NAME

edrcintro – Introduction and overview for EDRC, the Enterprise Disaster Recovery Console

AVAILABILITY

WA2L/edrc

DESCRIPTION

EDRC is a package that enables you to recover your environment in an efficient and reliable way. The EDRC is an integral part of the "Emergency Handbook" and a whole disaster recovery plan and process.

This manpage gives an overview over all commands and directories that are part of the WA2L/edrc package.

The command for the **Enterprise Disaster Recovery Console**, the interactive program to control a disaster recovery or also useful to simplify system administration tasks, is **edrc**. See **edrc(1m)** for a detail description of the console.

REVISION-HISTORY

The revision history of WA2L/edrc is in a separate man page. See **edrcrevision(1)** to check the changes between the WA2L/edrc releases.

COMMANDS**A**

ansi2txt(3) converts a stream of vt100 (ansi) codes on the **stdin** into readable text on the **stdout**. A file can be specified instead of **stdin**.

appendpdf(3) Copy the contents of *file2.pdf* to the end of *file1.pdf*. The concatenated file is written to the specified output file or to **stdout**.

apply2file(1) apply a data stream provided via pipe to a target file if the content differs from the target file. This is useful to edit files or to generate files which are system dependent.

Example:

```
banner `hostname` | \
  apply2file -o -u root -g root -p 640 \
  -f /etc/issue

cat /etc/rc.config.d/samba | \
  sed -e 's/RUN_SAMBA=.* /RUN_SAMBA=1/g' | \
  apply2file -o -f /etc/rc.config.d/samba
```

apply2sw_inventory(1)

apply a data stream to a software inventory file. See also **swvi(1)**.

aproot(3)

print installation root of WA2L/edrc.

aprevision(3)

print application revision of the WA2L/edrc package.

apropos(1)

search the whatis database for strings.

ascii(3)

This is not a command, but a documentation of ASCII character set encoded in octal, decimal, and hexadecimal.

asup(1)

application support configuration short start for **edrc**. See **sat(1)** for more information.

awk(1)

manual page of **awk**, pattern-directed scanning and processing language.

B**banner(3)**

print big banner text as known from the login banners.

bash(1)

manual page of **bash**, GNU Bourne-Again SHell.

batteryalert(1)

monitor battery capacity and alert to all terminals on low charge.

binprobe(1m)

probe (compiled) executables and perl scripts if they are able to start on the current operating system.

bget(1)

basic tool to make HTTP GET requests and monitor the results.

busy(1)

print a rotating slash. This command does nothing productive. It might be useful to keep a line open when for instance a firewall cuts the connection if a TCP timeout is reached.

bwcreate(1m)

create a BarbedWire file that contains file properties and checksum of files on filesystems defined in the **bwcreate.cfg(4)** file. The BarbedWire file is used to track changes on (operating system) files.

| | |
|-------------------------|--|
| bzcat (1) | decompresses .bz2 files to stdout. |
| bzdiff (1) | compare bzip2 compressed files. |
| bzgrep (1) | search possibly bzip2 compressed files for a regular expression |
| bunzip2 (1) | unzip a block-sorting .bz2 file. |
| bzip2 (1) | a block-sorting file compressor to generate .bz2 files. |
| bzip2recover (1) | recovers data from damaged bzip2 files. |
| bzmore (1) | file perusal filter for crt viewing of bzip2 compressed text. |

C

| | |
|----------------------|---|
| catcomp (1) | cat a file out of a .tar.gz , .tgz or .cpio.gz file without decompressing the archive. |
| ccrypt (1) | ccrypt is a utility for encrypting and decrypting files and streams. It was designed to replace the standard unix crypt utility, which is notorious for using a very weak encryption algorithm. ccrypt is based on the Rijndael block cipher, which was also chosen by the U.S. government as the Advanced Encryption Standard (AES, see http://www.nist.gov/aes/). This cipher is believed to provide very strong cryptographic security. |
| cfg2html (1m) | This command creates a HTML (and ASCII) system documentation for HP-UX 10+11, AIX, SCO-UX, Solaris and Linux Systems. Plugins for SAP, Oracle, Informix, MC/SG, FibreChannel, TIP/ix, Mass Storage like XP48/256/512, Network Node Manager and OmniBack etc. are included. See also https://cfg2html.com/ . |
| checkopt (3) | check list of used options matches against a table of allowed option combinations. This command is intended to be used to efficiently parse arguments in a script. |
| choice (3) | an interactive choice command for use in own recovery scripts and contributed commands. |
| cltrash (1) | perform cleanup tasks for files trashed with the trash command. |

| | |
|--------------------------|--|
| cmdlist (1m) | list all available commands in WA2L/edrc with some credentials, as: TYPE, location, operating system and start mode. See also compatibility (1). |
| cmmon (1m) | monitor of all MC/SG packages on HP-UX systems having MC/ServiceGuard installed. If an interval of 0 is specified a one time output is provided, else the output is continuously. |
| cmswitch (1m) | switch a MC/SG package to a node. Using this interactive command is much faster then entering all commands needed for a cluster package switch from one to an other node. You can restart a package if you specify the host where the package is currently running as the target node. Be aware that the cmswitch command does not check if it is possible to switch the package to the specified target node, therefore you should check the possible package switch positions first using the cmmon command. |
| compatibility (1) | This is not a command, but a documentation of the "WA2L/edrc command compatibility overview (compatibility matrix)" by Christian Walther. |
| connect (3) | connect is a proxy tool to enable OpenSSH and other TCP/IP utilities to run through SOCKS4/5 and HTTP proxy gateways. The arguments host and port are for the target hostname and port number to connect to. |
| consolidate (1) | filter to consolidate structured unix file content. |
| cpanm (1) | get, unpack build and install modules from CPAN. The cpanm command settings are tuned for the WA2L/edrc package and the Perl environment distributed with the package. |
| cpio (1) | copy file archives in and out; duplicate directory trees. |
| crfile (1) | create a dump file with a specific size. |
| crond (3) | <p>daemon to execute scheduled commands. The crond integrated into WA2L/edrc allows to schedule jobs independent of the system.</p> <p>To add/edit crontab(4) entries, use the ecrontab(1) command and to show the next scheduled commands ecronnext(1).</p> <p>The crond(3) service is handled thru edrcinit(1m).</p> |

| | |
|--------------------------|--|
| cronhandler (1) | handle cron and at jobs in a cluster environment. With cronhandler you can transfer crontab entries and even defined at jobs from one cluster node to an other depending on username. at jobs are time-adjusted if necessary. |
| crypt (1) | encrypt and decrypt files and streams. Note: the cipher used by Unix crypt has been broken and is not secure. |
| csv (3) | filter providing commands to process CSV data. |
| csvcat (3) | prepare and print a CSV file or stream for further processing. Comment lines that begin with a hash (#) and empty lines are eliminated. Lines that are distributed over multiple lines thru a backslash (\) at the end of the line are joined. White spaces before and after the field separator (;) are eliminated. |
| csvq (3) | csvq is a command line tool to operate CSV files. You can read, update, delete CSV records with SQL-like query. You can also execute multiple operations sequentially in managed transactions by passing a procedure or using the interactive shell. In the multiple operations, you can use variables, cursors, temporary tables, and other features. |
| csv2worksheet (3) | load a CSV file (comma separated file) into an existing Excel spreadsheet. It is possible to load the data into an existing worksheet (tab) or to create a new worksheet if the worksheet with the name specified does not exist. This is an easy method to create "nice looking" Excel reports based on plain ASCII data without the need to create Excel makros or to develop complicated programs that create the whole Excel sheet. The idea is to load the data into a separate "data" worksheet (tab) and to perform the calculations, graphics, statistics etc. in a worksheet (tab) that is not touched by the data load. With this method it is even possible to create Excel reports directly on Unix systems without manual intervention. |

D

| | |
|---------------------------|---|
| daemon_wrapper (1) | start commands that run as daemons out of the edrc/lib/daemon directory. |
| days (3) | evaluate days since January 1st of a given date. If no date is specified the number of days from January 1st until the current date is printed (this equals to date +%j on HP-UX systems). |
| dbrep (1) | execute reports against an Oracle database. |
| dig (1) | send domain name query packets to name servers. |

directories(3) expand a file list data stream with the overlying directories.

Example:

```
find /data/myApp -mtime 7 -print | directories |\
  cpio -pdvm /backup/myApp/20091212
```

dmidecode(3) **dmidecode** is a tool for dumping a computer's DMI (some say SMBIOS) table contents in a human-readable format. This table contains a description of the system's hardware components, as well as other useful pieces of information such as serial numbers and BIOS revision. Thanks to this table, you can retrieve this information without having to probe for the actual hardware.

dos2ux(3) convert ASCII file format between DOS and UNIX file format.

duvi(1) edit the **..du_index** file used by **du_report** to document your system.

du_report(1) create a system report (with filesystems, directories, sizes and directory descriptions).

E

ecronnext(1) show the commands that are scheduled next in the **crontab(4)** entries of the **crond(3)** bundled with WA2L/edrc.

ecrontab(1) add/edit **crontab(4)** entries of the **crond(3)** bundled with WA2L/edrc.

edrc(1m) this is the Enterprise Disaster Recovery Console. From here almost all recovery steps on UNIX can be performed.

edrcenv(1) print the official WA2L/edrc environment variables.

edrcinit(1m) handle services start/stop/restart, primarily for daemons included in WA2L/edrc, but other services can be handled as well. **edrcinit** supports to monitor and to restart a failed service based on the definitions made in the **edrcinit.cfg** config file.

edrclicense(4) GNU General Public License for the WA2L/edrc package.

| | |
|------------------------------|--|
| edrcman (1) | show manual pages of WA2L/edrc without the need to change the \$MANPATH by hand. |
| edrcpack (1m) | deprecated, use pack (1m) to create a software package of the application. |
| edrcperm.no_shell (3) | pseudo shell to prevent shell exits within edrc possible in vi (1), view (1) and more (1) if the invocation of the functionality <i>shell</i> is denied with the related setting in DENY_LIST in the edrc.cfg file. |
| edrcports (4) | directory of network ports and protocols used by default by the WA2L/edrc package. |
| edrcrevision (1) | This is not a command, but a documentation of the "revision history of WA2L/edrc" by Christian Walther. |
| edrcroot (3) | print installation root of WA2L/edrc. This command is identical with approot and will be removed as soon as all commands within EDRC use approot to resolve the installation root. |
| edrcsetup (1m) | This is not a command, but a documentation of "How to install WA2L/edrc (Quick Installation Guide)" by Christian Walther. |
| envpasswdstrip (1) | strip passwords from _env files. This might be useful if you like to share recovery scripts but don't like to hand out the passwords. |
| epub2pdf (1) | epub2pdf is a command-line tool that quickly generates PDF files from EPUB ebooks. It allows the user to specify page size, fonts, margins, and default paragraph alignment. See also http://epub2pdf.com/ |
| eshell (1) | start shell . This command is located in the pbin/ directory to enable the user to conveniently start the shell command in his own user context. |
| eterm (1) | <p>start edrc, asup, psup, shell etc. from pbin/ directory in a separate X-terminal window.</p> <p>The eterm command also supports to create Desktop icons in the Gnome desktop environment.</p> <p>This command is located in the pbin/ directory to enable the user to conveniently start it.</p> |

exiftool(1) Read and write meta information in files. **exiftool** has been written by Phil Harvey. See also: <http://www.sno.phy.queensu.ca/~phil/exiftool/>

expect(3) programmed dialog with interactive programs. **expect** is a program that "talks" to other interactive programs according to a script. Following the script, **expect** knows what can be expected from a program and what the correct response should be. An interpreted language provides branching and high-level control structures to direct the dialog. In addition, the user can take control and interact directly when desired, afterward returning control to the script.

F

fcreate(3) create a file if it does not exist. Optionally text can be written to the file created. The intention of this command is to use it to create lock files within shell scripts.

fields2swvi(3) convert a data stream to a correct swvi input sequence. **fields2swvi** is used by **apply2sw_inventory** internally. See also **swvi(1)** and **apply2sw_inventory(1)**.

filedist(1) distribute file(s) to a list of other systems.

filegrep(1) grep for a pattern in all underlying ASCII files. Files located in a **.sav** directory or files saved with the **sav(1)** command are excluded from the search. See also **scriptgrep(1)**.

filelink(1) create hardlinks between identical files in two directory trees.

filesize(3) print the size of a given file.

filewatch(3) watch the file size progress of a given running command.

fit(3) alias for **fit2width(3)**.

fit2width(3) fit a data stream to a certain width. This command can be used together with **tty_columns** to fit a stream to the current width of a terminal (tty).

fmatch(3) prints the values of the given key from the file csv database specified on command line or in the **\$FMATCH_DATA_FILE** environment variable.

| | |
|---------------------|---|
| fnmatch(3) | match a stream with a wildcard expression. |
| freespace(3) | print free space of the filesystem where the given directory is located on. |
| fssum(1) | summarize filesystems based on definitions in a configuration file. This command is used to create a filesystem summary grouped by product. |
| ftps(1) | secure FTP is an FTP program that allows for a secure connection to be made to an FTP server via a Secure Sockets Layer (SSL). This version of secure FTP supports both implicit and explicit SSL connections. See also http://www.glub.com/products/secureftp/ |

G

| | |
|-------------------------|---|
| gawk(1) | manual page of gawk , GNU Project's implementation of the AWK programming language. |
| gecos(3) | return the GECOS (=comment) field of a defined user account. |
| getfilesystem(3) | print the file system where the current working directory is related to. |
| gethostbyname(1) | host lookup using gethostbyname() system call. This tool is useful to check if your /etc/nsswitch.conf works properly. |
| getmountpoint(3) | print the mount point where the current working directory is related to. |
| gid(3) | return the group-id (GID) of an existing group. |
| glibc.version(3) | print version number of the glibc library. |
| group(3) | return the group name of an existing group for a given group-id. |
| gs(3) | <p>The gs command invokes Ghostscript, an interpreter of Adobe Systems' PostScript™ and Portable Document Format (PDF) languages.</p> <p>gs reads "<i>files</i>" in sequence and executes them as Ghostscript programs. After doing this, it reads further input from the standard input stream (normally the keyboard), interpreting each line separately and output to an output device (may be a file or an X11 window preview, see below).</p> |

The interpreter exits gracefully when it encounters the **quit** command (either in a file or from the keyboard), at end-of-file, or at an interrupt signal (such as **Control-C** at the keyboard).

gunzip(1) compress or expand files.

gzip(1) compress or expand files.

H

h2(1) H2 is a relational database management system written in Java. It can be embedded in Java applications or run in the client-server mode. The disk footprint (size of the jar file) is about 1.5 MB.

histlist(3) print a table of history files including the resolution of usage begin, usage end, history file size and history file name.
The begin can be resolved properly only if the history file names comply to the history file names as produced by the **shell**(1) command when started outside **edrc**.

homedir(3) return the homedir of a user.

hostaliases(3) return aliases for a given host.

hostlist(3) return a hostlist. This command is used to centralize the configuration of a list of hosts to a single configfile.

hostlistdat2cfg(3) convert a **hostlist.dat** file that has the structure

Example:

```
#
# Format:
#
# <CUSTOMER>; <ENVIRONMENT>; <GROUPS>; <OPTIONS>; <HOSTS>
#
ACME;DEVELOPMENT ;@APP ;;host-001 host-002;
ACME;DEVELOPMENT ;@DB ;;host-003;
ACME;TEST ;@APP ;;host-101 host-103;
ACME;PREPRODUCTION ;@APP ;;host-201 host-202 host-205;
ACME;PRODUCTION ;@APP ;;host-303 host-308 host-309;
```

into settings that can be used in the **hostlist.cfg** file.

This command will significantly simplify the definition of host lists of large environments and will make the more complicated constructs obsolete where using the **fmatch(3)** command in the **hostlist.cfg(4)** configuration file.

Despite the many options that the **hostlistdat2cfg** provides, normally only the **-m** and the **-o** options will be used in the **hostlist.cfg** config file. See also samples in the **edrc/var/samples/hostlist** directory.

| | |
|-------------------------|---|
| html2mht(3) | convert a HTML file to a single web archive file (MHT) that can be viewed using for instance the Microsoft Internet Explorer (TM) or an other MHT viewer. html2mht is currently able to convert local HTML files having the image files locally stored. CSS and JavaScripts have to be within the HTML file to get a good result when viewing the converted file. |
| hwinventory(1) | command to print a minimal set of inventory information needed for asset management. |
| I | |
| ident(3) | continuous output of characters received via stdin with a leading ident on each line. This command is depreciated, use indent(3) for new scripts. |
| indent(3) | continuous output of characters received via stdin with a leading ident on each line. |
| info(1) | read Info documents. |
| ini(1) | initialize the environment based on named definitions specified in etc/env . Each shell has its own ini.<shell> binary to initialize the environment based on the definitions. So it is not necessary to use different syntax for different shells, this is done by the ini.<shell> command. The interactive ini command is a shell alias pointing to the relating ini.<shell> command. The alias in the ksh shell therefore calls the ini.ksh command, a C-shell would call the ini.csh command. |
| input(3) | an interactive input command for use in own recovery scripts and contributed commands. |
| input_targets(3) | special purpose input to query lists of hosts. The prompt cannot be changed and is set to "Target hosts". The input and the optional command argument is a space separated list of hosts and hostgroups. If the input differs from the default the input prompt is repeated to allow verification and corrections. If no <i>target_list</i> is specified in input_targets <i>target_list</i> the default target list provided in the input prompt is as it is resolved by hostlist(3) . |

| | |
|-----------------------------|--|
| ipcalc (1) | ipcalc takes an IP address and netmask and calculates the resulting broadcast, network, Cisco wildcard mask, and host range. By giving a second netmask, you can design subnets and supernets. |
| ipsort (1) | with this command you can sort a data stream which has IP addresses in the first column. |
| is_config_byhand (3) | evaluate if a given file is listed in a config_byhand file. If so return 'True' else return 'False'. This command can be used in pre_exec and post_exec scripts within sysconfig . |
| is_existing (3) | check if a file/directory/link etc. is existing and accessible by the calling user. This command does not hang if for instance the NFS resource where the file/directory/link is located is not available. There is the possibility to specify a timeout value when the default of 0 second is not sufficient. |
| is_osid (3) | evaluate if the operating system id returned by osid (3) matches to one os-id specified by the -o option. This command is used to limit a script execution to supported operating systems only. Example: <pre>is_osid -s \$0 -o HP-11,Solaris exit \$?</pre> |
| is_permitted (3) | the main intention of this command is to check if a certain functionality is permitted for execution in contributed commands. In recovery scripts global functionality and script functionality can be checked for startup permission. This enables you to minimize possible by-passes of the denials defined in the DENY_LIST in the edrc config file edrc.cfg (4) when you use an edrc configuration for system management purposes. |
| is_running (3) | evaluate if a given cluster package is up. Return 'True' if it is up, otherwise return nothing, therefore this command can be used in crontab to run a certain line only if the specified cluster package is running on this host. Example: <pre>0 1 * * * ["`/opt/edrc/lib/is_running psoftprod`"] \ && /opt/psoft/bin/my_command</pre> |
| is_up (3) | evaluate if a system is up thru pinging it with a one second timeout. |
| is_user (3) | evaluate if the user that started the command matches to one username specified by the -u option. This command is used to limit a script execution to supported users only. |

is_weekend(3) return True if the current day is at the weekend, else return False.

is_writeable(3) check if write access to a file or a directory is possible. Return 'True'/'0' if write access is possible, otherwise return 'False'/'1'.

J

java(1) start **java** based on the setting in **java_wrapper.cfg**. The **java** command is started thru the **.java_wrapper**.

java_wrapper(1) wrap programs written in java that they can be started the same way at it would be native commands. The search order to the **java** command installed on the system or eventually distributed with WA2L/edrc has to be set in the configuration file **java_wrapper.cfg** if it is not found.

job(1) job sequencer. This command can be used to serialize jobs on a UNIX system. It has a similar user interface to the **at** command. The advantages of this command are multiple queue support, execution of jobs in the current user environment and a logging facility.

joblog(1) monitor the logfile of the **job** command.

jobstart(1) start jobs using a simple interface, where a job is identified by a **JOBNAME**.

jobwatch(1) monitor the state of jobs in a certain queue. The output is similar to the **top** command.

jq(3) **jq** is a lightweight and flexible command-line **JSON** processor.

See <https://stedolan.github.io/jq/manual/> and <https://stedolan.github.io/jq/tutorial/> for more information.

K

kalc(1) **kalc** is a programmable scientific calculator, using RPN (Reverse Polish Notation). It includes over 200 functions and a built-in help system. **kalc** works with real numbers, complex numbers and also integers in other numeric bases. Its has a complete programming language, with control-flow structures such as if and while. It has "unlimited" memory for you to store objects.

ksh(1) manual page of **ksh**, KornShell, a standard/restricted command and programming language.

| | |
|------------------------|---|
| kshell (1) | print path of the Korn- or Bourne Again shell available on the system. |
| ksh_wrapper (1) | wrap Korn- and Bourne Again shell scripts to avoid using <code>#!/bin/ksh</code> in the magic key. However, due to the fact that some scripts need Korn shell functionality either ksh or bash has to be installed in <code>/bin</code> , <code>/sbin</code> , <code>/usr/contrib/bin</code> or <code>/usr/local/bin</code> . |
| L | |
| lbanner (3) | print a ASCII banner as the banner (3) command does, but allow more options, as character size, fill character and banner orientation. |
| lcat (1) | alias for logcat (1). |
| leo (1) | leo is a command line interface to the german/english/french/spanish/... dictionary on http://dict.leo.org/ . It supports almost all features which the website supports, plus more. Results will be printed to the terminal. By default the searched key word will be highlighted. leo has been written by Thomas Linden <tom@daemon.de>. See also: http://search.cpan.org/~tlinden/ |
| lgcheckd (1m) | a daemon to check logfiles for patterns and to create a consolidated findings report. This is the more efficient and leaner variant of the logcheckd (1m) daemon command that operates on the same configuration file format, the same pattern files and interfaces as logcheckd (1m) for easy migration. |
| lgcpattern (3) | check/analyse/verify a logcheckd.pattern (4) file definition against a data stream. This utility helps to create the definitions in a pattern file. |
| lgrep (1) | alias for loggrep (1). |
| listtemp (3) | list temporary directories created with maketemp (3) and resolve if the related process that created the temp dir is still running. This command can be used for system housekeeping. |
| ll (1) | long file listing. This command calls internally ls -laF [options] and is to enable the user to use ll when calling rcmd even on operating systems where ll (1) is not provided. |

| | |
|-----------------------|---|
| llcomp (1) | detailed list of the contents of a compressed tar archive (.tar.gz , .tgz or .cpio.gz files) without decompressing it. |
| locate (1) | search for pattern in the locate database produced by updatedb (1m). |
| locations (1) | print a list of corporate locations with local time. |
| log (3) | write a log message to the logfile for use in contributed commands. |
| logcat (1) | cat selected time range (from/to) in log files having time stamps. To grep selected time range (from/to) in log files having time stamps use the loggrep (1) command. |
| logcheckd (1m) | a daemon to check logfiles for patterns and to create a consolidated findings report. The report can be mailed to a list of recipients. See also the new log checking daemon lgcheckd (1m). |
| logcut (1) | shorten logfiles to a number of rows. |
| loggrep (1) | grep selected time range (from/to) in log files having time stamps. |
| logrotate (1) | rotate logfiles and preserve a number of old logfiles. |
| logtail (1) | give a selection of common logfiles, which can be listed in \$HOME/.mylog_files , \$HOME/.log_files or in etc/log_files.cfg and start tail -f <selected_file> . |
| logview (1) | give a selection of common logfiles, which can be listed in \$HOME/.mylog_files , \$HOME/.log_files or in etc/log_files.cfg and start view <selected_file> . |
| lots (1m) | long term data save handling. |
| lotsctl (1) | lots control menu configuration short start for edrc . lotsctl provides an easy to use user interface to the lots (1m) command. In addition to the lots (1m) command, some reporting functionality is provided. See sat (1) for more information. |

| | |
|---------------------|--|
| lscomp (1) | list the contents of a compressed tar archive (.tar.gz , .tgz or .cpio.gz files) without decompressing it. |
| lscp (1) | <p>print a list of cp commands with files in the current working directory to the screen. This might be useful if you have to copy files and adjust the filenames of many recovery scripts.</p> <p>Example:</p> <pre>lscp > a; vi a; sh a; rm a</pre> |
| lsmv (1) | <p>print a list of mv commands with files in the current working directory to the screen. This might be useful if you have to adjust filenames of many recovery scripts.</p> <p>Example:</p> <pre>lsmv > a; vi a; sh a; rm a</pre> |
| lsof (1) | list open files. |
| lspm (1) | list installed perl modules including version and installation path. See also pmdesc (1). |
| lua (1) | lua is the standalone Lua interpreter. It loads and executes Lua programs, either in textual source form or in precompiled binary form. lua can be used as a batch interpreter and also interactively. |
| luac (1) | luac is the Lua compiler. It translates programs written in the Lua programming language into binary files containing precompiled chunks that can be later loaded and executed. |
| luaenv (3) | <p>print the environment used by lua to access the Lua modules bundled with WA2L/edrc. To set the environment prior to execution of lua, invoke:</p> <pre>eval `luaenv`</pre> |
| luarocks (1) | <p>start the luarocks command with settings tuned for the WA2L/edrc package and the Lua environment distributed with the package.</p> <p>See also https://luarocks.org/ and https://github.com/luarocks/luarocks/blob/main/docs/index.md for additional information.</p> |

| | |
|--------------------------------|--|
| lua version (3) | print the <i>major:minor</i> version of lua 3. |
| lua _wrapper (1) | wrap Lua scripts and programs to avoid using <code>#!/usr/bin/lua</code> or similar path names in the magic key. This enhances the portability of WA2L/edrc commands written in Lua to systems where Lua is not installed in the default install locations. lua has to be installed in edrc/bin/ , /bin/ , /sbin/ , /usr/bin/ , /usr/local/bin/ or /usr/contrib/bin/ . Further lua locations can be configured in the optional config file |
| lynx (1) | Lynx is a fully-featured World Wide Web (WWW) client for users running cursor-addressable, charactercell display devices (e.g., vt100 terminals, vt100 emulators running on Windows 95/NT or Macintoshes, or any other "curses-oriented" display). It will display hypertext markup language (HTML) documents containing links to files residing on the local system, as well as files residing on remote systems running Gopher, HTTP, FTP, WAIS, and NNTP servers. |
| M | |
| mail _file (1) | send a mail with a message content and file attachment(s). |
| maketemp (3) | create a unique non existing temporary directory with secure permissions. Use removetemp (3) to remove a temporary directory created with maketemp . |
| makeuser (1) | user friendly interface to mkuser . |
| mandir (4) | This is not a command, but a documentation of a "directory of manual page online resources" compiled by Christian Walther. |
| man2html (3) | converts a manual page as found in file (or stdin , in case no file argument, or the argument - , is given) from man-style nroff into HTML, and prints the result on stdout . |
| manvi (1) | edit manual pages in WA2L/edrc. It is possible to specify additional directories to be searched for manual pages in the configuration file manvi.cfg . |
| mc (1) | GNU Midnight Commander is a directory browser/file manager for Unix like operating systems. If the environment variable \$MCTERM is not set, the terminal emulation is set to <i>xterm</i> , what is fine for most cases. |
| mcedit (1) | Internal file editor of GNU Midnight Commander. If the environment variable \$MCTERM is not set, the terminal emulation is set to <i>xterm</i> , what is fine for most cases. |

| | |
|----------------------|---|
| mcview (1) | Internal file viewer of GNU Midnight Commander. If the environment variable \$MCTERM is not set, the terminal emulation is set to <i>xterm</i> , what is fine for most cases. |
| md2html (3) | convert markdown file to HTML. |
| md5string (3) | calculate MD5 checksums for strings line by line. |
| mediawiki (3) | get/put MediaWiki pages from/to a MediaWiki server. The communication does not need the MediaWiki API (api.php), therefore also MediaWiki servers running on older versions then 1.13 are supported. |
| mkuser (3) | create and initialize a new directory for a user. |
| msg (3) | write a message to the screen for use in own recovery scripts and contributed commands. |
| msmtp (3) | an SMTP client as an alternative to sendmail (8). |

N

| | |
|-----------------|---|
| name (1) | print description of a file or directory examined from the file header. |
| nano (1) | Nano's ANOther editor, an enhanced free Pico clone. nano is a small, free and friendly editor which aims to replace Pico, the default editor included in the non-free Pine package. Rather than just copying Pico's look and feel, nano also implements some missing (or disabled by default) features in Pico, such as "search and replace" and "go to line and column number". nano is included mainly into WA2L/edrc due to the possibility to run it in restricted mode (-R , or as rnano) and in a real viewer mode (-v) without the possibility of bypassing it, as view does allow with the :w! command. |

Example use of **nano** in recovery scripts:

as normal editor:

```
nano $file > `tty`
```

as editor with the restriction to edit only the given file:

```
rnano $file > `tty`
```

as a real read only viewer only allowing to view the given file:

```
rnano -v $file > `tty`
```

nc(3) **nc** is a simple Unix utility which reads and writes data across network connections, using TCP or UDP protocol.

nginx(3) a HTTP and reverse proxy server, mail proxy server. nginx (pronounced engine-x for its high performance, stability, rich feature set, simple configuration, and low resource consumption.

nmap(1) **nmap** (Network Mapper) is an open source tool for network exploration and security auditing. It was designed to rapidly scan large networks, although it works fine against single hosts. **nmap** uses raw IP packets in novel ways to determine what hosts are available on the network, what services (application name and version) those hosts are offering, what operating systems (and OS versions) they are running, what type of packet filters/firewalls are in use, and dozens of other characteristics. While Nmap is commonly used for security audits, many systems and network administrators find it useful for routine tasks such as network inventory, managing service upgrade schedules, and monitoring host or service uptime.

nologin(1) nologin shell to block users from login in to the system.

nping(1) **nping** is an open-source tool for network packet generation, response analysis and response time measurement. **nping** allows users to generate network packets of a wide range of protocols, letting them tune virtually any field of the protocol headers. While **nping** can be used as a simple ping utility to detect active hosts, it can also be used as a raw packet generator for network stack stress tests, ARP poisoning, Denial of Service attacks, route tracing, and other purposes.

