ENTRY_DIR directory.
- cmd/chg contrib/scriptpack: only ask for removal of pwsafe.dat if it exists in the related recovery script tree.
- cmd/fix contrib/scriptpack: ensure correct output when copying script files.
- cmd/chg HP-11/cpio: new version 2.10 .
- cmd/chg HP-11i/cpio: new version 2.10 .
- cmd/fix scriptdocbook: bug that wrote to /devnull instead of /dev/null.
- cmd/fix is_up: correct intern handling of return code of ping which caused that is_up never checked the ssh port when ping is not allowed thru firewalls.
- cmd/new HP-11ia/portscan: compiled.
- cmd/fix: lots: internal fix in get_diskusagestats(). This bug was not visible to the user.
- cmd/chg lots: use scriptrevision command internally.
- cmd/new Linux/dmidecode: DMI table decoder.
- cmd/chg .os_wrapper: allows configuration for each wrapped command.
- cmd/fix .os_wrapper: argument passing to wrapped commands allows strings containing white spaces.
- cmd/fix .perl_wrapper: argument passing to wrapped perl scripts allows strings containing white spaces.
- cmd/chg Linux/collectd: version 4.9.1.
- cmd/new scriptrevision: return revision of a (script) file having the [##] revision notation as resolved also by the revision command.
- cmd/chg server_environment: cache meta data format changed, the md5sum command is no longer required.
- cmd/chg hostlist: cache meta data format changed, the md5sum command is no longer required.
- cmd/chg du_report: exclude /zones /proc /tmp file systems depending on the OSID.
- cmd/chg sw_report: exclude /zones /proc /tmp file systems depending on the OSID.
- cmd/new banner: to print login banner.
- cmd/new hwinventory: to print the minimal set of needed asset management information.

1.5.32

Fri Jan 27 04:40:06 CEST 2010 release

- cfg/chg edrcrevision.cfg: new release 1.5.32 (Thu Jan 21 21:28:24 CET 2010)
- cfg/chg kshrc: new alias histlist to print a list of history files including the timerange.
- man/cor lots.1m: SYNOPSIS, OPTIONS, typing errors.
- man/cor directories.3: formatting.
- man/chg compatibility.1: mediawiki and CMS:Mediawiki compatible to Solaris and HP-11ia.
- man/chg compatibility.1: fcreate.
- man/chg lots.1m: description of all job properties printed when using -a print_job.
- man/chg EDRC.1: add histlist (3).
- man/chg EDRC.1: add fcreate (3).
- man/chg compatibility.1: add histlist (3).
- man/chg edrcintro.1: add histlist (3).
- man/chg edrcintro.1: add fcreate (3).
- man/chg lots.1m: BUGS added.
- cmd/chg CMS:Mediawiki: compiled for Solaris and HP-11ia.
- cmd/fix directories: eliminate empty line output.
- cmd/fix sysconfig: avoid 'sed: -e expression #1, char 29: Invalid range end' error while writing settings.
- cmd/chg edrc: write logheader to SHELL logfiles.
- cmd/chg lots: print total source size when invoking -a list_jobs.
- cmd/chg lots: print PURGETIMEDAT when invoking -a list_jobs.
- cmd/chg lots: when issuing -a print_logtail the screen is fully filled with the logfile.
- cmd/chg lots: LOCK_TIMEOUT default is now 22 hours.

- cmd/chg lots: print 'collect disk usage statistics' when collecting it to avoid the impression that the command hangs.
- cmd/chg lots: perform disk usage collection at maximum once per session, not once per action.
- cmd/chg lots: all GByte outputs have 5 digits after the comma.
- cmd/chg shell: shell history file name when invoking shell outside edrc, save shell history in SHELL log-file when invoking from within edrc.
- cmd/new histlist: print a list of history files.
- cmd/chg usage: avoid repeating outputs of identical usages when in the definition file tabs where used.
- cmd/new fcreate: create a file if it does not already exist.

1.5.31

Sun Jan 17 18:47:41 CET 2010 release

- cfg/chg edrcrevision.cfg: new release 1.5.31 (Fri Aug 14 15:23:25 CEST 2009)
- cfg/chg pack/edrc/shar.header: Copyright 2003-2010
- cfg/chg bin/index.html.template: Copyright 2003-2010
- cfg/chg contrib/edrc/license: Copyright 2003-2010
- cfg/chg contrib/edrc/scriptdocbook: Copyright 2003-2010
- cfg/chg contrib/edrc/scriptpack: Copyright 2003-2010
- cfg/chg logcheckd.cfg: using the options REPORT_MAIL_CC and REPORT_MAIL_BCC the reports can also be mailed to carbon copy and blind carbon copy recipients.
- man/new consolidate.1
- man/new stat.1
- man/new CMS::MediaWiki.3
- man/chg compatibility.1: CMS::MediaWiki.
- man/chg perl_modules.3: CMS::MediaWiki.
- man/chg edrcintro.1: SEE ALSO section updated with missing Perl modules.
- man/chg EDRC.1: add mediawiki.3.
- man/chg edrcintro: short introduction to mediawiki command.
- man/chg vsdfml.3: description of MEDIAWIKI format option.
- man/chg contrib.edrc.1m: description of pwsafe.
- man/chg contrib.edrc.1m: description of checklist.
- man/new lots.1m
- man/new schedule.dat.4
- man/chg EDRC.1: lots, lots.cfg, datalist.dat, schedule.dat, volume.dat.
- man/chg edrcintro.1: lots description, SEE ALSO.
- man/new volume.dat.4
- man/new datalist.dat.4
- man/new lots.cfg.4
- man/chg logcheckd.cfg.4: description of REPORT_MAIL_CC and REPORT_MAIL_BCC.
- man/chg logcheckd.1m: description of REPORT_MAIL_CC and REPORT_MAIL_BCC.
- man/new mediawiki.3
- man/chg stat.3: description of -a all option.
- man/new pwcrypt.1
- man/new revision.1
- man/chg name.1: formatting, SEE ALSO.
- man/new symlink.1
- man/new directories.3
- man/chg sparse.3: SEE ALSO.
- man/cor edrcintro.1: description example of stat.
- man/chg busy.1: description of \$BUSY_TURNING_INTERVAL.
- cmd/chg contrib/scriptdocbook: start command in index.html.
- cmd/chg contrib/scriptdocbook: print filename at end of zipping it.
- cmd/chg HP-11ia/cpio: version 2.10.
- cmd/fix contrib/scriptdocbook: unset suffix error when 'set_dir' is denied.

- cmd/new CMS::MediaWiki: Perl extension for creating, reading and updating MediaWiki pages.
- cmd/new mediawiki: get/put page from/to MediaWiki.
- cmd/fix logrotate: fix "logrotate[35]: approot: not found" error.
- cmd/chg vsdfml: new MEDIAWIKI format output.
- cmd/fix vsdfml: escape backslashes in input to ensure proper backslash output.
- cmd/fix contrib/doc: leading blanks of output examples (O: txt) are no longer removed.
- cmd/new contrib/pwsafe: interactive password safe with the possibility to encrypt the password data file.
- cmd/chg contrib/calc: the command is denied from startup if shell is listed in DENY_LIST, functionality contrib.calc.shell does not exist any more.
- cmd/fix edrc: avoid "Terminated ..." error.
- cmd/fix edrc: avoid "find : cannot find current directory" error.
- cmd/chg lsmv: first column is dynamic, now.
- cmd/chg lscp: first column is dynamic, now.
- cmd/chg contrib/doc: redirect potential man error messages to /dev/null.
- cmd/fix contrib/doc: escape backslash in input to ensure the backslash in the output.
- cmd/chg contrib/doc: provide the .VB / .VE makros.
- cmd/chg contrib/doc: <pre>, </pre> markup supported, now.
- cmd/new contrib/checklist: print a checklist that can be used to track disaster recovery progress based on the recovery script tree.
- cmd/new contrib/scriptpack: pack the script tree to a package.
- cmd/new expand file list with overlying directories.
- cmd/new HP-11ia/info:
- cmd/chg pack: include overlying directories also into patch.
- cmd/chg Linux/gzip: version 1.3.12 -> 1.3.14.
- cmd/chg edrc: copyright 2010
- cmd/chg llcomp: print zip compression comment, too.
- cmd/fix contrib/doc: avoid "bad string" error.
- cmd/fix filesize: avoid -b usage error.
- cmd/fix bin/*/cfg2html: ensure, that the commands in ./plugins are found by cfg2html.
- cmd/chg HP-11*/cfg2html: version 4.53.
- cmd/chg bin/<OSID>/gzip: is now a symbolic link to the command with the name gzip-<VERSION>.
- cmd/chg bin/<OSID>/cpio: is now a symbolic link to the command with the name cpio-<VERSION>.
- cmd/chg logcheckd: reports can now be sent to CC and BCC recipients, too.
- cmd/chg csv2worksheet: use the new POI Java library poi-3.6-20091214.jar.
- cmd/chg stat: new -a all stat field to print all stat information in one query as a csv output.
- cmd/chg busy: using \$BUSY_TURNING_INTERVAL the speed of the rotating slash can be set, now.
- opt/new filedist: -t hostlist.
- opt/new stat: -s all.

1.5.30

Thu Aug 13 14:28:05 CEST 2009 release

- cfg/chg edrcrevision.cfg: new release 1.5.30 (Mon Aug 10 21:28:29 CEST 2009)
- cfg/chg bin/usage.list: add lspm.
- man/chg mail_file.1: change cole to carbon.
- man/new File::Tail.3: Perl extension for reading from continuously updated files.
- cmd/chg contrib/scriptdocbook: query ScriptDocBook suffix.
- cmd/chg fssum: the system in the fssum.cfg file can be a regular expression, too.
- cmd/chg mail_file: change cole to carbon.
- cmd/chg streamcat: reduce CPU consumption (this is only an intermediate solution).
- cmd/new lib/perl/pm: new module File::Tail.

1.5.29

Thu Aug 6 13:36:53 CEST 2009 release

- cfg/chg edrcrevision.cfg: new release 1.5.29 (Sat Jul 18 16:08:53 CEST 2009)
- cfg/chg edrcman.cfg: accept also white space separated MAN_PATH setting. This enables to use wild-cards.

- cfg/chg kshrc: ensure that the manvi alias starts always the real command in a ksh or clone.
- man/new MediaWiki::API.3
- man/chg EDRC.1: add sortc (3).
- man/chg EDRC.1: add lspm (1).
- man/chg edrcintro.1: short description for sortc.
- man/chg edrcintro.1: short description for lspm.
- man/chg compatibility: add sortc.
- man/chg fssum.cfg.4: ensure that the complete file format string is printed on Solaris, too.
- man/chg fssum.cfg.4: description behaviour when specifying "h:localhost:".
- man/chg logcheckd.cfg.4: ensure that the complete file format string is printed on Solaris, too.
- man/new lspm.1: list installed Perl modules.
- man/chg perl_modules.3: add reference to lspm.
- cmd/new lib/perl/pm: new module Unicode:String.
- cmd/new lib/perl/pm: new module MediaWiki:API and required dependencies.
- cmd/chg pack: more verbosity on package creation to give the user the visibility that the package creation is progressing.
- cmd/chg rcmd: do not set the LC_ALL environment variable internally. This influenced certain commands started with rcmd.
- cmd/chg edrcman: also compute white space separated MAN_PATH in edrcman.cfg.
- cmd/chg cltrash logtail passwdcombine edrc cronhandler edrcinit job logcheckd passwdsyncd patchinstall checkopt collectd fmatch hostlist ini.bash listtemp pkg_hostname pscount resolve_targetlist role_option server_environment thttpd scriptextract bwcreate cmmon cmswitch consolidate du_report edrcenv filedist filelink fssum ipsort locations lscp lsmv makeuser name pack passwdsort pstree rcmd revision sw_report sysconfig usage user_info whoisin ypxfr_all: do not set the LC_ALL environment variable internally to avoid unwanted side effects.
- cmd/new sortc: sort date in the "C" locale.
- cmd/chg DocBrowser: displays a loading image while loading the main browser window.
- cmd/chg contrib/scriptdocbook: displays a loading image while loading the main browser window.
- cmd/new streamcat: continuous output of a stream received via stdin to stdout.
- cmd/chg edrc: avoid command hanging as observed on on certain legacy Linux systems.
- cmd/chg fssum: when localhost as system is specified in the fssum.cfg file it will be replaced with the hostname in the report.
- cmd/fix fssum: report sum calculation, when issuing fssum without options, does not cause a value overflow any more.
- cmd/new lspm: list installed Perl modules.

1.5.28

Tue Jul 14 15:01:59 CEST 2009 release

- cfg/chg edrcrevision.cfg: new release 1.5.28 (Fri Jul 10 11:16:54 CEST 2009)
- cfg/chg kshrc: load working variables at the very last stage to ensure that the important parts of the kshrc file are processed independent from disturbing variable content.
- man/chg sav.1: description of handling of files located in special operating system directories.
- cmd/chg sav: automatically save files residing in additional directories then /etc/rc.config.d in a \$TODAY subdir.
- cmd/fix edrc: error message when invoking the 'log' edrc command.
- cmd/fix edrc: indefinite loop when distributing to a single system.

1.5.27

Fri Jul 10 10:44:55 CEST 2009 release

- cfg/chg edrcrevision.cfg: new release 1.5.27 (Tue Jun 9 12:40:41 CEST 2009)
- cfg/chg logcheckd/WA2L.css: printing definitions.
- cfg/chg kshrc: start of editors (vi, vim, view) does no longer influence the \$COLUMNS, \$LINES environment variables in the shell.
- cfg/chg shell.cfg: EDRC_SW_BASEDIR replaced with EDRC_SW_PATH.
- cfg/chg shell.cfg: SHELL_BANNER to be displayed when shell is called outside of edrc.

- man/chg csv2worksheet.3: description of -s option, EXAMPLES text formatting changed.
- man/chg edrcintro.1: short description of consolidate.
- man/chg EDRC.1: consolidate.
- man/chg compatibility.1: consolidate.
- man/chg logcheckd.style.4: description of additional CSS classes.
- man/chg logcheckd.1m: description of <number>.excluded files.
- cmd/chg csv2worksheet: possibility to explicitly load data as text using the -c cols option.
- cmd/new consolidate: to consolidate structured unix file data.
- cmd/fix logcheckd/interface/CAUnicenter: remove trailing pipe character from log entry.
- cmd/fix logcheckd: preserve quotes when relaying log entries to the interfaces.
- cmd/chg logcheckd: additional CSS classes introduced to control the layout more fine-grained.
- cmd/chg logcheckd: no longer represent EXCLUDE hits as <CR> in collect directory.
- cmd/fix edrc: bug on parallel distributions when having a DIST_TYPE=parallel:xy where xy is less than the total number of distribution targets.
- cmd/fix edrc: messed up logfile on parallel distribution.
- cmd/chg tsize: new option 'vi' to influence max. columns mainly on HP-UX when initializing terminals prior to vi, vim, view start.
- cmd/chg shell: connection speed enhanced, ~/.eshell/cache no longer used.
- cmd/chg log: now allowed to write to named pipes, too.
- cmd/chg logview: avoid vim warning 'output is not a tty'.

1.5.26

Fri Jun 12 09:54:10 CEST 2009 release

- cfg/chg edrcrevision.cfg: new release 1.5.26 (Tue Jun 9 12:40:41 CEST 2009)
- cfg/chg logcheckd/WA2L.css: div.timing -> span.timing, div.separator -> span.separator.
- cfg/chg logcheckd/WA2L.css: rows in Overview table are highlighted on mouse hover.
- cfg/chg kshrc: on HP-* set terminal width to a maximum of 200 characters when starting vi, vim, view to avoid "Terminal too wide" error.
- man/chg mail_file.cfg.4: description of MAIL_HUB and MAIL_HUB_USER.
- man/chg mail_file.1: description of mail hub functionality.
- man/chg lsof.1: for version 4.82.
- man/chg lsof: version 4.82 for Linux, HP-11i, HP-11, Solaris.
- man/new top.1: for Solaris.
- man/chg edrcintro.1: top.
- man/chg EDRC.1: top.
- man/chg compatibility.1: top.
- cmd/chg logcheckd: logfile content HTML in LogCheck report to support one line copy-paste from report to mail or text editor without having breaks after the timestamp separator.
- cmd/chg logcheckd: title on all fields.
- cmd/chg mail_file: mail via hub.
- cmd/new top: for Solaris.
- cmd/chg edrc: on HP-* set terminal width to a maximum of 200 characters when starting vi, vim, view to avoid "Terminal too wide" error.

1.5.25

Tue Jun 9 10:15:45 CEST 2009 release

- cfg/chg edrcrevision.cfg: new release 1.5.25 (Fri Jun 5 21:06:15 CEST 2009)
- cfg/chg patchinstall.cfg: new settings BACKUP_PATCHED_FILES_GENERATIONS, BACKUP_CORPSES_GENERATIONS to define the number of backup generations kept while purging old backup copies.
- cfg/chg edrc.cfg: new setting BACKUP_GENERATIONS to specify the number of kept script backups when using the 'distribute' command.
- man/chg patchinstall.1m: description of the purging steps, change of the example output.
- man/chg patchinstall.cfg.4: description of BACKUP_PATCHED_FILES_GENERATIONS and BACKUP_CORPSES_GENERATIONS options.

- man/chg edrc.cfg.4: description of BACKUP_GENERATION option.
- man/chg lsof: version 4.81 for HP-11 and HP-11i.
- cmd/fix passwdsyncd: error prone resolving of remote home.
- cmd/fix shell: egrep error message.
- cmd/new cfg2html: version 4.41 for HP-11, HP-11ia.
- cmd/new msmtmp: an SMTP client.
- cmd/chg patchinstall: can now purge old backups of patched files and corpses.
- cmd/chg edrcinit: review.
- cmd/chg scriptextract: can now purge old backups of distributed scripts.
- cmd/fix pack: timestamp is always in GMT.
- cmd/chg lsof: version 4.81 for HP-11 and HP-11i.

1.5.24

Fri Jun 5 11:06:37 CEST 2009 release

- cfg/chg edrcrevision.cfg: new release 1.5.24 (Tue Jun 2 18:54:49 CEST 2009)
- cfg/chg logcheckd.cfg: ALERT_MAIL_TO and ALERT_MAIL_SECTION to handle system personnel information.
- man/chg logcheckd.cfg.4: description of settings ALERT_MAIL_TO and ALERT_MAIL_SECTION.
- cmd/fix shell: avoid ~user/.eshell/cache cannot create error.
- cmd/chg logcheckd: can now send an alert mail on analysis suspension, resumption and on non-interactive report creation to inform system management personnel about the filesystem shortage.
- cmd/fix sparse: syntax error.
- cmd/fix contrib/clonemenu: does not report a clone target menu as not empty if only files exist in the .sav directory.

1.5.23

Mon May 16 18:56:29 CEST 2011 release

- cfg/chg edrcrevision.cfg: new release 1.5.23 (Fri May 29 19:48:36 CEST 2009)
- cfg/chg WA2L.css: new tags to allow current log count marking.
- man/chg logcheckd.1m: add pattern file row numbers to example 1), explain the criteria to avoid the filesystem fill up.
- man/chg logcheckd.1m: description of -a defined and -a monitored options.
- man/chg edrcintro.1: description of edrc/.ssh directory in section FILES.
- man/chg logcheckd.style.4: new tags to allow current log count marking.
- cmd/chg logcheckd: when verifying a pattern file using the -a verify option, the row number of the patching line in the patternfile is printed left to the matched log file entry.
- cmd/chg logcheckd: current counts that are bigger and equal to zero can be marked, now.
- cmd/chg install: set ownership of edrc/.ssh based on input.
- cmd/chg: scriptdocbook: HTML code enhanced.
- cmd/cor: filesize: unit shortcuts in usage message output.
- cmd/cor: freespace: unit shortcuts in usage message output.
- cmd/new: logcheckd/interface/CAUnicenter: interface for CAUnicenter Log agent.
- opt/new logcheckd: -a defined / -a monitored to list the defined / currently monitored logfiles.
- dir/new edrc/.ssh: *empty* directory to ensure ssh execution in some circumstances (do *not* save ssh files into this directory).

1.5.22

Mon May 16 18:56:29 CEST 2011 release

- cfg/chg edrcrevision.cfg: new release 1.5.22 (Wed May 20 09:10:38 CEST 2009)
- cfg/chg logcheckd.cfg: INTERFACES, INTERFACECONFIGDIR to configure the external interfaces.
- man/cor contrib.1m: example 2 code.
- man/chg contrib.edrc.1m: description of contrib.scriptdocbook(1m).
- man/chg logcheckd.cfg.4: description of INTERFACES, INTERFACECONFIGDIR settings.
- man/chg logcheckd.1m: description of interfaces and iconfig directories.
- man/chg EDRC.1: add edrcinit.1m, edrcinit.cfg.4.
- man/chg edrcintro.1: add edrcinit.1m.

- cmd/chg httpd: internal function renaming to enhance compatibility.
- cmd/chg hostlist: output formatting of hostlists when using the -p option.
- cmd/chg contrib/doc: troff formatting of doc tags O: and F:.
- cmd/chg contrib/scriptdocbook: active trunks are represented, now.
- cmd/chg contrib/scriptdocbook: new section "ICON INDEX" in main page.
- cmd/chg contrib/scriptdocbook: man page contrib.edrc.1m also added to ScriptDocBook.
- cmd/chg logcheckd: duration output in non-engineering format.
- cmd/chg logcheckd: external interface support.
- cmd/fix watchdog: print list on Solaris did not return a list, even when watchdogs were running.
- cmd/fix watchdog: -L did not succeed on Solaris.
- cmd/fix watchdog: formatting of output table when issuing the -l option.
- cmd/chg pslist: avoid egrep errors (as "egrep: \$ anchor not at end of pattern.") on wrong patterns.
- cmd/chg pslist: avoid "zonename: not found" error on Solaris.
- cmd/fix mail_file: avoid "could not open /dev/kbd" and related errors as seen on Solaris.
- cmd/fix mail_file: option parsing which caused usage message on certain subject texts.
- cmd/chg shell: has a simple cache of remote WA2L/edrc installation homes.
- cmd/new edrcinit: handle WA2L/edrc services.
- cmd/chg untgz uncgz lscomp llcomp catcomp whatis apropos yesterday tomorrow today remote_shell
remote_copy removetemp maketemp listtemp ini.sh ini.ksh ini.csh ini.bash freespace filesize
edrcroot aproot: react on EDRC_DEBUG_<COMMAND> on all hardlinked variants of the
command.
- opt/chg logcheckd: -a state to -a status.

1.5.21

Tue May 19 19:45:11 CEST 2009 release

- cfg/chg edrcrevision.cfg: new release 1.5.21 (Fri May 8 19:17:41 CEST 2009)
- cfg/fix kshrc: correct output of a, b, c, d shell commands.
- cfg/chg logcheckd.cfg: new setting ANALYSIS_SUSPENSION.
- cfg/chg logcheckd.cfg: new setting MIN_FREESPACE.
- man/chg edrc.1m: description of the behaviour of direct trunks.
- man/chg contrib.edrc.1m: add contrib.scriptdocbook.
- man/chg logcheckd.cfg.4: CHECK_INTERVAL description.
- man/chg edrcman.1: description of -w option, SEE ALSO, FILES.
- man/chg shell.1: options.
- man/chg logcheckd.pattern.4: description that identical section names can appear multiple times in a pattern file.
- man/chg logcheckd.1m: description of analysis suspension.
- man/chg regexintro.4: example for the usage of "*".
- man/new man2html.3
- man/chg vsdfml.3: explain format option.
- cmd/chg contrib/scripttree: compress titles as done in edrc.
- cmd/chg contrib/doc: internal improvement to be able to use the command in an other contributed command.
- cmd/chg edrc: if on direct trunks a list of targets is given, probe the whole list and establish the trunk to the first target that is up.
- cmd/fix edrc: report if a trunk specification is bugous. This has been done in previous versions, but the exit code was overwritten by a later update.
- cmd/new contrib/scriptdocbook: create a DocBrowser book for a recovery script tree.
- cmd/chg DocBrowser: allow to resize the menu panel.
- cmd/fix logcheckd: usage display when -a verify patternfile LEVEL is used.
- cmd/fix logcheckd: setting of CHECK_INTERVAL default.
- cmd/fix logcheckd: locking error (Solaris problem only).
- cmd/fix is_writeable: when probing file access, remove tailing /-es of file/dir specified to be more os compatible.

- cmd/fix sav: "timezone: command not found" error.
- cmd/chg edrcman: has now a config file where extensions to the MANPATH can be specified.
- cmd/chg contrib/logs: extra line feed before --- line to avoid messy line breaks on logfiles not having a line feed as the last character.
- cmd/chg contrib/logs: additional selection "(t)his" to redisplay the currently selected logfile.
- cmd/chg cronhandler: internal improvement to enhance compatibility when handling the lock file.
- cmd/chg watchdog: internal improvement to enhance compatibility when handling the lock file.
- cmd/chg passwdsyncd: internal improvement to enhance compatibility when handling the lock file.
- cmd/chg passwdsyncd_apply: internal improvement to enhance compatibility when handling the lock file.
- cmd/chg logcheckd: internal improvement to enhance compatibility when handling the lock file.
- cmd/chg logcheckd: avoid file system fill ups caused by the daemon.
- cmd/fix job: release number.
- cmd/chg shell: possibility to connect to remote hosts via edrc mechanism and start the shell on the remote system.
- cmd/chg shell: separate shell history per tty session.
- cmd/chg pscount: more tolerant CSV input processing.
- cmd/new man2html: convert troff to HTML.
- opt/new logcheckd: -a state , to check if a daemon is running.
- opt/chg hostlist: -p, to print the configures host groups.
- opt/new vsdfml: format, to format files into man-troff.

1.5.20

Fri May 8 00:35:15 CEST 2009 release

- cfg/chg edrcrevision.cfg: new release 1.5.20 (Thu May 7 23:15:17 CEST 2009)
- man/chg shlib.3: FILES section.
- man/chg perl_wrapper.3: SEE ALSO.
- cmd/fix edrc: error while distributing in parallel mode.
- cmd/chg edrc: menu title output compressed.
- cmd/chg pscount: sort the output of the uncounted process list.
- cmd/fix hostlist: do not hang when cache files are empty.
- cmd/chg lib/perl/pm: compiled all Perl modules for i586-linux-thread-multi.
- cmd/chg shlib: standard library path for Solaris and Linux.
- cmd/chg .os_wrapper: shared library environment variable exporting.
- cmd/chg .perl_wrapper: library environment variable exporting.
- cmd/fix fssum: EXCLUDE handling.

1.5.19

Mon May 4 17:54:49 CEST 2009 release

- cfg/chg edrcrevision.cfg: new release 1.5.19 (Thu Apr 30 15:57:28 CEST 2009)
- man/cor edrcsetup.1m: ssh-keygen command.
- man/new fssum.cfg.4
- man/new shlib.3
- man/new psjoin.3
- cmd/new psjoin: concatenate PostScript files.
- cmd/chg nano: default tabstop is 4 now.
- cmd/chg rnano: default tabstop is 4 now.
- cmd/fix edrc: remote home resolution while executing the "distribute" command.
- cmd/chg shlib: set an os standard path for Linux, too.

1.5.18

Thu Apr 30 10:12:48 CEST 2009 release

- cfg/chg edrcrevision.cfg: new release 1.5.18 (Fri Dec 12 20:09:59 MET 2008)
- cfg/chg timezone.cfg: comments in file changed.
- cfg/chg shell.cfg: use is_existing to resolve the software location.
- cfg/chg kshrc: print of \$MANPATH now based on edrcman -w output.
- cfg/chg thttpd.cfg: renamed to thttpd.doc.cfg.

- cfg/new thttpd.vsdms.cfg: httpd configuration for the vsdms (under development).
- cfg/new thttpd.base.cfg: httpd configuration for the base httpd configuration (under development).
- cfg/new termcap: terminal capability definition for commands relying on termcap instead of terminfo.
- cfg/chg *.cfg: VAR='homedir'/dir to VAR='homedir/dir' to profit from the default when the user ACME does not exist on a system. This enhances bootstrap start after installation.
- cfg/chg excrc: remove ignorecase option.
- man/new compatibility.1: command compatibility overview.
- man/chg shell.1: description of termsize, vi, view and vim.
- man/chg sqlite.1: hint how to read the HTML documentation.
- man/cor EDRC.1: section of sysconfig.cfg.
- man/chg EDRC.1: reference to the *.zip archive in edrc/doc containing all documentation files.
- man/chg edrcintro.1: section of sysconfig.cfg.
- man/chg edrcintro.1: examples for select_columns, print_list, print_index.
- man/chg edrcintro.3: add perlenv short description.
- man/new print_list.3
- man/new print_header.3
- man/new print_index.3
- man/new timezone.cfg.3
- man/new timezone.cfg.4
- man/new whereami.1
- man/new logview.1
- man/new logtail.1
- man/new nologin.1
- man/new xbfd.1m
- man/new collectd.3
- man/new collectd.conf.4
- man/new collectd-*.4
- man/new types.db.4
- man/new tty_columns.3
- man/new select_columns.3
- man/new tty_variable.3
- man/new input_targets.3
- man/chg input: input_targets added to SEE ALSO section.
- man/new pl.1
- man/chg edrcsetup.1m: reference to patchinstall.1m.
- man/chg edrcsetup.1m: section REQUIREMENTS, additional references in section SEE ALSO, additional information to the ~edrc/bin/sys configuration.
- man/chg pack.1m: reference to edrcsetup.1m.
- man/cor pack.1m: formatting in SEE ALSO section.
- man/chg patchinstall.1m: reference to edrcsetup.1m.
- man/chg edrcrevision.1: action/object to object/action.
- man/chg edrcrevision.1: separate releases using subsections.
- man/new termcap.4
- man/chg manpages.4: additional escape sequences, simplification, new section title for used troff commands.
- man/cor sqlite.1: setting of quotations.
- man/new pmdesc.1
- man/new CGI.3
- man/new CGI::Auth.3
- man/new CGI::Cookie.3
- man/new DBD::DBM.3
- man/new DBD::SQLite.3
- man/new DBI.3