O

omniutil(1m) a collection of OmniBack (OBII) enhancement utilities.

os_wrapper(1) wrap os dependent binaries to allow transparent shellscript programming.

osid(3) evaluate the systems operating system id.

osid.probe(3) library command to probe if the setting in **osid.dat** is compatible to the related compiled binaries in **bin/OSID/** and **lib/OSID/**.

osup(1) operation support configuration short start for **edrc**. See **sat**(1) for more information.

outex(1)

produce output of a selected logfile (without path) that is saved in **edrc/var/log/** that can be used in **contrib.doc(1m)** in the **OUTPUT-EXAMPLE** section.

The intension is to use the **outex logfile** command directly from within **vi** when editing a recovery script, as:

```
# D: Restore database.
#
~
~
~
: . !outex 2020-06-02_10.52.05__db_restore.log
```

This will include the contents of the logfile **edrc/var/log/2020-06-02_10.52.05__db_restore.log** (without logfile header) into the **vi** session. Each line will be prepended by the **# O:** documentation tag.

The specified *logfile* can also be a gzipped file, as: **2020-06-02_10.52.05__db_restore.log.gz**

Furthermore if the specified logfile **2020-06-02_10.52.05__db_restore.log** does not exist, but the **2020-06-02_10.52.05__db_restore.log.gz** does, the contents of the compressed file is included and vice versa.

P**pack(1m)**

create a shell archive (example: **edrc-1.4.08-200502150919.sh**) of WA2L/edrc that can be used to install WA2L/edrc on all supported operating systems. Log-files, backup files, lock files etc. are excluded from the package.

passwdcombine(1)

combine password files or password databases. This is useful if you have to apply a new set of users to a system and you like to prevent a change of certain users (as system users).

passwdsort(1)

sort a passwd file or data stream from stdin by UID.

passwdsyncd(1m)

a daemon to synchronize passwords over several systems. The daemon can be switched centrally to a maintenance mode. While in maintenance mode the synchronizations on all nodes taking part on a synchronization is on hold. The behavior of **passwdsyncd** can be configured in **passwdsyncd.cfg**.

passwdsyncd_apply(3)

apply passwords distributed with **passwdsyncd** to the target system.

patchinstall(1m)

patch an WA2L/edrc installation. **patchinstall** also cleans up corpses of older WA2L/edrc versions. All patched files and cleaned up corpses are backed up.

- pdfmetaedit(1)** GUI to edit meta data of a PDF file. This command was developed by "zarro". See also <http://zaro.github.io/pdf-metadata-editor/>.
- pdfscissors(1)** GUI to crop PDF file for eBook reader. This command was developed by Abdullah Al Mazed (Gagan). See also <http://pdfscissors.com/>.
- perlenv(3)** print the environment used by **perl** to access the Perl modules bundled with WA2L/edrc. To set the environment prior to execution of **perl**, invoke:
- ```
eval `perlenv`
```
- See also **perl\_modules(3)** for additional information.
- perlversion(3)** print perl version of **perl** interpreter found on the system. See also **perl\_wrapper(3)** for additional information.
- perl\_wrapper(1)** wrap Perl scripts to avoid using `#!/usr/bin/perl` or similar path names in the magic key. This enhances the portability of WA2L/edrc commands written in Perl to systems where perl is not installed in the default install locations. **perl** has to be installed in `/bin`, `/sbin`, `/usr/local/bin` or `/usr/contrib/bin`. Further **perl** locations can be configured in the config file **perl\_wrapper.cfg**.
- pf\_wrapper(1)** Wrap WA2L/edrc commands to be started thru **pfexec(1)** or **sudo(8)**.
- To use the commands in **pbin/** add the directory to the user's **\$PATH** variable:
- ```
[ /home/fred ]
[ fred@host-001 ][bash]: vi ~/.bashrc
:
27 # Add edrc/pbin to $PATH
28 PATH=~edrc/pbin:$PATH; export PATH
~
~
```
- pip(1)** start the **pip** command **pip3(1)** with settings tuned for the WA2L/edrc package and the Python3 virtual environment (**venv**) distributed with the package.
- pip3(1)** the **pip** command is the Python package manager. The **pip** command call within WA2L/edrc handles the virtual environment **venv** distributed with WA2L/edrc.
- pid(1)** select (grep) a given pattern out of the process list.

| | |
|-------------------------|--|
| pkgdir (1m) | This is not a command, but a documentation of a "directory of package/software handling commands" compiled by Christian Walther. |
| pkg_hostname (3) | return MC/ServiceGuard package name the current working directory is related to. If the directory is not related to a package the hostname is returned. This command can be used to set the user's prompt depending on the path the user is currently in. |
| pkzip (1) | compression utility. |
| pl (1) | pl is a program that produces plots and charts from data, and produces results that can be viewed on web pages, paper, slides, or interactively on the screen. A user developed script file may be supplied for greater flexibility and customization. pl may be executed from the command line or as a CGI program. |
| pmdesc (3) | List name, version, and description of all installed perl modules and PODs. See also lsbm (1). |
| pod2html (3) | Converts files from POD (Plain Old Documentation) format to HTML format. See also: https://perldoc.perl.org/perlpod and perlpod (4). |
| portscan (3) | scan a target system for active ports. It is possible to specify the minimum port where the scan should start and the maximum port number where the scan should stop. Ports that are active are returned to stdout . |
| print_header (3) | print a standard report header to the terminal. The output is limited to the current terminal width if the environment variable \$PRINT_FIT2WIDTH is not set to <i>False</i> . |
| print_index (3) | print a standard report column index to the terminal. The output is limited to the current terminal width if the environment variable \$PRINT_FIT2WIDTH is not set to <i>False</i> . |

Example:

```
cat<<EOM | print_index
ZIP;Postal Zip Code
CITY;Name of the City
STATE;State
CNT;Country Shortcut
COUNTRY; Country Full Name
EOM
```

COLUMN INDEX:

```
ZIP ..... Postal Zip Code      CNT ..... Country Shortcut
CITY ..... Name of the City     COUNTRY .. Country Full Name
STATE .... State
```

print_list(3)

the intention of this command is to print a list to a terminal in a good readable format. A csv file provided via pipe is printed to stdout. The first row is treated as header row. The width of all columns is dynamically adjusted to the row with containing the longest entry. Furthermore the output is limited to the current terminal width if the environment variable **\$PRINT_FIT2WIDTH** is not set to *False*. To select named columns prior to print the list with **print_list** use **select_columns(3)**.

Example 1:

```
cat<<EOM | print_list
ZIP;CITY;STATE;CNT;COUNTRY
93117;Goleta;CA;USA;United States of America
8222;Beringen;SH;CH;Switzerland
8005;Cape Town;WC;RSA;South Africa
EOM
```

| ZIP | CITY | STATE | CNT | COUNTRY |
|-------|-----------|-------|-----|--------------------------|
| 93117 | Goleta | CA | USA | United States of America |
| 8222 | Beringen | SH | CH | Switzerland |
| 8005 | Cape Town | WC | RSA | South Africa |

(3)

Example 2:

```
cat<<EOM | select_columns ";" "CNT;ZIP;CITY" | print_list
ZIP;CITY;STATE;CNT;COUNTRY
93117;Goleta;CA;USA;United States of America
8222;Beringen;SH;CH;Switzerland
8005;Cape Town;WC;RSA;South Africa
EOM
```

| CNT | ZIP | CITY |
|-----|-------|-----------|
| USA | 93117 | Goleta |
| CH | 8222 | Beringen |
| RSA | 8005 | Cape Town |

(3)

pscount(3)

count processes and evaluate if the situation correlates to a defined situation as received thru stdin.
This command is intended to be used to check if the correct number of needed processes for an application are running on the system.

Example:

```
cat << EOM | pscount
1; 1;Oracle Listener ;oracle;./tnslsnr LISTENER .+;
1;10;Oracle DB Writer;oracle;ora_dbw[0-9]_ACMEDB;
1; ;Oracle Connects ;oracle;oracleACMEDB .+;
EOM
```

| DESCRIPTION | MIN | MAX | CURRENT | STATE |
|------------------|-----|-----|---------|-------|
| ----- | --- | --- | ----- | ----- |
| Oracle Listener | 1 | 1 | 1 | OK |
| Oracle DB Writer | 1 | 10 | 2 | OK |
| Oracle Connects | 1 | | 0 | FAIL |
| *TOTAL* | 3 | 11 | 3 | FAIL |
| (4) | | | | |

- psjoin(3)

join concatenates several PostScript files and generate a single PostScript document. The output, concatenated PostScript document, will be written to the standard output.

The input PostScript files must comply with the DSC (Document Structuring Convention). **psjoin** can fail to work depends to the input PostScript file or combination of the input PostScript files.
- pslist(3)

list and select processes in a cross operating system compatible format. When not invoked with the **-l** (= long output) option, only a list of the process-ids of the selected processes is printed.
- ps2pdf(3)

convert PostScript files to PDF.
- pstree(1)

print a process tree.
- psup(1)

production support configuration short start for **edrc** . See **sat(1)** for more information.
- purgetemp(3)

remove all temporary directories in a base dir that where created by **maketemp(3)** and have the state **IS_ACTIVE=False**.
- pwcrypt(1)

encrypt a plain password.
- pwsafe(3)

this command that can be called from outside of **edrc(1m)** allows also to access the password safe of a recovery script tree.

In this case the master password has to be provided thru the environment variable **\$PWSAFE_MASTERPASSWORD**.

Of course one using this command should be careful about how to handle the master password.

See **contrib.edrc(1m)**, **contrib.pwsafe(1m)** and **pwsafe(3)** for more information.

pythonenv(3) print the environment used by **python** to access the Python modules bundled with WA2L/edrc. To set the environment prior to execution of **python3**, invoke:

```
eval `pythonenv`
```

pythonversion(3) print the *major.minor* version of **python3**.

python_wrapper(1) wrap Python scripts to avoid using `#!/usr/bin/python3` or similar path names in the magic key. This enhances the portability of WA2L/edrc commands written in Python to systems where Python is not installed in the default install locations. **python3** has to be installed in `/bin`, `/sbin`, `/usr/bin`, `/usr/local/bin` or `/usr/contrib/bin`. Further **python** locations can be configured in the optional config file **python_wrapper.cfg**.

R

random(3) return a random number or a random item of a specified item list.

rcat(1) display (**cat**) remote- or local file(s).

rcomm(1) compare (**comm**) remote- or local file(s).

rcmd(1) run a command or a set of commands on a set of hosts. You can specify the command(s) in the command line, if you don't you are prompted for it.

rdiff(1) show differences (**diff**) of remote- or local file(s).

readline(3) read long input lines from **stdin** and return the input to **stdout**. The maximum length of the input is 10240 characters (10 kBytes), input longer then this maximum is ignored and truncated.

regexintro(4) This is not a command, but a documentation that gives an "Introduction to Regular Expression Usage" compiled by Christian Walther.

resolve_targetlist(3) resolve a targetlist which may consist of a list of hosts and hostgroups.

rel2abs(3) convert a relative filename to an absolute.

| | |
|-------------------------|---|
| remote_copy (3) | wrapper for remote copies. This command enables you to write scripts independent of the current security policy of your systems. Internally remote_copy uses r cp or s cp dependent of the configuration settings. Furthermore this command provides a caching mechanism which remembers successful connection modes to speed up future connections. |
| remote_shell (3) | wrapper for remote shells. This command enables you to write scripts independent of the current security policy of your systems. Internally remote_shell uses remsh , rsh or ssh dependent of the configuration settings. Furthermore this command provides a caching mechanism which remembers successful connection modes to speed up future connections. |
| removetemp (3) | remove a temporary directory created with maketemp (3). |
| repeat (3) | the repeat command re-executes the single subsequent command for count number of times. |
| revision (1) | print the most recent revision entry of a file examined from the file header. |
| rl (1) | shortcut for the rlogin command. See rlogin (1) manpage for additional information. |
| rnano (1) | Restricted mode for Nano's ANOther editor (nano), an enhanced free Pico clone. rnano is a restricted version of nano, which only edits specific files and doesn't allow the user access to the filesystem or a command shell. See example usage in intro of nano above. |
| role_option (3) | return the value of a certain option related to a role in an environment. This function is used to support a role based user creation model based on role templates which can be defined in the relating configuration file role_option.cfg . |
| rosid (3) | evaluate the systems operating system id of a remote system. |
| rsat (1) | start sat on a remote system. The list of hosts provided can be specified in the configuration file rsat.cfg . |
| rssh (1) | connect to a remote system using ssh (1). When invoking the rssh command the remote user and the remote host is queried interactively, where the last chosen user- and host-name is provided as default |

input.

When a symlink to the **rssh** command in the format **rssh-user@host** is created, the newly created command variant will connect directly to the *host* with the *user* and the remote system will query for the password.

The main purpose for this is to create a pseudo user (without password) and add the command variant **rssh-user@host** to the shell field of the **/etc/passwd** field to allow to use a local system to be used as a direct terminal to a remote system, as for example:

```
acme:x:1291:1291:acme login terminal:/tmp:/home/fred/bin/rssh-f
```

This would allow you to enter *acme* as login on the local system that will connect to the remote *host* where the login password of the *user* will be queried.

rsync(1)

rsync is a program that behaves in much the same way that **rcp** does, but has many more options and uses the **rsync** remote-update protocol to greatly speed up file transfers when the destination file is being updated.

S

sat(1)

short start of **edrc** with an other configuration which points to an own script tree. Internally **sat** calls **edrc -c edrc.sat.cfg**. **sat** stands for "system administration tool". If additional short starts are needed, create a symlink from the new short start command to **sat**.

Example:

```
cd ~edrc/bin
ln -s sat new_shortstart
```

When starting **new_shortstart** internally **edrc -c edrc.new_shortstart.cfg** will be called.

Currently the following short start commands are distributed with WA2L/edrc: **asup** (Application **S**upport Configuration), **psup** (Production **S**upport Configuration), **osup** (Operation **S**upport Configuration), **lotsctl** (Long Term data Save Control Configuration).

sav(1)

save a file to a backup with preserving the filepermissions and file dates.

screen(1)

screen is a full-screen window manager that multiplexes a physical terminal between several processes (typically interactive shells). Each virtual terminal provides the functions of a DEC VT100 terminal and, in addition, several control functions from the ISO 6429 (ECMA 48, ANSI X3.64) and ISO 2022 standards (e.g. insert/delete line and support for multiple character sets). There is a scroll-back history buffer for each virtual terminal and a copy-and-paste mechanism that allows moving text regions between windows.

| | |
|-----------------------------|---|
| scriptextract (3) | extract scripts distributed with the distribute EDRC command. |
| scriptgrep (1) | grep all recovery scripts for a pattern. Files in .sav directories and files not following the name convention *:* are excluded from the search. See also filegrep (1). |
| scriptheadersync (1) | synchronize the header entries in recovery scripts with the actual filename of the script. The script starts in the current working directory and searches all underlying directories for recovery scripts matching the filename convention: <i><menu-point>:<scriptname></i> . |
| scriptmenupath (3) | return recovery script menu path when called from a recovery script or _env file in the form 'menu -> submenu -> subsubmenu -> menupoint'. |
| scriptrevision (3) | print the revision number of a (script)file following the [##] revision notation as also resolved by revision (1). |
| scriptsequence (3) | <p>check if recovery scripts are called in ascending sequence. If not a message is printed or the script is aborted. scriptsequence must be called from a recovery script or _env file to give the user more awareness if the sequence is broken.</p> <p>Usage example (query to abort or not):</p> <pre>scriptsequence exit</pre> <p>Usage example (inform only):</p> <pre>scriptsequence -a inform exit</pre> |
| scripttitle (3) | print recovery script title (menupoint, description and duration as defined in doc tag) when called from a recovery script or _env file to give the user more awareness which menu point is started. |
| seconds (3) | calculate seconds since the Epoch for a given date and time. Use timer to evaluate the seconds since the Epoch for the current moment. |
| sectioncat (3) | cat section (<i>[SECTION]</i>) of a text file. |
| sed1line (1) | This is not a command, but a documentation of "USEFUL ONE-LINE SCRIPTS FOR SED (Unix stream editor)" compiled by Eric Pemet. |

select_columns(3) filter to select named columns that are separated by a field separator from **stdin** and print the selected columns to **stdout**. The first row of the data stream must contain the row header. Columns that do not exist, are printed as empty columns.

Example:

```
cat<<EOM | select_columns ";" "CNT;ZIP;CITY"
ZIP;CITY;STATE;CNT;COUNTRY
93117;Goleta;CA;USA;United States of America
8222;Beringen;SH;CH;Switzerland
8005;Cape Town;WC;RSA;South Africa
EOM
```

```
CNT;ZIP;CITY;
USA;93117;Goleta;
CH;8222;Beringen;
RSA;8222;Cape Town;
```

server_environment(3)

return a name for the environment of the server where running the command. In the configuration file **server_environment.cfg** it can be defined which server relates to what environment. The **server_environment** command can be used to develop scripts which act specific on different environments without hardcoding hostnames into the scripts.

Example:

```
case `server_environment` in
    TEST)
        Max_load=100
        Mail_to=fred.developer@acme.com
        ;;
    PREPRODUCTION)
        Max_load=200
        Mail_to=barney.verifier@acme.com
        ;;
    PRODUCTION)
        Max_load=250
        Mail_to=wilma.production@acme.com
        ;;
    unknown)
        echo "server environment unknown, aborting."
        exit 1
        ;;
esac
```

sh(1)

manual page of **sh**, command interpreter (shell).

shell(1)

the **shell** command provides a slightly reduced environment as the **shell** command started within **edrc**. The differences to the **shell** start in **edrc** is, that the environment variables **\$EDRC_SESSION**, **\$EDRC_SCRIPTS_BASEDIR**, **\$EDRC_ENV**, **\$EDRC_CONFIGFILE**, **\$EDRC_RECOVERYTIME**,

\$EDRC_DIST_USER, **\$EDRC_NLS_DATE_FORMAT**, **\$EDRC_NLS_LANG**, **\$NLS_DATE_FORMAT** and **\$NLS_LANG** are not set. Call the **edrcenv**(1) command to display the official WA2L/edrc environment variables.

shellinaboxd(3)

publish command line shell through AJAX web interface.

In WA2L/edrc the **shellinaboxd** server process is configured in the **edrc/etc/shellinaboxd.cfg** configuration file and started thru **edrcinit**(1m). Use the command:

```
edrcinit start shellinaboxd
```

to start the shell web server process.

In the default configuration, the user then can connect to the address **https://servername:8806** and work with the command line shell thru the web browser without the need of installing a terminal emulation program locally. A connect to **http://servername:8806** is redirected to the **https** address.

See also: <http://code.google.com/p/shellinabox/> and <http://www.tecmint.com/shell-in-a-box-a-web-based-ssh-terminal-to-access-remote-linux-servers/>.

shlib(3)

print the environment variables needed by the dynamic linker **ld**(1) to locate the shared libraries. If a script need to set this environment variables (**\$LD_LIBRARY_PATH** and **\$SHLIB_PATH**), use

```
eval `shlib`
```

instead of setting them by your own. This ensures, that all scripts will continue to run, even when the directory structure in WA2L/edrc changes.

sortc(3)

sorting data in the "C" locale. Internally the **sort**(1) command is called.

sortv(3)

Provide a version sort functionality as provided by the **sort -V** command to operating systems, where **sort**(1) lacks this functionality.

sparse(3)

filter to identify sparse files. The filelist received thru **stdin** is searched for sparse files and the file names of all identified sparse files, or all non-sparse file names (**-v**), are printed to **stdout**. This enables to use the output directly for further processing thru a pipe for instance.

Examples:

Find sparse files in the current directory:

```
find . -print | sparse
```

Copy all sparse files:

```
find . -print | sparse | cpio -pdvm --sparse /destination
```

Copy all non-sparse files:

```
find . -print | sparse -v | cpio -pdvm /destination
```

- splitvt(1)** This program splits the screen into two windows, one above the other, and runs a shell in each one.
- ssh-exec(1)** execute commands provided thru **stdin** on a remote system using **ssh**.
- Example:
- ```
ssh-exec -u fred -t acme-007 <<EOC
date
uptime
uname -a
EOC
```
- ssh-exec** also supports to remote control commands using **expect(3)** without the need to write whole **expect** "wrapper" scripts or without even writing **expect** code.
- ssh-keyadd(1m)** Add SSH public keys to a users (normally root's) **authorized\_key** file(s). Furthermore the SSH daemon configuration file is modified that way that it is allowed to connect as root. To make the configuration change active, the HUP signal is sent to the SSH daemon.
- sshpass(1)** **sshpass** is a utility designed for running **ssh** using the mode referred to as "keyboard-interactive" password authentication, but in non-interactive mode.
- sqlite(1)** SQLite is a software library that implements a self-contained, serverless, zero-configuration, transactional SQL database engine. SQLite is the most widely deployed SQL database engine in the world. It is used in countless desktop computer applications as well as consumer electronic devices including cellphones, PDAs, and MP3 players. The source code for SQLite is in the public domain. See <http://www.sqlite.org/docsrc> for more information.
- stat(1)** This command returns the file status information returned by the **stat(2)** system call.
- To print the modification time in a consistent format use
- ```
timer `stat -s mtime -f my_file`
```
- The advantage of using this command instead of
- ```
ls -al my_file
```
- is, that the output format does not change over time, as the **ls** does.
- strace(1)** trace system calls on Linux. This command is called internally, if the **truss** command is invoked on Linux.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>streamcat(3)</b> | continuous unbuffered output of an input stream received thru <b>stdin</b> to <b>stdout</b> .                                                                                                                                                                                                                                                                                                                               |
| <b>svi(1)</b>       | edit the file in a <b>sysconfig</b> repository which is related to the local (active) file on the system. This command is equal to the <b>sysvi</b> command.                                                                                                                                                                                                                                                                |
| <b>sw_report(1)</b> | create a software inventory report of a system. This command takes the <b>..sw_inventory</b> files as a base for information.                                                                                                                                                                                                                                                                                               |
| <b>swvi(1)</b>      | edit the <b>..sw_inventory</b> file used by <b>sw_report</b> to create a software inventory of your system.                                                                                                                                                                                                                                                                                                                 |
| <b>symlink(1)</b>   | create a symbolic link. In addition to the <b>ln -s</b> command <b>symlink</b> removes an existing symbolic link or file with the same name prior to the symbolic link creation. If the <b>-l</b> option is specified <b>symlink</b> only proceeds if the file is an existing symbolic link; the intention of this option is to use <b>symlink</b> to switch an existing symbolic link from one to another target.          |
| <b>sys(1)</b>       | System configuration handling and some automated EDRC tasks, as WA2L/edrc package distribution and patch installation. See <b>sys(1)</b> for more information.                                                                                                                                                                                                                                                              |
| <b>sysconfig(1)</b> | configure a system with a prepared set of files with a single command.                                                                                                                                                                                                                                                                                                                                                      |
| <b>sysinfo(1)</b>   | prints information on overall system statistics. If called with an option to specify a dedicated information, the current time, the number of seconds since the Epoch and the relating information is printed separated by a deliminators on a single line. The main intention of the command was to print the system uptime in a more computable fashion ( <b>sysinfo -u</b> ) then returned by the <b>uptime</b> command. |
| <b>syscp(1)</b>     | copy an (active) file on the system to the related <b>sysconfig</b> repository.                                                                                                                                                                                                                                                                                                                                             |
| <b>sysdiff(1)</b>   | list if an (active) file on the system applied with <b>sysconfig</b> differs to the file(s) in the related repository. The files are considered as different if the content or the filepermissions differ. To obtain a plain list of files that differ from the applied file, redirect the output to <b>stderr</b> .                                                                                                        |
| <b>syspoll(1)</b>   | poll systems and execute a query. The main purpose is to centrally control report data collection.                                                                                                                                                                                                                                                                                                                          |

**sysvi**(1) edit the file in a **sysconfig** repository which is related to the local (active) file on the system. This command is equal to the **svi** command.

**sys2html**(1m) create a 'System Configuration' HTML report similar to **cfg2html**(1m) from remote systems without the need to install it on the systems where the configuration shall be collected.

## T

**tcpdump**(1) dump traffic on a network.

**textblock**(3) format a stream into a justified text block with an optional hanging first line.

**textcolor**(3) set the terminal text color. The *ATTRIBUTE* option can be set to **RESET**, **BRIGHT**, **DIM**, **UNDERLINE**, **BLINK**, **REVERSE** or **HIDDEN**. The *FOREGROUND* and *BACKGROUND* options can be set to **BLACK**, **RED**, **GREEN**, **YELLOW**, **BLUE**, **MAGENTA**, **CYAN** or **WHITE**.