- man/new HTML::Parser.3
- man/new MIME::Lite.3
- man/new perl_modules.3: lists all provided perl module man pages.
- man/new perl_wrapper.1
- man/new ksh_wrapper.1
- man/new html2mht.3
- man/new perlenv.3
- man/fix logrotate.cfg.4: description of LOGBASE default.
- man/fix makeuser.cfg.4: description of LOG default.
- man/new is_osid.3
- man/cor select_columns.3: example 2.
- man/cor sysconfig.1: example 3 output.
- man/chg vsdfml: can receive text thru a pipe via stdin when using the pseudo file name -.
- man/chg fit2width.3: optional width option.
- man/chg regexintro.4: remove description of sub-expressions.
- man/new hostaliases.3
- man/chg checkopt.3: example 1 code.
- man/chg filedist.1: hostaliases(3) to SEE ALSO section.
- man/chg rcmd.1: hostaliases(3) to SEE ALSO section.
- man/chg log: add edrcintro(1) to SEE ALSO section.
- man/new fssum.1.
- man/chg compatibility: bundled perl modules are listed, too.
- cmd/fix sw_report: argument parsing of -h option.
- doc/new edrc_manpages-<VERSION>.zip: a zip file containing all documentation files is added to the edrc/doc directory and referenced by the EDRC.1 man page and the EDRC.html title page.
- cmd/chg tsize: performance increase.
- cmd/chg cmon: allow execution HP-1* -> HP-.*.
- cmd/chg cmswitch: allow execution HP-1* -> HP-.*.
- cmd/new Solaris/zdiff: new.
- cmd/new Solaris/zgrep: new.
- cmd/new Solaris/zless: new.
- cmd/new Solaris/zmore: new.
- cmd/chg edrcenv: more precise EDRC_DEBUG_* environment variable selection.
- cmd/chg cmon: improve compatibility, avoid "command not found" error on systems, where MC/ServiceGuard is not installed.
- cmd/new select_columns: filter to select named columns from stdin and print it to stdout.
- cmd/chg approot: avoid "permission denied" error when current working directory has specific permission settings especially on Solaris.
- cmd/chg thttpd: usage message extended.
- opt/chg thttpd: status to query the status of the webserver started with thttpd start.
- cmd/fix pscount: check if maximal process counts are numbers.
- cmd/chg apropos: fit output to terminal width.
- cmd/chg whatis: fit output to terminal width.
- cmd/new Solaris/sysinfo: compiled for Solaris.
- cmd/chg timezone: avoid error output on system wide timezone resolution on Solaris.
- cmd/chg timezone: enhance time zone resolution on Linux.
- cmd/chg cfg2html: version 1.6.4 for Solaris.
- cmd/chg cfg2html: version 4.23 for HP-11i and HP-11ia.
- cmd/chg cfg2html: version 1.58-2009/02/18 for Linux.
- cmd/chg csv2worksheet: use the new POI Java library poi-3.2-FINAL-20081019.jar.
- cmd/new is_existing: resolve if a file/dir/link exists without hanging if the resource (e.g. NFS) is not available.
- cmd/new Solaris/gunzip: as symlink to gzip.

- cmd/chg shell: do not set the USAGE_PATH environment variable.
- cmd/chg usage: include the directories edrc/lib/kshrc, edrc/lib/perl, edrc/lib/daemon to the usage output.
- cmd/new collectd: daemon to collect system statistics.
- cmd/new portscan: scan ports of a target system and return the ports that answer.
- cmd/chg is_up: when ping does not succeed to test if the remote host is up also try to connect using alternate network ports.
- cmd/chg shell: do not use the \$HOME environment variable to resolve the user's home directory.
- cmd/chg edrc: break multi line menu entries.
- cmd/chg tty_variable: performance increase by avoiding a tempfile.
- cmd/chg edrc: a forced line break can be added to a menu entry by entering an ";".
- cmd/chg shell: set the \$USER environment variable via the id command.
- cmd/chg Linux/lsof: new version 4.81.
- cmd/chg bin/*/lsof: use more compatible method to resolve newest installed binary version.
- cmd/chg bin/*/mc: use more compatible method to resolve newest installed binary version.
- cmd/chg bin/*/cfg2html: use more compatible method to resolve newest installed binary version.
- cmd/chg bin/*/nano: use more compatible method to resolve newest installed binary version.
- cmd/chg bin/*/bzip2: use more compatible method to resolve newest installed binary version.
- cmd/chg lib/*/expect: use more compatible method to resolve newest installed binary version.
- cmd/chg passwdsyncd_apply: ensure the entry of the command name and the correct session (=pid) into the log file passwdsyncd.log.
- cmd/chg ini.*: set \$HOME explicitly.
- cmd/chg usage: set \$HOME explicitly.
- cmd/new pl: ploticus.
- cmd/chg: thttpd can now distinguish between different web applications.
- cmd/chg bin/*/lsof: react on EDRC_DEBUG_OS_WRAPPER, due to the fact that this script is "the longer arm" of the .os_wrapper command.
- cmd/chg bin/*/mc: react on EDRC_DEBUG_OS_WRAPPER, due to the fact that this script is "the longer arm" of the .os_wrapper command.
- cmd/chg bin/*/cfg2html: react on EDRC_DEBUG_OS_WRAPPER, due to the fact that this script is "the longer arm" of the .os_wrapper command.
- cmd/chg bin/*/nano: react on EDRC_DEBUG_OS_WRAPPER, due to the fact that this script is "the longer arm" of the .os_wrapper command.
- cmd/chg bin/*/bzip2: react on EDRC_DEBUG_OS_WRAPPER, due to the fact that this script is "the longer arm" of the .os_wrapper command.
- cmd/chg lib/*/expect: react on EDRC_DEBUG_OS_WRAPPER, due to the fact that this script is "the longer arm" of the .os_wrapper command.
- cmd/chg bin/Linux/truss: react on EDRC_DEBUG_OS_WRAPPER, due to the fact that this script is "the longer arm" of the .os_wrapper command.
- cmd/chg edrc: ensure terminal initialization, if the configured terminal does not exist on the system.
- cmd/chg woist: ensure execution, even when csh is not available on the system.
- cmd/chg repeat: ensure execution, even when csh is not installed on the system.
- cmd/chg Linux/splitvt: start splitvt-<Version> and set the TERMCAP variable on systems that do not have /etc/termcap installed.
- cmd/chg edrc: ensure remote \$HOME resolution, even when csh or ksh is not installed on the remote system.
- cmd/chg edrc: enhanced localhost resolution when distributing scripts and establishing trunks.
- cmd/chg passwdsyncd: ensure remote \$HOME resolution, even when csh or ksh is not installed on the remote system.
- cmd/chg cronhandler: ensure execution, even when csh is not installed on the system.
- cmd/chg Linux/sqlite: version 3.6.13.
- cmd/new pmdesc: print all installed perl modules.
- cmd/chg .perl_wrapper: structure of bundled perl modules.
- cmd/fix .perl_wrapper: module (@INC) initialization.

- cmd/chg .perl_wrapper: set the LD_LIBRARY_PATH and SHLIB_PATH to the osid related libs directory as done in the os_wrapper.
- cmd/chg .os_wrapper: check if wrapped program file exists and return an appropriate error message otherwise.
- cmd/chg .ksh_wrapper: ensure that .os_wrapper cannot be called directly.
- cmd/chg .ksh_wrapper: check if wrapped program file exists and return an appropriate error message otherwise.
- cmd/chg .os_wrapper: ensure that .os_wrapper cannot be called directly.
- cmd/chg .java_wrapper: enhanced error message if wrapped program file does not exist.
- cmd/chg .java_wrapper: ensure that .java_wrapper cannot be called directly.
- cmd/chg .daemon_wrapper: check if wrapped program file exists and return an appropriate error message otherwise.
- cmd/chg .daemon_wrapper: ensure that .daemon_wrapper cannot be called directly.
- cmd/fix du_report: ensure that du_report appears in ERROR messages.
- cmd/new perlenv: to print the enhanced perl environment variables.
- cmd/new html2mht: convert HTML file to single web archive file (MHT).
- cmd/cor thttpd: Usage message.
- cmd/fix pscount: message output contains correct scriptname.
- cmd/chg sw_report: allow external setting of PRINT_FIT2WIDTH. Default is 'False'.
- cmd/chg fssum: command redesign for enhanced compatibility, speed and program structure.
- cmd/new hostaliases: resolve aliases for a host.
- cmd/chg msg: avoid awk error when usage is not correct.
- cmd/fix crfile: error of unary test operator on line 222.
- cmd/new sparse: filter to identify sparse files.
- cmd/new contrib/license: print WA2L/edrc license terms.
- cmd/chg vsdfml: can receive text thru a pipe via stdin when using the pseudo file name -.
- cmd/fix vsdfml: correct error message output.
- cmd/chg print_header: set timezone.
- cmd/chg cmmon: set timezone.
- cmd/chg mkuser: set timezone.
- cmd/chg pscount: set timezone.
- cmd/chg sav: set timezone.
- cmd/chg fit2width: the width option is optional now.
- cmd/chg sw_report: use xbfd internally to resolve the filesystems.
- cmd/chg apply2file apply2sw_inventory asup bwcreate crfile dbrep du_report duvi edrcpack esat filedist filelink fssum locations logrotate mail_file makeuser omniutil osup pack psup sat sav sw_report swvi symlink sys sysconfig user_info vadsf whereami woist xlog ypxfr_all fields2swvi filesize fmatch freespace hostlist is_config_byhand is_osid listtemp maketemp mkuser passwdsyncd_apply pscount pslist remote_copy remote_shell removetemp role_option server_environment timezone cltrash logcut passwdcombine rsat svi syscp sysdiff sysvi trash untrash cronhandler joblog jobwatch logcheckd passwdsyncd patchinstall watchdog: more strict option parsing.
- cmd/chg filedist: enhanced localhost resolution.
- cmd/chg rcmd: enhanced localhost resolution.
- cmd/chg rcmd: print "...(localhost)..." message when executing command on localhost.
- cmd/new WA2L::Util: perl module.
- cmd/chg log: avoid 'permission denied' error.
- cmd/fix xlog: error message output.
- cmd/fix mail_file: error message output.
- cmd/chg contrib/clonemenu: clone hint in menu title splited to two lines.
- cmd/chg bwcreate catcomp checkopt cltrash cmmon cmswitch collectd cronhandler du_report edrc edrcenv filedist filelink fmatch fssum hostlist ini.bash ini.csh ini.ksh ini.sh ipsort job joblog jobwatch listtemp llcomp locations logtail logview lscomp lscp lsmv maketemp makeuser name omniutil pack passwdcombine passwdsort passwdsyncd passwdsyncd_apply patchinstall

pkg_hostname pscount pstree rcmd removetemp resolve_targetlist revision role_option
 server_environment sw_report sysconfig thttpd trash uncgz utgz untrash usage user_info
 whoisin ypxfr_all: unset GZIP environment variable to ensure correct gzip functionality, set
 LC_ALL=C to ensure consistent sorting.

- cmd/fix sysconfig: date format of comment in sysconfig settings file.
- cmd/fix pack: only return a package if the generation was completely successful.
- cmd/new shlib: print shared library path variables.
- cmd/fix fmatch: "cannot shift" error on Solaris.

1.5.17

Fri Dec 12 14:00:11 MET 2008 release

- cfg/chg edrcrevision.cfg: new release 1.5.17 (Thu Dec 11 20:22:26 MET 2008)
- cfg/chg kshrc: new alias termize to set the COLUMNS and LINES environment variables.
- cfg/chg kshrc: set COLUMNS and LINES variables prior to the call of vi, vim and view.
- man/chg edrcintro.1: short description of tsize.
- cmd/fix pscount: if min/max is not a number, handle it as it is not defined.
- cmd/fix pscount: avoid awk error output while escaping the characters while producing the output in
 pscount -p.
- cmd/chg edrc: set COLUMNS and LINES prior to start the viewer and editor.
- cmd/new tsize: print terminal size to be used to initialize the COLUMNS and LINES environment variables.
- cmd/chg checkopt: used option resolving changed to enhance compatibility.

1.5.16

Tue Dec 9 17:48:18 MET 2008 release

- cfg/chg edrcrevision.cfg: new release 1.5.16 (Thu Nov 27 00:01:44 MET 2008 release)
- cfg/chg kshrc: check if less is installed on the system, else use more.
- cfg/chg kshrc: set username in prompt based on id.
- man/chg EDRC.1: add readline.3.
- man/chg edrcintro.1: readline short description.
- man/chg contrib.edrc.1m: short description for contrib/edrc/sane.
- man/chg logcheckd.1m: moved pattern files from edrc/lib/logcheckd/pattern/ to edrc/var/logcheckd/pattern/.
- man/chg logcheckd.pattern.4: moved pattern files from edrc/lib/logcheckd/pattern/ to
 edrc/var/logcheckd/pattern/.
- man/chg logcheckd.cfg.4: moved pattern files from edrc/lib/logcheckd/pattern/ to edrc/var/logcheckd/pattern/.
- opt/new pscount: -p to print a process list of a system.
- cmd/new readline: read long input lines from stdin.
- cmd/chg input: support long line input on Solaris, too.
- cmd/chg many: internal improvement in querying osid.
- cmd/chg edrc: prompted trunks can now be canceled.
- cmd/chg edrc: when a file is edited or viewed this is reflected in the window title now, too.
- cmd/chg contrib/edrc/sane: stty sane as contributed command.
- cmd/chg pscount: print a summary line at the end of the process table showing the totals of the rows MIN,
 MAX, CURRENT and STATE.
- cmd/chg pslist: command performance tuning.
- cmd/chg pslist: more strict option parsing.
- cmd/chg pslist: no longer print a line feed, when no process was selected.
- cmd/chg title: performance enhanced.
- cmd/chg logcheckd: moved pattern files from lib/logcheckd to var/logcheckd
- cmd/chg sysconfig: ensure proper message output.
- cmd/chg passwdsyncd: ensure proper message output.
- cmd/chg scriptextract: ensure proper output on systems having bugous tr installed.
- cmd/chg patchinstall: change umask for Solaris.

1.5.15

Sun Nov 23 12:52:24 MET 2008 release

- cfg/chg edrcrevision.cfg: new release 1.5.15 (Sat Nov 22 18:32:42 MET 2008)
- man/chg edrcintro.1: description of pscount.
- man/chg edrcintro.1: man section of pslist.
- cmd/chg pslist: moved from bin to lib.
- cmd/new pscount: command to count system processes and evaluate if the situation correlates to a defined number of required processes.
- cmd/chg contrib/edrc/clonemenu: compatibility improvement to be able to run on Solaris, too.
- cmd/chg contrib/edrc/clonemenu: messages adjusted.

1.5.14

Fri Nov 21 12:56:24 MET 2008 release

- cfg/chg edrcrevision.cfg: new release 1.5.14 (Tue Nov 18 22:25:46 MET 2008)
- cfg/chg kshrc: .. alias removed.
- cfg/chg kshrc: usage strings adjusted.
- man/chg shell.1: review.
- cmd/fix maketemp: use correct POSIX compatibility setting for HP-*.
- cmd/chg maketemp: print activity "Unknown" for temporary directories where not all information could be determined to judge tempdir activity.
- cmd/chg maketemp: compatibility improvement.
- cmd/fix print_list: avoid awk error "escaped \. treated as plain .".
- cmd/chg random: new debug method.
- cmd/chg trash,untrash,cltrash: new debug method.
- cmd/chg tolower: compatibility improvement.
- cmd/chg toupper: compatibility improvement.
- cmd/chg log: compatibility improvement.
- cmd/chg msg: compatibility improvement.
- cmd/chg passwdsyncd: compatibility improvement.
- cmd/chg passwdsyncd_apply: compatibility improvement.
- cmd/chg sysvi,sysdiff,syscp,svi: compatibility improvement.
- cmd/chg logcheckd: compatibility improvement.
- cmd/chg edrc: log edrc version index on startup and program quit.
- cmd/chg lib/<OSID>/many: error output to stderr.
- cmd/chg bin/<OSID>/many: error output to stderr.
- cmd/chg pkg_hostname: further tuning.

1.5.13

Fri Nov 14 01:48:59 MET 2008 release

- cfg/chg edrcrevision.cfg: new release 1.5.13 (Mon Sep 22 13:51:46 CEST 2008)
- cfg/new timezone.cfg: configuration file for timezone.
- cfg/chg kshrc: TZ is set from timezone.cfg
- cfg/chg kshrc: more and less use tabstops of 4 to be consistent with the common vi/vim settings in WA2L/edrc and use a more alias on systems where the tabstop cannot be set in more.
- cfg/chg rcmd.cfg: new SUMMARY setting to print a summary of the remote command invocations.
- cfg/new perl_wrapper.cfg: to configure .perl_wrapper.
- cfg/new ksh_wrapper.cfg: to configure .ksh_wrapper.
- dir/new var/sw: to store the packed software to or store WA2L/edrc patches if no other location is specified in the enterprise.
- man/cor tolower.3: formatting.
- man/cor toupper.3: formatting.
- man/cor fmatch.3: formatting.
- man/chg sysconfig.1: step 8) of system configuration.
- man/cor sysconfig.1: examples output and description.
- man/chg edrcintro.1: tomorrow, yesterday, is_weekend description.

- man/chg edrcintro.1: today description.
- man/chg syscp: names in examples aligned to other manpages.
- man/chg days: YYYY-MM-DD format.
- man/cor sysinfo: examples.
- man/new yesterday.3
- man/new tomorrow.3
- man/new today.3
- man/new untgz.1
- man/new timer.1
- man/new fit2width.3
- man/new pstree.3
- man/new indent.3
- man/new ident.3
- man/chg edrcintro: indent/ident descriptions.
- man/new group.3
- man/new is_weekend.3
- man/new sysvi.1
- man/new svi.1
- man/chg edrcintro: checkopt description.
- man/chg edrcintro: lib/perl/pm description.
- man/chg edrcintro: user description.
- man/chg checkopt.3
- man/new uncgz.3
- man/new user.3
- man/new sys.1
- man/chg edrcsetup.1m: reference to sys (1), use of edrc/bin/sys to start the WA2L/edrc maintenance menu.
- man/chg log: \$TZ environment variable.
- man/chg days: \$TZ environment variable.
- man/new pslst.1
- man/chg approot.3: SEE ALSO section.
- man/chg edrcroot.3: SEE ALSO section.
- man/chg rcmd.cfg.4: description of SUMMARY setting.
- man/new is_up.3
- man/chg EDRC.1: include hint about starting the thttpd to view documentation from remote.
- man/chg edrc.1m: add description to new trunk type prompt:nolocal for defining trunks with no Localhost selection.
- man/chg edrc.1m: add description to new edrc command tz to set the time zone within edrc.
- man/chg edrc.1m: description of the new \$EDRC_DEBUG environment variable.
- man/chg edrc.cfg.4: add tz to DENY_LIST description.
- man/new sqlite.1
- man/chg crfile.1: -a option (=accelerated file creation for root) removed.
- man/new shell.1
- man/chg listtemp.1: description of the PROCESS column output.
- man/chg server_environment.3: description of the -R option including an additional usage example.
- doc/new sqlite-3.6.3.html
- cmd/chg days: now accepts dates in the format YYYY-MM-DD, too.
- cmd/new today: return date of today.
- cmd/new yesterday: returns date of yesterday.
- cmd/new tomorrow: returns date of tomorrow.
- cmd/new is_weekend: returns True on weekend days (Saturday and Sunday), else False.
- cmd/chg cfg2html: version 1.63 for Solaris
- cmd/chg sat: more strict option parsing, ego message is no longer printed when -V or -s is used.

- cmd/new DocBrowser: display the documentation in WA2L/DocBrowser, too.
- cmd/fix fit2width: avoid error on systems where awk has restriction on number of fields.
- cmd/chg edrc: .sav directories are no longer distributed when invoking the distribute command in edrc.
- cmd/chg edrc: the dialog of the trunk command in edrc accepts now also the '.' to specify the current directory in addition to the '' input.
- cmd/chg edrc: the terminal window title is set to <user>@<hostname> when started. When trunks are established, the title will also represent the user and host where currently connected to.
- cmd/chg edrc: the timezone is set from the timezone.cfg file.
- cmd/chg edrc: print a INFO message when a newer edrc [index] is installed on the system.
- cmd/fix edrc: do not dive into submenu when trunk prompt on a prompted trunk is interrupted pressing Ctrl+C.
- cmd/chg edrc: new trunk type prompt:nolocal to provide a trunk target list excluding the Local: entry.
- cmd/chg edrc: TRUNK TARGETS numbering changed to provide an identical numbering for trunk types prompt and prompt:nolocal.
- cmd/chg edrc: avoid "No Type" error on terminal initialization.
- cmd/chg edrc: new command tz to set the timezone within edrc.
- man/chg edrc.1m: description of new trunk type direct:nolocal.
- cmd/fix contrib/scriptstats: correct output on missing diff dist file.
- cmd/new indent: identical to the already existing ident command, that is depreciated now. ident will continue to exist due to compatibility reasons.
- cmd/chg makeuser: use indent internally instead of ident.
- cmd/chg omniutil: use indent internally instead of ident.
- cmd/cor print_list: usage text spelling.
- cmd/chg print_list: if the \$PRINT_FIT2WIDTH is set to False the output is not limited to the terminal width.
- cmd/chg input: less aggressive tty restore on abort.
- cmd/new group: print the group name for a given group-id.
- cmd/new checkopt: check options.
- cmd/chg usage: internal improvements.
- cmd/chg name: use less on Linux.
- cmd/chg revision: use less on Linux, three digits for revision number.
- cmd/new title: set the terminal title.
- cmd/chg shell: /usr/ucb is included in the \$PATH now, too.
- cmd/chg shell: the terminal window title is set to <user>@<hostname> when started.
- cmd/chg server_environment: now caches the resolved information.
- opt/new server_environment: -R to print the whole record as variables.
- cmd/chg server_environment: performance improvement.
- cmd/new sqlite: sqlite version 3.6.3 .
- cmd/chg .perl_wrapper: now supports the use of additional Perl modules installed in edrc/lib/perl/pm .
- cmd/chg .perl_wrapper: can be configured in perl_wrapper.cfg, now.
- cmd/new uncgz: unpack gzipped cpio file(s).
- cmd/new user: return user name for a given uid.
- cmd/new sys: edrc short start to load the edrc.sys.cfg configuration that is provided for WA2L/edrc maintenance.
- cmd/new timezone: returns the timezone.
- cmd/chg many: set timezone (TZ) environment variable.
- cmd/chg mc: restore terminal window title after exit.
- cmd/chg mcview: restore terminal window title after exit.
- cmd/chg mcedit: restore terminal window title after exit.
- cmd/new wget: for Solaris.
- cmd/chg swvi: output speed up when resolving the primary group of the RUN_USER.
- cmd/chg du_report: exclude index files in parallel WA2L/edrc installations.
- cmd/chg du_report: use standard header.

- cmd/chg du_report: exit code=2 when a non-root user calls it.
- cmd/new pslist: list and select processes in a cross operating system compatible format.
- cmd/chg rcmd: if configured in the rcmd.cfg file a summary of succeeded/failed remote command invocations is printed.
- cmd/chg filedist: if configured in the filedist.cfg a summary of succeeded/failed file distributions is printed.
- cmd/chg uid: internal implementation changed to ensure a more consistent output.
- cmd/new tz: to set the \$TZ variable in the shell.
- cmd/new debug: to toggle the \$DEBUG variable in the shell.
- cmd/new edrcdebug: to toggle the \$EDRC_DEBUG variable in the shell.
- cmd/fix uniqpath: no error when -h is invoked.
- cmd/chg .java_wrapper: review, use uniqpath internally.
- cmd/chg .java_wrapper: internal improvement.
- cmd/chg .ksh_wrapper: internal improvement.
- cmd/chg .perl_wrapper: internal improvement.
- cmd/fix choice: do not exit, when no default value is specified and the input is empty.
- cmd/chg all: internal replace of \$DEBUG with \$EDRC_DEBUG and \$EDRC_DEBUG_<COMMAND-NAME> to separate command debugging completely from script debugging.
- cmd/chg shell: set \$EDRC_DEBUG to False on startup.
- cmd/chg shell: startup mode to ensure online patching.
- cmd/chg pkg_hostname: avoid error output when getcwd fails.
- cmd/new getmountpoint: compiled for Solaris.
- cmd/new getfilesystem: compiled for Solaris.
- cmd/fix crfile: now runs on Solaris also successful.
- cmd/chg crfile: -a option (=accelerated file creation for root) removed.
- cmd/chg edrcenv: displays defined EDRC_DEBUG_* variables, too.
- cmd/chg pkg_hostname: tuned.
- cmd/chg maketemp: new process resolution uses pslist, now. PPID and process resolution changed.
- cmd/chg maketemp: enhanced flagfile format.
- cmd/chg listtemp: displays information according to the new flagfile format. The status of temporary directories created with the old flagfile format are still displayed correctly.
- cmd/chg sysvi: export the editor settings also to vim.
- cmd/new print_header: print a standard report header.
- cmd/fix Solaris/lynx: prevent "cannot open terminal" error.
- cmd/new print_index: print a standard column index.
- cmd/chg sw_report: uses maketemp to handle tempfiles, now.
- cmd/chg sw_report: internal improvements.
- cmd/chg sw_report: exclude index files in parallel WA2L/edrc installations.
- cmd/chg scriptheadersync: uses maketemp to handle tempfiles, now.

1.5.12

Sun Sep 21 11:56:04 CEST 2008 release

- cfg/chg edrcrevision.cfg: new release 1.5.12 (Sat Sep 20 17:02:11 CEST 2008)
- cmd/chg makeuser: when querying uid, sort output list by UID field, when querying gid, sort output list by UID field.
- man/cor freespace: calculation example.
- man/chg filesize: calculation example.
- cmd/chg input: on Ctrl+C, input exits with exit code 2.
- man/chg input: Exit status 2.
- man/new fmatch.3
- man/fix edrcintro.1: replace \$DATA_FILE by \$FMATCH_DATA_FILE.
- man/chg regexintro.4: hint to avoid \{m,n\} construct for compatibility reasons.
- man/new tolower.3
- man/new toupper.3

- cmd/fix tolower: usage message.
- cmd/fix toupper: usage message.

1.5.11

Thu Sep 18 22:40:36 CEST 2008 release

- cfg/chg edrcrevision.cfg: new release 1.5.11 (Thu Sep 11 21:15:49 CEST 2008)
- cmd/fix edrc: on errors on scriptextract count errors as failure.
- cmd/chg scriptextract: exitcode > 0 on all errors.
- cmd/new freespace: print freespace of a directory on a filesystem.
- cmd/fix pack: computes relative directories specified in -d correctly, now.
- cmd/new filesize: print the size of a file.
- man/chg edrcintro.1: freespace and filesize description.
- man/chg sysconfig.1: EXAMPLES enhanced.
- man/chg sysconfig.1: description of the use of CONFIG_BYHAND setting.
- man/chg sysconfig.cfg.4: description of CONFIG_BYHAND setting.
- man/new freespace.3
- man/new filesize.3
- cmd/fix hostlist: cache computation on HPUX.
- cmd/chg sysconfig: avoid creation of .EDRC.config_byhand. and .EDRC.sysconfig. when the name file is empty.
- opt/new sysconfig.cfg: CONFIG_BYHAND setting to enable replacing (REPLACE) or merge (MERGE) of the applied config_byhand file entries. Default is REPLACE as the behaviour before the existence of the CONFIG_BYHAND option.

1.5.10

Sun Sep 7 14:03:11 CEST 2008 release

- cfg/chg edrcrevision.cfg: new release 1.5.10 (Mon Aug 18 12:14:23 CEST 2008)
- cmd/fix print_list: avoid syntax error on Solaris when calling "cat file | print_list = 2".
- cmd/chg patchinstall: ensure corpse remove counting on Solaris, too. "file does not exist" error suppressed when backing up files to be patched.
- cmd/chg sysconfig: change umask for Solaris operating systems to ensure proper target file permissions. The environment variable SYSCONFIG_ROOTDIR and SYSCONFIG_FORCE is also exported to the check script, now.
- cfg/chg kshrc: export EDITOR variable, to enable crontab editing.
- cmd/chg hostlist: now supports a resolution caching functionality to improve performance in complex hostlist.cfg definitions.
- cfg/chg hostlist.cfg: new settings CACHE and CACHE_DEPENDENCY to support the resolution cache.
- cmd/chg shar.setup shar.install/install: when installing the WA2L/edrc shell archive, free space in /tmp is checked now, too. The \$TMPDIR environment variable can be set to point to a directory having sufficient free space. The installation logfile in /tmp now has the process id of the installation in the name, too.
- cmd/fix shar.install/install: when only extracting the package, this is also possible now if the package name is not edrc. When installing on Solaris permissions were not set correctly when the umask of the calling shell was not set to 000, this workaround is now no longer needed.
- man/chg edrcsetup.1m: description of the \$TMPDIR variable and the checked space requirements in the temporary directory and the installation directory.
- cmd/fix crfile: tempfile cleanup.
- cmd/new uid: return the UID of a given user.
- cmd/new gid: return the GID of a given group.
- cmd/new gecost: return the gecost (=comment) field of the user account.
- cmd/fix edrc: ensure user name setting in script templates, _env and _trunk settings even when \$USER in the calling shell is not set.
- cmd/fix edrc: menu points were sometimes not displayed correctly on some Linux versions and on Solaris.
- cmd/chg edrc: list failed/aborted hosts at the end of distribute command completion.

- cmd/fix edrc: correct counting of success/fail/abort for distribution summary.
- cmd/chg vsdfml: no longer influence to the tty settings.
- cmd/chg input: no longer influence to the tty settings.
- man/new uid.3
- man/new gid.3
- man/new gecost.3
- cmd/chg makeuser: resolve information from various name services, list information from LDAP, too.
- man/chg makeuser.1: description of LDAP, NIS and FILES use as name service source.
- man/chg hostlist.3: add reference to edrc/var/samples/hostlist/ where configuration examples can be found.
- man/chg server_environment.3: add reference to edrc/var/samples/hostlist/ where configuration examples can be found.
- man/chg pack.1m: add example 0) where the most simplest usage of pack is shown.
- man/chg patchinstall.1m: new example to remove corpses without installing a new patch.
- man/chg sysconfig.1: more information in DESCRIPTION section.
- man/new ll.1
- man/new envpasswdstrip.1
- man/chg manpages.4: add COPYRIGHT section to manpage structure description.
- man/chg *.*: add COPYRIGHT section to all manpages of WA2L/edrc .