**thttpd**(3) **thttpd** is a simple, small, fast, and secure HTTP server.

**timer**(1) return the number of seconds since the Epoch or return the date based on the given number of seconds since the Epoch. Use **seconds** to evaluate the number of seconds for a specific date.

**timezone**(3) return the timezone as set in the **timezone.cfg** file or as defined system wide.

**title**(1) set the title of the terminal window. There are two predefined titles that can be chosen using the **short** or **long** option. It is also possible to define an own title text.

**today**(3) return the date of today. It is also possible to specify the format of the return value as known from the **date**(1) command. This command can be substituted directly by **date** and does exist, to have an equivalent command to **tomorrow**(3) and **yesterday**(3) returning the value in the identical format.

**tolower**(3) return a given string in lowercase.

**tomorrow**(3) return the date of tomorrow. It is also possible to specify the format of the return value as known from the **date**(1) command.

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>top</b> (1)           | displays the top processes on the system and periodically updates the information. Raw CPU percentage is used to rank the processes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>toupper</b> (3)       | return a given string in uppercase.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>tpl</b> (1)           | select and print a template file to <b>stdout</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>tput_examples</b> (3) | examples on the use of the <b>tput</b> (1) command to control terminal outputs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>traceroute</b> (1m)   | print the route packets take to network host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>trash</b> (1)         | remove file(s) and create a <b>&lt;filename&gt;.TRASHED</b> file that contains information about the removal and the possibility of a restore of the file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>truss</b> (1)         | <b>truss</b> traces the system calls a process invokes and the signals it receives. It displays arguments in a symbolic way, shows the first bytes of read and write buffers as well as signal information when available. <b>tusc</b> can attach to live processes by providing PIDs (process IDs) as argument(s).                                                                                                                                                                                                                                                                                                                                                                                |
| <b>tscat</b> (3)         | filter to add a timestamp and a filename to a stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>tsize</b> (3)         | <p>this command returns the current width and height of the terminal in the <b>COLUMNS</b> and <b>LINES</b> variables. This output can be used directly to initialize the environment variables using the <b>eval</b> command:</p> <pre>eval `tsize`</pre> <p>The output of <b>tsize</b> is identical to the <b>resize</b>(1) command as provided when X11 is installed. As long as <b>resize</b> is available on the system it is used internally to resolve the terminal size, if not, a fallback exists to evaluate the terminal without the use of <b>resize</b>. Therefore it is not imperative to have X11 installed on the system when using <b>tsize</b> to resolve the terminal size.</p> |
| <b>ttyplay</b> (1)       | player of the tty session recorded by <b>ttyrec</b> (1).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ttyrec</b> (1)        | a tty recorder.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>ttytime</b> (1)       | print the time of the recorded session data by <b>ttyrec</b> (1).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**tty\_columns(3)** return the current width of the terminal (tty).

**tty\_variable(3)** return the current value of a terminal (tty) setting.

**tzdump(3)** dump the contents of a zoneinfo file.

## U

**uid(3)** return the user-id (UID) of an existing user.

**uncbz(1)** unpack b2zipped cpio file(s) to the current directory. The source file remains packed.

**uncbz2(1)** unpack b2zipped cpio file(s) to the current directory. The source file remains packed.

**uncgz(1)** unpack gzipped cpio file(s) to the current directory. The source file remains packed.

**unzip(1)** unpack zipped cpio file(s) to the current directory. The source file remains packed.

**unczst(1)** unpack zstd-compressed cpio file(s) to the current directory. The source file remains packed.

**unczstd(1)** unpack zstd-compressed cpio file(s) to the current directory. The source file remains packed.

**undeb(1)** unpack file(s) of a rpm file(s) to the current directory. The source file remains packed.

**uniqpath(3)** removes duplicate entries in a colon separated string without changing the field order. This command can be used to tidy up **\$PATH**, **\$MANPATH** or **\$USAGE\_PATH** settings.

**unrpm(1)** unpack file(s) of a rpm file(s) to the current directory. The source file remains packed.

|                     |                                                                                                                                                                                                                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>untbz(1)</b>     | unpack b2zipped tar file(s) to the current directory. The source file remains packed.                                                                                                                                                                                                                 |
| <b>untbz2(1)</b>    | unpack b2zipped tar file(s) to the current directory. The source file remains packed.                                                                                                                                                                                                                 |
| <b>untgz(1)</b>     | unpack gzipped tar file(s) to the current directory. The source file remains packed.                                                                                                                                                                                                                  |
| <b>untrash(1)</b>   | restore file(s) removed by <b>trash</b> .                                                                                                                                                                                                                                                             |
| <b>untxz(1)</b>     | unpack xz-ed tar file(s) to the current directory. The source file remains packed.                                                                                                                                                                                                                    |
| <b>untzst(1)</b>    | unpack zstd-compressed tar file(s) to the current directory. The source file remains packed.                                                                                                                                                                                                          |
| <b>untzstd(1)</b>   | unpack zstd-compressed tar file(s) to the current directory. The source file remains packed.                                                                                                                                                                                                          |
| <b>unzip(1)</b>     | <b>unzip</b> will list, test, or extract files from a ZIP archive, commonly found on MS-DOS systems.                                                                                                                                                                                                  |
| <b>unzstd(1)</b>    | expand files.                                                                                                                                                                                                                                                                                         |
| <b>updatedb(1m)</b> | create the locate database to be queried by <b>locate(1)</b> .                                                                                                                                                                                                                                        |
| <b>usage(1)</b>     | print a short usage of non standard commands available in WA2L/edrc.                                                                                                                                                                                                                                  |
| <b>user(3)</b>      | return the user name of an existing user for a given user-id.                                                                                                                                                                                                                                         |
| <b>user_info(1)</b> | print information of a user defined on the system. This is an interface to read with one command in a structured matter from several files which are needed to finally define a user on a Unix/Linux system (passwd, group, samba user map, ftpusers, trusted system settings where applicable, ...). |

**uudecode(1)** **uudecode** transforms uuencoded files into their original form.

**uuencode(1)** **uuencode** is used to create an ASCII representation of a file that can be sent over channels that may otherwise corrupt the data. Specifically, email cannot handle binary data and will often even insert a character when the six character sequence "Orom " is seen.

**ux2dos(3)** convert ASCII file format between UNIX and DOS file format.

## V

**vadsp(1)** display additional information of a VA-7410 of HP on HP Unix systems attached to a VirtualArray.

**vcap(1), vmore(1), vdiff(1), vgrep(1), vlist(1), vpurge(1), vrestore(1), vsav(1)**  
the **v(sav|cat|more|diff|grep|list|purge|restore)** commands enable to save, print, compare, grep, list, purge and restore *versions* of a given *file*.

**vsdfml(3)** very simple document formatting language. The main purpose is to highlight documentation files on terminal output when writing recovery scripts whose purpose is to display only information and not to execute commands. To benefit from **vsdfml** you have to add it to the magic key of your information "recovery script": **#!/bin/sh vsdfml**. Lines starting with a hash ( # ) are considered as comments and are not printed. Repetitive empty lines are reduced to one line.

**vvi(1)** versioned file editor using **vi(1)** respectively the editor set in **\$EDITOR**.  
Prior to editing the given files each file is saved using **vsav(1)**.

## W

**watchdog(1)** a watchdog to check a certain condition. If the checked condition matches, bite.

**wa2lc(3)** directory of additional C include files provided in the WA2L/edrc package.

**wa2ledrc\_edrcapi(1)** web application **WA2L/edrc:edrcapi** (EDRC REST API) to serve WA2L/edrc information in API fashion.

**wa2ledrc\_report(1)** web application **WA2L/edrc:report** (OPERATING SYSTEM REPORT PORTAL) to serve mainly static operating system reports that are saved in a simple directory structure ( **<Customer>/<Report\_Name>/<Report\_file>** ). A main goal is to provide a web interface without the need of extensive configuration. However, a user administration web interface is included.

The portal can be provided for a single customer e.g. when running directly in the

customer's environment, or for a consolidated multiple customer view for system administration personnel.

#### **wa2ledrc\_shellinaboxd(1)**

web application **WA2L/edrc:shellinaboxd** to serve WA2L/edrc command line over Web browser.

#### **wget(1)**

GNU Wget is a free utility for non-interactive download of files from the Web. It supports HTTP, HTTPS, and FTP protocols, as well as retrieval through HTTP proxies.

#### **whatis(1)**

search the whatis database for complete words.

#### **whereami(1)**

print the server environment where logged on. In addition the structured user definition information of the current user is printed.

#### **whoisin(1)**

print a list of users who are logged in on certain (remote) hosts.

#### **wmic(1)**

client to use the Windows Management Instrumentation from Linux.

#### **wine(1)**

client to execute commands remotely on Windows from Linux.

#### **woist(1)**

search a path for a file.

### **X**

#### **xbdf(1m)**

a platform independent version of the **bdf** respectively **df -k** command. Line breaks are removed, as experienced on HP-UX in certain circumstances.

#### **xlog(1)**

write date from stdin to a logfile. Each line is preceded with a date, time, sequence and tag entry. A common use might be in crontab instead of piping outputs to **/dev/null**.

Example:

```
a_command 2>&1 | xlog -t a_cmd -f /var/adm/log/a_command.log
```

#### **xml2csv(3)**

convert XML schema to CSV.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>xml2json</b> (3)  | convert XML schema to JSON.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>xmore</b> (1)     | display file(s) page by page in WA2L/edrc recovery scripts. The <b>more</b> (1) or <b>less</b> (1) command do not stop for user input after displaying a page if used in a recovery scripts.                                                                                                                                                                                                                                                                                              |
| <b>xpid</b> (1)      | <p>select processes from the process command part of the process list. This is a convenience command to the <b>pslist</b>(1) command.</p> <p>Internally the <b>xpid</b> command calls currently <b>pslist -l -c '.*selection.*'</b> .</p> <p>The <b>xpid</b> command is intended for manual command line use only, for script use the <b>pslist</b> command should be used because the output of the <b>xpid</b> command is not intended for further processing and might be changed.</p> |
| <b>xtee</b> (1)      | an enhanced version of the standard <b>tee</b> command. This one appends the standard output with extra data and session columns to the logfile. It is planned to use this command by <b>edrc</b> internally to save the standard output of the recovery scripts to the logfiles.                                                                                                                                                                                                         |
| <b>Y</b>             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>yesterday</b> (3) | return the date of yesterday. It is also possible to specify the format of the return value as known from the <b>date</b> (1) command.                                                                                                                                                                                                                                                                                                                                                    |
| <b>ypxfr_all</b> (1) | transfer NIS maps from a NIS master server.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Z</b>             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>zcat</b> (1)      | <b>zcat</b> is identical to <b>gzip -c</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>zdiff</b> (1)     | compare compressed files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>zgrep</b> (1)     | search possibly compressed files for a regular expression.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>zip</b> (1)       | <b>zip</b> is a compression and file packaging utility for Unix, VMS, MSDOS, OS/2, Windows NT, Minix, Atari and Macintosh, Amiga and Acorn RISC OS.                                                                                                                                                                                                                                                                                                                                       |
| <b>zless</b> (1)     | file perusal filter for crt viewing of compressed text.                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                 |                                                         |
|-----------------|---------------------------------------------------------|
| <b>zmore(1)</b> | file perusal filter for crt viewing of compressed text. |
| <b>zstd(1)</b>  | compress or expand files.                               |

## FILES

The **name(1)** command can be used to list a short description of files and directories.

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>.ssh</b>              | DO NOT SAVE *ANY* DATA INTO THIS DIRECTORY.<br><br>This directory contains *no* <b>ssh</b> keys, <b>ssh</b> authorized key files or <b>ssh</b> configuration files. The <b>ssh</b> files are saved in the <b>var/connection/</b> structure. See below for more information.<br><br>The reason why this directory exists is, that on certain operating systems under special conditions (as HP-UX 11.11 having the random number generator patch not installed), the connection in OpenSSH mode fails when using the commands <b>rcmd</b> , <b>filedist</b> , <b>remote_copy</b> , <b>remote_shell</b> or when establishing trunks in <b>edrc</b> . |
| <b>pbins/</b>            | binary directory for commands that could be started with elevated permissions. This directory only contains symlinks to the <b>.pf_wrapper</b> . See <b>pf_wrapper(1)</b> for additional information.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>sbin/</b>             | this is the location of the <b>edrc</b> command. This directory should not be included in \$PATH.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>bin/</b>              | some general use commands. This directory is in \$PATH.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>bin/&lt;OSID&gt;/</b> | operating system dependent commands. These commands are mostly compiled for the designated operating system. The command call occurs via the <b>os_wrapper</b> command and never via a \$PATH enhancement or a direct call.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>contrib/edrc/</b>     | contributed commands to <b>edrc</b> . Do not change the <b>edrc</b> program if you miss a general command. Create the command in this directory and you will be able to invoke it as it is an <b>edrc</b> internal command. This will protect you from losing your work after an upgrade of <b>edrc</b> and will keep the <b>edrc</b> command itself stable.                                                                                                                                                                                                                                                                                       |
| <b>doc/</b>              | some printable documentation, including all man pages, in PDF, PostScript and HTML format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>etc/</b>              | configuration files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>lib/</b>              | commands which are mostly used within scripts. Some of them require some environment settings. This directory is in \$PATH.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>lib/&lt;OSID&gt;/</b> | operating system dependent library commands. These commands are mostly compiled for the designated operating system. The command call occurs via the <b>os_wrapper</b> command and never via a \$PATH enhancement or a direct call.                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>lib/&lt;OSID&gt;/libs/</b> | shared libraries needed by the compiled operating system dependent commands located in <b>bin/&lt;OSID&gt;/</b> and <b>lib/&lt;OSID&gt;/</b> started thru the <b>os_wrapper</b> . The <b>os_wrapper(3)</b> ensures that this directory is added to the <b>\$LD_LIBRARY_PATH</b> and the <b>\$SHLIB_PATH</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>lib/daemon/</b>            | Korn shell scripts called via <b>daemon_wrapper(1)</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>lib/dbrep/</b>             | SQL reports used by <b>dbrep(1)</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>lib/edrc/</b>              | library functions called by the <b>edrc(1m)</b> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>lib/icons/</b>             | icon images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>lib/java/</b>              | location of Java <b>.class</b> , <b>.jar</b> , <b>.class.javaopt</b> and <b>.jar.javaopt</b> files. The Java programs are called via the <b>java_wrapper(1)</b> . Therefore when calling java commands in WA2L/edrc this is transparent to the user and the command can be called by simply entering <b>my_command my_options</b> , there is no need to call <b>java java_options my_command my_options</b> as it is normally the case. Using the <b>java_wrapper(1)</b> there is no need to write a start script for each Java program. If a certain Java program needs special options passed to java, those options can be specified in the config file <b>lib/java/filename.class.javaopt</b> or <b>lib/java/filename.jar.javaopt</b> with the <b>JAVA_OPTIONS</b> setting. |
| <b>lib/ksh/</b>               | Korn shell scripts called via <b>ksh_wrapper(1)</b> . In WA2L/edrc Korn shell scripts are not executed via the magic key <b>#!/bin/ksh</b> due to the fact that this is less portable than Bourne shell scripts. Shell locations can be configured in the configuration file <b>ksh_wrapper.cfg</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>lib/logcheckd/</b>         | files used by the <b>logcheckd(1m)</b> when generating LogCheck reports.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>lib/lua/</b>               | Lua scripts called via <b>lua_wrapper(1)</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>lib/lua/lum/</b>           | additional Lua modules used by the Lua scripts/programs started thru the <b>lua_wrapper(1)</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>lib/pack/</b>              | library functions used by <b>pack(1m)</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>lib/perl/</b>              | Perl scripts called via <b>perl_wrapper(1)</b> . In WA2L/edrc Perl scripts are not executed via the magic key <b>#!/usr/bin/perl</b> due to the fact that this startup is dependent on the installation directory of <b>perl(1)</b> , which is not necessarily identical on all systems where WA2L/edrc is installed.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>lib/perl/pm/</b>           | additional Perl modules used by the Perl scripts started thru the <b>perl_wrapper(3)</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>lib/ploticus/</b>          | files read by the ploticus command <b>pl(1)</b> , especially when using the <b>-prefab</b> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

The <i>&lt;Customer&gt;</i> has to be set identical to the value returned by the <b>server_environment -C</b> command.<br>The default EDRC configuration file <b>edrc.sat.cfg</b> points to this directory and is used if you invoke the <b>sat</b> command.                                                                                                                                                                                                                                                                                     |
| <b>scripts/&lt;Customer&gt;-sat/sup:Support/asup:ApplicationSupport/</b>                           | Script tree to be created for Application Support to automate common application operation support tasks for the <i>&lt;Customer&gt;</i> where the system belongs to. The <i>&lt;Customer&gt;</i> has to be set identical to the value returned by the <b>server_environment -C</b> command.<br>The EDRC configuration file <b>edrc.asup.cfg</b> points to this directory and is used if you invoke the <b>asup</b> command.<br><br>The <b>edrc.asup.cfg</b> configures less permissions (editing of menus and menu points etc.) for its users. Because it is a sub-directory of the <b>sat</b> menu tree, it can nevertheless be managed centrally by the user of the <b>sat</b> command. |

**scripts/<Customer>-sat/sup:Support/osup:OperationSupport/**

Script tree to be created for Operation Support to automate common operation support tasks for the <Customer> where the system belongs to. The <Customer> has to be set identical to the value returned by the **server\_environment -C** command.

The EDRC configuration file **edrc.osup.cfg** points to this directory and is used if you invoke the **asup** command.

The **edrc.osup.cfg** configures less permissions (editing of menus and menu points etc.) for its users. Because it is a sub-directory of the **sat** menu tree, it can nevertheless be managed centrally by the user of the **sat** command.

**scripts/<Customer>-sat/sup:Support/psup:ProductionSupport/**

Script tree to be created for Production Support to automate common production support tasks for the <Customer> where the system belongs to. The <Customer> has to be set identical to the value returned by the **server\_environment -C** command.

The EDRC configuration file **edrc.psup.cfg** points to this directory and is used if you invoke the **asup** command.

The **edrc.psup.cfg** configures less permissions (editing of menus and menu points etc.) for its users. Because it is a sub-directory of the **sat** menu tree, it can nevertheless be managed centrally by the user of the **sat** command.

**.sav**

backup directory in a recovery script tree. Whenever a file in **edrc** is edited or removed a backup copy is automatically saved into the **.sav** directory of the current menu (=subdir). Therefore, if you like to restore a file to a prior version, invoke the **shell** command in **edrc**, change to the **.sav** directory and restore the desired file using the normal operating system commands.

**src/**

source code of certain programs.

**var/**

var directory of WA2L/edrc.

**var/backup/**

several backups.

**var/barbedwire/**

**bwcreate**(1m) cache information.

**var/cache/**

cache base directory.

**var/cache/<command>/**

cache directory for a certain <command>.

**var/connection/**

this directory holds connection and security information used for connections to other hosts. See **edrc.cfg**(4) for more information about the currently possible *DIST\_MODE* settings and **edrc**(1m), **remote\_copy**(3) and **remote\_shell**(3) for a more detailed description of the **var/connection** directory.

|                                    |                                                                                                                                                                                                                                                                         |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>var/contrib/edrc/</b>           | var directory for contributed commands to <b>edrc</b> . See <b>edrc(1m)</b> for information how to use this directory.                                                                                                                                                  |
| <b>var/csv2worksheet/</b>          | template spreadsheet files for the <b>csv2worksheet(1m)</b> command.                                                                                                                                                                                                    |
| <b>var/dns/&lt;dns-server&gt;/</b> | var directory of DNS server(s) bundled with the WA2L/edrc package.                                                                                                                                                                                                      |
| <b>var/edrcinit/</b>               | persistent data of <b>edrcinit(1m)</b> .                                                                                                                                                                                                                                |
| <b>var/fonts/</b>                  | additional fonts.                                                                                                                                                                                                                                                       |
| <b>var/locate/</b>                 | databases for the <b>locate(1)</b> command.                                                                                                                                                                                                                             |
| <b>var/lock/</b>                   | lockfiles. Do not edit them by hand.                                                                                                                                                                                                                                    |
| <b>var/log/</b>                    | all logfiles of the EDRC environment. Here the logfile of <b>edrc</b> and the output of all recovery scripts is saved. Therefore customizing scripts don't have to implement an own logging mechanism. All output sent to stdout will be saved in a designated logfile. |
| <b>var/logcheckd/</b>              | collect, report, state and pattern information used and written by the <b>logcheckd(1m)</b> command.                                                                                                                                                                    |
| <b>var/lots/</b>                   | default var directory of <b>lots(1m)</b> .                                                                                                                                                                                                                              |
| <b>var/makeuser/classes/</b>       | this directory contains example user classes files used by <b>makeuser</b> .                                                                                                                                                                                            |
| <b>var/manvi/</b>                  | manual page templates for <b>manvi(1)</b> .                                                                                                                                                                                                                             |
| <b>var/notes/</b>                  | free text notes. The contents of this directory is excluded from the package.                                                                                                                                                                                           |
| <b>var/omniutil/pd/</b>            | this directory contains the OBII Oracle pointer directory structure templates.                                                                                                                                                                                          |
| <b>var/pack/</b>                   | state information for <b>pack</b> . Do not edit it by hand.                                                                                                                                                                                                             |
| <b>var/passwdsyncd/</b>            | default spool directory for the password sync daemon <b>passwdsyncd</b> .                                                                                                                                                                                               |
| <b>var/pscount/</b>                | process reference information used by the <b>pscount(3)</b> command.                                                                                                                                                                                                    |
| <b>var/repl/</b>                   | this directory is used to save scripts replicated with the <b>distribute</b> EDRC command.                                                                                                                                                                              |
| <b>var/samples/</b>                | this directory contains configuration samples for reference and inspiration.                                                                                                                                                                                            |
| <b>var/settings/</b>               | persistent settings.                                                                                                                                                                                                                                                    |

|                                            |                                                                                                                                                         |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>var/shell/</b>                          | here the shell history of the interactive shell built in to <b>edrc</b> and the history of <b>edrc</b> are kept.                                        |
| <b>var/spool/</b>                          | spool directories for <b>crond</b> (3).                                                                                                                 |
| <b>var/sw/</b>                             | directory to <b>pack</b> (1m) the WA2L/edrc package to or to store delivered WA2L/edrc patches. The content of this directory is excluded from packing. |
| <b>var/sysconfig/development.acme.com/</b> | in this directory a template directory structure used for <b>sysconfig</b> is saved.                                                                    |
| <b>var/tmp/</b>                            | temporary files to be kept within the application.                                                                                                      |
| <b>var/trash/</b>                          | default 'Recycle Bin' directory for <b>trash</b> and the related commands.                                                                              |
| <b>var/vsav/</b>                           | directory to save versions of a file by <b>vsav</b> and related commands to it.                                                                         |
| <b>var/www/</b>                            | web files for <b>thttpd</b> (3) web server.                                                                                                             |

## NOTES

Many thanks to Stefan Huber (EDS, Information Business GmbH, Switzerland). The OmniBack recovery scripts used in the disaster recovery project in 2003 were based on his excellent knowledge of HP-DataProtector (OmniBack).

Special thanks to Reimund Mueller (EDS, Information Business GmbH, Switzerland), who acted as editor of the "1 / Allgemein" part of the "Emergency Handbook" in his leisure time.

The WA2L/edrc package came into being during a disaster recovery project realized for an insurance company in Switzerland in 2003. A huge portion of the WA2L/edrc package has been developed by the author Christian Walther <wa2l@users.sourceforge.net> in his leisure time.

Now in 2023 the WA2L/edrc has a lifespan of 20 years; it turns out that it is still useful for new disaster recovery solutions and system administration simplification.

The source of the commands **sav(1)**, **homedir(3)**, **mkuser(3)**, **woist(1)** and **pid(1)** is the **SFI-Director**.

The following commands were inspired by the **SFI-Director**: **osid(3)**, **nologin(1)** and **sysconfig(1)**. The **SFI-Director**, was an excellent (GPL) toolset for managing NIS and NIS++, distributing software over several Unix/Linux flavors, central user profile management, configuring and documenting systems and much more developed by Peter Stevens. Unlike many other script based tools all commands were realized as very reliable and stable shell scripts and demonstrated by example that it is possible to implement reliable and portable applications as shell scripts. All commands and files of the **SFI Director** were well documented. The sources of the script based **SFI-Director** are no longer available online.

Check out other WA2L projects on Sourceforge: <https://sourceforge.net/u/wa2l/profile/>.

## BUGS

Bugs and limitations are generally documented in the related manual pages.

## AUTHOR

WA2L/edrc was developed by Christian Walther. Send suggestions and bug reports to [wa2l@users.sourceforge.net](mailto:wa2l@users.sourceforge.net).

**NAME**

ansi2txt – Translates vt100 codes into readable text (or html)

**SYNOPSIS**

**ansi2txt** [OPTION] [INPUT FILE]

**DESCRIPTION**

Ansi2txt converts a stream of vt100 (ansi) codes on the stdin into readable text on the stdout. An INPUT file can be specified instead of stdin.

Ansi2html (ansi2txt -html) renders the vt100 codes into a html file that looks quite a lot like your terminal did.

**OPTIONS****-w WIDTH**

If specified the output rendering screen will be limited to WIDTH characters wide.

**-h HEIGHT**

If specified the output rendering screen will be limited to HEIGHT character rows, overflow will overprint.

**-rv** Reverse video

**-html** Output as html

**-txt** Output as text

**-refresh secs**

In html mode add <meta http-equiv="refresh" content="secs"> to <head>

**-v** Version

**--help** Displays usage information

**BUGS**

Double height text in html mode only renders the top row, the bottom double height text row is not rendered. Double width is rendered as ordinary characters separated by spaces. Scrolling windows are not implemented.

**NAME**

appendpdf – Append one PDF to another

**SYNOPSIS**

```
appendpdf [options] file1.pdf file2.pdf [outfile.pdf]
```

**Options:**

|              |                                               |
|--------------|-----------------------------------------------|
| -p --prepend | prepend the document instead of appending it  |
| -f --forms   | wipe all forms and annotations from the PDF   |
| -o --order   | preserve the internal PDF ordering for output |
| -v --verbose | print diagnostic messages                     |
| -h --help    | verbose help message                          |
| -V --version | print CAM::PDF version                        |

**DESCRIPTION**

Copy the contents of file2.pdf to the end of file1.pdf. This may break complex PDFs which include forms, so the --forms option is provided to eliminate those elements from the resulting PDF.

**SEE ALSO**

CAM::PDF

*deletepdfpage.pl*

**AUTHOR**

See CAM::PDF

**NAME**

apply2file – apply data stream to file

**SYNOPSIS**

**edrc/bin/apply2file** [ **-h** ]

**apply2file** [ **-o** ] [ **-s** ] [ **-u** *user* ] [ **-g** *group* ] [ **-p** *perm* ] **-f** *target\_file*

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

Apply a data stream provided via pipe to a target file. The target file is untouched if the data stream does not differ from the target file. This is useful to edit files or to generate files which are system dependent.