1.5.09

Sun Aug 17 15:34:51 CEST 2008 release

- cfg/chg edrcrevision.cfg: new release 1.5.09 (Thu Jul 24 18:25 CEST 2008 release)
- man/new mail_file.1
- man/new mail_file.cfg.4
- man/chg edrcintro.1: mail_file.cfg (4) added in SEE ALSO section.
- man/new makeuser.1
- cmd/chg makeuser: return exit code 2 when makeuser is not started with the correct user account
- man/new makeuser.cfg.4
- man/new userclass.index.4
- cmd/chg .perl_wrapper: add /opt/perl/bin to standard path search due to perl installations on HP-UX. use whereami instead of woist when perl was not found in standard path search.
- cmd/fix .perl_wrapper: ksh removed as execution shell when perl was not found in searched locations.
- man/new trash.cfg.1
- cmd/chg server_environment: internal improvement.
- cmd/fix shar.install/install: install log error messages when package could not be installed.
- man/cor filedist.1: orthography.
- man/new pkg_hostname.3
- cmd/fix omniutil: do not apply the template if the corresponding version directory does not exist in the template .tar.gz file.
- cmd/chg omniutil: use ident and do_exit() internally, exit codes aligned.
- cmd/chg input: ensure proper terminal behaviour when using the NO_ECHO option and the user presses Ctrl+C during input.
- man/new omniutil.1
- man/new omniutil.cfg.4
- man/new usage.1
- man/new maketemp.3
- cmd/new fmatch: return values selected for a certain key.
- cmd/fix remote_copy: failing (no connect) error when connection cache and NO_PROBE_INTERVAL indicated to do the connection probing.
- cmd/new ll: beside the ll alias in the shell, have the ll command also available as binary. This helps if rcmd is invoked on systems that do not know the ll command.
- man/new removetemp.3
- cmd/fix sysconfig/tools/HP-11/edit_netconf: tempdir cleanup.

- cmd/chg mc: remove locale files from package.
- cmd/chg nano: remove locale files from package.
- cmd/chg httpd: usage message and option parsing changed.
- cmd/chg edrcman: use uniqpath in \$PATH and \$MANPATH.
- dir/new var/samples/: configuration samples.
- man/new listtemp.3
- cmd/chg cfg2html: version 1.51 for Linux, version 3.66 for HP-.*.

1.5.08

Sun Jul 20 14:29:49 CEST 2008 release

- cfg/chg edrcrevision.cfg: new release 1.5.08 (Sat Jun 14 01:23:13 CEST 2008 release)
- cmd/chg hostlist: more efficient HOSTGRP resolution.
- cmd/chg server_environment: output order when calling server_environment -l.
- cmd/new shell: shell having a similar environment as the shell started thru the shell command within edrc.
- cmd/chg vsdfml: use xmore only when started within edrc, avoid terminal echo suppression when exiting vsdfml with Ctrl+C.
- man/new regexintro.4
- cmd/new uniqpath: removes duplicate entries from a colon separated string as known from the \$PATH, \$MANPATH, \$USAGE_PATH.
- cmd/chg untgz: code formatting.
- cmd/chg .os_wrapper .perl_wrapper .ksh_wrapper .daemon_wrapper sysconfig edrc watchdog rcmd filedist: remove duplicates in \$PATH setting using uniqpath.
- cfg/chg kshrc: use uniqpath in ap, cwdadd, addc wd.
- man/new uniqpath.3
- cmd/chg untgz: print usage message when no files are specified.
- cmd/new expect: programmed dialog with interactive programs.
- cmd/fix edrcman: Osid dependent \$MANPATH is now correctly resolved.
- cmd/chg nano: include ncurses libraries for Solaris.
- cmd/new connect: make socket connection using SOCKS4/5 and HTTP tunnel.
- man/chg logcheckd.1m: example added.
- man/chg logcheckd.pattern.4: example added.
- man/new libexpect.3
- cmd/chg lib/<OSID>/libs: move os dependent libraries to edrc/lib/<OSID>/libs to eliminate duplicates and to simplify upgrades.
- cmd/chg .os_wrapper: set LD_LIBRARY_PATH and SHLIB_PATH if the command is installed with WA2L/edrc and point to edrc/lib/<OSID>/libs.
- cmd/new bz* for Solaris
- man/new bz*.1 for Solaris
- cmd/chg lib/<OSID>/tcpdump: direct startup, because library settings could be moved to .os_wrapper.
- cmd/chg lib/<OSID>/rsync: direct startup, because library settings could be moved to .os_wrapper.
- cmd/chg lib/<OSID>/cfg2html: dynamic version resolution.
- cmd/chg lib/<OSID>/nano: no more use of tail -l.
- cmd/chg edrcman: the environment variable to be set to check other operating systems man pages is \$MAN_OSID and no longer \$OSID.
- man/chg edrcman.1: change \$OSID to \$MAN_OSID.
- cmd/fix logview, logtail: repeat selection output on wrong selections.
- cmd/fix crfile: error on free space resolution on systems having long special file path.
- cmd/new patchinstall: patch a WA2L/edrc installation.
- cfg/new patchinstall.cfg: configuration file for patchinstall.
- cmd/chg revision: filter selection to avoid syntax errors.
- cmd/chg name: filter selection to avoid syntax errors.
- cmd/new input_target: special purpose input to query lists of hosts.
- cmd/chg tty_variable: more strict variable resolution.
- cfg/chg kshrc: save \$TERM, tty erase.

- cmd/chg edrc: new edrc command 'top' to browse to the root menu.
- cmd/chg shar.install/install: save install logfile to edrc/var/log/install.log, too.
- man/chg edrcsetup.1m: description of edrc/var/log/install.log
- doc/chg edrc_manpages-<VERSION>.html/*.html: Package: WA2L/edrc <VERSION> is added to html page.
- cmd/chg logtail: first print the terminal size to screen.
- cmd/chg mkuser: speed up execution.
- cmd/chg logtail: resolution of tilde syntax (~user) in config file.
- man/new patchinstall.1m
- man/new patchinstall.cfg.3
- cmd/chg .os_wrapper: add Stdlib_path to LD_LIBRARY_PATH and SHLIB_PATH.
- cmd/chg ident: moved to lib/perl, use of .perl_wrapper for startup.
- cmd/chg lynx, lsof, du_report, crfile, filelink, revision, is_running, remote_copy, user_info, mc, script-stats, doc, logs, dirwatch: replace the usage of tail -<rows> with the more portable sed command.
- cmd/chg edrc: distinguish between the different tail -<rows> variants.
- cmd/chg pack: performance increase of pack -L by factor 14. This causes a performance increase by factor 5 of patchinstall.
- cmd/chg csv2worksheet: use the new POI Java library poi-3.1-FINAL-20080629.jar.
- cmd/chg catcomp: avoid error "/opt/edrc/bin/catcomp: -: does not exist".
- man/new logrotate.1
- cmd/chg logrotate: exit code on missing configfile changed from 1 to 3.
- cmd/fix vsdfml: printing of terminal control characters on HP-UX when using vsdfml from outside of edrc.
- man/new logrotate.cfg.4
- cmd/chg logrotate: now sets defaults when LOGBASE or DEFAULT_SAVES in config file are not set.
- cmd/chg logcut: use of library functions, -p output changed
- cmd/fix du_report: avoid error messages on missing index files when using the index file cache file.
- man/new logcut.cfg.4
- cmd/fix edrc: print correct path on established trunks.

1.5.07

Sat Jun 7 20:13:37 CEST 2008 release

- cfg/chg edrcrevision.cfg: new release 1.5.07 (Sun May 11 12:53:17 CEST 2008)
- cmd/fix name: fix error when using command in directories where a directory with the name *text* or *script* exists.
- cmd/fix revision: fix error when using command in directories where a directory with the name *text* or *script* exists.
- cmd/chg listtemp, maketemp, removetemp: convert relative pathnames given in -d option to absolute.
- cmd/chg logcheckd: hostname is added to logfile names, section markers added to HTML report output to allow report post processing.
- cmd/chg logcheckd: tooltips added to overview table and logfile section levels.
- man/chg vsdfml.3: magic key in example changed from /bin/ksh to /bin/sh.
- cmd/chg contrib/pstree: ensure that only process id numbers can be specified.
- cmd/chg edrc: trunk behaviour: session names are transferred to remote hosts, session names remain read only when source host session name was read only.
- cmd/chg edrc: it is now ensured that ad hoc session names are unique, too.
- cmd/chg edrc: when setting the session name with the -n option the @ID@ field provides the functionality to set the name of the session with an ID part that is either the process id of the started edrc session or, if a session with the same name already exists, a random value. This avoids session name clashes of session names set by hand in a started edrc session by the 'name' command and sessions started with the -n option.
- cmd/chg edrc: avoid the creation/renaming of menupoints and menus to command equivalents.
- cmd/chg sat: sat now starts edrc with -n SAT_@ID@ and no longer with -n SAT_\$\$ to support session name transfer thru trunks and to avoid session name clashes.

- man/chg edrc.1m: description of @ID@ field and behaviour of transferring session names to trunk targets.
- man/chg logcheckd.1m: description of report structure added.
- cmd/fix edrc: on unsuccessful trunk establishment due to 'host not up' no longer dive into the local sub-menu.
- man/chg sat.1 asup.1 psup.1 osup.1: description of <id> assignment adjusted to the new @ID@ feature for naming an edrc session.
- cmd/fix contrib/doc: suppress multiple empty lines in output when running on Solaris, too.
- cmd/chg edrc: correct initialization of vim on systems where vim is started thru the vi command.
- cmd/chg contrib/logs: correct initialization of vim on systems where vim is started thru the vi command.
- cmd/fix duvi: missing initialization of trap signals corrected.
- cmd/fix filedist: correct use of ASCII header option to allow proper cross operating system file distributions.
- cmd/fix shar.install/install: correct user creation on non-redhat Linux systems.
- cmd/chg shar.install/install: fail output if user/group creation generated an non-successful return value.
- cmd/chg osid: on duplicate osid.dat entries only the first matching entry is returned and not all entries.
- cmd/chg pack: -n option (=no timestamp update) replaced with -t (=timestamp update), no timestamp update is default, now.
- cmd/chg pack: more strict usage parsing.
- man/chg pack.1m: option -n replaced with -t, usage description more precise.
- cmd/new var/sysconfig/HP-11/edit_netconf: interactively edit /etc/rc.config.d/netconf formatted files on HP UNIX for usage in post_exec scripts in sysconfig.
- cmd/chg Linux/cfg2html: new version 1.45.
- cmd/chg HP-UX/lsof: new version 4.80.
- chg/src lsof: new version 4.80.
- cmd/chg HP-UX/nano: distribute libncurses.sl and libintl.sl also with WA2L/edrc
- cmd/chg mc: set TERM to 'xterm' if \$MCTERM is not defined.
- man/chg edrcintro.1: description of \$MCTERM added to the short description of mc.
- cmd/chg pack: application timestamp prefix can be specified separately from the APPLICATION_BASEDIR.
- cfg/chg pack.cfg: new option TIMESTAMP_PREFIX to separate the timestamp from the application prefix.
- cmd/chg pack: -l option also lists the timestamps for the different releases available.
- man/chg pack.1m: -l option description.
- man/chg pack.cfg.4: description of new option TIMESTAMP_PREFIX added.
- cmd/chg usage: -h message enhanced, internal improvements, USAGE_PATH environment variable recognized.
- cmd/chg makeuser: classes/.index file format with field COMPANY expanded, output format when entering '?' changed (now print_list is used internally).
- cmd/chg Linux/lsof: new version 4.80.
- cfg/new HP-11ia: directories prepared in edrc/bin, edrc/lib and edrc/man for Itanium version of HP-UX.
- cmd/chg homedir: answer speed increased by factor 200.
- cmd/chg woist: cleanup of internal function homedir().
- man/chg edrcman.1: sections ENVIRONMENT, EXIT STATUS and EXAMPLES added.
- cmd/chg maketemp: usage message enhanced with EXAMPLES.
- cmd/chg removetemp: usage message enhanced with EXAMPLES.
- cmd/chg listtemp: usage message enhanced with EXAMPLES.
- cmd/fix shar.install/install: package extract when package name does not start with 'edrc-'.
- cmd/new var/sysconfig/default/create_users: create users based on a passwd format input.
- cmd/fix sysconfig: \$EDRC_SCRIPTNAME is set correctly to the check script while executing it. Therefore if the msg command is used within the check script, the output is complete, now.
- man/chg csv2worksheet.3: reference of file edrc/var/csv2worksheet/io.xls in the FILES section.
- cmd/chg whereami: output of 'Customer:' added.
- cmd/chg edrc: when executing the 'distribute' command, specified hostgroups (@GRP) are resolved now, too.

- man/chg edrc.1m: description that @HOSTGRP can be entered in the target system specification during script distribution.
- cmd/chg contrib/calc: to exit the calculator the only command is 'exit', 'quit' is no longer accepted to be in line with the general edrc commands. Improved error handling, basic fraud handling.
- cmd/fix edrc: when running on Linux the viewing of logfiles could not properly handle compressed logfiles.
- cmd/fix contrib/logs: when running on Linux the viewing of logfiles could not properly handle compressed logfiles.
- man/fix logcheckd.1m: pattern file location corrected to lib/logcheckd/pattern.
- man/chg logcheckd.cfg: description of variables which are allowed to be used in the eval resolve_mode.
- cmd/chg is_osid: now the * (multiple characters) and ? (one single character) placeholders are supported.
- cmd/chg contrib/omnimon: support a more wide range of osids.
- cmd/chg contrib/drvstat: support a more wide range of osids.
- cmd/chg contrib/cmviewcl: support a more wide range of osids.
- cmd/chg cmswitch: support a more wide range of osids.
- cmd/chg cmmon: support a more wide range of osids.
- cmd/fix logcheckd: export \$TODAY variable to eval resolve_mode logfile specifications.
- cmd/chg print_list: now a left indent can be specified as an optional option. Therefore the construct 'cat file | print_list ":" | indent 2 | fit2width -m 'tty_columns'' can be replaced with 'cat file | print_list ":" 2', now.
- cmd/chg contrib/scriptstats: use the new indent of print_list.
- cmd/chg makeuser: use the new indent option of print_list.
- man/new sysconfig.tools.3
- man/chg sysconfig.1: reference to sysconfig.tools.3.
- cmd/new tolower: translate a given string to lowercase.
- cmd/new toupper: translate a given string to uppercase.
- cmd/new filegrep: grep for something in all underlying ASCII files, files in .sav directories and files saved with the sav command are excluded from the search.
- cmd/chg makeuser: output formatting.
- cmd/chg mkuser: transfer symbolic links to homedirectories, too.
- cmd/chg contrib/doc: permission change due to display problems on certain Linux operating systems.
- cmd/fix apply2sw_inventory: PATH setting corrected to avoid command hang on certain systems.
- cmd/chg logcheckd: more strict config file parsing.
- cmd/new HP-11ia: compiled commands for osid HP-11ia added: bunzip2, bzip2, bzcat, bzdiff, bzgrep, bzip2, cpio, gnutar, gunzip, gzip, lsof, lynx, mc, mcedit, mcview, nano, pwcrypt, rsync, splitvt, sysinfo, tcpdump, timer, truss, ttyplay, ttyrec, ttytime, tusc, unzip, wget, zcat, zdiff, zgrep.
- cmd/chg cltrash logtail logview rsat svi syscp sysdiff sysvi trash untrash: moved to edrc/lib/ksh, due to the fact that used statements are on Solaris only available in ksh.
- cmd/new untgz: unpack gzipped tar file(s).
- cmd/chg all: setting of \$PATH unified in all commands.
- chg/osid: can now distinguish between different machine types (hardware), too.
- man/new osid.cfg.4
- man/chg osid.dat: description of the new two osid.dat file formats.
- cmd/chg pack: add PACK_OSID_DAT_SFI and PACK_OSID_DAT_WA2L to sadm file.
- cmd/chg shar.install/install: consider osid.cfg and the two possible osid.dat formats.