**OPTIONS**

- h**           usage message.
- o**           if target file exists, preserve target file permissions. In this case the options **-u**, **-g** and **-p** are ignored.
- s**           save the target file prior to the applying of the data stream. To save the target file the **sav(1)** command is used internally.
- u** *user*     username or UID of the target file.
- g** *group*    groupname or GID of the target file.
- p** *perm*     filepermissions of the target file.
- f** *target\_file*  
              target file where to install the stream.

**EXIT STATUS**

- 0**           no error.
- 2**           operating system not supported, see **osid(3)**
- 4**           usage displayed.

- 5 the data is identical with the existing file and the data stream is not applied to the target file.
- 6 **apply2file** could not write to the target file.

## FILES

-

## EXAMPLES

- 1) write system information to /etc/issue

```
{
 echo
 host=`hostname`
 banner $host
 echo
 uname -rsm
 echo
} | \
apply2file -o -u root -g root -p 640 \
-f /etc/issue
```

- 2) enable the startup of a daemon (samba in this case)

```
cat /etc/rc.config.d/samba | \
sed -e 's/RUN_SAMBA=.* /RUN_SAMBA=1/g' | \
apply2file -o -f /etc/rc.config.d/samba
```

## SEE ALSO

**edrcintro(1)**, **sav(1)**, **chmod(1)**, **chown(1)**

## NOTES

**apply2file** should be used in **pre\_exec** and **post\_exec** scripts of **sysconfig** to avoid altering of system files if not needed.

## BUGS

-

**AUTHOR**

apply2file was developed by Christian Walther. Send suggestions and bug reports to [wa2l@users.sourceforge.net](mailto:wa2l@users.sourceforge.net).

**COPYRIGHT**

Copyright © 2010 Christian Walther

**NAME**

apply2sw\_inventory – apply data stream with named swvi fields to software inventory file

**SYNOPSIS**

edrc/bin/apply2sw\_inventory [ **-h** ]

apply2sw\_inventory [ **-d** *output\_dir* ] [ **-r** ]

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

This is the scripting frontend to the interactive **swvi** command.

With **apply2sw\_inventory** it is possible to automatically update a software inventory file in a install script without the need to enter the software inventory information by hand using the **swvi** command or to write directly to the **..sw\_inventory** file which format might change in future releases.

For more information about the software inventory creation and maintenance see **swvi**(1) and **sw\_report**(1).

As in the **swvi** command, only the entries for **SOFTWARE**, **VERSION**, **INST\_USER** and **INST\_GROUP** are compulsory. The sequence of the entries provided is not significant. For a complete list and description of all entries see **swvi**(1).

See section **EXAMPLES** for common usages of **apply2sw\_inventory** in an install script.

**OPTIONS**

**-h**           usage message.

**-d** *output\_dir*  
directory where the software inventory is modified.

**-r**           remove (clear) contents of an eventually existing inventory file. This option equals to the **-r** option of **swvi**. If not specified the software specification provided is appended (equals to **swvi -a**) to the software inventory file.

**ENVIRONMENT**

-

**EXIT STATUS**

|          |                                                               |
|----------|---------------------------------------------------------------|
| <b>0</b> | no error.                                                     |
| <b>1</b> | software inventory not modified.                              |
| <b>2</b> | operating system not supported, see <b>osid(3)</b> .          |
| <b>3</b> | cannot write to the <i>output_dir</i> directory.              |
| <b>4</b> | usage displayed.                                              |
| <b>5</b> | the command has been aborted pressing <i>Ctrl+C</i> .         |
| <b>6</b> | <b>apply2sw_inventory</b> could not write to the target file. |

**FILES****..sw\_inventory**

software inventory file. This file contains the software information (version, name, ...) for a software installed into a certain directory and is used to create a software inventory with the **sw\_report(1)** command.

**EXAMPLES**

- 1) Install script for automated installation of WA2L/edrc having an interactive install procedure

This are the major parts of a simplified installation script to give an idea of updating/creating the software inventory file without manual intervention.

This installation script installs WA2L/edrc that is available in the package file **/dat/sw/apps/edrc-1.5.02/edrc-1.5.02-20070428.sh** to the installation directory **/opt**. All manual input queried by the shell archive **edrc-1.5.02-20070428.sh** is provided via input redirection. After that the software inventory file is updated using **apply2sw\_inventory**. Because in this case WA2L/edrc is the only software in the installation directory the probably existing software inventory file is cleared using the **-r** option ahead of writing to it.

```
#!/bin/sh
#
My_INSTALL - My Install Script for: EDRC Shell archive
#
[00] 21.09.2005 CWa Initial Version
#

Const
PATH=$PATH:~edrc/bin ; export PATH

## 2) Install script of the GNU C compilers using a HP-UX depot

This are the major parts of a simplified installation script to give an idea of updating/creating the software inventory file without manual intervention.

This installation script installs the GNU C compilers that are available in the HP-UX depot file **/dat/sw/apps/gcc-3.3.2/gcc-3.3.2-hppa-11.11.depot.gz** to the installation directory **/usr/local**. The installation is performed with the **swinstall** command of HP-UX. After that the software inventory file is updated using **apply2sw\_inventory**. Due to the fact that in **/usr/local** often many different software are installed the most likely existing software inventory should not be cleared ahead of writing to it. That's why **apply2sw\_inventory** is called without the remove (clear) option.

```

#!/bin/sh
#
My_INSTALL - My Install Script for: GNU C Compiler
#
[00] 21.09.2005 CWa Initial Version

## NAME

approot – print the root of the WA2L/edrc installation

## SYNOPSIS

**edrc/lib/approot**

## AVAILABILITY

WA2L/edrc

## DESCRIPTION

With **approot** the root of the WA2L/edrc software installation is printed. This command is used inside the command to evaluate the basedir.

## EXIT STATUS

**0** always

## SEE ALSO

**edrcintro(1)**, **edrcroot(3)**

## NOTES

**approot** will replace **edrcroot** completely as soon as all commands has been migrated to use **approot** instead of **edrcroot**.

## BUGS

-

## AUTHOR

approot was developed by Christian Walther. Send suggestions and bug reports to [wa2l@users.sourceforge.net](mailto:wa2l@users.sourceforge.net).

## NAME

apprevision – return (version) revision number of WA2L/edrc

## SYNOPSIS

**edrc/lib/apprevision**

## AVAILABILITY

WA2L/edrc

## DESCRIPTION

The **apprevision** program returns the revision number of the WA2L/edrc package.

The output is identical to **sat -V** and **edrc -V**, but the response is much faster. The exit codes and the error messages of **apprevision** is identical to the calls of **sat -V** and **edrc -V**.

## OPTIONS

-

## ENVIRONMENT

-

## EXIT STATUS

**3** version printed.

**9** the **edrcrevision.cfg** file is missing or the **VERSION** or **PATCHLEVEL** options within this file are not set properly.

## FILES

**etc/edrcrevision.cfg**

configuration file which holds the current version and patchlevel of EDRC. See **edrcrevision.cfg(4)** for more information.

## EXAMPLES

**NAME**

apropos – search the whatis database for strings

**SYNOPSIS**

**edrc/bin/apropos** *keyword* ...

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

**apropos** searches a set of database files containing short descriptions of system commands for keywords and displays the result on the standard output.

**OPTIONS**

**keyword** keyword to be searched.

**FILES**

**whatis** whatis databases in the \$MANPATH.

**SEE ALSO**

**edrcintro(1)**, **edrcman(1)**, **man(1)**, **whatis(1)**

**NOTES**

Parts of this manpage were extracted from the documentation of the apropos man page written by John W. Eaton and modified to fit into WA2L/edrc package.

**BUGS**

-

**AUTHOR**

apropos was developed by John W. Eaton, <jwe@che.utexas.edu>, Department of Chemical Engineering, The University of Texas at Austin, Austin Texas 78712 and integrated into WA2L/edrc by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net .

**NAME**

ascii – ASCII character set encoded in octal, decimal, and hexadecimal

**DESCRIPTION**

ASCII is the American Standard Code for Information Interchange. It is a 7-bit code. Many 8-bit codes (e.g., ISO 8859-1) contain ASCII as their lower half. The international counterpart of ASCII is known as ISO 646-IRV.

The following table contains the 128 ASCII characters.

C program '\x' escapes are noted.

| Oct | Dec | Hex | Char                      | Oct | Dec | Hex | Char   |
|-----|-----|-----|---------------------------|-----|-----|-----|--------|
| 000 | 0   | 00  | NUL '\0' (null character) | 100 | 64  | 40  | @      |
| 001 | 1   | 01  | SOH (start of heading)    | 101 | 65  | 41  | A      |
| 002 | 2   | 02  | STX (start of text)       | 102 | 66  | 42  | B      |
| 003 | 3   | 03  | ETX (end of text)         | 103 | 67  | 43  | C      |
| 004 | 4   | 04  | EOT (end of transmission) | 104 | 68  | 44  | D      |
| 005 | 5   | 05  | ENQ (enquiry)             | 105 | 69  | 45  | E      |
| 006 | 6   | 06  | ACK (acknowledge)         | 106 | 70  | 46  | F      |
| 007 | 7   | 07  | BEL '\a' (bell)           | 107 | 71  | 47  | G      |
| 010 | 8   | 08  | BS '\b' (backspace)       | 110 | 72  | 48  | H      |
| 011 | 9   | 09  | HT '\t' (horizontal tab)  | 111 | 73  | 49  | I      |
| 012 | 10  | 0A  | LF '\n' (new line)        | 112 | 74  | 4A  | J      |
| 013 | 11  | 0B  | VT '\v' (vertical tab)    | 113 | 75  | 4B  | K      |
| 014 | 12  | 0C  | FF '\f' (form feed)       | 114 | 76  | 4C  | L      |
| 015 | 13  | 0D  | CR '\r' (carriage ret)    | 115 | 77  | 4D  | M      |
| 016 | 14  | 0E  | SO (shift out)            | 116 | 78  | 4E  | N      |
| 017 | 15  | 0F  | SI (shift in)             | 117 | 79  | 4F  | O      |
| 020 | 16  | 10  | DLE (data link escape)    | 120 | 80  | 50  | P      |
| 021 | 17  | 11  | DC1 (device control 1)    | 121 | 81  | 51  | Q      |
| 022 | 18  | 12  | DC2 (device control 2)    | 122 | 82  | 52  | R      |
| 023 | 19  | 13  | DC3 (device control 3)    | 123 | 83  | 53  | S      |

## NOTES

### History

An **ascii** manual page appeared in Version 7 of AT&T UNIX.

On older terminals, the underscore code is displayed as a left arrow, called backarrow, the caret is displayed as an up-arrow and the vertical bar has a hole in the middle.

Uppercase and lowercase characters differ by just one bit and the ASCII character 2 differs from the double quote by just one bit, too. That made it much easier to encode characters mechanically or with a non-microcontroller-based electronic keyboard and that pairing was found on old teletypes.

The ASCII standard was published by the United States of America Standards Institute (USASI) in 1968.

**COLOPHON**

This page is part of release 4.15 of the Linux *man-pages* project. A description of the project, information about reporting bugs, and the latest version of this page, can be found at <https://www.kernel.org/doc/man-pages/>.

**NAME**

asup – start edrc with a special Application Support configuration

**SYNOPSIS**

**edrc/bin/asup** [ **-h** | **-V** ]

**asup** [ **-s** ] [ **-t** ]

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

Short start of **edrc** with an other configuration which points to an own script tree. Internally **asup** calls **edrc -c edrc.asup.cfg -n ASUP\_@ID@** .

**asup** stands for "Application SUPport".

The session name (as shown in the menu) is automatically set to **ASUP\_<id>** . Where **<id>** is the process id of the started **edrc** instance if not already a session with the same name exists, if so the **<id>** is set to a random number.

If additional short starts are needed, create a symlink from the new short start command to **sat** ( see section **EXAMPLES** ).

**OPTIONS**

**-h**           usage message.

**-V**           print version and patch level of **edrc**. For an explanation of the release numbering system see **edrcrevision(1)**.

**-s**           silent startup. Startup without showing the EDRC banner.

**-t**           no terminal initialization. Sometimes the terminal initialization causes unwanted behavior. To skip terminal initialization, invoke **edrc** with this option.

**ENVIRONMENT**

-

**EXIT STATUS**

see **edrc**(1m).

**FILES**

**etc/edrc.asup.cfg**

configuration file of **asup**, see **edrc.cfg**(4) for more information.

Other files see section **FILES** in **edrc**(1m).

**EXAMPLES****1) create a new short start**

This creates a new short start command **new\_shortstart** that will load the configuration file **edrc.new\_shortstart.cfg**. The session name will automatically be set to **NEW\_SHORTSTART\_<id>** .

```
[/root]
[root@rh7mzv7t001] [bash]: cd ~edrc/bin

[/opt/edrc/bin]
[root@rh7mzv7t001] [bash]: ln -s sat new_shortstart
```

**NAME**

awk – pattern-directed scanning and processing language

**SYNOPSIS**

**awk** [ **-F** *fs* ] [ **-v** *var=value* ] [ '*prog*' | **-f** *progfile* ] [ *file* ... ]

**DESCRIPTION**

*Awk* scans each input *file* for lines that match any of a set of patterns specified literally in *prog* or in one or more files specified as **-f** *progfile*. With each pattern there can be an associated action that will be performed when a line of a *file* matches the pattern. Each line is matched against the pattern portion of every pattern-action statement; the associated action is performed for each matched pattern. The file name **-** means the standard input. Any *file* of the form *var=value* is treated as an assignment, not a filename, and is executed at the time it would have been opened if it were a filename. The option **-v** followed by *var=value* is an assignment to be done before *prog* is executed; any number of **-v** options may be present. The **-F** *fs* option defines the input field separator to be the regular expression *fs*.

An input line is normally made up of fields separated by white space, or by regular expression **FS**. The fields are denoted **\$1**, **\$2**, ..., while **\$0** refers to the entire line. If **FS** is null, the input line is split into one field per character.

A pattern-action statement has the form

```
pattern { action }
```

A missing { *action* } means print the line; a missing pattern always matches. Pattern-action statements are separated by newlines or semicolons.

An action is a sequence of statements. A statement can be one of the following:

```
if(expression) statement [else statement]
while(expression) statement
for(expression ; expression ; expression) statement
for(var in array) statement
do statement while(expression)
break
continue
{ [statement ...] }
expression # commonly var = expression
print [expression-list] [> expression]
printf format [, expression-list] [> expression]
return [expression]
next # skip remaining patterns on this input line
nextfile # skip rest of this file, open next, start at top
delete array[expression] # delete an array element
delete array # delete all elements of array
exit [expression] # exit immediately; status is expression
```

Statements are terminated by semicolons, newlines or right braces. An empty *expression-list* stands for **\$0**. String constants are quoted " ", with the usual C escapes recognized within. Expressions take on string or numeric values as appropriate, and are built using the operators + - \* / % ^ (exponentiation), and concatenation (indicated by white space). The operators ! ++ -- += -= \*= /= %= ^= > >= < <= == != ?: are also available in expressions. Variables may be scalars, array elements (denoted *x[i]*) or fields. Variables are initialized to the null string. Array subscripts may be any string, not necessarily numeric; this allows for a form of associative memory. Multiple subscripts such as [*i,j,k*] are permitted; the constituents are concatenated, separated by the value of **SUBSEP**.

The **print** statement prints its arguments on the standard output (or on a file if **>file** or **>>file** is present or on a pipe if **|cmd** is present), separated by the current output field separator, and terminated by the output record separator. *file* and *cmd* may be literal names or parenthesized expressions; identical string values in different statements denote the same open file. The **printf** statement formats its expression list according to

the format (see *printf*(3)). The built-in function **close**(*expr*) closes the file or pipe *expr*. The built-in function **fflush**(*expr*) flushes any buffered output for the file or pipe *expr*.

The mathematical functions **exp**, **log**, **sqrt**, **sin**, **cos**, and **atan2** are built in. Other built-in functions:

**length** the length of its argument taken as a string, or of **\$0** if no argument.

**rand** random number on (0,1)

**srand** sets seed for **rand** and returns the previous seed.

**int** truncates to an integer value

**substr**(*s, m, n*)

the *n*-character substring of *s* that begins at position *m* counted from 1.

**index**(*s, t*)

the position in *s* where the string *t* occurs, or 0 if it does not.

**match**(*s, r*)

the position in *s* where the regular expression *r* occurs, or 0 if it does not. The variables **RSTART** and **RLENGTH** are set to the position and length of the matched string.

**split**(*s, a, fs*)

splits the string *s* into array elements *a*[1], *a*[2], ..., *a*[*n*], and returns *n*. The separation is done with the regular expression *fs* or with the field separator **FS** if *fs* is not given. An empty string as field separator splits the string into one array element per character.

**sub**(*r, t, s*)

substitutes *t* for the first occurrence of the regular expression *r* in the string *s*. If *s* is not given, **\$0** is used.

**gsub** same as **sub** except that all occurrences of the regular expression are replaced; **sub** and **gsub** return the number of replacements.

**sprintf**(*fmt, expr, ...*)

the string resulting from formatting *expr ...* according to the *printf*(3) format *fmt*

**system**(*cmd*)

executes *cmd* and returns its exit status

**tolower**(*str*)

returns a copy of *str* with all upper-case characters translated to their corresponding lower-case equivalents.

**toupper**(*str*)

returns a copy of *str* with all lower-case characters translated to their corresponding upper-case equivalents.

The “function” **getline** sets **\$0** to the next input record from the current input file; **getline <file** sets **\$0** to the next record from *file*. **getline x** sets variable *x* instead. Finally, *cmd* | **getline** pipes the output of *cmd* into **getline**; each call of **getline** returns the next line of output from *cmd*. In all cases, **getline** returns 1 for a successful input, 0 for end of file, and -1 for an error.

Patterns are arbitrary Boolean combinations (with **!**, **||**, and **&&**) of regular expressions and relational expressions. Regular expressions are as in *egrep*; see *grep*(1). Isolated regular expressions in a pattern apply to the entire line. Regular expressions may also occur in relational expressions, using the operators **~** and **!~**. */rel* is a constant regular expression; any string (constant or variable) may be used as a regular expression, except in the position of an isolated regular expression in a pattern.

A pattern may consist of two patterns separated by a comma; in this case, the action is performed for all lines from an occurrence of the first pattern though an occurrence of the second.

A relational expression is one of the following:

*expression matchop regular-expression*  
*expression relop expression*  
*expression in array-name*  
*(expr,expr,...) in array-name*

where a relop is any of the six relational operators in C, and a matchop is either ~ (matches) or !~ (does not match). A conditional is an arithmetic expression, a relational expression, or a Boolean combination of these.

The special patterns **BEGIN** and **END** may be used to capture control before the first input line is read and after the last. **BEGIN** and **END** do not combine with other patterns.

Variable names with special meanings:

#### **CONVFMT**

conversion format used when converting numbers (default **%.6g**)

**FS** regular expression used to separate fields; also settable by option **-Ffs**.

**NF** number of fields in the current record

**NR** ordinal number of the current record

**FNR** ordinal number of the current record in the current file

#### **FILENAME**

the name of the current input file

**RS** input record separator (default newline)

**OFS** output field separator (default blank)

**ORS** output record separator (default newline)

**OFMT** output format for numbers (default **%.6g**)

#### **SUBSEP**

separates multiple subscripts (default 034)

**ARGC** argument count, assignable

**ARGV** argument array, assignable; non-null members are taken as filenames

#### **ENVIRON**

array of environment variables; subscripts are names.

Functions may be defined (at the position of a pattern-action statement) thus:

**function foo(a, b, c) { ...; return x }**

Parameters are passed by value if scalar and by reference if array name; functions may be called recursively. Parameters are local to the function; all other variables are global. Thus local variables may be created by providing excess parameters in the function definition.

#### **EXAMPLES**

```
length($0) > 72
 Print lines longer than 72 characters.

{ print $2, $1 }
 Print first two fields in opposite order.

BEGIN { FS = ", [\t]* | [\t]+" }
 { print $2, $1 }
 Same, with input fields separated by comma and/or blanks and tabs.

 { s += $1 }

END { print "sum is", s, " average is", s/NR }
 Add up first column, print sum and average.
```

```
/start/, /stop/
```

Print all lines between start/stop pairs.

```
BEGIN { # Simulate echo(1)
 for (i = 1; i < ARGV; i++) printf "%s ", ARGV[i]
 printf "\n"
 exit }
```

## BUGS

There are no explicit conversions between numbers and strings. To force an expression to be treated as a number add 0 to it; to force it to be treated as a string concatenate "" to it.

The scope rules for variables in functions are a botch; the syntax is worse.

**NAME**

banner – make posters in large letters

**SYNOPSIS**

**edrc/lib/banner** "*strings*"

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

**banner** prints its arguments (each with a maximum of 10 characters) in large letters to **stdout** .

Each argument is printed on a separate line. Note that multiple-word strings must be enclosed in quotes in order to be printed on the same line.

**OPTIONS**

usage message.

"*a string*" string to be printed in large letters. The qotes are only needed when a multiple word string has to be printed on the same output line.

**ENVIRONMENT**

-

**EXIT STATUS**

**0** no error.

**4** usage displayed.

**FILES**

-

**EXAMPLES**

-

**SEE ALSO**

**NAME**

**bash** – GNU Bourne-Again SHell

**SYNOPSIS**

**bash** [options] [file]

**COPYRIGHT**

Bash is Copyright © 1989-2005 by the Free Software Foundation, Inc.

**DESCRIPTION**

**Bash** is an **sh**-compatible command language interpreter that executes commands read from the standard input or from a file. **Bash** also incorporates useful features from the *Korn* and *C* shells (**ksh** and **csh**).

**Bash** is intended to be a conformant implementation of the Shell and Utilities portion of the IEEE POSIX specification (IEEE Standard 1003.1). **Bash** can be configured to be POSIX-conformant by default.

**OPTIONS**

In addition to the single-character shell options documented in the description of the **set** builtin command, **bash** interprets the following options when it is invoked:

- c** *string* If the **-c** option is present, then commands are read from *string*. If there are arguments after the *string*, they are assigned to the positional parameters, starting with **\$0**.
- i** If the **-i** option is present, the shell is *interactive*.
- l** Make **bash** act as if it had been invoked as a login shell (see **INVOCATION** below).
- r** If the **-r** option is present, the shell becomes *restricted* (see **RESTRICTED SHELL** below).
- s** If the **-s** option is present, or if no arguments remain after option processing, then commands are read from the standard input. This option allows the positional parameters to be set when invoking an interactive shell.
- v** Print shell input lines as they are read.
- x** Print commands and their arguments as they are executed.
- D** A list of all double-quoted strings preceded by **\$** is printed on the standard output. These are the strings that are subject to language translation when the current locale is not **C** or **POSIX**. This implies the **-n** option; no commands will be executed.
- [+O]** *[shopt\_option]*  
*shopt\_option* is one of the shell options accepted by the **shopt** builtin (see **SHELL BUILTIN COMMANDS** below). If *shopt\_option* is present, **-O** sets the value of that option; **+O** unsets it. If *shopt\_option* is not supplied, the names and values of the shell options accepted by **shopt** are printed on the standard output. If the invocation option is **+O**, the output is displayed in a format that may be reused as input.
- A **--** signals the end of options and disables further option processing. Any arguments after the **--** are treated as filenames and arguments. An argument of **-** is equivalent to **--**.

**Bash** also interprets a number of multi-character options. These options must appear on the command line before the single-character options to be recognized.

**--debugger**

Arrange for the debugger profile to be executed before the shell starts. Turns on extended debugging mode (see the description of the **extdebug** option to the **shopt** builtin below) and shell function tracing (see the description of the **-o functrace** option to the **set** builtin below).

**--dump-po-strings**

Equivalent to **-D**, but the output is in the GNU *gettext* **po** (portable object) file format.

**--dump-strings**

Equivalent to **-D**.

**--help** Display a usage message on standard output and exit successfully.

**--init-file** *file***--rcfile** *file*

Execute commands from *file* instead of the standard personal initialization file *~/.bashrc* if the shell is interactive (see **INVOCATION** below).

**--login**

Equivalent to **-l**.

**--noediting**

Do not use the GNU **readline** library to read command lines when the shell is interactive.

**--noprofile**

Do not read either the system-wide startup file */etc/profile* or any of the personal initialization files *~/.bash\_profile*, *~/.bash\_login*, or *~/.profile*. By default, **bash** reads these files when it is invoked as a login shell (see **INVOCATION** below).

**--norc**

Do not read and execute the personal initialization file *~/.bashrc* if the shell is interactive. This option is on by default if the shell is invoked as **sh**.

**--posix**

Change the behavior of **bash** where the default operation differs from the POSIX standard to match the standard (*posix mode*).

**--restricted**

The shell becomes restricted (see **RESTRICTED SHELL** below).

**--verbose**

Equivalent to **-v**.

**--version**

Show version information for this instance of **bash** on the standard output and exit successfully.

**ARGUMENTS**

If arguments remain after option processing, and neither the **-c** nor the **-s** option has been supplied, the first argument is assumed to be the name of a file containing shell commands. If **bash** is invoked in this fashion, **\$0** is set to the name of the file, and the positional parameters are set to the remaining arguments. **Bash** reads and executes commands from this file, then exits. **Bash**'s exit status is the exit status of the last command executed in the script. If no commands are executed, the exit status is 0. An attempt is first made to open the file in the current directory, and, if no file is found, then the shell searches the directories in **PATH** for the script.

**INVOCATION**

A *login shell* is one whose first character of argument zero is a **-**, or one started with the **--login** option.

An *interactive* shell is one started without non-option arguments and without the **-c** option whose standard input and error are both connected to terminals (as determined by *isatty(3)*), or one started with the **-i** option. **PS1** is set and **\$-** includes **i** if **bash** is interactive, allowing a shell script or a startup file to test this state.

The following paragraphs describe how **bash** executes its startup files. If any of the files exist but cannot be read, **bash** reports an error. Tildes are expanded in file names as described below under **Tilde Expansion** in the **EXPANSION** section.

When **bash** is invoked as an interactive login shell, or as a non-interactive shell with the **--login** option, it first reads and executes commands from the file */etc/profile*, if that file exists. After reading that file, it looks for *~/.bash\_profile*, *~/.bash\_login*, and *~/.profile*, in that order, and reads and executes commands from the first one that exists and is readable. The **--noprofile** option may be used when the shell is started to inhibit this behavior.

When a login shell exits, **bash** reads and executes commands from the file *~/.bash\_logout*, if it exists.

When an interactive shell that is not a login shell is started, **bash** reads and executes commands from *~/.bashrc*, if that file exists. This may be inhibited by using the **--norc** option. The **--rcfile file** option will force **bash** to read and execute commands from *file* instead of *~/.bashrc*.

When **bash** is started non-interactively, to run a shell script, for example, it looks for the variable **BASH\_ENV** in the environment, expands its value if it appears there, and uses the expanded value as the name of a file to read and execute. **Bash** behaves as if the following command were executed:

```
if [-n "$BASH_ENV"]; then . "$BASH_ENV"; fi
```

but the value of the **PATH** variable is not used to search for the file name.

If **bash** is invoked with the name **sh**, it tries to mimic the startup behavior of historical versions of **sh** as closely as possible, while conforming to the POSIX standard as well. When invoked as an interactive login shell, or a non-interactive shell with the **--login** option, it first attempts to read and execute commands from */etc/profile* and *~/.profile*, in that order. The **--noprofile** option may be used to inhibit this behavior. When invoked as an interactive shell with the name **sh**, **bash** looks for the variable **ENV**, expands its value if it is defined, and uses the expanded value as the name of a file to read and execute. Since a shell invoked as **sh** does not attempt to read and execute commands from any other startup files, the **--rcfile** option has no effect. A non-interactive shell invoked with the name **sh** does not attempt to read any other startup files. When invoked as **sh**, **bash** enters *posix* mode after the startup files are read.

When **bash** is started in *posix* mode, as with the **--posix** command line option, it follows the POSIX standard for startup files. In this mode, interactive shells expand the **ENV** variable and commands are read and executed from the file whose name is the expanded value. No other startup files are read.

**Bash** attempts to determine when it is being run by the remote shell daemon, usually *rshd*. If **bash** determines it is being run by *rshd*, it reads and executes commands from *~/.bashrc*, if that file exists and is readable. It will not do this if invoked as **sh**. The **--norc** option may be used to inhibit this behavior, and the **--rcfile** option may be used to force another file to be read, but *rshd* does not generally invoke the shell with those options or allow them to be specified.

If the shell is started with the effective user (group) id not equal to the real user (group) id, and the **-p** option is not supplied, no startup files are read, shell functions are not inherited from the environment, the **SHELLOPTS** variable, if it appears in the environment, is ignored, and the effective user id is set to the real user id. If the **-p** option is supplied at invocation, the startup behavior is the same, but the effective user id is not reset.

## DEFINITIONS

The following definitions are used throughout the rest of this document.

**blank** A space or tab.

**word** A sequence of characters considered as a single unit by the shell. Also known as a **token**.

**name** A *word* consisting only of alphanumeric characters and underscores, and beginning with an alphabetic character or an underscore. Also referred to as an **identifier**.

**metacharacter**

A character that, when unquoted, separates words. One of the following:

| & ; ( ) < > space tab

**control operator**

A *token* that performs a control function. It is one of the following symbols:

|| & && ; ; ( ) | <newline>

## RESERVED WORDS

*Reserved words* are words that have a special meaning to the shell. The following words are recognized as reserved when unquoted and either the first word of a simple command (see **SHELL GRAMMAR** below) or the third word of a **case** or **for** command:

! case do done elif else esac fi for function if in select then until  
while { } time [[ ]]

## SHELL GRAMMAR

### Simple Commands

A *simple command* is a sequence of optional variable assignments followed by **blank**-separated words and redirections, and terminated by a *control operator*. The first word specifies the command to be executed, and is passed as argument zero. The remaining words are passed as arguments to the invoked command.

The return value of a *simple command* is its exit status, or 128+*n* if the command is terminated by signal *n*.

## Pipelines

A *pipeline* is a sequence of one or more commands separated by the character `|`. The format for a pipeline is:

```
[time [-p]] [!] command [| command2 ...]
```

The standard output of *command* is connected via a pipe to the standard input of *command2*. This connection is performed before any redirections specified by the command (see **REDIRECTION** below).

The return status of a pipeline is the exit status of the last command, unless the **pipefail** option is enabled. If **pipefail** is enabled, the pipeline's return status is the value of the last (rightmost) command to exit with a non-zero status, or zero if all commands exit successfully. If the reserved word **!** precedes a pipeline, the exit status of that pipeline is the logical negation of the exit status as described above. The shell waits for all commands in the pipeline to terminate before returning a value.

If the **time** reserved word precedes a pipeline, the elapsed as well as user and system time consumed by its execution are reported when the pipeline terminates. The **-p** option changes the output format to that specified by POSIX. The **TIMEFORMAT** variable may be set to a format string that specifies how the timing information should be displayed; see the description of **TIMEFORMAT** under **Shell Variables** below.

Each command in a pipeline is executed as a separate process (i.e., in a subshell).

## Lists

A *list* is a sequence of one or more pipelines separated by one of the operators **;**, **&**, **&&**, or **||**, and optionally terminated by one of **;**, **&**, or **<newline>**.

Of these list operators, **&&** and **||** have equal precedence, followed by **;** and **&**, which have equal precedence.

A sequence of one or more newlines may appear in a *list* instead of a semicolon to delimit commands.

If a command is terminated by the control operator **&**, the shell executes the command in the *background* in a subshell. The shell does not wait for the command to finish, and the return status is 0. Commands separated by a **;** are executed sequentially; the shell waits for each command to terminate in turn. The return status is the exit status of the last command executed.

The control operators **&&** and **||** denote AND lists and OR lists, respectively. An AND list has the form

```
command1 && command2
```

*command2* is executed if, and only if, *command1* returns an exit status of zero.

An OR list has the form

```
command1 || command2
```

*command2* is executed if and only if *command1* returns a non-zero exit status. The return status of AND and OR lists is the exit status of the last command executed in the list.

## Compound Commands

A *compound command* is one of the following:

(*list*) *list* is executed in a subshell environment (see **COMMAND EXECUTION ENVIRONMENT** below). Variable assignments and builtin commands that affect the shell's environment do not remain in effect after the command completes. The return status is the exit status of *list*.

{ *list*; } *list* is simply executed in the current shell environment. *list* must be terminated with a newline or semicolon. This is known as a *group command*. The return status is the exit status of *list*. Note that unlike the metacharacters ( and ), { and } are *reserved words* and must occur where a reserved word is permitted to be recognized. Since they do not cause a word break, they must be separated from *list* by whitespace.

((*expression*))

The *expression* is evaluated according to the rules described below under **ARITHMETIC EVALUATION**. If the value of the expression is non-zero, the return status is 0; otherwise the return status is 1. This is exactly equivalent to **let "expression"**.

**[[ *expression* ]]**

Return a status of 0 or 1 depending on the evaluation of the conditional expression *expression*. Expressions are composed of the primaries described below under **CONDITIONAL EXPRESSIONS**. Word splitting and pathname expansion are not performed on the words between the **[[** and **]]**; tilde expansion, parameter and variable expansion, arithmetic expansion, command substitution, process substitution, and quote removal are performed. Conditional operators such as **-f** must be unquoted to be recognized as primaries.

When the **==** and **!=** operators are used, the string to the right of the operator is considered a pattern and matched according to the rules described below under **Pattern Matching**. If the shell option **nocasematch** is enabled, the match is performed without regard to the case of alphabetic characters. The return value is 0 if the string matches (**==**) or does not match (**!=**) the pattern, and 1 otherwise. Any part of the pattern may be quoted to force it to be matched as a string.

An additional binary operator, **=~**, is available, with the same precedence as **==** and **!=**. When it is used, the string to the right of the operator is considered an extended regular expression and matched accordingly (as in *regex(3)*). The return value is 0 if the string matches the pattern, and 1 otherwise. If the regular expression is syntactically incorrect, the conditional expression's return value is 2. If the shell option **nocasematch** is enabled, the match is performed without regard to the case of alphabetic characters. Substrings matched by parenthesized subexpressions within the regular expression are saved in the array variable **BASH\_REMATCH**. The element of **BASH\_REMATCH** with index 0 is the portion of the string matching the entire regular expression. The element of **BASH\_REMATCH** with index *n* is the portion of the string matching the *n*th parenthesized subexpression.

Expressions may be combined using the following operators, listed in decreasing order of precedence:

**( *expression* )**

Returns the value of *expression*. This may be used to override the normal precedence of operators.

**! *expression***

True if *expression* is false.

***expression1* && *expression2***

True if both *expression1* and *expression2* are true.

***expression1* || *expression2***

True if either *expression1* or *expression2* is true.

The **&&** and **||** operators do not evaluate *expression2* if the value of *expression1* is sufficient to determine the return value of the entire conditional expression.

**for *name* [ **in** *word* ] ; **do** *list* ; **done****

The list of words following **in** is expanded, generating a list of items. The variable *name* is set to each element of this list in turn, and *list* is executed each time. If the **in** *word* is omitted, the **for** command executes *list* once for each positional parameter that is set (see **PARAMETERS** below). The return status is the exit status of the last command that executes. If the expansion of the items following **in** results in an empty list, no commands are executed, and the return status is 0.

**for (( *expr1* ; *expr2* ; *expr3* )) ; **do** *list* ; **done****

First, the arithmetic expression *expr1* is evaluated according to the rules described below under **ARITHMETIC EVALUATION**. The arithmetic expression *expr2* is then evaluated repeatedly until it evaluates to zero. Each time *expr2* evaluates to a non-zero value, *list* is executed and the arithmetic expression *expr3* is evaluated. If any expression is omitted, it behaves as if it evaluates to 1. The return value is the exit status of the last command in *list* that is executed, or false if any of the expressions is invalid.

**select *name* [ **in** *word* ] ; **do** *list* ; **done****

The list of words following **in** is expanded, generating a list of items. The set of expanded words is printed on the standard error, each preceded by a number. If the **in** *word* is omitted, the

positional parameters are printed (see **PARAMETERS** below). The **PS3** prompt is then displayed and a line read from the standard input. If the line consists of a number corresponding to one of the displayed words, then the value of *name* is set to that word. If the line is empty, the words and prompt are displayed again. If EOF is read, the command completes. Any other value read causes *name* to be set to null. The line read is saved in the variable **REPLY**. The *list* is executed after each selection until a **break** command is executed. The exit status of **select** is the exit status of the last command executed in *list*, or zero if no commands were executed.

**case word in** [ (*pattern* [*pattern*] ... ) *list* ;; ] ... **esac**

A **case** command first expands *word*, and tries to match it against each *pattern* in turn, using the same matching rules as for pathname expansion (see **Pathname Expansion** below). The *word* is expanded using tilde expansion, parameter and variable expansion, arithmetic substitution, command substitution, process substitution and quote removal. Each *pattern* examined is expanded using tilde expansion, parameter and variable expansion, arithmetic substitution, command substitution, and process substitution. If the shell option **nocasematch** is enabled, the match is performed without regard to the case of alphabetic characters. When a match is found, the corresponding *list* is executed. After the first match, no subsequent matches are attempted. The exit status is zero if no pattern matches. Otherwise, it is the exit status of the last command executed in *list*.

**if list; then list; [ elif list; then list; ] ... [ else list; ] fi**

The **if list** is executed. If its exit status is zero, the **then list** is executed. Otherwise, each **elif list** is executed in turn, and if its exit status is zero, the corresponding **then list** is executed and the command completes. Otherwise, the **else list** is executed, if present. The exit status is the exit status of the last command executed, or zero if no condition tested true.

**while list; do list; done**

**until list; do list; done**

The **while** command continuously executes the **do list** as long as the last command in *list* returns an exit status of zero. The **until** command is identical to the **while** command, except that the test is negated; the **do list** is executed as long as the last command in *list* returns a non-zero exit status. The exit status of the **while** and **until** commands is the exit status of the last **do list** command executed, or zero if none was executed.

### Shell Function Definitions

A shell function is an object that is called like a simple command and executes a compound command with a new set of positional parameters. Shell functions are declared as follows:

[ **function** ] *name* () *compound-command* [*redirection*]

This defines a function named *name*. The reserved word **function** is optional. If the **function** reserved word is supplied, the parentheses are optional. The *body* of the function is the compound command *compound-command* (see **Compound Commands** above). That command is usually a *list* of commands between { and }, but may be any command listed under **Compound Commands** above. *compound-command* is executed whenever *name* is specified as the name of a simple command. Any redirections (see **REDIRECTION** below) specified when a function is defined are performed when the function is executed. The exit status of a function definition is zero unless a syntax error occurs or a readonly function with the same name already exists. When executed, the exit status of a function is the exit status of the last command executed in the body. (See **FUNCTIONS** below.)

### COMMENTS

In a non-interactive shell, or an interactive shell in which the **interactive\_comments** option to the **shopt** builtin is enabled (see **SHELL BUILTIN COMMANDS** below), a word beginning with # causes that word and all remaining characters on that line to be ignored. An interactive shell without the **interactive\_comments** option enabled does not allow comments. The **interactive\_comments** option is on by default in interactive shells.

## QUOTING

*Quoting* is used to remove the special meaning of certain characters or words to the shell. Quoting can be used to disable special treatment for special characters, to prevent reserved words from being recognized as such, and to prevent parameter expansion.

Each of the *metacharacters* listed above under **DEFINITIONS** has special meaning to the shell and must be quoted if it is to represent itself.

When the command history expansion facilities are being used (see **HISTORY EXPANSION** below), the *history expansion* character, usually `!`, must be quoted to prevent history expansion.

There are three quoting mechanisms: the *escape character*, single quotes, and double quotes.

A non-quoted backslash (`\`) is the *escape character*. It preserves the literal value of the next character that follows, with the exception of `<newline>`. If a `\<newline>` pair appears, and the backslash is not itself quoted, the `\<newline>` is treated as a line continuation (that is, it is removed from the input stream and effectively ignored).

Enclosing characters in single quotes preserves the literal value of each character within the quotes. A single quote may not occur between single quotes, even when preceded by a backslash.

Enclosing characters in double quotes preserves the literal value of all characters within the quotes, with the exception of `$`, `'`, `\`, and, when history expansion is enabled, `!`. The characters `$` and `'` retain their special meaning within double quotes. The backslash retains its special meaning only when followed by one of the following characters: `$`, `'`, `"`, `\`, or `<newline>`. A double quote may be quoted within double quotes by preceding it with a backslash. If enabled, history expansion will be performed unless an `!` appearing in double quotes is escaped using a backslash. The backslash preceding the `!` is not removed.

The special parameters `*` and `@` have special meaning when in double quotes (see **PARAMETERS** below).

Words of the form `$'string'` are treated specially. The word expands to *string*, with backslash-escaped characters replaced as specified by the ANSI C standard. Backslash escape sequences, if present, are decoded as follows:

|                   |                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------|
| <code>\a</code>   | alert (bell)                                                                                   |
| <code>\b</code>   | backspace                                                                                      |
| <code>\e</code>   | an escape character                                                                            |
| <code>\f</code>   | form feed                                                                                      |
| <code>\n</code>   | new line                                                                                       |
| <code>\r</code>   | carriage return                                                                                |
| <code>\t</code>   | horizontal tab                                                                                 |
| <code>\v</code>   | vertical tab                                                                                   |
| <code>\\</code>   | backslash                                                                                      |
| <code>\'</code>   | single quote                                                                                   |
| <code>\nnn</code> | the eight-bit character whose value is the octal value <i>nnn</i> (one to three digits)        |
| <code>\xHH</code> | the eight-bit character whose value is the hexadecimal value <i>HH</i> (one or two hex digits) |
| <code>\cx</code>  | a control- <i>x</i> character                                                                  |

The expanded result is single-quoted, as if the dollar sign had not been present.

A double-quoted string preceded by a dollar sign (`$`) will cause the string to be translated according to the current locale. If the current locale is **C** or **POSIX**, the dollar sign is ignored. If the string is translated and replaced, the replacement is double-quoted.

## PARAMETERS

A *parameter* is an entity that stores values. It can be a *name*, a number, or one of the special characters listed below under **Special Parameters**. A *variable* is a parameter denoted by a *name*. A variable has a *value* and zero or more *attributes*. Attributes are assigned using the **declare** builtin command (see **declare** below in **SHELL BUILTIN COMMANDS**).

A parameter is set if it has been assigned a value. The null string is a valid value. Once a variable is set, it may be unset only by using the **unset** builtin command (see **SHELL BUILTIN COMMANDS** below).

A *variable* may be assigned to by a statement of the form

```
name=[value]
```

If *value* is not given, the variable is assigned the null string. All *values* undergo tilde expansion, parameter and variable expansion, command substitution, arithmetic expansion, and quote removal (see **EXPANSION** below). If the variable has its **integer** attribute set, then *value* is evaluated as an arithmetic expression even if the  $\$(...)$  expansion is not used (see **Arithmetic Expansion** below). Word splitting is not performed, with the exception of "\$@" as explained below under **Special Parameters**. Pathname expansion is not performed. Assignment statements may also appear as arguments to the **alias**, **declare**, **typeset**, **export**, **readonly**, and **local** builtin commands.

In the context where an assignment statement is assigning a value to a shell variable or array index, the += operator can be used to append to or add to the variable's previous value. When += is applied to a variable for which the integer attribute has been set, *value* is evaluated as an arithmetic expression and added to the variable's current value, which is also evaluated. When += is applied to an array variable using compound assignment (see **Arrays** below), the variable's value is not unset (as it is when using =), and new values are appended to the array beginning at one greater than the array's maximum index. When applied to a string-valued variable, *value* is expanded and appended to the variable's value.

### Positional Parameters

A *positional parameter* is a parameter denoted by one or more digits, other than the single digit 0. Positional parameters are assigned from the shell's arguments when it is invoked, and may be reassigned using the **set** builtin command. Positional parameters may not be assigned to with assignment statements. The positional parameters are temporarily replaced when a shell function is executed (see **FUNCTIONS** below).

When a positional parameter consisting of more than a single digit is expanded, it must be enclosed in braces (see **EXPANSION** below).

### Special Parameters

The shell treats several parameters specially. These parameters may only be referenced; assignment to them is not allowed.

- \* Expands to the positional parameters, starting from one. When the expansion occurs within double quotes, it expands to a single word with the value of each parameter separated by the first character of the **IFS** special variable. That is, "\$\*" is equivalent to "\$1c\$2c...", where *c* is the first character of the value of the **IFS** variable. If **IFS** is unset, the parameters are separated by spaces. If **IFS** is null, the parameters are joined without intervening separators.
- @ Expands to the positional parameters, starting from one. When the expansion occurs within double quotes, each parameter expands to a separate word. That is, "\$@" is equivalent to "\$1" "\$2" ... If the double-quoted expansion occurs within a word, the expansion of the first parameter is joined with the beginning part of the original word, and the expansion of the last parameter is joined with the last part of the original word. When there are no positional parameters, "\$@" and @\$ expand to nothing (i.e., they are removed).
- # Expands to the number of positional parameters in decimal.
- ? Expands to the status of the most recently executed foreground pipeline.
- Expands to the current option flags as specified upon invocation, by the **set** builtin command, or those set by the shell itself (such as the **-i** option).
- \$ Expands to the process ID of the shell. In a () subshell, it expands to the process ID of the current shell, not the subshell.
- ! Expands to the process ID of the most recently executed background (asynchronous) command.
- 0 Expands to the name of the shell or shell script. This is set at shell initialization. If **bash** is invoked with a file of commands, \$0 is set to the name of that file. If **bash** is started with the **-c** option, then \$0 is set to the first argument after the string to be executed, if one is present. Otherwise, it is set to the file name used to invoke **bash**, as given by argument zero.
- At shell startup, set to the absolute pathname used to invoke the shell or shell script being executed as passed in the environment or argument list. Subsequently, expands to the last argument to the previous command, after expansion. Also set to the full pathname used to invoke each command executed and placed in the environment exported to that command. When checking mail, this

parameter holds the name of the mail file currently being checked.

### Shell Variables

The following variables are set by the shell:

**BASH** Expands to the full file name used to invoke this instance of **bash**.

#### **BASH\_ARGC**

An array variable whose values are the number of parameters in each frame of the current bash execution call stack. The number of parameters to the current subroutine (shell function or script executed with **.** or **source**) is at the top of the stack. When a subroutine is executed, the number of parameters passed is pushed onto **BASH\_ARGC**. The shell sets **BASH\_ARGC** only when in extended debugging mode (see the description of the **extdebug** option to the **shopt** builtin below)

#### **BASH\_ARGV**

An array variable containing all of the parameters in the current bash execution call stack. The final parameter of the last subroutine call is at the top of the stack; the first parameter of the initial call is at the bottom. When a subroutine is executed, the parameters supplied are pushed onto **BASH\_ARGV**. The shell sets **BASH\_ARGV** only when in extended debugging mode (see the description of the **extdebug** option to the **shopt** builtin below)

#### **BASH\_COMMAND**

The command currently being executed or about to be executed, unless the shell is executing a command as the result of a trap, in which case it is the command executing at the time of the trap.

#### **BASH\_EXECUTION\_STRING**

The command argument to the **-c** invocation option.

#### **BASH\_LINENO**

An array variable whose members are the line numbers in source files corresponding to each member of **FUNCNAME**. **\${BASH\_LINENO[\$i]}** is the line number in the source file where **\${FUNCNAME[\$i]}** was called. The corresponding source file name is **\${BASH\_SOURCE[\$i]}**. Use **LINENO** to obtain the current line number.

#### **BASH\_REMATCH**

An array variable whose members are assigned by the **=~** binary operator to the **[[** conditional command. The element with index 0 is the portion of the string matching the entire regular expression. The element with index *n* is the portion of the string matching the *n*th parenthesized subexpression. This variable is read-only.

#### **BASH\_SOURCE**

An array variable whose members are the source filenames corresponding to the elements in the **FUNCNAME** array variable.

#### **BASH\_SUBSHELL**

Incremented by one each time a subshell or subshell environment is spawned. The initial value is 0.

#### **BASH\_VERSINFO**

A readonly array variable whose members hold version information for this instance of **bash**. The values assigned to the array members are as follows:

|                         |                                                 |
|-------------------------|-------------------------------------------------|
| <b>BASH_VERSINFO[0]</b> | The major version number (the <i>release</i> ). |
| <b>BASH_VERSINFO[1]</b> | The minor version number (the <i>version</i> ). |
| <b>BASH_VERSINFO[2]</b> | The patch level.                                |
| <b>BASH_VERSINFO[3]</b> | The build version.                              |
| <b>BASH_VERSINFO[4]</b> | The release status (e.g., <i>beta1</i> ).       |
| <b>BASH_VERSINFO[5]</b> | The value of <b>MACHTYPE</b> .                  |

#### **BASH\_VERSION**

Expands to a string describing the version of this instance of **bash**.

#### **COMP\_CWORD**

An index into **\${COMP\_WORDS}** of the word containing the current cursor position. This variable is available only in shell functions invoked by the programmable completion facilities (see **Programmable Completion** below).

**COMP\_LINE**

The current command line. This variable is available only in shell functions and external commands invoked by the programmable completion facilities (see **Programmable Completion** below).

**COMP\_POINT**

The index of the current cursor position relative to the beginning of the current command. If the current cursor position is at the end of the current command, the value of this variable is equal to **\${#COMP\_LINE}**. This variable is available only in shell functions and external commands invoked by the programmable completion facilities (see **Programmable Completion** below).

**COMP\_WORDBREAKS**

The set of characters that the Readline library treats as word separators when performing word completion. If **COMP\_WORDBREAKS** is unset, it loses its special properties, even if it is subsequently reset.

**COMP\_WORDS**

An array variable (see **Arrays** below) consisting of the individual words in the current command line. The words are split on shell metacharacters as the shell parser would separate them. This variable is available only in shell functions invoked by the programmable completion facilities (see **Programmable Completion** below).

**DIRSTACK**

An array variable (see **Arrays** below) containing the current contents of the directory stack. Directories appear in the stack in the order they are displayed by the **dirs** builtin. Assigning to members of this array variable may be used to modify directories already in the stack, but the **pushd** and **popd** builtins must be used to add and remove directories. Assignment to this variable will not change the current directory. If **DIRSTACK** is unset, it loses its special properties, even if it is subsequently reset.

**EUID** Expands to the effective user ID of the current user, initialized at shell startup. This variable is readonly.

**FUNCNAME**

An array variable containing the names of all shell functions currently in the execution call stack. The element with index 0 is the name of any currently-executing shell function. The bottom-most element is "main". This variable exists only when a shell function is executing. Assignments to **FUNCNAME** have no effect and return an error status. If **FUNCNAME** is unset, it loses its special properties, even if it is subsequently reset.

**GROUPS**

An array variable containing the list of groups of which the current user is a member. Assignments to **GROUPS** have no effect and return an error status. If **GROUPS** is unset, it loses its special properties, even if it is subsequently reset.

**HISTCMD**

The history number, or index in the history list, of the current command. If **HISTCMD** is unset, it loses its special properties, even if it is subsequently reset.

**HOSTNAME**

Automatically set to the name of the current host.

**HOSTTYPE**

Automatically set to a string that uniquely describes the type of machine on which **bash** is executing. The default is system-dependent.

**LINENO**

Each time this parameter is referenced, the shell substitutes a decimal number representing the current sequential line number (starting with 1) within a script or function. When not in a script or function, the value substituted is not guaranteed to be meaningful. If **LINENO** is unset, it loses its special properties, even if it is subsequently reset.

**MACHTYPE**

Automatically set to a string that fully describes the system type on which **bash** is executing, in the standard GNU *cpu-company-system* format. The default is system-dependent.

**OLDPWD**

The previous working directory as set by the **cd** command.

**OPTARG**

The value of the last option argument processed by the **getopts** builtin command (see **SHELL BUILTIN COMMANDS** below).

**OPTIND**

The index of the next argument to be processed by the **getopts** builtin command (see **SHELL BUILTIN COMMANDS** below).

**OSTYPE**

Automatically set to a string that describes the operating system on which **bash** is executing. The default is system-dependent.

**PIPESTATUS**

An array variable (see **Arrays** below) containing a list of exit status values from the processes in the most-recently-executed foreground pipeline (which may contain only a single command).

**PPID** The process ID of the shell's parent. This variable is readonly.

**PWD** The current working directory as set by the **cd** command.

**RANDOM**

Each time this parameter is referenced, a random integer between 0 and 32767 is generated. The sequence of random numbers may be initialized by assigning a value to **RANDOM**. If **RANDOM** is unset, it loses its special properties, even if it is subsequently reset.

**REPLY**

Set to the line of input read by the **read** builtin command when no arguments are supplied.

**SECONDS**

Each time this parameter is referenced, the number of seconds since shell invocation is returned. If a value is assigned to **SECONDS**, the value returned upon subsequent references is the number of seconds since the assignment plus the value assigned. If **SECONDS** is unset, it loses its special properties, even if it is subsequently reset.

**SHELLOPTS**

A colon-separated list of enabled shell options. Each word in the list is a valid argument for the **-o** option to the **set** builtin command (see **SHELL BUILTIN COMMANDS** below). The options appearing in **SHELLOPTS** are those reported as *on* by **set -o**. If this variable is in the environment when **bash** starts up, each shell option in the list will be enabled before reading any startup files. This variable is read-only.

**SHLVL**

Incremented by one each time an instance of **bash** is started.

**UID** Expands to the user ID of the current user, initialized at shell startup. This variable is readonly.

The following variables are used by the shell. In some cases, **bash** assigns a default value to a variable; these cases are noted below.

**BASH\_ENV**

If this parameter is set when **bash** is executing a shell script, its value is interpreted as a filename containing commands to initialize the shell, as in *~/.bashrc*. The value of **BASH\_ENV** is subjected to parameter expansion, command substitution, and arithmetic expansion before being interpreted as a file name. **PATH** is not used to search for the resultant file name.

**CDPATH**

The search path for the **cd** command. This is a colon-separated list of directories in which the shell looks for destination directories specified by the **cd** command. A sample value is `". : ~ : /usr "`.

**COLUMNS**

Used by the **select** builtin command to determine the terminal width when printing selection lists. Automatically set upon receipt of a SIGWINCH.

**COMPREPLY**

An array variable from which **bash** reads the possible completions generated by a shell function invoked by the programmable completion facility (see **Programmable Completion** below).

**EMACS**

If **bash** finds this variable in the environment when the shell starts with value `t`, it assumes that the shell is running in an emacs shell buffer and disables line editing.