1.5.06

Sun May 4 18:22:09 CEST 2008 release

- cfg/chg edrcrevision.cfg: new release 1.5.06 (Thu May 1 17:31:50 CEST 2008)
- man/new logcheckd.pattern.4
- cmd/fix logcheckd: no hyperlink for section [EXCLUDE] in report section 'Overview'.
- cmd/chg logcheckd: less aggressive report removal when using -a reset.
- opt/new logcheckd: -a verify, to verify a patternfile.
- man/chg logcheckd.1m: description of -a verify added.

- man/new logcheckd.style.4
- cmd/chg csv2worksheet: use the new POI Java library poi-3.0.2-FINAL-20080204.jar .

1.5.05

Fri Apr 25 21:56:58 CEST 2008 release

- cfg/chg edrcrevision.cfg: new release 1.5.05 (Wed Apr 16 13:25:00 CEST 2008)
- cmd/chg shar.install/install: change uid/gid of connection dir edrc/var/connection/<user>/*
- cmd/fix pack: "bad substitution error" fixed. This happened when running pack on Solaris
- cmd/new logcheckd: a daemon to check logfiles for patterns and to create a consolidated findings report.
- cfg/new logcheckd.cfg: config file for logcheckd.
- man/chg edrcintro.1: logcheckd.1m added, files section completed.
- cfg/chg WA2L/edrc: var/ezreport, lib/ezreport, var/sfi directories removed
- cfg/chg usage.list: usage strings of commands in lib/daemon added
- man/chg edrcsetup: change the command of security file generation to ensure more straight forward setup.
- man/new logcheckd.cfg.4

1.5.04

Wed Apr 9 17:12:38 METDST 2008 release

- cfg/chg edrcrevision.cfg: new release 1.5.04 (Sat Feb 2 15:41:50 CET 2008)
- man/chg edrcsetup.1m: add shar execution output example.
- cmd/chg shar.install/install: avoid creating the homedir and do not create the secure group in Linux when user creation is selected.
- man/chg edrc.1m: example for exceptional advanced trunk specification
- cmd/chg edrc: the TARGET_MENUPATH setting in trunk specifications can now hold target menus only consisting of the path as displayed on the edrc prompt (e.g. /Support/ApplicationSupport) without having to specify the menupoint (e.g. /sup:Support/asup:ApplicationSupport). This enables the user to change the target menupoints and the trunk is still working.
- cmd/fix edrc: on advanced trunk specifications (using TARGET_MENUPATH), the path displayed in the prompt can be misleading, this has been fixed. If you establish advanced trunks from version 1.5.04 to 1.5.03 or vice versa the trunk will work properly, but the prompt won't not be correct.
- cmd/chg edrc: to print spaces in a trunk comment output (TYPE=prompt), they have to be replaced by a % in the definition.
- cmd/fix print_list: it is now possible to start print_list from outside of edrc -> shell, too.
- man/new filedist.1
- man/new filedist.cfg.4
- man/new filedist.block.4
- man/new rcmd.1
- man/new rcmd.cfg.4
- cmd/chg cmmon: move cmmon from edrc/contrib/edrc to edrc/bin to have the command available in the shell, too. cmmon is still available as contributed command.
- cmd/chg cmswitch: move cmswitch from edrc/contrib/edrc to edrc/bin to have the command available in the shell, too. cmswitch is still available as contributed command.
- man/chg edrcintro.1: added cmmon and cmswitch.
- opt/new server_environment.1: new option -C to print the customer of the environment.
- cmd/fix makeuser: check input of GID, UID, USERCLASS to ensure correct inputs.
- opt/new input: MAXLEN=len, MINLEN=len to check the input length.
- man/chg input.3: description of MAXLEN and MINLEN added.
- cmd/new sysdiff: list if a file applied with sysconfig differs to the file in the sysconfig repository.
- man/new user_info.1
- man/new user_info.cfg.4
- man/chg sysconfig: examples added.
- cmd/chg sysconfig: set EDRC_SCRIPTNAME to 'pre_exec'/'post_exec' when calling the pre- / post-exec scripts. From now on when using the msg command within pre- and post-exec scripts the correct prefix is printed.
- man/new is_sysconfig_byhand.3

- man/new hostlist.3
- man/new hostlist.cfg.4
- man/new server_environment.3
- man/new server_environment.cfg.4
- cmd/chg server_environment: remove unwanted characters from output
- man/new syscp.1
- opt/new sysdiff: -v for verbose output
- cmd/fix swvi: depreciated tempfile removal
- cmd/fix job, jobwatch, joblog: depreciated tempfile removal
- cmd/fix du_report: depreciated tempfile removal
- cmd/fix rsat: unused variable \$Tmp removed
- cmd/new .daemon_wrapper: start commands that act as daemons out of the lib/daemon/
- cmd/chg job, joblog, jobwatch, passwdsyncd, watchdog, cronhandler: start via .daemon_wrapper. From now on it is possible to patch those commands even if there is already an instance running.
- cmd/fix job, joblog, jobwatch: tempfiles are cleaned up properly now.
- opt/chg watchdog: -L option can now also list stop commands for the running watchdogs.
- cmd/chg pack: add the timestamp file of the release also to a PATCH.
- cmd/chg cronhandler: is now able to run on Linux and Solaris. cronhandler does now longer access the spool directory (except when running on Solaris the atjobs spool directory is accessed to get the content of a job), on ll other cases it is based now completely on the official cron/at commands.
- cmd/chg job: when entering a job the prompt is now "job>" instead of only ">".
- cmd/chg cronhandler: at queues are now also supported
- cmd/chg watchdog: temporary directory is /var/tmp and not /tmp any more.
- cmd/chg job: temporary directory is /var/tmp and not /tmp any more.
- man/chg passwdsyncd.1m: added exit code 11 description.
- cmd/fix fit2width: bug when running on Solaris fixed.
- cmd/fix server_environment: bug when running on Solaris fixed.

1.5.03

Sun Dec 16 14:04:55 CET 2007 release

- cfg/chg edrcrevision.cfg: new release 1.5.03 (Sun Dec 16 14:04:08 CET 2007)
- man/fix remote_shell: CONNECTION_MODE resolution
- man/fix remote_copy: CONNECTION_MODE resolution

1.5.02

Sun Dec 16 13:59:11 CET 2007 release

- cmd/chg edrc: edrcperm format output, location of lib/edrc.<name> files moved to lib/edrc/<name>
- chg/src Makefile: standardized, each command has an own src directory now
- cmd/chg lscomp, llcomp, catcomp: supports now .jar and .bw files, too
- man/chg lscomp.1, llcomp.1, catcomp.1: .jar and .bw added
- cmd/chg sysconfig: scripts located in var/sysconfig/tools/<OSID> and var/sysconfig/tools/default can be called from check-, pre_exec- and post_exec scripts.
- man/chg sysconfig.1: description of tool directories.
- cmd/new getmountpoint: print mountpoint of current working directory. This command is much faster as "bdf ." especially on HP-UX having large file systems.
- cmd/chg pkg_hostname: use getmountpoint if it exists for a certain osid otherwise still the not completely reliable method via the mount command is used as fallback.
- cmd/chg stat: can now return file permission as octal number.
- cmd/chg edrc: is no longer dependent on locally created 'edrc' user, the user can be created in any name service (NIS, NIS+, ...)
- cmd/chg passwdsyncd: is no longer dependent on locally created 'edrc' user, the user can be created in any name service (NIS, NIS+, ...)
- cmd/new lynx: a character oriented Web browser
- cmd/chg .os_wrapper: \$PATH is enhanced to edrc/bin and edrc/lib.

- cmd/new wget: the non-interactive network downloader
- cmd/new getfilesystem: print mountpoint of current working directory. This command is much faster as "bdf ." especially on HP-UX having large file systems.
- opt/new user_info: -c to specify a config file
- man/new getfilesystem.3:
- man/new getmountpoint.3:
- man/new days.3:
- man/new seconds.3:
- cmd/chg input: enhanced stability on computed input values
- opt/new input: IPV4, HH:MM, HH:MM:SS, NO_ECHO , MM/DD, MM/DD/YYYY
- opt/new remote_shell: -t to create a tty on remote system
- opt/new remote_shell, remote_copy: -f to force connection mode without connection cache involvement
- cmd/chg edrc: trunk mode support
- man/chg edrc.1m: description of trunk, renamescript, renamemenu command, guideline for differential, full distribution use
- cmd/new contrib/ping: send ICMP ECHO_REQUEST packets to network hosts as contributed command
- cmd/chg rsat: connection mode fix set to OpenSSH, due to the need of a TTY on a remote system
- cfg/chg rsat.cfg: CONNECTION_MODE setting removed
- cmd/chg filedist: the file to be distributed is no longer saved to /var prior to distribution. Messages on failure are more precise. Logging enhanced.
- cmd/chg remote_copy: show correct default connection mode in usage message
- man/new bwcreate.1m, bwcreate.cfg.4
- opt/new pack: -L to list files that would be packed
- man/new apply2sw_inventory.1
- cmd/chg apply2sw_inventory: exit status 2 returned if command was not able to write to the output directory is changed to 3 due to the usage of this exit code for two return situations.
- man/chg cfg2html.8: new cfg2html.1m
- man/new contrib.1m
- cmd/chg edrc: direct trunk invocation enhancement
- man/new input.3
- man/cor watchdog.1
- cmd/new print_list: format a csv list to a formatted list with dynamic column widths and adjustment to the current terminal width.
- man/new pack.1m, pack.cfg.4, edrcpack.1m
- man/chg several: use of .VB, VE makros to switch to courier font and back (seen in PDF file)
- cmd/chg remote_shell, remote_copy: cache handling changed to gain connection performance especially for forced connections.
- opt/new remote_shell.cfg, remote_copy.cfg: OPENSSH_OPTIONS to pass additional options to ssh and scp to influence the general behavior
- cmd/chg edrcman: react on external setting of \$OSID (Osid='osid' -> Osid=\${OSID:='osid'}).
- opt/new rcmd: -r [num] to retry rcmd calls on unsuccessful connections
- cmd/chg rcmd: has now a logfile, review
- cmd/chg edrc: command renamescript to rename an existing script, renamemenu to rename an existing menu
- cmd/new ttyrec: a tty recorder
- cmd/new ttyplay: play files recorded by ttyrec
- cmd/new ttytime: show times in files recorded by ttyrec
- man/new edrcrevision.cfg.4
- cmd/fix edrc: display of menupoint title if there is only one menupoint (=script) in a submenu
- man/new edrcperm.no_shell.3, edrcenv
- cmd/new maketemp: create a unique temporary directory
- cmd/new removetemp: remove a temporary directory created by maketemp
- cmd/chg edrc: tempfile handling enhanced

- cmd/chg many: tempfile changed to use maketemp and removetemp
- cmd/chg csv2worksheet: use new PIO version poi-3.0-rc4-20070503.jar
- cmd/new contributed/locations: print corporate locations
- man/new contrib.edrc.1m: list of contributed commands distributed with WA2L/edrc
- cmd/chg edrcman: add 1m to MANSECT. Therefore the .1m symlinks in the man stricture are not needed any more
- cmd/chg user_info: new field LOCKOUT. This field is set to y if any lock is set for a user account.
- cmd/chg contributed/doc: now documentation for menus can be displayed, too
- cmd/new mc: Midnight Commander
- cmd/new mcview: Midnight Commander file viewer
- cmd/new mcedit: Midnight Commander file editor
- man/new contrib.doc.1m
- cmd/new nano, rnano: an editor that can be restricted
- cmd/new nano.1, rnano.1, nanorc.4: manpages for nano and rnano
- cmd/fix edrc: menu point output corrected if menu point is not executable
- opt/new input: YYYY-MM-DD, the military date format
- cmd/chg input: leap years are checked, now
- cmd/chg contributed/cmswitch: enhanced for WA2L/edrc external use
- cmd/chg xmore: --MORE-- output goes to /dev/tty and not to stdout any more
- cmd/chg remote_shell: enable TTY allocation for rtools connections
- cfg/chg edrc.cfg: many more fine grained denials
- cmd/chg edrc: export edrc config file to recovery scripts and contributed commands in the \$EDRC_CONFIGFILE environment variable
- cmd/chg edrcenv: output of \$EDRC_CONFIGFILE environment variable
- cmd/new is_permitted: check if a functionality is permitted to be executed based on the DENY_LIST in edrc.cfg
- cmd/new contributed/logs: enhanced log viewer
- man/new vsdfml.3: very simple document formatting language
- cmd/chg edrc: help of contributed commands is resolved from contributed command header and no longer from *.help files
- cmd/new contributed/clonemenu: clone an existing menu
- opt/new choice: NOT_NULL, to prevent no input
- opt/new crfile: -a for accelerated usage (in some circumstances)
- cmd/chg crfile: allow usage for non-root users, too. In non-accelerated mode create a file consisting of zeroes. Space check corrected.
- cmd/chg shar.setup: obsolescent tail option +N replaced with -n
- cmd/chg shar.install.tar.gz/install: obsolescent tail option +N replaced with -n
- cmd/chg shar.install.tar.gz/install: enhanced post installation instruction output
- cmd/chg edrcsetup.1m: description of existing configurations expanded, ssh setup simplified
- cmd/chg cfg2html: actual versions cfg2html_hpux-b.3.46 and cfg2html_linux-1.40 integrated
- man/new: sat.1 asup.1 osup.1 psup.1
- cmd/chg edrc: avoid breakouts during trunk establishment
- cmd/new zdiff zgrep zless zmore
- man/new zdiff.1 zgrep.1 zless.1 zmore.1
- cmd/chg gzip: version 1.3.12
- cmd/chg csv2worksheet: using newest POI API poi-3.0.1-FINAL-20070705.jar
- cmd/chg edrc: use less as pager for Linux
- cfg/chg edrc.cfg: new option LOGCOMPRESS
- cmd/chg contributed/logs: is capable to handle compressed logfiles transparently
- cmd/chg edrc: is capable to handle compressed logfiles transparently, logheader of <contrib_cmd>.nolog is logged too
- man/chg edrc.cfg.4: option LOGCOMPRESS added
- cmd/chg edrcman: proper functionality even when no system wide man page configuration exists