**FCEDIT**

The default editor for the **fc** builtin command.

**FIGNORE**

A colon-separated list of suffixes to ignore when performing filename completion (see **README** below). A filename whose suffix matches one of the entries in **FIGNORE** is excluded from the list of matched filenames. A sample value is `". o : ~ "`.

**GLOBIGNORE**

A colon-separated list of patterns defining the set of filenames to be ignored by pathname expansion. If a filename matched by a pathname expansion pattern also matches one of the patterns in **GLOBIGNORE**, it is removed from the list of matches.

**HISTCONTROL**

A colon-separated list of values controlling how commands are saved on the history list. If the list of values includes *ignorespace*, lines which begin with a **space** character are not saved in the history list. A value of *ignoredups* causes lines matching the previous history entry to not be saved. A value of *ignoreboth* is shorthand for *ignorespace* and *ignoredups*. A value of *erasedups* causes all previous lines matching the current line to be removed from the history list before that line is saved. Any value not in the above list is ignored. If **HISTCONTROL** is unset, or does not include a valid value, all lines read by the shell parser are saved on the history list, subject to the value of **HISTIGNORE**. The second and subsequent lines of a multi-line compound command are not tested, and are added to the history regardless of the value of **HISTCONTROL**.

**HISTFILE**

The name of the file in which command history is saved (see **HISTORY** below). The default value is `~/.bash_history`. If unset, the command history is not saved when an interactive shell exits.

**HISTFILESIZE**

The maximum number of lines contained in the history file. When this variable is assigned a value, the history file is truncated, if necessary, by removing the oldest entries, to contain no more than that number of lines. The default value is 500. The history file is also truncated to this size after writing it when an interactive shell exits.

**HISTIGNORE**

A colon-separated list of patterns used to decide which command lines should be saved on the history list. Each pattern is anchored at the beginning of the line and must match the complete line (no implicit `*` is appended). Each pattern is tested against the line after the checks specified by **HISTCONTROL** are applied. In addition to the normal shell pattern matching characters, `&` matches the previous history line. `&` may be escaped using a backslash; the backslash is removed before attempting a match. The second and subsequent lines of a multi-line compound command are not tested, and are added to the history regardless of the value of **HISTIGNORE**.

**HISTSIZE**

The number of commands to remember in the command history (see **HISTORY** below). The default value is 500.

**HISTTIMEFORMAT**

If this variable is set and not null, its value is used as a format string for *strftime*(3) to print the time stamp associated with each history entry displayed by the **history** builtin. If this variable is set, time stamps are written to the history file so they may be preserved across shell sessions.

**HOME**

The home directory of the current user; the default argument for the **cd** builtin command. The value of this variable is also used when performing tilde expansion.

**HOSTFILE**

Contains the name of a file in the same format as */etc/hosts* that should be read when the shell needs to complete a hostname. The list of possible hostname completions may be changed while the shell is running; the next time hostname completion is attempted after the value is changed, **bash** adds the contents of the new file to the existing list. If **HOSTFILE** is set, but has no value, **bash** attempts to read */etc/hosts* to obtain the list of possible hostname completions. When **HOSTFILE** is unset, the hostname list is cleared.

**IFS**

The *Internal Field Separator* that is used for word splitting after expansion and to split lines into words with the **read** builtin command. The default value is "<space><tab><newline>".

**IGNOREEOF**

Controls the action of an interactive shell on receipt of an **EOF** character as the sole input. If set, the value is the number of consecutive **EOF** characters which must be typed as the first characters on an input line before **bash** exits. If the variable exists but does not have a numeric value, or has no value, the default value is 10. If it does not exist, **EOF** signifies the end of input to the shell.

**INPUTRC**

The filename for the **readline** startup file, overriding the default of *~/.inputrc* (see **README** below).

**LANG** Used to determine the locale category for any category not specifically selected with a variable starting with **LC\_**.

**LC\_ALL**

This variable overrides the value of **LANG** and any other **LC\_** variable specifying a locale category.

**LC\_COLLATE**

This variable determines the collation order used when sorting the results of pathname expansion, and determines the behavior of range expressions, equivalence classes, and collating sequences within pathname expansion and pattern matching.

**LC\_CTYPE**

This variable determines the interpretation of characters and the behavior of character classes within pathname expansion and pattern matching.

**LC\_MESSAGES**

This variable determines the locale used to translate double-quoted strings preceded by a \$.

**LC\_NUMERIC**

This variable determines the locale category used for number formatting.

**LINES** Used by the **select** builtin command to determine the column length for printing selection lists. Automatically set upon receipt of a SIGWINCH.

**MAIL** If this parameter is set to a file name and the **MAILPATH** variable is not set, **bash** informs the user of the arrival of mail in the specified file.

**MAILCHECK**

Specifies how often (in seconds) **bash** checks for mail. The default is 60 seconds. When it is time to check for mail, the shell does so before displaying the primary prompt. If this variable is unset, or set to a value that is not a number greater than or equal to zero, the shell disables mail checking.

**MAILPATH**

A colon-separated list of file names to be checked for mail. The message to be printed when mail arrives in a particular file may be specified by separating the file name from the message with a '?'. When used in the text of the message, **\$\_** expands to the name of the current mailfile. Example:

```
MAILPATH=/var/mail/bfox?"You have mail":~/shell-mail?"$_ has mail!"
```

**Bash** supplies a default value for this variable, but the location of the user mail files that it uses is system dependent (e.g., /var/mail/\$USER).

#### OPTERR

If set to the value 1, **bash** displays error messages generated by the **getopts** builtin command (see **SHELL BUILTIN COMMANDS** below). **OPTERR** is initialized to 1 each time the shell is invoked or a shell script is executed.

#### PATH

The search path for commands. It is a colon-separated list of directories in which the shell looks for commands (see **COMMAND EXECUTION** below). A zero-length (null) directory name in the value of **PATH** indicates the current directory. A null directory name may appear as two adjacent colons, or as an initial or trailing colon. The default path is system-dependent, and is set by the administrator who installs **bash**. A common value is /usr/gnu/bin:/usr/local/bin:/usr/ucb:/bin:/usr/bin.

#### POSIXLY\_CORRECT

If this variable is in the environment when **bash** starts, the shell enters *posix mode* before reading the startup files, as if the **--posix** invocation option had been supplied. If it is set while the shell is running, **bash** enables *posix mode*, as if the command **set -o posix** had been executed.

#### PROMPT\_COMMAND

If set, the value is executed as a command prior to issuing each primary prompt.

#### PS1

The value of this parameter is expanded (see **PROMPTING** below) and used as the primary prompt string. The default value is "**\s-\v\\$**".

#### PS2

The value of this parameter is expanded as with **PS1** and used as the secondary prompt string. The default is ">".

#### PS3

The value of this parameter is used as the prompt for the **select** command (see **SHELL GRAMMAR** above).

#### PS4

The value of this parameter is expanded as with **PS1** and the value is printed before each command **bash** displays during an execution trace. The first character of **PS4** is replicated multiple times, as necessary, to indicate multiple levels of indirection. The default is "+".

#### SHELL

The full pathname to the shell is kept in this environment variable. If it is not set when the shell starts, **bash** assigns to it the full pathname of the current user's login shell.

#### TIMEFORMAT

The value of this parameter is used as a format string specifying how the timing information for pipelines prefixed with the **time** reserved word should be displayed. The % character introduces an escape sequence that is expanded to a time value or other information. The escape sequences and their meanings are as follows; the braces denote optional portions.

|          |                                                 |
|----------|-------------------------------------------------|
| % %      | A literal %.                                    |
| %[p][l]R | The elapsed time in seconds.                    |
| %[p][l]U | The number of CPU seconds spent in user mode.   |
| %[p][l]S | The number of CPU seconds spent in system mode. |
| %P       | The CPU percentage, computed as (%U + %S) / %R. |

The optional *p* is a digit specifying the *precision*, the number of fractional digits after a decimal point. A value of 0 causes no decimal point or fraction to be output. At most three places after the decimal point may be specified; values of *p* greater than 3 are changed to 3. If *p* is not specified, the value 3 is used.

The optional *l* specifies a longer format, including minutes, of the form *MMmSS.FFs*. The value of *p* determines whether or not the fraction is included.

If this variable is not set, **bash** acts as if it had the value **\$'\nreal\t%3lR\nuser\t%3lU\nsys\t%3lS'**. If the value is null, no timing information is displayed. A trailing newline is added when the format string is displayed.

#### TMOUT

If set to a value greater than zero, **TMOUT** is treated as the default timeout for the **read** builtin. The **select** command terminates if input does not arrive after **TMOUT** seconds when input is

coming from a terminal. In an interactive shell, the value is interpreted as the number of seconds to wait for input after issuing the primary prompt. **Bash** terminates after waiting for that number of seconds if input does not arrive.

### TMPDIR

If set, **Bash** uses its value as the name of a directory in which **Bash** creates temporary files for the shell's use.

### auto\_resume

This variable controls how the shell interacts with the user and job control. If this variable is set, single word simple commands without redirections are treated as candidates for resumption of an existing stopped job. There is no ambiguity allowed; if there is more than one job beginning with the string typed, the job most recently accessed is selected. The *name* of a stopped job, in this context, is the command line used to start it. If set to the value *exact*, the string supplied must match the name of a stopped job exactly; if set to *substring*, the string supplied needs to match a substring of the name of a stopped job. The *substring* value provides functionality analogous to the *%?* job identifier (see **JOB CONTROL** below). If set to any other value, the supplied string must be a prefix of a stopped job's name; this provides functionality analogous to the *%string* job identifier.

### histchars

The two or three characters which control history expansion and tokenization (see **HISTORY EXPANSION** below). The first character is the *history expansion* character, the character which signals the start of a history expansion, normally '!'. The second character is the *quick substitution* character, which is used as shorthand for re-running the previous command entered, substituting one string for another in the command. The default is '^'. The optional third character is the character which indicates that the remainder of the line is a comment when found as the first character of a word, normally '#'. The history comment character causes history substitution to be skipped for the remaining words on the line. It does not necessarily cause the shell parser to treat the rest of the line as a comment.

### Arrays

**Bash** provides one-dimensional array variables. Any variable may be used as an array; the **declare** builtin will explicitly declare an array. There is no maximum limit on the size of an array, nor any requirement that members be indexed or assigned contiguously. Arrays are indexed using integers and are zero-based.

An array is created automatically if any variable is assigned to using the syntax *name[subscript]=value*. The *subscript* is treated as an arithmetic expression that must evaluate to a number greater than or equal to zero. To explicitly declare an array, use **declare -a name** (see **SHELL BUILTIN COMMANDS** below). **declare -a name[subscript]** is also accepted; the *subscript* is ignored. Attributes may be specified for an array variable using the **declare** and **readonly** builtins. Each attribute applies to all members of an array.

Arrays are assigned to using compound assignments of the form *name=(value1 ... valuen)*, where each *value* is of the form *[subscript]=string*. Only *string* is required. If the optional brackets and subscript are supplied, that index is assigned to; otherwise the index of the element assigned is the last index assigned to by the statement plus one. Indexing starts at zero. This syntax is also accepted by the **declare** builtin. Individual array elements may be assigned to using the *name[subscript]=value* syntax introduced above.

Any element of an array may be referenced using *\${name[subscript]}*. The braces are required to avoid conflicts with pathname expansion. If *subscript* is @ or \*, the word expands to all members of *name*. These subscripts differ only when the word appears within double quotes. If the word is double-quoted, *\${name[\*]}* expands to a single word with the value of each array member separated by the first character of the **IFS** special variable, and *\${name[@]}* expands each element of *name* to a separate word. When there are no array members, *\${name[@]}* expands to nothing. If the double-quoted expansion occurs within a word, the expansion of the first parameter is joined with the beginning part of the original word, and the expansion of the last parameter is joined with the last part of the original word. This is analogous to the expansion of the special parameters \* and @ (see **Special Parameters** above). *\${#name[subscript]}* expands to the length of *\${name[subscript]}*. If *subscript* is \* or @, the expansion is the number of elements in the array. Referencing an array variable without a subscript is equivalent to referencing element

zero.

The **unset** builtin is used to destroy arrays. **unset** *name*[*subscript*] destroys the array element at index *subscript*. Care must be taken to avoid unwanted side effects caused by filename generation. **unset** *name*, where *name* is an array, or **unset** *name*[*subscript*], where *subscript* is \* or @, removes the entire array.

The **declare**, **local**, and **readonly** builtins each accept a **-a** option to specify an array. The **read** builtin accepts a **-a** option to assign a list of words read from the standard input to an array. The **set** and **declare** builtins display array values in a way that allows them to be reused as assignments.

## EXPANSION

Expansion is performed on the command line after it has been split into words. There are seven kinds of expansion performed: *brace expansion*, *tilde expansion*, *parameter and variable expansion*, *command substitution*, *arithmetic expansion*, *word splitting*, and *pathname expansion*.

The order of expansions is: brace expansion, tilde expansion, parameter, variable and arithmetic expansion and command substitution (done in a left-to-right fashion), word splitting, and pathname expansion.

On systems that can support it, there is an additional expansion available: *process substitution*.

Only brace expansion, word splitting, and pathname expansion can change the number of words of the expansion; other expansions expand a single word to a single word. The only exceptions to this are the expansions of "\$@" and "\${name[@]}" as explained above (see **PARAMETERS**).

### Brace Expansion

*Brace expansion* is a mechanism by which arbitrary strings may be generated. This mechanism is similar to *pathname expansion*, but the filenames generated need not exist. Patterns to be brace expanded take the form of an optional *preamble*, followed by either a series of comma-separated strings or a sequence expression between a pair of braces, followed by an optional *postscript*. The preamble is prefixed to each string contained within the braces, and the postscript is then appended to each resulting string, expanding left to right.

Brace expansions may be nested. The results of each expanded string are not sorted; left to right order is preserved. For example, `a{d,c,b}e` expands into 'ade ace abe'.

A sequence expression takes the form `{x..y}`, where *x* and *y* are either integers or single characters. When integers are supplied, the expression expands to each number between *x* and *y*, inclusive. When characters are supplied, the expression expands to each character lexicographically between *x* and *y*, inclusive. Note that both *x* and *y* must be of the same type.

Brace expansion is performed before any other expansions, and any characters special to other expansions are preserved in the result. It is strictly textual. **Bash** does not apply any syntactic interpretation to the context of the expansion or the text between the braces.

A correctly-formed brace expansion must contain unquoted opening and closing braces, and at least one unquoted comma or a valid sequence expression. Any incorrectly formed brace expansion is left unchanged. A { or , may be quoted with a backslash to prevent its being considered part of a brace expression. To avoid conflicts with parameter expansion, the string \${ is not considered eligible for brace expansion.

This construct is typically used as shorthand when the common prefix of the strings to be generated is longer than in the above example:

```
mkdir /usr/local/src/bash/{old,new,dist,bugs}
```

or

```
chown root /usr/{ucb/{ex,edit},lib/{ex?.?*,how_ex}}
```

Brace expansion introduces a slight incompatibility with historical versions of **sh**. **sh** does not treat opening or closing braces specially when they appear as part of a word, and preserves them in the output. **Bash** removes braces from words as a consequence of brace expansion. For example, a word entered to **sh** as `file{1,2}` appears identically in the output. The same word is output as `file1 file2` after expansion by **bash**. If strict compatibility with **sh** is desired, start **bash** with the **+B** option or disable brace expansion with the **+B** option to the **set** command (see **SHELL BUILTIN COMMANDS** below).

### Tilde Expansion

If a word begins with an unquoted tilde character ('~'), all of the characters preceding the first unquoted slash (or all characters, if there is no unquoted slash) are considered a *tilde-prefix*. If none of the characters in the tilde-prefix are quoted, the characters in the tilde-prefix following the tilde are treated as a possible *login name*. If this login name is the null string, the tilde is replaced with the value of the shell parameter **HOME**. If **HOME** is unset, the home directory of the user executing the shell is substituted instead. Otherwise, the tilde-prefix is replaced with the home directory associated with the specified login name.

If the tilde-prefix is a '~+', the value of the shell variable **PWD** replaces the tilde-prefix. If the tilde-prefix is a '~-', the value of the shell variable **OLDPWD**, if it is set, is substituted. If the characters following the tilde in the tilde-prefix consist of a number *N*, optionally prefixed by a '+' or a '-', the tilde-prefix is replaced with the corresponding element from the directory stack, as it would be displayed by the **dirs** builtin invoked with the tilde-prefix as an argument. If the characters following the tilde in the tilde-prefix consist of a number without a leading '+' or '-', '+' is assumed.

If the login name is invalid, or the tilde expansion fails, the word is unchanged.

Each variable assignment is checked for unquoted tilde-prefixes immediately following a ':' or the first '='. In these cases, tilde expansion is also performed. Consequently, one may use file names with tildes in assignments to **PATH**, **MAILPATH**, and **CDPATH**, and the shell assigns the expanded value.

### Parameter Expansion

The '\$' character introduces parameter expansion, command substitution, or arithmetic expansion. The parameter name or symbol to be expanded may be enclosed in braces, which are optional but serve to protect the variable to be expanded from characters immediately following it which could be interpreted as part of the name.

When braces are used, the matching ending brace is the first '}' not escaped by a backslash or within a quoted string, and not within an embedded arithmetic expansion, command substitution, or parameter expansion.

`${parameter}`

The value of *parameter* is substituted. The braces are required when *parameter* is a positional parameter with more than one digit, or when *parameter* is followed by a character which is not to be interpreted as part of its name.

If the first character of *parameter* is an exclamation point, a level of variable indirection is introduced. **Bash** uses the value of the variable formed from the rest of *parameter* as the name of the variable; this variable is then expanded and that value is used in the rest of the substitution, rather than the value of *parameter* itself. This is known as *indirect expansion*. The exceptions to this are the expansions of `${!prefix*}` and `${!name[@]}` described below. The exclamation point must immediately follow the left brace in order to introduce indirection.

In each of the cases below, *word* is subject to tilde expansion, parameter expansion, command substitution, and arithmetic expansion. When not performing substring expansion, **bash** tests for a parameter that is unset or null; omitting the colon results in a test only for a parameter that is unset.

`${parameter:-word}`

**Use Default Values.** If *parameter* is unset or null, the expansion of *word* is substituted. Otherwise, the value of *parameter* is substituted.

`${parameter:=word}`

**Assign Default Values.** If *parameter* is unset or null, the expansion of *word* is assigned to *parameter*. The value of *parameter* is then substituted. Positional parameters and special parameters may not be assigned to in this way.

`${parameter:?word}`

**Display Error if Null or Unset.** If *parameter* is null or unset, the expansion of *word* (or a message to that effect if *word* is not present) is written to the standard error and the shell, if it is not interactive, exits. Otherwise, the value of *parameter* is substituted.

`${parameter:+word}`

**Use Alternate Value.** If *parameter* is null or unset, nothing is substituted, otherwise the expansion of *word* is substituted.

`${parameter:offset}`

`${parameter:offset:length}`

**Substring Expansion.** Expands to up to *length* characters of *parameter* starting at the character specified by *offset*. If *length* is omitted, expands to the substring of *parameter* starting at the character specified by *offset*. *length* and *offset* are arithmetic expressions (see **ARITHMETIC EVALUATION** below). *length* must evaluate to a number greater than or equal to zero. If *offset* evaluates to a number less than zero, the value is used as an offset from the end of the value of *parameter*. If *parameter* is `@`, the result is *length* positional parameters beginning at *offset*. If *parameter* is an array name indexed by `@` or `*`, the result is the *length* members of the array beginning with `${parameter[offset]}`. A negative *offset* is taken relative to one greater than the maximum index of the specified array. Note that a negative offset must be separated from the colon by at least one space to avoid being confused with the `:-` expansion. Substring indexing is zero-based unless the positional parameters are used, in which case the indexing starts at 1.

`${!prefix*}`

`${!prefix@}`

Expands to the names of variables whose names begin with *prefix*, separated by the first character of the **IFS** special variable.

`${!name[@]}`

`${!name[*]}`

If *name* is an array variable, expands to the list of array indices (keys) assigned in *name*. If *name* is not an array, expands to 0 if *name* is set and null otherwise. When `@` is used and the expansion appears within double quotes, each key expands to a separate word.

`${#parameter}`

The length in characters of the value of *parameter* is substituted. If *parameter* is `*` or `@`, the value substituted is the number of positional parameters. If *parameter* is an array name subscripted by `*` or `@`, the value substituted is the number of elements in the array.

`${parameter#word}`

`${parameter##word}`

The *word* is expanded to produce a pattern just as in pathname expansion. If the pattern matches the beginning of the value of *parameter*, then the result of the expansion is the expanded value of *parameter* with the shortest matching pattern (the `"#"` case) or the longest matching pattern (the `"##"` case) deleted. If *parameter* is `@` or `*`, the pattern removal operation is applied to each positional parameter in turn, and the expansion is the resultant list. If *parameter* is an array variable subscripted with `@` or `*`, the pattern removal operation is applied to each member of the array in turn, and the expansion is the resultant list.

`${parameter%word}`

`${parameter%%word}`

The *word* is expanded to produce a pattern just as in pathname expansion. If the pattern matches a trailing portion of the expanded value of *parameter*, then the result of the expansion is the expanded value of *parameter* with the shortest matching pattern (the `"%"` case) or the longest matching pattern (the `"%%"` case) deleted. If *parameter* is `@` or `*`, the pattern removal operation is applied to each positional parameter in turn, and the expansion is the resultant list. If *parameter* is an array variable subscripted with `@` or `*`, the pattern removal operation is applied to each member of the array in turn, and the expansion is the resultant list.

`${parameter/pattern/string}`

The *pattern* is expanded to produce a pattern just as in pathname expansion. *Parameter* is expanded and the longest match of *pattern* against its value is replaced with *string*. If *pattern* begins with `/`, all matches of *pattern* are replaced with *string*. Normally only the first match is replaced. If *pattern* begins with `#`, it must match at the beginning of the expanded value of

*parameter*. If *pattern* begins with %, it must match at the end of the expanded value of *parameter*. If *string* is null, matches of *pattern* are deleted and the *l* following *pattern* may be omitted. If *parameter* is @ or \*, the substitution operation is applied to each positional parameter in turn, and the expansion is the resultant list. If *parameter* is an array variable subscripted with @ or \*, the substitution operation is applied to each member of the array in turn, and the expansion is the resultant list.

### Command Substitution

*Command substitution* allows the output of a command to replace the command name. There are two forms:

`$(command)`

or

``command``

**Bash** performs the expansion by executing *command* and replacing the command substitution with the standard output of the command, with any trailing newlines deleted. Embedded newlines are not deleted, but they may be removed during word splitting. The command substitution `$(cat file)` can be replaced by the equivalent but faster `$(<file)`.

When the old-style backquote form of substitution is used, backslash retains its literal meaning except when followed by \$, `, or \. The first backquote not preceded by a backslash terminates the command substitution. When using the `$(command)` form, all characters between the parentheses make up the command; none are treated specially.

Command substitutions may be nested. To nest when using the backquoted form, escape the inner backquotes with backslashes.

If the substitution appears within double quotes, word splitting and pathname expansion are not performed on the results.

### Arithmetic Expansion

Arithmetic expansion allows the evaluation of an arithmetic expression and the substitution of the result. The format for arithmetic expansion is:

`$((expression))`

The *expression* is treated as if it were within double quotes, but a double quote inside the parentheses is not treated specially. All tokens in the expression undergo parameter expansion, string expansion, command substitution, and quote removal. Arithmetic expansions may be nested.

The evaluation is performed according to the rules listed below under **ARITHMETIC EVALUATION**. If *expression* is invalid, **bash** prints a message indicating failure and no substitution occurs.

### Process Substitution

*Process substitution* is supported on systems that support named pipes (*FIFOs*) or the `/dev/fd` method of naming open files. It takes the form of `<(list)` or `>(list)`. The process *list* is run with its input or output connected to a *FIFO* or some file in `/dev/fd`. The name of this file is passed as an argument to the current command as the result of the expansion. If the `>(list)` form is used, writing to the file will provide input for *list*. If the `<(list)` form is used, the file passed as an argument should be read to obtain the output of *list*.

When available, process substitution is performed simultaneously with parameter and variable expansion, command substitution, and arithmetic expansion.

### Word Splitting

The shell scans the results of parameter expansion, command substitution, and arithmetic expansion that did not occur within double quotes for *word splitting*.

The shell treats each character of **IFS** as a delimiter, and splits the results of the other expansions into words on these characters. If **IFS** is unset, or its value is exactly `<space><tab><newline>`, the default, then any sequence of **IFS** characters serves to delimit words. If **IFS** has a value other than the default, then sequences of the whitespace characters **space** and **tab** are ignored at the beginning and end of the word, as long as the whitespace character is in the value of **IFS** (an **IFS** whitespace character). Any character in **IFS**

that is not **IFS** whitespace, along with any adjacent **IFS** whitespace characters, delimits a field. A sequence of **IFS** whitespace characters is also treated as a delimiter. If the value of **IFS** is null, no word splitting occurs.

Explicit null arguments ("" or '') are retained. Unquoted implicit null arguments, resulting from the expansion of parameters that have no values, are removed. If a parameter with no value is expanded within double quotes, a null argument results and is retained.

Note that if no expansion occurs, no splitting is performed.

### Pathname Expansion

After word splitting, unless the **-f** option has been set, **bash** scans each word for the characters **\***, **?**, and **[**. If one of these characters appears, then the word is regarded as a *pattern*, and replaced with an alphabetically sorted list of file names matching the pattern. If no matching file names are found, and the shell option **nullglob** is disabled, the word is left unchanged. If the **nullglob** option is set, and no matches are found, the word is removed. If the **failglob** shell option is set, and no matches are found, an error message is printed and the command is not executed. If the shell option **nocaseglob** is enabled, the match is performed without regard to the case of alphabetic characters. When a pattern is used for pathname expansion, the character **"."** at the start of a name or immediately following a slash must be matched explicitly, unless the shell option **dotglob** is set. When matching a pathname, the slash character must always be matched explicitly. In other cases, the **"."** character is not treated specially. See the description of **shopt** below under **SHELL BUILTIN COMMANDS** for a description of the **nocaseglob**, **nullglob**, **failglob**, and **dotglob** shell options.

The **GLOBIGNORE** shell variable may be used to restrict the set of file names matching a *pattern*. If **GLOBIGNORE** is set, each matching file name that also matches one of the patterns in **GLOBIGNORE** is removed from the list of matches. The file names **"."** and **".."** are always ignored when **GLOBIGNORE** is set and not null. However, setting **GLOBIGNORE** to a non-null value has the effect of enabling the **dotglob** shell option, so all other file names beginning with a **"."** will match. To get the old behavior of ignoring file names beginning with a **"."**, make **"\*."** one of the patterns in **GLOBIGNORE**. The **dotglob** option is disabled when **GLOBIGNORE** is unset.

### Pattern Matching

Any character that appears in a pattern, other than the special pattern characters described below, matches itself. The NUL character may not occur in a pattern. A backslash escapes the following character; the escaping backslash is discarded when matching. The special pattern characters must be quoted if they are to be matched literally.

The special pattern characters have the following meanings:

- \*** Matches any string, including the null string.
- ?** Matches any single character.
- [...]** Matches any one of the enclosed characters. A pair of characters separated by a hyphen denotes a *range expression*; any character that sorts between those two characters, inclusive, using the current locale's collating sequence and character set, is matched. If the first character following the **[** is a **!** or a **^** then any character not enclosed is matched. The sorting order of characters in range expressions is determined by the current locale and the value of the **LC\_COLLATE** shell variable, if set. A **-** may be matched by including it as the first or last character in the set. A **]** may be matched by including it as the first character in the set.

Within **[** and **]**, *character classes* can be specified using the syntax **[*class*]**, where *class* is one of the following classes defined in the POSIX standard:

**alnum alpha ascii blank cntrl digit graph lower print punct space upper word xdigit**

A character class matches any character belonging to that class. The **word** character class matches letters, digits, and the character **\_**.

Within **[** and **]**, an *equivalence class* can be specified using the syntax **[*=c*]**, which matches all characters with the same collation weight (as defined by the current locale) as the character *c*.

Within [ and ], the syntax [*symbol*.] matches the collating symbol *symbol*.

If the **extglob** shell option is enabled using the **shopt** builtin, several extended pattern matching operators are recognized. In the following description, a *pattern-list* is a list of one or more patterns separated by a |. Composite patterns may be formed using one or more of the following sub-patterns:

```
?(pattern-list)
 Matches zero or one occurrence of the given patterns
*(pattern-list)
 Matches zero or more occurrences of the given patterns
+(pattern-list)
 Matches one or more occurrences of the given patterns
@(pattern-list)
 Matches one of the given patterns
!(pattern-list)
 Matches anything except one of the given patterns
```

### Quote Removal

After the preceding expansions, all unquoted occurrences of the characters \, ', and " that did not result from one of the above expansions are removed.

### REDIRECTION

Before a command is executed, its input and output may be *redirected* using a special notation interpreted by the shell. Redirection may also be used to open and close files for the current shell execution environment. The following redirection operators may precede or appear anywhere within a *simple command* or may follow a *command*. Redirections are processed in the order they appear, from left to right.

In the following descriptions, if the file descriptor number is omitted, and the first character of the redirection operator is <, the redirection refers to the standard input (file descriptor 0). If the first character of the redirection operator is >, the redirection refers to the standard output (file descriptor 1).

The word following the redirection operator in the following descriptions, unless otherwise noted, is subjected to brace expansion, tilde expansion, parameter expansion, command substitution, arithmetic expansion, quote removal, pathname expansion, and word splitting. If it expands to more than one word, **bash** reports an error.

Note that the order of redirections is significant. For example, the command

```
ls > dirlist 2>&1
```

directs both standard output and standard error to the file *dirlist*, while the command

```
ls 2>&1 > dirlist
```

directs only the standard output to file *dirlist*, because the standard error was duplicated as standard output before the standard output was redirected to *dirlist*.

**Bash** handles several filenames specially when they are used in redirections, as described in the following table:

```
/dev/fd/fd
 If fd is a valid integer, file descriptor fd is duplicated.
/dev/stdin
 File descriptor 0 is duplicated.
/dev/stdout
 File descriptor 1 is duplicated.
/dev/stderr
 File descriptor 2 is duplicated.
/dev/tcp/host/port
 If host is a valid hostname or Internet address, and port is an integer port number or service name, bash attempts to open a TCP connection to the corresponding socket.
```

**/dev/udp/host/port**

If *host* is a valid hostname or Internet address, and *port* is an integer port number or service name, **bash** attempts to open a UDP connection to the corresponding socket.

A failure to open or create a file causes the redirection to fail.

Redirections using file descriptors greater than 9 should be used with care, as they may conflict with file descriptors the shell uses internally.

### Redirecting Input

Redirection of input causes the file whose name results from the expansion of *word* to be opened for reading on file descriptor *n*, or the standard input (file descriptor 0) if *n* is not specified.

The general format for redirecting input is:

**[n]<word**

### Redirecting Output

Redirection of output causes the file whose name results from the expansion of *word* to be opened for writing on file descriptor *n*, or the standard output (file descriptor 1) if *n* is not specified. If the file does not exist it is created; if it does exist it is truncated to zero size.

The general format for redirecting output is:

**[n]>word**

If the redirection operator is **>**, and the **noclobber** option to the **set** builtin has been enabled, the redirection will fail if the file whose name results from the expansion of *word* exists and is a regular file. If the redirection operator is **>|**, or the redirection operator is **>** and the **noclobber** option to the **set** builtin command is not enabled, the redirection is attempted even if the file named by *word* exists.

### Appending Redirected Output

Redirection of output in this fashion causes the file whose name results from the expansion of *word* to be opened for appending on file descriptor *n*, or the standard output (file descriptor 1) if *n* is not specified. If the file does not exist it is created.

The general format for appending output is:

**[n]>>word**

### Redirecting Standard Output and Standard Error

**Bash** allows both the standard output (file descriptor 1) and the standard error output (file descriptor 2) to be redirected to the file whose name is the expansion of *word* with this construct.

There are two formats for redirecting standard output and standard error:

**&>word**

and

**>&word**

Of the two forms, the first is preferred. This is semantically equivalent to

**>word 2>&1**

### Here Documents

This type of redirection instructs the shell to read input from the current source until a line containing only *word* (with no trailing blanks) is seen. All of the lines read up to that point are then used as the standard input for a command.

The format of here-documents is:

**<<[-]word**  
*here-document*  
*delimiter*

No parameter expansion, command substitution, arithmetic expansion, or pathname expansion is performed on *word*. If any characters in *word* are quoted, the *delimiter* is the result of quote removal on *word*, and

the lines in the here-document are not expanded. If *word* is unquoted, all lines of the here-document are subjected to parameter expansion, command substitution, and arithmetic expansion. In the latter case, the character sequence `\<newline>` is ignored, and `\` must be used to quote the characters `\`, `$`, and `'`.

If the redirection operator is `<<-`, then all leading tab characters are stripped from input lines and the line containing *delimiter*. This allows here-documents within shell scripts to be indented in a natural fashion.

### Here Strings

A variant of here documents, the format is:

```
<<<word
```

The *word* is expanded and supplied to the command on its standard input.

### Duplicating File Descriptors

The redirection operator

```
[n]<&word
```

is used to duplicate input file descriptors. If *word* expands to one or more digits, the file descriptor denoted by *n* is made to be a copy of that file descriptor. If the digits in *word* do not specify a file descriptor open for input, a redirection error occurs. If *word* evaluates to `-`, file descriptor *n* is closed. If *n* is not specified, the standard input (file descriptor 0) is used.

The operator

```
[n]>&word
```

is used similarly to duplicate output file descriptors. If *n* is not specified, the standard output (file descriptor 1) is used. If the digits in *word* do not specify a file descriptor open for output, a redirection error occurs. As a special case, if *n* is omitted, and *word* does not expand to one or more digits, the standard output and standard error are redirected as described previously.

### Moving File Descriptors

The redirection operator

```
[n]<&digit-
```

moves the file descriptor *digit* to file descriptor *n*, or the standard input (file descriptor 0) if *n* is not specified. *digit* is closed after being duplicated to *n*.

Similarly, the redirection operator

```
[n]>&digit-
```

moves the file descriptor *digit* to file descriptor *n*, or the standard output (file descriptor 1) if *n* is not specified.

### Opening File Descriptors for Reading and Writing

The redirection operator

```
[n]<>word
```

causes the file whose name is the expansion of *word* to be opened for both reading and writing on file descriptor *n*, or on file descriptor 0 if *n* is not specified. If the file does not exist, it is created.

## ALIASES

*Aliases* allow a string to be substituted for a word when it is used as the first word of a simple command. The shell maintains a list of aliases that may be set and unset with the **alias** and **unalias** builtin commands (see **SHELL BUILTIN COMMANDS** below). The first word of each simple command, if unquoted, is checked to see if it has an alias. If so, that word is replaced by the text of the alias. The characters `/`, `$`, `'`, and `=` and any of the shell *metacharacters* or quoting characters listed above may not appear in an alias name. The replacement text may contain any valid shell input, including shell metacharacters. The first word of the replacement text is tested for aliases, but a word that is identical to an alias being expanded is not expanded a second time. This means that one may alias **ls** to **ls -F**, for instance, and **bash** does not try to recursively expand the replacement text. If the last character of the alias value is a *blank*, then the next

command word following the alias is also checked for alias expansion.

Aliases are created and listed with the **alias** command, and removed with the **unalias** command.

There is no mechanism for using arguments in the replacement text. If arguments are needed, a shell function should be used (see **FUNCTIONS** below).

Aliases are not expanded when the shell is not interactive, unless the **expand\_aliases** shell option is set using **shopt** (see the description of **shopt** under **SHELL BUILTIN COMMANDS** below).

The rules concerning the definition and use of aliases are somewhat confusing. **Bash** always reads at least one complete line of input before executing any of the commands on that line. Aliases are expanded when a command is read, not when it is executed. Therefore, an alias definition appearing on the same line as another command does not take effect until the next line of input is read. The commands following the alias definition on that line are not affected by the new alias. This behavior is also an issue when functions are executed. Aliases are expanded when a function definition is read, not when the function is executed, because a function definition is itself a compound command. As a consequence, aliases defined in a function are not available until after that function is executed. To be safe, always put alias definitions on a separate line, and do not use **alias** in compound commands.

For almost every purpose, aliases are superseded by shell functions.

## FUNCTIONS

A shell function, defined as described above under **SHELL GRAMMAR**, stores a series of commands for later execution. When the name of a shell function is used as a simple command name, the list of commands associated with that function name is executed. Functions are executed in the context of the current shell; no new process is created to interpret them (contrast this with the execution of a shell script). When a function is executed, the arguments to the function become the positional parameters during its execution. The special parameter **#** is updated to reflect the change. Special parameter **0** is unchanged. The first element of the **FUNCNAME** variable is set to the name of the function while the function is executing. All other aspects of the shell execution environment are identical between a function and its caller with the exception that the **DEBUG** and **RETURN** traps (see the description of the **trap** builtin under **SHELL BUILTIN COMMANDS** below) are not inherited unless the function has been given the **trace** attribute (see the description of the **declare** builtin below) or the **-o functrace** shell option has been enabled with the **set** builtin (in which case all functions inherit the **DEBUG** and **RETURN** traps).

Variables local to the function may be declared with the **local** builtin command. Ordinarily, variables and their values are shared between the function and its caller.

If the builtin command **return** is executed in a function, the function completes and execution resumes with the next command after the function call. Any command associated with the **RETURN** trap is executed before execution resumes. When a function completes, the values of the positional parameters and the special parameter **#** are restored to the values they had prior to the function's execution.

Function names and definitions may be listed with the **-f** option to the **declare** or **typeset** builtin commands. The **-F** option to **declare** or **typeset** will list the function names only (and optionally the source file and line number, if the **extdebug** shell option is enabled). Functions may be exported so that subshells automatically have them defined with the **-f** option to the **export** builtin. A function definition may be deleted using the **-f** option to the **unset** builtin. Note that shell functions and variables with the same name may result in multiple identically-named entries in the environment passed to the shell's children. Care should be taken in cases where this may cause a problem.

Functions may be recursive. No limit is imposed on the number of recursive calls.

## ARITHMETIC EVALUATION

The shell allows arithmetic expressions to be evaluated, under certain circumstances (see the **let** and **declare** builtin commands and **Arithmetic Expansion**). Evaluation is done in fixed-width integers with no check for overflow, though division by 0 is trapped and flagged as an error. The operators and their precedence, associativity, and values are the same as in the C language. The following list of operators is grouped into levels of equal-precedence operators. The levels are listed in order of decreasing precedence.

```

id++ id--
 variable post-increment and post-decrement
++id --id
 variable pre-increment and pre-decrement
- +
 unary minus and plus
! ~
 logical and bitwise negation
**
 exponentiation
* / %
 multiplication, division, remainder
+ -
 addition, subtraction
<< >>
 left and right bitwise shifts
<= >= < >
 comparison
== !=
 equality and inequality
&
 bitwise AND
^
 bitwise exclusive OR
|
 bitwise OR
&&
 logical AND
||
 logical OR
expr?expr:expr
 conditional operator
= *= /= %= += -= <<= >>= &= ^= |=
 assignment
expr1 , expr2
 comma

```

Shell variables are allowed as operands; parameter expansion is performed before the expression is evaluated. Within an expression, shell variables may also be referenced by name without using the parameter expansion syntax. A shell variable that is null or unset evaluates to 0 when referenced by name without using the parameter expansion syntax. The value of a variable is evaluated as an arithmetic expression when it is referenced, or when a variable which has been given the *integer* attribute using **declare -i** is assigned a value. A null value evaluates to 0. A shell variable need not have its integer attribute turned on to be used in an expression.

Constants with a leading 0 are interpreted as octal numbers. A leading 0x or 0X denotes hexadecimal. Otherwise, numbers take the form [*base#*]n, where *base* is a decimal number between 2 and 64 representing the arithmetic base, and *n* is a number in that base. If *base#* is omitted, then base 10 is used. The digits greater than 9 are represented by the lowercase letters, the uppercase letters, @, and \_, in that order. If *base* is less than or equal to 36, lowercase and uppercase letters may be used interchangeably to represent numbers between 10 and 35.

Operators are evaluated in order of precedence. Sub-expressions in parentheses are evaluated first and may override the precedence rules above.

## CONDITIONAL EXPRESSIONS

Conditional expressions are used by the **[[** compound command and the **test** and **[** builtin commands to test file attributes and perform string and arithmetic comparisons. Expressions are formed from the following unary or binary primaries. If any *file* argument to one of the primaries is of the form */dev/fd/n*, then file descriptor *n* is checked. If the *file* argument to one of the primaries is one of */dev/stdin*, */dev/stdout*, or */dev/stderr*, file descriptor 0, 1, or 2, respectively, is checked.

Unless otherwise specified, primaries that operate on files follow symbolic links and operate on the target of the link, rather than the link itself.

```

-a file True if file exists.
-b file True if file exists and is a block special file.
-c file True if file exists and is a character special file.

```

**-d file** True if *file* exists and is a directory.  
**-e file** True if *file* exists.  
**-f file** True if *file* exists and is a regular file.  
**-g file** True if *file* exists and is set-group-id.  
**-h file** True if *file* exists and is a symbolic link.  
**-k file** True if *file* exists and its “sticky” bit is set.  
**-p file** True if *file* exists and is a named pipe (FIFO).  
**-r file** True if *file* exists and is readable.  
**-s file** True if *file* exists and has a size greater than zero.  
**-t fd** True if file descriptor *fd* is open and refers to a terminal.  
**-u file** True if *file* exists and its set-user-id bit is set.  
**-w file** True if *file* exists and is writable.  
**-x file** True if *file* exists and is executable.  
**-O file** True if *file* exists and is owned by the effective user id.  
**-G file** True if *file* exists and is owned by the effective group id.  
**-L file** True if *file* exists and is a symbolic link.  
**-S file** True if *file* exists and is a socket.  
**-N file** True if *file* exists and has been modified since it was last read.  
**file1 -nt file2**  
 True if *file1* is newer (according to modification date) than *file2*, or if *file1* exists and *file2* does not.  
**file1 -ot file2**  
 True if *file1* is older than *file2*, or if *file2* exists and *file1* does not.  
**file1 -ef file2**  
 True if *file1* and *file2* refer to the same device and inode numbers.  
**-o optname**  
 True if shell option *optname* is enabled. See the list of options under the description of the **-o** option to the **set** builtin below.  
**-z string**  
 True if the length of *string* is zero.  
*string*  
**-n string**  
 True if the length of *string* is non-zero.  
*string1* == *string2*  
 True if the strings are equal. = may be used in place of == for strict POSIX compliance.  
*string1* != *string2*  
 True if the strings are not equal.  
*string1* < *string2*  
 True if *string1* sorts before *string2* lexicographically in the current locale.  
*string1* > *string2*  
 True if *string1* sorts after *string2* lexicographically in the current locale.  
*arg1* **OP** *arg2*  
**OP** is one of **-eq**, **-ne**, **-lt**, **-le**, **-gt**, or **-ge**. These arithmetic binary operators return true if *arg1* is equal to, not equal to, less than, less than or equal to, greater than, or greater than or equal to *arg2*, respectively. *Arg1* and *arg2* may be positive or negative integers.

## SIMPLE COMMAND EXPANSION

When a simple command is executed, the shell performs the following expansions, assignments, and redirections, from left to right.

1. The words that the parser has marked as variable assignments (those preceding the command name) and redirections are saved for later processing.
2. The words that are not variable assignments or redirections are expanded. If any words remain after expansion, the first word is taken to be the name of the command and the remaining words

are the arguments.

3. Redirections are performed as described above under **REDIRECTION**.
4. The text after the = in each variable assignment undergoes tilde expansion, parameter expansion, command substitution, arithmetic expansion, and quote removal before being assigned to the variable.

If no command name results, the variable assignments affect the current shell environment. Otherwise, the variables are added to the environment of the executed command and do not affect the current shell environment. If any of the assignments attempts to assign a value to a readonly variable, an error occurs, and the command exits with a non-zero status.

If no command name results, redirections are performed, but do not affect the current shell environment. A redirection error causes the command to exit with a non-zero status.

If there is a command name left after expansion, execution proceeds as described below. Otherwise, the command exits. If one of the expansions contained a command substitution, the exit status of the command is the exit status of the last command substitution performed. If there were no command substitutions, the command exits with a status of zero.

## COMMAND EXECUTION

After a command has been split into words, if it results in a simple command and an optional list of arguments, the following actions are taken.

If the command name contains no slashes, the shell attempts to locate it. If there exists a shell function by that name, that function is invoked as described above in **FUNCTIONS**. If the name does not match a function, the shell searches for it in the list of shell builtins. If a match is found, that builtin is invoked.

If the name is neither a shell function nor a builtin, and contains no slashes, **bash** searches each element of the **PATH** for a directory containing an executable file by that name. **Bash** uses a hash table to remember the full pathnames of executable files (see **hash** under **SHELL BUILTIN COMMANDS** below). A full search of the directories in **PATH** is performed only if the command is not found in the hash table. If the search is unsuccessful, the shell prints an error message and returns an exit status of 127.

If the search is successful, or if the command name contains one or more slashes, the shell executes the named program in a separate execution environment. Argument 0 is set to the name given, and the remaining arguments to the command are set to the arguments given, if any.

If this execution fails because the file is not in executable format, and the file is not a directory, it is assumed to be a *shell script*, a file containing shell commands. A subshell is spawned to execute it. This subshell reinitializes itself, so that the effect is as if a new shell had been invoked to handle the script, with the exception that the locations of commands remembered by the parent (see **hash** below under **SHELL BUILTIN COMMANDS**) are retained by the child.

If the program is a file beginning with **#!**, the remainder of the first line specifies an interpreter for the program. The shell executes the specified interpreter on operating systems that do not handle this executable format themselves. The arguments to the interpreter consist of a single optional argument following the interpreter name on the first line of the program, followed by the name of the program, followed by the command arguments, if any.

## COMMAND EXECUTION ENVIRONMENT

The shell has an *execution environment*, which consists of the following:

- open files inherited by the shell at invocation, as modified by redirections supplied to the **exec** builtin
- the current working directory as set by **cd**, **pushd**, or **popd**, or inherited by the shell at invocation
- the file creation mode mask as set by **umask** or inherited from the shell's parent
- current traps set by **trap**

- shell parameters that are set by variable assignment or with **set** or inherited from the shell's parent in the environment
- shell functions defined during execution or inherited from the shell's parent in the environment
- options enabled at invocation (either by default or with command-line arguments) or by **set**
- options enabled by **shopt**
- shell aliases defined with **alias**
- various process IDs, including those of background jobs, the value of **\$\$**, and the value of **\$PPID**

When a simple command other than a builtin or shell function is to be executed, it is invoked in a separate execution environment that consists of the following. Unless otherwise noted, the values are inherited from the shell.

- the shell's open files, plus any modifications and additions specified by redirections to the command
- the current working directory
- the file creation mode mask
- shell variables and functions marked for export, along with variables exported for the command, passed in the environment
- traps caught by the shell are reset to the values inherited from the shell's parent, and traps ignored by the shell are ignored

A command invoked in this separate environment cannot affect the shell's execution environment.

Command substitution, commands grouped with parentheses, and asynchronous commands are invoked in a subshell environment that is a duplicate of the shell environment, except that traps caught by the shell are reset to the values that the shell inherited from its parent at invocation. Builtin commands that are invoked as part of a pipeline are also executed in a subshell environment. Changes made to the subshell environment cannot affect the shell's execution environment.

If a command is followed by a **&** and job control is not active, the default standard input for the command is the empty file */dev/null*. Otherwise, the invoked command inherits the file descriptors of the calling shell as modified by redirections.

## ENVIRONMENT

When a program is invoked it is given an array of strings called the *environment*. This is a list of *name=value* pairs, of the form *name=value*.

The shell provides several ways to manipulate the environment. On invocation, the shell scans its own environment and creates a parameter for each name found, automatically marking it for *export* to child processes. Executed commands inherit the environment. The **export** and **declare -x** commands allow parameters and functions to be added to and deleted from the environment. If the value of a parameter in the environment is modified, the new value becomes part of the environment, replacing the old. The environment inherited by any executed command consists of the shell's initial environment, whose values may be modified in the shell, less any pairs removed by the **unset** command, plus any additions via the **export** and **declare -x** commands.

The environment for any *simple command* or function may be augmented temporarily by prefixing it with parameter assignments, as described above in **PARAMETERS**. These assignment statements affect only the environment seen by that command.

If the **-k** option is set (see the **set** builtin command below), then *all* parameter assignments are placed in the environment for a command, not just those that precede the command name.

When **bash** invokes an external command, the variable **\_** is set to the full file name of the command and passed to that command in its environment.

## EXIT STATUS

For the shell's purposes, a command which exits with a zero exit status has succeeded. An exit status of zero indicates success. A non-zero exit status indicates failure. When a command terminates on a fatal signal *N*, **bash** uses the value of  $128+N$  as the exit status.

If a command is not found, the child process created to execute it returns a status of 127. If a command is found but is not executable, the return status is 126.

If a command fails because of an error during expansion or redirection, the exit status is greater than zero.

Shell builtin commands return a status of 0 (*true*) if successful, and non-zero (*false*) if an error occurs while they execute. All builtins return an exit status of 2 to indicate incorrect usage.

**Bash** itself returns the exit status of the last command executed, unless a syntax error occurs, in which case it exits with a non-zero value. See also the **exit** builtin command below.

## SIGNALS

When **bash** is interactive, in the absence of any traps, it ignores **SIGTERM** (so that **kill 0** does not kill an interactive shell), and **SIGINT** is caught and handled (so that the **wait** builtin is interruptible). In all cases, **bash** ignores **SIGQUIT**. If job control is in effect, **bash** ignores **SIGTTIN**, **SIGTTOU**, and **SIGTSTP**.

Non-builtin commands run by **bash** have signal handlers set to the values inherited by the shell from its parent. When job control is not in effect, asynchronous commands ignore **SIGINT** and **SIGQUIT** in addition to these inherited handlers. Commands run as a result of command substitution ignore the keyboard-generated job control signals **SIGTTIN**, **SIGTTOU**, and **SIGTSTP**.

The shell exits by default upon receipt of a **SIGHUP**. Before exiting, an interactive shell resends the **SIGHUP** to all jobs, running or stopped. Stopped jobs are sent **SIGCONT** to ensure that they receive the **SIGHUP**. To prevent the shell from sending the signal to a particular job, it should be removed from the jobs table with the **disown** builtin (see **SHELL BUILTIN COMMANDS** below) or marked to not receive **SIGHUP** using **disown -h**.

If the **huponexit** shell option has been set with **shopt**, **bash** sends a **SIGHUP** to all jobs when an interactive login shell exits.

If **bash** is waiting for a command to complete and receives a signal for which a trap has been set, the trap will not be executed until the command completes. When **bash** is waiting for an asynchronous command via the **wait** builtin, the reception of a signal for which a trap has been set will cause the **wait** builtin to return immediately with an exit status greater than 128, immediately after which the trap is executed.

## JOB CONTROL

*Job control* refers to the ability to selectively stop (*suspend*) the execution of processes and continue (*resume*) their execution at a later point. A user typically employs this facility via an interactive interface supplied jointly by the system's terminal driver and **bash**.

The shell associates a *job* with each pipeline. It keeps a table of currently executing jobs, which may be listed with the **jobs** command. When **bash** starts a job asynchronously (in the *background*), it prints a line that looks like:

```
[1] 25647
```

indicating that this job is job number 1 and that the process ID of the last process in the pipeline associated with this job is 25647. All of the processes in a single pipeline are members of the same job. **Bash** uses the *job* abstraction as the basis for job control.

To facilitate the implementation of the user interface to job control, the operating system maintains the notion of a *current terminal process group ID*. Members of this process group (processes whose process group ID is equal to the current terminal process group ID) receive keyboard-generated signals such as **SIGINT**. These processes are said to be in the *foreground*. *Background* processes are those whose process group ID differs from the terminal's; such processes are immune to keyboard-generated signals. Only foreground processes are allowed to read from or write to the terminal. Background processes which attempt to read from (write to) the terminal are sent a **SIGTTIN** (**SIGTTOU**) signal by the terminal driver, which, unless caught, suspends the process.

If the operating system on which **bash** is running supports job control, **bash** contains facilities to use it. Typing the *suspend* character (typically **^Z**, Control-Z) while a process is running causes that process to be stopped and returns control to **bash**. Typing the *delayed suspend* character (typically **^Y**, Control-Y) causes the process to be stopped when it attempts to read input from the terminal, and control to be returned to **bash**. The user may then manipulate the state of this job, using the **bg** command to continue it in the background, the **fg** command to continue it in the foreground, or the **kill** command to kill it. A **^Z** takes effect immediately, and has the additional side effect of causing pending output and typeahead to be discarded.

There are a number of ways to refer to a job in the shell. The character **%** introduces a job name. Job number *n* may be referred to as **%n**. A job may also be referred to using a prefix of the name used to start it, or using a substring that appears in its command line. For example, **%ce** refers to a stopped **ce** job. If a prefix matches more than one job, **bash** reports an error. Using **%?ce**, on the other hand, refers to any job containing the string **ce** in its command line. If the substring matches more than one job, **bash** reports an error. The symbols **%%** and **%+** refer to the shell's notion of the *current job*, which is the last job stopped while it was in the foreground or started in the background. The *previous job* may be referenced using **%-**. In output pertaining to jobs (e.g., the output of the **jobs** command), the current job is always flagged with a **+**, and the previous job with a **-**. A single **%** (with no accompanying job specification) also refers to the current job.

Simply naming a job can be used to bring it into the foreground: **%1** is a synonym for “**fg %1**”, bringing job 1 from the background into the foreground. Similarly, “**%1 &**” resumes job 1 in the background, equivalent to “**bg %1**”.

The shell learns immediately whenever a job changes state. Normally, **bash** waits until it is about to print a prompt before reporting changes in a job's status so as to not interrupt any other output. If the **-b** option to the **set** builtin command is enabled, **bash** reports such changes immediately. Any trap on **SIGCHLD** is executed for each child that exits.

If an attempt to exit **bash** is made while jobs are stopped, the shell prints a warning message. The **jobs** command may then be used to inspect their status. If a second attempt to exit is made without an intervening command, the shell does not print another warning, and the stopped jobs are terminated.