- cmd/chg logtail: resolve method of user \$HOME
- cmd/chg logview: resolve method of user \$HOME
- cmd/new thttpd: tiny HTTPd
- cmd/chg cronhandler: review due to lost of a cron file after a system crash
- cfg/new cronhandler.cfg: new
- cmd/new listtemp: list temporary directories created with maketemp including state information.
- cmd/chg rcmd: logfile location can be configured in the config file now
- cfg/chg rcmd.cfg: new option LOG to define the log directory
- man/new cronhandler.cfg
- cmd/chg pack: improve timestamp preserving
- man/chg edrcsetup.1m: manual install instructions removed
- cmd/chg filedist: logfile location can be configured in the config file now
- opt/new user_info: -R prints complete user record in a processable form
- cmd/chg user_info: internal cache
- opt/new input: European date format DD.MM.YYYY, DD.MM
- man/cor edrcsetup.1m: formatting of user input commands
- man/new crfile.1
- man/new du_report.1
- cmd/new edrc: trunkbypass to globally bypass an active trunk
- man/new scriptheadersync.1
- cmd/chg install: check needed install space
- cmd/chg edrc: prevent compression of edrc.log when LOGCOMPRESS is set to True
- cmd/chg contributed/logs: add an additional line during output
- cfg/chg edrc.cfg: new option TMP_DIR
- man/chg edrc.cfg.4: new option TMP_DIR
- cmd/new contributed/scriptstats: print statistics about the recovery script menu tree
- man/new msg.3
- man/new log.3
- cmd/chg log: output to stderr if \$EDRC_LOGFILE is not set, set session to process id of calling script if \$EDRC_SESSION is not set
- cmd/chg edrc: enhancements of trunk options (TARGET_MENUPATH, TARGET_CONFIG) allowing hierarchical trunk configurations, performance tuning in trunk specification resolution

1.5.01

Sun Feb 4 23:15:04 CET 2007 release

- cmd/fix sav: save file in /etc/rc.config.d into a subdirectory even if the current working directory is not /etc/rc.config.d .
- opt/new hostlist: -l, to return the hostlist comma separated. Default is still to return a space separated list.
- man/new sav: source is SFI-QIF
- cmd/new resolve_targetlist: resolve a list of targets which may consist of hosts and hostgroups.
- cmd/chg user_info: output of encrypted password when calling user_info -u username
- cmd/new mail_file: send a mail with an attachment.
- cfg/new rcmd.cfg: SET_UMASK to set the umask on the remote system as it is on the local system.
- opt/new role_option: -c config_file to be able to specify a different configuration file.
- man/new edrcsetup: text moved from doc/install-steps.
- cmd/chg contributed/doc: structure and tags changed, speed increased
- cmd/chg edrcpack: default is to create a shell archive now.
- cmd/chg edrcpack: do not pack dot-files and directories from source directory
- cmd/chg input: log input to \$EDRC_LOGFILE, new options NO_LOG and LOG_STARS to control logging functionality and to suppress password logging to a logfile.
- cmd/chg change: log input to \$EDRC_LOGFILE, new options NO_LOG and LOG_STARS to control logging functionality and to suppress password logging to a logfile.
- cmd/chg user_info: LAST_LOGIN field returns the number of days since the last successful login.
- cmd/chg user_info: LAST_SMBACCESS field returns the number of days since the last samba access

- cfg/new user_info.cfg: new option SMBACCESSLOG
- cmd/fix edrcpack: log output corrected
- cmd/chg install: non verbose installation does log extraction to logfile
- man/new watchdog.1
- man/new watchdog.cfg.4
- man/new choice.3
- man/new name.1
- man/new apply2file.1
- man/new duvi.1
- man/new du_index.1
- cmd/chg sysconfig: check file- and directory permissions to install the files & directories, too
- man/chg sysconfig.1: file install description enhances with hint that file permissions and ownership are considered as well
- cmd/chg edrc: use remote_copy, remote_shell, log, msg commands instead of internal functions. logview alias removed. contributed commands lview and ltail renamed to logview and logtail. Output of contributed commands is logged depending of the existence of a <contrib_cmd>.nolog file in the contrib/edrc/ directory.
- cmd/new remote_copy: wrapper for remote copies (rcp, scp)
- cmd/new remote_shell: wrapper for remote shells (rsh, remsh, ssh)
- cmd/chg edrcpack: do not exclude ~edrc/.ssh directory from package, exclude connection/cache/*
- cfg/new remote_shell.cfg: config file for remote_shell
- cfg/new remote_copy.cfg: config file for remote_copy
- man/chg EDRC.1
- man/chg edrcintro.1
- man/chg edrc.1m
- man/chg edrc.cfg.4
- cmd/chg passwdsyncd: use remote_copy and remote_shell for synchronization
- cmd/chg filedist: use remote_copy and remote_shell for distribution. root is no longer needed to be allowed to connect from remote.
- cfg/new filedist.cfg: REMOTE_CMD_PATH to the cpio and gzip commands on remote systems.
- man/chg edrcsetup.1m: revision, enhancements
- opt/chg sat: -h displays no longer usage of edrc
- cmd/new rsat: remote start of sat
- opt/new tty_variable: [device], to specify the tty device if needed
- cmd/chg tty_variable: fallback to /dev/tty if the current terminal is "not a tty"
- cmd/chg filedist: log output enhanced
- cmd/fix filedist: input not logged to logfile any more
- cmd/chg rsat: put path to remote systems
- cfg/chg rsat.cfg: REMOTE_PATH to set the path on remote systems
- cmd/chg edrcpack: splitting of shell archives and patch archives, provide a setup script for splitted archives, complete cleanup of -a option
- opt/chg edrcpack: -g option removed
- cmd/chg edrc: menu display is now compatible with Suse- and FC4 Linux, parallel script distribution possible
- man/chg edrc.cfg.4: DIST_TYPE
- man/chg edrcsetup.1m: complete review, secure shell config description added
- cmd/chg apply2file, dbrep, du_report, logcut, passwdcombine, svi, sw_report, syscp, svi, scritpextract, sysconfig: *Linux* ECHO="echo -e" -> ECHO="/bin/echo -e"
- cfg/chg kshrc: shd function to show the \$DISPLAY variable content
- cmd/new ksh_wrapper: wrap ksh to avoid the #!/bin/ksh magic key
- cmd/chg syscp, sysvi, sw_report, du_report, apply2file, dbrep: #!/bin/ksh -> #!/bin/sh
- cmd/chg passwdcombine, logcut, random: starting via ksh_wrapper
- cmd/chg edrc: can be started without ksh, too

- cmd/fix is_config_byhand: evaluation of .EDRC.config_byhand files
- cmd/new pstree: print a process tree
- cmd/new dig: send domain name query packets to name servers
- cmd/chg install: cancel option added
- man/new mkuser.3:
- cmd/new apropos: search whatis database
- cmd/new whatis: search whatis database
- man/new apropos.1: search whatis database
- man/new whatis.1: search whatis database
- man/new passwdsyncd.1m: password sync daemon
- man/new lscp.1:
- man/new lsmv.1:
- doc/chg all: Makefile improved to generate the PDF, HTML, PS documents
- man/new trash.1
- cmd/new rsync
- cfg/new rsyncd.conf
- man/new rsync.1 rsyncd.conf.4
- cmd/new java: start java
- cmd/new java_wrapper: wrap java programs
- cmd/new bget: get HTTP
- man/new bget.1
- cmd/new seconds: calculate seconds since the Epoch for a given date and time
- cmd/new ident: continuous output with ident
- man/new manpages: manpages documentation
- cmd/new repeat: repeat a command multiple times
- man/chg edrcrevision.1: reformatted
- cmd/chg ini.ksh: review, ported to Linux
- cmd/fix watchdog: output channel assignment
- cmd/fix watchdog: environment variable setting to ensure nested watchdog starts
- opt/new watchdog: -L, to list all running commands as command line arguments
- cmd/fix passwdsyncd: output channel asininity
- man/new cltrash.1:
- man/chg trash.1: FILES section precised
- cmd/cor cltrash: file header
- cmd/fix remote_copy: connection cache read while probe the connection
- cmd/new csv2worksheet: load CSV data into an existing Excel spreadsheet
- man/new csv2worksheet.3:
- cmd/chg java_wrapper: method of loading the *.javaopt files changed to provide more flexibility
- cmd/new ccrypt: encrypt and decrypt files and streams
- cmd/new crypt: encrypt and decrypt files and streams using the old Unix crypt method.
- cmd/chg os_wrapper: checks if OS command is executable and if the filename exactly matches
- cmd/new sysinfo: print information on overall system statistics (uptime, ram, swap,...)
- man/new sysinfo.1:
- man/new lsof.1:
- cmd/chg filedist: more possibilities in controlling the blockage of file distribution
- cfg/chg filedist.block: format changed to 3 fields. To migrate current filedist.block file to the new format, add "block:" in the first row of each rule line.
- cmd/chg passwdsyncd: different encryption modes supported to enhance security
- cmd/chg passwdsyncd_apply: different encryption modes supported to enhance security
- cfg/chg passwdsyncd.cfg: ENCRYPTION_MODE (Enigma, AES, NO) to configure password information transfer
- man/new passwdsyncd.cfg:
- cmd/new splitvt: split a screen into two windows

- man/new splitvt.1:
- cmd/new xmore: more for use in recovery scripts
- cmd/new vsdfml: very simple document formatting language to be used in information "recovery scripts"
- cmd/new perl_wrapper: wrap perl scripts to ensure better portability.
- cmd/chg edrcpack: writes package information to var/edrcpack/sadm/ to provide more information about the package. This sadm file is part of patches and full releases.
- cmd/new zcat: symbolic links to gzip, where installed with WA2L/edrc
- cmd/chg cronhandler: crontab is loaded using the official crontab command, now
- cmd/chg edrc: header in menus, permission specification
- cfg/chg edrc.cfg: DENY_LIST
- opt/new server_environment: -s servername to resolve server names different from host where logged on
- cmd/new edrc.no_shell: pseudo shell to prevent shell exits if 'shell' is denied in DENY_LIST of edrc.cfg
- cmd/chg edrc: new command removemenu to remove an existing menu and removescript to remove an existing recovery script. No it is not any more needed to exit to the shell to remove a script or menu
- cmd/chg edrc: \$TODAY is exported to the contributed commands and the recovery scripts, too.
- cmd/chg edrcenv: print the content of the \$TODAY variable, too
- opt/new input: ALPHA, DIGIT, ALNUM, ALNUM+SPACE, ALNUM+_ to allow certain input only
- cmd/chg input: prevent return value to be resolved, as happened when * has been entered, depending on cwd the filenames were returned
- cmd/chg edrc: use option ALNUM+_ in input calls in functions to commands newmenu, newscrip, removescript, removemenu to control inputs
- man/chg edrc.1m: description of .sav directory
- man/chg edrcintro.1: description of .sav directory
- cmd/new stat: return stat() information of a file
- cmd/new bwcreate: create a BarbedWire file to track file changes
- cfg/new bwcreate.cfg: cfgfile for bwcreate
- opt/chg omniutil: -a omnitrig, was not implemented and cannot be realized the way intended to
- cmd/new pack: replaces edrcpack to pack the application into a package
- cmd/chg edrcpack: displays a depreciated message and uses a subset of options of 'pack'
- cmd/chg scriptextract: scriptextract -> edrc.scriptextract
- man/chg scriptextract.cfg: man page removed
- cmd/chg edrccheck: removed
- cmd/chg edrc: the help command is no longer influenced by the more_file permission
- man/new swvi.1: man page for swvi
- cmd/cor swvi: usage message corrected
- man/chg duvi.1: cross reference to swvi added
- man/chg edrcintro.1: term_cap short description removed
- cmd/chg llcomp: complete redesign, formats bzip2, zip, compress added
- cmd/chg lscomp: complete redesign, formats bzip2, zip, compress added
- cmd/chg catcomp: complete redesign, formats bzip2, zip, compress added
- man/chg llcomp.1: adjusted to enhanced functionality
- man/chg lscomp.1: adjusted to enhanced functionality
- man/chg catcomp.1: adjusted to enhanced functionality
- man/chg EDRC.1: zip, unzip added
- man/chg edrcintro.1: zip, unzip added
- cmd/chg is_running: sbit set to allow non-root users to resolve if the package is running. The filepermissions are checked by is_running
- cmd/chg busy: now multiple os aware.

1.5.00

Sun Jul 10 19:45:42 METDST 2005 release

1.4.08

Sun May 22 17:34:30 CEST 2005 release

- cmd/chg edrc: changes bold settings in prompt on terminal changes
- cmd/chg term_cap: removed
- cmd/new lscp: similar to lsmv
- cmd/chg filedist, rcmd: is now able to resolve hostgroups as: @GROUPNAME on interactive input
- cmd/chg pkg_hostname: set AWK to support the SunOS exception
- cmd/chg dbrep, job, joblog, jobwatch, pkg_hostname, ini.*, mkuser : use hostname instead of uname -n
- cmd/chg sysconfig: elimination of // in file output, output of write settings step
- cmd/chg edrcpack: can now create shell archives, too
- cfg/chg kshrc: cmc, cddoc alias
- cmd/chg rcmd: avoid local wildcard resolution on interactive command input, if configured: set path on remote hosts equal to local, invoke commands on remote hosts as script, execution shell is now configurable.
- cfg/new rcmd.cfg: options SET_PATH and EXEC_SHELL.
- cmd/chg edrcpack: shell archive enhanced, on -a only create .sh archive
- cmd/chg shell archive: proper cleanup on termination
- cmd/chg passwdsyncd: .tar.gz -> .cpio.gz
- cmd/chg passwdcyncd_apply: .tar.gz -> .cpio.gz
- doc/chg install-steps: complete review
- cmd/chg passwdsyncd, passwdsyncd_apply: test on HP-11(i) and review
- cmd/chg name: follow symlinks
- cmd/chg revision: follow symlinks
- cmd/new whereami: display server environment and user information of the system where logged on
- cmd/new edrc/contributed: whereami
- man/chg edrcintro: whereami added
- cmd/new trash, untrash: to trash and restore trashed files
- cmd/fix watchdog: list running watchdogs
- opt/chg watchdog: -r interval to control logging or check state
- cmd/new cltrash: clean trash (purge trash / remove trash info files)
- cmd/chg edrcpack: timestamp file format changed. Old format is still recognized to read. There is no need to edit old timestamps.
- cmd/chg scriptextract: adjust timestamp after script installation
- cmd/new syscp: copy a system file to the sysconfig repository
- cmd/new sysvi: equals to svi to unify command naming
- cmd/chg logrotate: all users are allowed to start the command
- cmd/chg logtail, logview: command reads also ~/.mylog_files and ~/.log_files
- cmd/new swvi: create/edit the ..sw_inventory file
- cmd/new sw_report: create a software inventory report.
- cmd/chg cfg2html: cd /tmp during command execution to prevent cfg2html to penetrate the system with tempfiles
- cmd/chg cfg2html_<os><version>: current versions of cfg2html for OS HP-11i, Linux, Solaris
- cmd/chg edrc: correct handling of wild cards in input prompt
- cmd/chg whereami: new fields SU_FROM, SU_TO
- cmd/new user_info: command to read user definition information. This command partly replaces functionality of the whereami command.
- cfg/new user_info.cfg: migrated from whereami.cfg
- cmd/chg whereami: user information resolving moved to command user_info
- cfg/chg whereami.cfg: completely replaced by user_info.cfg.
- man/chg edrcintro.1: Sections COMMANDS, FILE, SEE ALSO.
- doc/new edrc_manpages: in HTML format, locally browseable.
- cmd/new apply2sw_inventory: apply a data stream to a software inventory file.
- cmd/new fields2swvi: convert a data stream to a swvi input sequence.

- cmd/new is_writeable: check if write access to a file or directory is possible.
- cmd/new filelink: create hardlinks between files in two different directories.
- cmd/new lsof: list open files.
- cmd/fix edrcpack: exclude core files but do not exclude core directories.
- cmd/chg edrcpack: enhance usage message with more example usages.
- cmd/chg edrc: possibility to list the files to be distributed ahead of the distribution.
- cmd/fix edrc: evaluation if a file is empty.
- cmd/chg sat: session name changed from SYSTEM_ADMINISTRATION__PID-\$\$ to SAT-\$\$
- cmd/chg logrotate: use library log function, therefore log format changed.
- opt/chg makeuser: -U uid
- cmd/new role_option: to support role based user creation from templates
- cfg/new role_option.cfg: config file for role_option
- cfg/new edrc.cfg: new options RECOVERYPOINTINTIME_MESSAGE, SETENVIRONMENT_MESSAGE
- man/chg edrc.cfg.4: options RECOVERYPOINTINTIME_MESSAGE, SETENVIRONMENT_MESSAGE
- cmd/new homedir: evaluates the homedir of a user
- man/new homedir:
- cmd/chg shar-header, install: log inputs to logfile during installation
- man/new pid:
- man/new woist:
- cmd/new rl: shortcut for rlogin
- cmd/fix catcomp: use GNU cpio even if started outside of edrc

1.4.07

Sun Nov 7 11:16:36 MET 2004 release

- cmd/chg almost all: support a bigger range of operating system ids of one operating system, as Solaris -> Solaris*, Linux -> *Linux*, HP-11|HP-11i -> HP-11|HP-11i|HP-*
- cmd/chg HP-11i/cpio: replace HP11i/cpio with version 2.5
- man/new HP-11i/man1/cpio.1: manpage included
- cmd/chg lscomp, llcomp, catcomp: can now handle .tar.gz and .cpio.gz archives
- cmd/chg edrc: uses now .cpio.gz archive format to distribute scripts
- man/chg edrc: distribution file tar.gz -> cpio.gz
- man/chg edrcintro: enhancement of lscomp, llcomp, catcomp
- cmd/chg sysconfig: backup file tar.gz -> cpio.gz
- cmd/chg passwdcombine: passw save file tar.gz -> cpio.gz
- opt/chg hostlist: remove -s option, add -g option to specify a hostgroup
- cfg/chg hostlist.cfg: HOSTGRPS="@GRPA: host1 host2 @GRPX: host6 host7"
- man/cor sysconfig: typing errors
- cmd/chg edrcpack: edrcpack timestamps in var/edrcpack/ts-* are excluded from generated patch packages
- opt/new edrcpack: -e to exclude scripts directory from a patch archive
- cmd/chg sysconfig: allow "_" in configuration name and configuration description
- cmd/fix sysconfig: correct handling of multiple configuration display

1.4.06

Sat Jul 24 18:16:32 / Sun Aug 8 18:25:47 CEST 2004 release

- opt/new sysconfig: -o OSID, to apply a configuration to the system which is different from the result of the osid command.
- opt/new edrcpack: -p version, to create patch-packages
- cmd/fix fssum: can now handle multiple line bdf output
- cmd/new term_cap: return a termcap value
- cmd/new cdetc, cdvar: cd to application etc and var directory in shell
- cmd/new mkuser, makeuser: integrated into EDRC
- cmd/new server_environment: to print the environment a server belongs to
- man/chg edrcintro: add short descriptions for new commands, add edrcpack directory description in FILES section

- cmd/new xlog: write stdin to a log
- cmd/new pkg_hostname: return packagename or hostname depending on pwd
- cmd/new omniutil: a collection of OBII enhancements
- cmd/new logtail: tail -f common logfiles
- cmd/new logview: view common logfiles
- cmd/new watchdog: a watchdog
- cmd/new passwdsyncd: synchronize passwords

1.4.05

- undated release
- cmd/fix sysconfig: fix stty: this is no tty error.
- man/cor cronhandler: description of action=... files.

1.4.04

- undated release
- cmd/chg edrc: OpenSSH test, internal enhancements
- man/chg edrc: securtiy/<DIST_USER>/ description
- cmd/chg edrcpack: writes now to a logfile
- man/fix sysconfig: logfile description
- cmd/chg filedist: internal enhancements
- cmd/chg rcmd: OpenSS test, internal enhancements

1.4.03

- undated release
- cmd/fix sysconfig: config_byhand bug
- cmd/fix is_config_byhand: proper cleanup of tempfiles
- cfg/fix kshrc: export of HOST

1.4.02

- undated release
- cmd/chg sysconfig: can now handle config_byhand functionality
- opt/new sysconfig: -f option to force configuration (=ignore config_byhands)
- cmd/new rel2abs: convert a relative to an absolute filename
- cmd/new is_config_byhand: evaluate if a file is protected by a config_byhand file
- man/cor cronhandler: FILE section
- man/chg EDRC, edrcintro: new commands added
- man/chg sysconfig: config_byhand description
- cmd/fix bin/* lib/*: permissions and groups corrected

1.4.01

- undated release
- cmd/chg cronhandler: option -a write to save cron/at without removal from system
- man/chg cronhandler: according to the change

1.4.00

- Mon Apr 5 18:44:53 METDST 2004 release
- cmd/chg: replacement of edrcroot thru approot in all commands
- cmd/chg: removal of alpha command pwsync
- cmd/new tty_variable: to query tty settings
- cmd/chg tty_columns: internal use of tty_variable

1.3.08

- Fri Mar 26 10:46:59 MET 2004 release
- cmd/new approot: identical to edrcroot, which will be replaced completely soon.
- man/cor: permission correction of all manpages

1.3.07

- Fri Feb 27 12:43:30 MET 2004 release
- man/cor cronhandler: files corrected
- cmd/fix envpasswdstrip: rootdir evaluation corrected

1.3.06

Tue Feb 17 00:16:49 MET 2004 release

- cmd/new hostlist: return a list of hosts. Used to generalize configuration files
- cmd/new ypxfr_all, passwdsort: taken from tools-eds

1.3.05

undated release

- cmd/fix sysconfig: write correct settings file header

1.3.04

undated release

- cmd/new pkzip: for Linux, Solaris
- cmd/chg: uat and yauat related files moved to doc/notes/dvlp due to incomplete development state of those commands

1.3.03

undated release

- cmd/new pkzip: for HP-11, HP-11i

1.3.02

Fri Jan 30 17:58:12 MET 2004 release

- cmd/chg edrc: version and patchlevel moved to etc/edrcrevision.cfg
- cfg/new edrcrevision.cfg: new configuration file holding the current version and patchlevel of WA2L/edrc
- cmd/chg fssum: cluster package checks will be executed only if the underlying operating system supports it. Therefore rows with the 'p' option in the fssum.cfg file are ignored on systems which do not support cluster packages or for which the PACKAGE_CHECK function is not implemented within fssum.

1.3.01

Fri Jan 9 15:22:33 MET 2004 release

- cmd/chg passwdcombine: can handle now trusted system and /etc/passwd systems and is able to do a more filigree selection.
- cfg/new edrc: NOTRECOGNIZED_MESSAGE option to generate a WARNING message if a user entered a command in edrc that does not exist.

1.3.00

Sun Nov 2 12:17:50 CET 2003 release

- cmd/new edrc, filedist, rcmd: prepared for secure shell
- cfg/new edrc.cfg, filedist.cfg: DIST_MODE to configure rtools or OpenSSH
- cfg/new rcmd.cfg: EXEC_MODE to configure rtools or OpenSSH

1.2.01

undated release

- opt/new edrcpack: -s = split package into peaces which fit to a diskette

1.2.00

Sun Oct 26 15:55:14 CET 2003 release

- cmd/new fit2width: fit a stream to a width
- cmd/new tty_columns: evaluate tty width
- cmd/fix days, input, choice: path to osid command

1.1.04

undated release

- cmd/new fssum: generate filesystem summaries
- cmd/new edrccheck: check needed connections and permissions for edrc
- cmd/new days: evaluate days since Jan 1st
- cmd/chg is_running: is able to resolve aliases now, some path settings added
- man/cor sysconfig: Optional: NO in FILES Section, <OSID>/root

1.1.03

Sat Oct 11 15:25:17 MEST 2003 release

- new: HP-11i support. HP-11i will probably cover many of future HP UNIX releases.

1.1.02

Mon Sep 29 16:30:28 METDST 2003 release

- cmd/new dbrep: as enhancement of the no longer maintained dbstat command
- cmd/new ini, ini.<shell>: ad hoc environment initialization

1.1.01

Tue Sep 16 14:22:18 MEST 2003 release

- cmd/chg oerr: new option TNS

1.1.00

Tue Sep 2 16:46:56 MEST 2003 release

- cmd/fix cronhandler: exit if no user dirs in homedir

1.0.21

Mon Aug 18 09:12:20 METDST 2003 tmp release

- cmd/chg edrcman: supports OSID dependent manpages now

1.0.20

Wed Aug 6 15:07:53 MEST 2003 release

- cmd/new edrc: title to modify a menu title
- cmd/new tcpdump integrated
- opt/new filedist: can now block (prevent) files from distribution to/from certain hosts
- cmd/new oerr contributed command
- cmd/chg proc contributed command renamed to pid
- doc/chg install-steps: enhanced
- man/new osid (3)
- man/new osid.dat (4)

1.0.18

Sat May 10 19:49:29 CEST 2003 release

- cmd/fix edrc: syntax error correction in function set_terminal()

1.0.16

Mon Apr 14 13:49:47 METDST 2003 release

- cmd/new edrc: @ command which invokes the last menupoint chosen
- cmd/new edrc: EDRC_NLS_DATE_FORMAT, EDRC_NLS_LANG is exported to contrib commands, scripts and shell to avoid variable overwriting by recovery scripts
- cmd/new edrc: EDRC_DIST_USER is exported to contrib commands, scripts and shell. This variable is equal to DIST_USER in the configuration file cmd/new job, joblog, jobwatch: integrated into EDRC

1.0.15

Wed Apr 2 16:17:31 METDST 2003 release

- opt/new edrc: -t option to skip terminal initialization
- cmd/fix edrc: test of start user relocated in program, log output to syslog if edrc is invoked with the wrong user
- cmd/new lsmv: print a list of mv-commands to screen

1.0.14

Mon Mar 24 19:52:46 MET 2003 release

- cmd/chg edrc: prompt includes the hostname
- cmd/new edrc: erase command to set the erase terminal character

1.0.12

Tue Mar 18 21:07:15 MET 2003 release

- cmd/fix .os_wrapper: more accurate command evaluation
- cfg/chg kshrc: terminal settings
- cmd/chg edrc: terminal settings to ensure proper backspace handling
- cfg/chg edrc.cfg: TERM setting is now the default if the terminal cannot be evaluated by the system.
- cmd/chg edrc: xterm is temporarily substituted by tee -a to save the logs due to SIGSEGV error on HP-UX 11.00
- cmd/chg sysconfig: does handle the check file now (again)

- cfg/new kshrc: variable \$p in shell is the last visited directory ahead of exiting the shell. This variable is displayed if 'abc' is invoked in the shell.
- cfg/new kshrc: suspend signal is now handled in shell (^Z).
- man/cor catcomp.1, edrc.1m, edrc.cfg.4

1.0.09

Sat Mar 8 02:25:16 CET 2003 release

- cmd/new filedist: copy files to other hosts
- cmd/chg edrc: distribution hostlist has a leading and trailing space
- cmd/new logcut: shorten logfiles
- cmd/new locations: list corporate locations with local time
- cmd/new is_running: check if a cluster package is up

1.0.08

Thu Mar 6 14:24:04 MET 2003 release

- opt/new edrcpack: -t
- several bugfixes and justifications

1.0.07

Wed Mar 5 20:50:31 MET 2003 release

- cmd/fix: recursive login bug existing on HP-UX

1.0.00

Tue Mar 4 00:13:16 CET 2003 release

- chg/all owner changed to root:sys
- 1st semi-productive release

0.9.35

Sun Mar 2 21:09:49 CET 2003 release

- cmd/new svi: edit files in a sysconfig repository
- cmd/chg scriptextract: configfile is relative to edrc/etc now
- cmd/chg edrc: configfile is relative to edrc/etc now
- cmd/chg edrc: configfile is submitted to scriptextract while distributing scripts using the "distribute" EDRC command
- cmd/cor sysconfig: several message changes
- cmd/new sat: start edrc with a configuration for system administration
- man/cor man pages existing in 0.9.11 according to the correction hints of Craiq Schmid
- cmd/new contributed/countdown: a countdown handler
- cmd/new edrc: new directory var/contrib/edrc
- cmd/new edrc: EDRC_CONTRIB_VARDIR is exported to contributed commands

0.9.31

undated release

- cmd/new edrc: export of EDRC_SCRIPTS_BASEDIR to contrib commands, shell and recovery scripts.
- cmd/new edrcenv: print of EDRC_SCRIPTS_BASEDIR
- opt/new edrc: -s option which allows silent startup

0.9.29

undated release

- cfg/new sysconfig: backup filelist
- cmd/new xtee: is now a compiled c program due to troubles with the awk version.

0.9.22

undated release

- cmd/new edrc: check of SCRIPTS_BASEDIR, exit 7 if fail
- opt/new edrc: -n session_name

0.9.18

Fri Feb 14 02:11:42 CET 2003 release

- cmd/new edrc: history
- cmd/new edrc: busy, !!, !<num>
- cfg/new edrc.cfg: SHELL_LENGTH, SHELL_SEARCH

- cmd/fix edrc: signal handling ported to UNIX

0.9.11

Tue Feb 11 22:10:25 MET 2003 release

- man/cor
- man/new catcomp, edrc.help, lscomp, llcomp, edrcroot
- cmd/fix edrc: contrib commands log to the main logfile edrc.log

0.9.10

Sun Feb 9 14:00:11 CET 2003 release

- cmd/new edrc: ABORT_MODE, kill with USR1 and USR2
- man/chg edrc.lm: completed

0.9.09

Sat Feb 8 21:46:12 MET 2003 release

- cmd/chg edrc: the current PID is session name if no name is set.
- cmd/new edrc: log header output is configurable thru LOGHEAD_OUTPUT.
- opt/chg scriptextract: -v to -V for version output
- man/new scriptextract.cfg
- cmd/chg patchlevel numbers changed to two digits
- man/cor typing errors

0.8.1 ... 0.9.8

Other development versions.

0.8.0

Sat Feb 1 23:20:28 MET 2003 release

0.7.0

Sat Feb 1 23:20:28 MET 2003 release

0.2.0 ... 0.6.0

Other development versions.

0.1.0

First development version.