## PROMPTING

When executing interactively, **bash** displays the primary prompt **PS1** when it is ready to read a command, and the secondary prompt **PS2** when it needs more input to complete a command. **Bash** allows these prompt strings to be customized by inserting a number of backslash-escaped special characters that are decoded as follows:

|                   |                                                                                                                                                                                                       |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>\a</b>         | an ASCII bell character (07)                                                                                                                                                                          |
| <b>\d</b>         | the date in "Weekday Month Date" format (e.g., "Tue May 26")                                                                                                                                          |
| <b>\D{format}</b> | the <i>format</i> is passed to <i>strftime(3)</i> and the result is inserted into the prompt string; an empty <i>format</i> results in a locale-specific time representation. The braces are required |
| <b>\e</b>         | an ASCII escape character (033)                                                                                                                                                                       |
| <b>\h</b>         | the hostname up to the first ‘.’                                                                                                                                                                      |
| <b>\H</b>         | the hostname                                                                                                                                                                                          |
| <b>\j</b>         | the number of jobs currently managed by the shell                                                                                                                                                     |
| <b>\l</b>         | the basename of the shell's terminal device name                                                                                                                                                      |
| <b>\n</b>         | newline                                                                                                                                                                                               |
| <b>\r</b>         | carriage return                                                                                                                                                                                       |
| <b>\s</b>         | the name of the shell, the basename of <b>\$0</b> (the portion following the final slash)                                                                                                             |
| <b>\t</b>         | the current time in 24-hour HH:MM:SS format                                                                                                                                                           |
| <b>\T</b>         | the current time in 12-hour HH:MM:SS format                                                                                                                                                           |
| <b>\@</b>         | the current time in 12-hour am/pm format                                                                                                                                                              |
| <b>\A</b>         | the current time in 24-hour HH:MM format                                                                                                                                                              |
| <b>\u</b>         | the username of the current user                                                                                                                                                                      |

|                   |                                                                                                                       |
|-------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>\v</code>   | the version of <b>bash</b> (e.g., 2.00)                                                                               |
| <code>\V</code>   | the release of <b>bash</b> , version + patch level (e.g., 2.00.0)                                                     |
| <code>\w</code>   | the current working directory, with <b>\$HOME</b> abbreviated with a tilde                                            |
| <code>\W</code>   | the basename of the current working directory, with <b>\$HOME</b> abbreviated with a tilde                            |
| <code>!</code>    | the history number of this command                                                                                    |
| <code>#</code>    | the command number of this command                                                                                    |
| <code>\$</code>   | if the effective UID is 0, a #, otherwise a \$                                                                        |
| <code>\nnn</code> | the character corresponding to the octal number <i>nnn</i>                                                            |
| <code>\</code>    | a backslash                                                                                                           |
| <code>[</code>    | begin a sequence of non-printing characters, which could be used to embed a terminal control sequence into the prompt |
| <code>]</code>    | end a sequence of non-printing characters                                                                             |

The command number and the history number are usually different: the history number of a command is its position in the history list, which may include commands restored from the history file (see **HISTORY** below), while the command number is the position in the sequence of commands executed during the current shell session. After the string is decoded, it is expanded via parameter expansion, command substitution, arithmetic expansion, and quote removal, subject to the value of the **promptvars** shell option (see the description of the **shopt** command under **SHELL BUILTIN COMMANDS** below).

## READLINE

This is the library that handles reading input when using an interactive shell, unless the **--noediting** option is given at shell invocation. By default, the line editing commands are similar to those of emacs. A vi-style line editing interface is also available. To turn off line editing after the shell is running, use the **+o emacs** or **+o vi** options to the **set** builtin (see **SHELL BUILTIN COMMANDS** below).

### Readline Notation

In this section, the emacs-style notation is used to denote keystrokes. Control keys are denoted by *C-key*, e.g., *C-n* means Control-N. Similarly, *meta* keys are denoted by *M-key*, so *M-x* means Meta-X. (On keyboards without a *meta* key, *M-x* means ESC *x*, i.e., press the Escape key then the *x* key. This makes ESC the *meta prefix*. The combination *M-C-x* means ESC-Control-*x*, or press the Escape key then hold the Control key while pressing the *x* key.)

Readline commands may be given numeric *arguments*, which normally act as a repeat count. Sometimes, however, it is the sign of the argument that is significant. Passing a negative argument to a command that acts in the forward direction (e.g., **kill-line**) causes that command to act in a backward direction. Commands whose behavior with arguments deviates from this are noted below.

When a command is described as *killing* text, the text deleted is saved for possible future retrieval (*yanking*). The killed text is saved in a *kill ring*. Consecutive kills cause the text to be accumulated into one unit, which can be yanked all at once. Commands which do not kill text separate the chunks of text on the kill ring.

### Readline Initialization

Readline is customized by putting commands in an initialization file (the *inputrc* file). The name of this file is taken from the value of the **INPUTRC** environment variable. If that variable is unset, readline will read both */etc/inputrc* and *~/.inputrc*. When a program which uses the readline library starts up, the initialization file is read, and the key bindings and variables are set. There are only a few basic constructs allowed in the readline initialization file. Blank lines are ignored. Lines beginning with a **#** are comments. Lines beginning with a **\$** indicate conditional constructs. Other lines denote key bindings and variable settings.

The default key-bindings may be changed with an *inputrc* file. Other programs that use this library may add their own commands and bindings.

For example, placing

**M-Control-u**: universal-argument

or

**C-Meta-u**: universal-argument

into the *inputrc* would make **M-C-u** execute the readline command *universal-argument*.

The following symbolic character names are recognized: *RUBOUT*, *DEL*, *ESC*, *LFD*, *NEWLINE*, *RET*, *RETURN*, *SPC*, *SPACE*, and *TAB*.

In addition to command names, readline allows keys to be bound to a string that is inserted when the key is pressed (a *macro*).

### Readline Key Bindings

The syntax for controlling key bindings in the *inputrc* file is simple. All that is required is the name of the command or the text of a macro and a key sequence to which it should be bound. The name may be specified in one of two ways: as a symbolic key name, possibly with *Meta-* or *Control-* prefixes, or as a key sequence.

When using the form **keyname**:*function-name* or *macro*, **keyname** is the name of a key spelled out in English. For example:

```
Control-u: universal-argument
Meta-Rubout: backward-kill-word
Control-o: "> output"
```

In the above example, *C-u* is bound to the function **universal-argument**, *M-DEL* is bound to the function **backward-kill-word**, and *C-o* is bound to run the macro expressed on the right hand side (that is, to insert the text `> output` into the line).

In the second form, "**keyseq**":*function-name* or *macro*, **keyseq** differs from **keyname** above in that strings denoting an entire key sequence may be specified by placing the sequence within double quotes. Some GNU Emacs style key escapes can be used, as in the following example, but the symbolic character names are not recognized.

```
"\C-u": universal-argument
"\C-x\C-r": re-read-init-file
"\e[11~": "Function Key 1"
```

In this example, *C-u* is again bound to the function **universal-argument**. *C-x C-r* is bound to the function **re-read-init-file**, and *ESC [ 11 ~* is bound to insert the text `Function Key 1`.

The full set of GNU Emacs style escape sequences is

```
\C- control prefix
\M- meta prefix
\e an escape character
\\ backslash
\" literal "
\' literal '
```

In addition to the GNU Emacs style escape sequences, a second set of backslash escapes is available:

```
\a alert (bell)
\b backspace
\d delete
\f form feed
\n newline
\r carriage return
\t horizontal tab
\v vertical tab
\nnn the eight-bit character whose value is the octal value nnn (one to three digits)
\xHH the eight-bit character whose value is the hexadecimal value HH (one or two hex digits)
```

When entering the text of a macro, single or double quotes must be used to indicate a macro definition. Unquoted text is assumed to be a function name. In the macro body, the backslash escapes described above are expanded. Backslash will quote any other character in the macro text, including `"` and `'`.

**Bash** allows the current readline key bindings to be displayed or modified with the **bind** builtin command.

The editing mode may be switched during interactive use by using the **-o** option to the **set** builtin command (see **SHELL BUILTIN COMMANDS** below).

### Readline Variables

Readline has variables that can be used to further customize its behavior. A variable may be set in the *inputrc* file with a statement of the form

```
set variable-name value
```

Except where noted, readline variables can take the values **On** or **Off** (without regard to case). Unrecognized variable names are ignored. When a variable value is read, empty or null values, "on" (case-insensitive), and "1" are equivalent to **On**. All other values are equivalent to **Off**. The variables and their default values are:

#### **bell-style (audible)**

Controls what happens when readline wants to ring the terminal bell. If set to **none**, readline never rings the bell. If set to **visible**, readline uses a visible bell if one is available. If set to **audible**, readline attempts to ring the terminal's bell.

#### **bind-tty-special-chars (On)**

If set to **On**, readline attempts to bind the control characters treated specially by the kernel's terminal driver to their readline equivalents.

#### **comment-begin ("#")**

The string that is inserted when the readline **insert-comment** command is executed. This command is bound to **M-#** in emacs mode and to **#** in vi command mode.

#### **completion-ignore-case (Off)**

If set to **On**, readline performs filename matching and completion in a case-insensitive fashion.

#### **completion-query-items (100)**

This determines when the user is queried about viewing the number of possible completions generated by the **possible-completions** command. It may be set to any integer value greater than or equal to zero. If the number of possible completions is greater than or equal to the value of this variable, the user is asked whether or not he wishes to view them; otherwise they are simply listed on the terminal.

#### **convert-meta (On)**

If set to **On**, readline will convert characters with the eighth bit set to an ASCII key sequence by stripping the eighth bit and prefixing an escape character (in effect, using escape as the *meta prefix*).

#### **disable-completion (Off)**

If set to **On**, readline will inhibit word completion. Completion characters will be inserted into the line as if they had been mapped to **self-insert**.

#### **editing-mode (emacs)**

Controls whether readline begins with a set of key bindings similar to *emacs* or *vi*. **editing-mode** can be set to either **emacs** or **vi**.

#### **enable-keypad (Off)**

When set to **On**, readline will try to enable the application keypad when it is called. Some systems need this to enable the arrow keys.

#### **expand-tilde (Off)**

If set to **on**, tilde expansion is performed when readline attempts word completion.

#### **history-preserve-point (Off)**

If set to **on**, the history code attempts to place point at the same location on each history line retrieved with **previous-history** or **next-history**.

#### **horizontal-scroll-mode (Off)**

When set to **On**, makes readline use a single line for display, scrolling the input horizontally on a single screen line when it becomes longer than the screen width rather than wrapping to a new line.

#### **input-meta (Off)**

If set to **On**, readline will enable eight-bit input (that is, it will not strip the high bit from the characters it reads), regardless of what the terminal claims it can support. The name **meta-flag** is a

synonym for this variable.

**isearch-terminators (“C-[C-J”)**

The string of characters that should terminate an incremental search without subsequently executing the character as a command. If this variable has not been given a value, the characters *ESC* and *C-J* will terminate an incremental search.

**keymap (emacs)**

Set the current readline keymap. The set of valid keymap names is *emacs*, *emacs-standard*, *emacs-meta*, *emacs-ctlx*, *vi*, *vi-command*, and *vi-insert*. *vi* is equivalent to *vi-command*; *emacs* is equivalent to *emacs-standard*. The default value is *emacs*; the value of **editing-mode** also affects the default keymap.

**mark-directories (On)**

If set to **On**, completed directory names have a slash appended.

**mark-modified-lines (Off)**

If set to **On**, history lines that have been modified are displayed with a preceding asterisk (\*).

**mark-symlinked-directories (Off)**

If set to **On**, completed names which are symbolic links to directories have a slash appended (subject to the value of **mark-directories**).

**match-hidden-files (On)**

This variable, when set to **On**, causes readline to match files whose names begin with a *.* (hidden files) when performing filename completion, unless the leading *.* is supplied by the user in the filename to be completed.

**output-meta (Off)**

If set to **On**, readline will display characters with the eighth bit set directly rather than as a meta-prefixed escape sequence.

**page-completions (On)**

If set to **On**, readline uses an internal *more*-like pager to display a screenful of possible completions at a time.

**print-completions-horizontally (Off)**

If set to **On**, readline will display completions with matches sorted horizontally in alphabetical order, rather than down the screen.

**show-all-if-ambiguous (Off)**

This alters the default behavior of the completion functions. If set to **on**, words which have more than one possible completion cause the matches to be listed immediately instead of ringing the bell.

**show-all-if-unmodified (Off)**

This alters the default behavior of the completion functions in a fashion similar to **show-all-if-ambiguous**. If set to **on**, words which have more than one possible completion without any possible partial completion (the possible completions don't share a common prefix) cause the matches to be listed immediately instead of ringing the bell.

**visible-stats (Off)**

If set to **On**, a character denoting a file's type as reported by *stat(2)* is appended to the filename when listing possible completions.

### Readline Conditional Constructs

Readline implements a facility similar in spirit to the conditional compilation features of the C preprocessor which allows key bindings and variable settings to be performed as the result of tests. There are four parser directives used.

**\$if** The **\$if** construct allows bindings to be made based on the editing mode, the terminal being used, or the application using readline. The text of the test extends to the end of the line; no characters are required to isolate it.

**mode** The **mode=** form of the **\$if** directive is used to test whether readline is in emacs or vi mode. This may be used in conjunction with the **set keymap** command, for instance, to set bindings in the *emacs-standard* and *emacs-ctlx* keymaps only if readline is starting out in emacs mode.

**term** The **term=** form may be used to include terminal-specific key bindings, perhaps to bind the key sequences output by the terminal's function keys. The word on the right side of the = is tested against the both full name of the terminal and the portion of the terminal name before the first -. This allows *sun* to match both *sun* and *sun-cmd*, for instance.

#### **application**

The **application** construct is used to include application-specific settings. Each program using the readline library sets the *application name*, and an initialization file can test for a particular value. This could be used to bind key sequences to functions useful for a specific program. For instance, the following command adds a key sequence that quotes the current or previous word in Bash:

```
$if Bash
Quote the current or previous word
"C-xq": "\eb\\"\ef\"
$endif
```

**\$endif** This command, as seen in the previous example, terminates an **\$if** command.

**\$else** Commands in this branch of the **\$if** directive are executed if the test fails.

#### **\$include**

This directive takes a single filename as an argument and reads commands and bindings from that file. For example, the following directive would read */etc/inputrc*:

```
$include /etc/inputrc
```

### **Searching**

Readline provides commands for searching through the command history (see **HISTORY** below) for lines containing a specified string. There are two search modes: *incremental* and *non-incremental*.

Incremental searches begin before the user has finished typing the search string. As each character of the search string is typed, readline displays the next entry from the history matching the string typed so far. An incremental search requires only as many characters as needed to find the desired history entry. The characters present in the value of the **isearch-terminators** variable are used to terminate an incremental search. If that variable has not been assigned a value the Escape and Control-J characters will terminate an incremental search. Control-G will abort an incremental search and restore the original line. When the search is terminated, the history entry containing the search string becomes the current line.

To find other matching entries in the history list, type Control-S or Control-R as appropriate. This will search backward or forward in the history for the next entry matching the search string typed so far. Any other key sequence bound to a readline command will terminate the search and execute that command. For instance, a *newline* will terminate the search and accept the line, thereby executing the command from the history list.

Readline remembers the last incremental search string. If two Control-Rs are typed without any intervening characters defining a new search string, any remembered search string is used.

Non-incremental searches read the entire search string before starting to search for matching history lines. The search string may be typed by the user or be part of the contents of the current line.

### **Readline Command Names**

The following is a list of the names of the commands and the default key sequences to which they are bound. Command names without an accompanying key sequence are unbound by default. In the following descriptions, *point* refers to the current cursor position, and *mark* refers to a cursor position saved by the **set-mark** command. The text between the point and mark is referred to as the *region*.

### **Commands for Moving**

#### **beginning-of-line (C-a)**

Move to the start of the current line.

**end-of-line (C-e)**

Move to the end of the line.

**forward-char (C-f)**

Move forward a character.

**backward-char (C-b)**

Move back a character.

**forward-word (M-f)**

Move forward to the end of the next word. Words are composed of alphanumeric characters (letters and digits).

**backward-word (M-b)**

Move back to the start of the current or previous word. Words are composed of alphanumeric characters (letters and digits).

**clear-screen (C-l)**

Clear the screen leaving the current line at the top of the screen. With an argument, refresh the current line without clearing the screen.

**redraw-current-line**

Refresh the current line.

**Commands for Manipulating the History****accept-line (Newline, Return)**

Accept the line regardless of where the cursor is. If this line is non-empty, add it to the history list according to the state of the **HISTCONTROL** variable. If the line is a modified history line, then restore the history line to its original state.

**previous-history (C-p)**

Fetch the previous command from the history list, moving back in the list.

**next-history (C-n)**

Fetch the next command from the history list, moving forward in the list.

**beginning-of-history (M-<)**

Move to the first line in the history.

**end-of-history (M->)**

Move to the end of the input history, i.e., the line currently being entered.

**reverse-search-history (C-r)**

Search backward starting at the current line and moving ‘up’ through the history as necessary. This is an incremental search.

**forward-search-history (C-s)**

Search forward starting at the current line and moving ‘down’ through the history as necessary. This is an incremental search.

**non-incremental-reverse-search-history (M-p)**

Search backward through the history starting at the current line using a non-incremental search for a string supplied by the user.

**non-incremental-forward-search-history (M-n)**

Search forward through the history using a non-incremental search for a string supplied by the user.

**history-search-forward**

Search forward through the history for the string of characters between the start of the current line and the point. This is a non-incremental search.

**history-search-backward**

Search backward through the history for the string of characters between the start of the current line and the point. This is a non-incremental search.

**yank-nth-arg (M-C-y)**

Insert the first argument to the previous command (usually the second word on the previous line) at point. With an argument *n*, insert the *n*th word from the previous command (the words in the previous command begin with word 0). A negative argument inserts the *n*th word from the end of the previous command. Once the argument *n* is computed, the argument is extracted as if the “!*n*” history expansion had been specified.

**yank-last-arg (M-., M-\_)**

Insert the last argument to the previous command (the last word of the previous history entry). With an argument, behave exactly like **yank-nth-arg**. Successive calls to **yank-last-arg** move back through the history list, inserting the last argument of each line in turn. The history expansion facilities are used to extract the last argument, as if the "!"\$ history expansion had been specified.

**shell-expand-line (M-C-e)**

Expand the line as the shell does. This performs alias and history expansion as well as all of the shell word expansions. See **HISTORY EXPANSION** below for a description of history expansion.

**history-expand-line (M-^)**

Perform history expansion on the current line. See **HISTORY EXPANSION** below for a description of history expansion.

**magic-space**

Perform history expansion on the current line and insert a space. See **HISTORY EXPANSION** below for a description of history expansion.

**alias-expand-line**

Perform alias expansion on the current line. See **ALIASES** above for a description of alias expansion.

**history-and-alias-expand-line**

Perform history and alias expansion on the current line.

**insert-last-argument (M-., M-\_)**

A synonym for **yank-last-arg**.

**operate-and-get-next (C-o)**

Accept the current line for execution and fetch the next line relative to the current line from the history for editing. Any argument is ignored.

**edit-and-execute-command (C-xC-e)**

Invoke an editor on the current command line, and execute the result as shell commands. **Bash** attempts to invoke **\$FCEDIT**, **\$EDITOR**, and *emacs* as the editor, in that order.

**Commands for Changing Text****delete-char (C-d)**

Delete the character at point. If point is at the beginning of the line, there are no characters in the line, and the last character typed was not bound to **delete-char**, then return EOF.

**backward-delete-char (Rubout)**

Delete the character behind the cursor. When given a numeric argument, save the deleted text on the kill ring.

**forward-backward-delete-char**

Delete the character under the cursor, unless the cursor is at the end of the line, in which case the character behind the cursor is deleted.

**quoted-insert (C-q, C-v)**

Add the next character typed to the line verbatim. This is how to insert characters like C-q, for example.

**tab-insert (C-v TAB)**

Insert a tab character.

**self-insert (a, b, A, 1, !, ...)**

Insert the character typed.

**transpose-chars (C-t)**

Drag the character before point forward over the character at point, moving point forward as well. If point is at the end of the line, then this transposes the two characters before point. Negative arguments have no effect.

**transpose-words (M-t)**

Drag the word before point past the word after point, moving point over that word as well. If point is at the end of the line, this transposes the last two words on the line.

**upcase-word (M-u)**

Uppercase the current (or following) word. With a negative argument, uppercase the previous word, but do not move point.

**downcase-word (M-l)**

Lowercase the current (or following) word. With a negative argument, lowercase the previous word, but do not move point.

**capitalize-word (M-c)**

Capitalize the current (or following) word. With a negative argument, capitalize the previous word, but do not move point.

**overwrite-mode**

Toggle overwrite mode. With an explicit positive numeric argument, switches to overwrite mode. With an explicit non-positive numeric argument, switches to insert mode. This command affects only **emacs** mode; **vi** mode does overwrite differently. Each call to *readline()* starts in insert mode. In overwrite mode, characters bound to **self-insert** replace the text at point rather than pushing the text to the right. Characters bound to **backward-delete-char** replace the character before point with a space. By default, this command is unbound.

**Killing and Yanking****kill-line (C-k)**

Kill the text from point to the end of the line.

**backward-kill-line (C-x Rubout)**

Kill backward to the beginning of the line.

**unix-line-discard (C-u)**

Kill backward from point to the beginning of the line. The killed text is saved on the kill-ring.

**kill-whole-line**

Kill all characters on the current line, no matter where point is.

**kill-word (M-d)**

Kill from point to the end of the current word, or if between words, to the end of the next word. Word boundaries are the same as those used by **forward-word**.

**backward-kill-word (M-Rubout)**

Kill the word behind point. Word boundaries are the same as those used by **backward-word**.

**unix-word-rubout (C-w)**

Kill the word behind point, using white space as a word boundary. The killed text is saved on the kill-ring.

**unix-filename-rubout**

Kill the word behind point, using white space and the slash character as the word boundaries. The killed text is saved on the kill-ring.

**delete-horizontal-space (M-\)**

Delete all spaces and tabs around point.

**kill-region**

Kill the text in the current region.

**copy-region-as-kill**

Copy the text in the region to the kill buffer.

**copy-backward-word**

Copy the word before point to the kill buffer. The word boundaries are the same as **backward-word**.

**copy-forward-word**

Copy the word following point to the kill buffer. The word boundaries are the same as **forward-word**.

**yank (C-y)**

Yank the top of the kill ring into the buffer at point.

**yank-pop (M-y)**

Rotate the kill ring, and yank the new top. Only works following **yank** or **yank-pop**.

## Numeric Arguments

### **digit-argument** (M-0, M-1, ..., M--)

Add this digit to the argument already accumulating, or start a new argument. M-- starts a negative argument.

### **universal-argument**

This is another way to specify an argument. If this command is followed by one or more digits, optionally with a leading minus sign, those digits define the argument. If the command is followed by digits, executing **universal-argument** again ends the numeric argument, but is otherwise ignored. As a special case, if this command is immediately followed by a character that is neither a digit or minus sign, the argument count for the next command is multiplied by four. The argument count is initially one, so executing this function the first time makes the argument count four, a second time makes the argument count sixteen, and so on.

## Completing

### **complete** (TAB)

Attempt to perform completion on the text before point. **Bash** attempts completion treating the text as a variable (if the text begins with \$), username (if the text begins with ~), hostname (if the text begins with @), or command (including aliases and functions) in turn. If none of these produces a match, filename completion is attempted.

### **possible-completions** (M-?)

List the possible completions of the text before point.

### **insert-completions** (M-\*)

Insert all completions of the text before point that would have been generated by **possible-completions**.

### **menu-complete**

Similar to **complete**, but replaces the word to be completed with a single match from the list of possible completions. Repeated execution of **menu-complete** steps through the list of possible completions, inserting each match in turn. At the end of the list of completions, the bell is rung (subject to the setting of **bell-style**) and the original text is restored. An argument of *n* moves *n* positions forward in the list of matches; a negative argument may be used to move backward through the list. This command is intended to be bound to **TAB**, but is unbound by default.

### **delete-char-or-list**

Deletes the character under the cursor if not at the beginning or end of the line (like **delete-char**). If at the end of the line, behaves identically to **possible-completions**. This command is unbound by default.

### **complete-filename** (M-/)

Attempt filename completion on the text before point.

### **possible-filename-completions** (C-x /)

List the possible completions of the text before point, treating it as a filename.

### **complete-username** (M-~)

Attempt completion on the text before point, treating it as a username.

### **possible-username-completions** (C-x ~)

List the possible completions of the text before point, treating it as a username.

### **complete-variable** (M-\$)

Attempt completion on the text before point, treating it as a shell variable.

### **possible-variable-completions** (C-x \$)

List the possible completions of the text before point, treating it as a shell variable.

### **complete-hostname** (M-@)

Attempt completion on the text before point, treating it as a hostname.

### **possible-hostname-completions** (C-x @)

List the possible completions of the text before point, treating it as a hostname.

### **complete-command** (M-!)

Attempt completion on the text before point, treating it as a command name. Command completion attempts to match the text against aliases, reserved words, shell functions, shell builtins, and finally executable filenames, in that order.

**possible-command-completions (C-x !)**

List the possible completions of the text before point, treating it as a command name.

**dynamic-complete-history (M-TAB)**

Attempt completion on the text before point, comparing the text against lines from the history list for possible completion matches.

**complete-into-braces (M-{)**

Perform filename completion and insert the list of possible completions enclosed within braces so the list is available to the shell (see **Brace Expansion** above).

**Keyboard Macros****start-kbd-macro (C-x (**

Begin saving the characters typed into the current keyboard macro.

**end-kbd-macro (C-x )**

Stop saving the characters typed into the current keyboard macro and store the definition.

**call-last-kbd-macro (C-x e)**

Re-execute the last keyboard macro defined, by making the characters in the macro appear as if typed at the keyboard.

**Miscellaneous****re-read-init-file (C-x C-r)**

Read in the contents of the *inputrc* file, and incorporate any bindings or variable assignments found there.

**abort (C-g)**

Abort the current editing command and ring the terminal's bell (subject to the setting of **bell-style**).

**do-uppercase-version (M-a, M-b, M-x, ...)**

If the metaified character *x* is lowercase, run the command that is bound to the corresponding uppercase character.

**prefix-meta (ESC)**

Metafy the next character typed. **ESC f** is equivalent to **Meta-f**.

**undo (C-\_, C-x C-u)**

Incremental undo, separately remembered for each line.

**revert-line (M-r)**

Undo all changes made to this line. This is like executing the **undo** command enough times to return the line to its initial state.

**tilde-expand (M-&)**

Perform tilde expansion on the current word.

**set-mark (C-@, M-<space>)**

Set the mark to the point. If a numeric argument is supplied, the mark is set to that position.

**exchange-point-and-mark (C-x C-x)**

Swap the point with the mark. The current cursor position is set to the saved position, and the old cursor position is saved as the mark.

**character-search (C-])**

A character is read and point is moved to the next occurrence of that character. A negative count searches for previous occurrences.

**character-search-backward (M-C-])**

A character is read and point is moved to the previous occurrence of that character. A negative count searches for subsequent occurrences.

**insert-comment (M-#)**

Without a numeric argument, the value of the readline **comment-begin** variable is inserted at the beginning of the current line. If a numeric argument is supplied, this command acts as a toggle: if the characters at the beginning of the line do not match the value of **comment-begin**, the value is inserted, otherwise the characters in **comment-begin** are deleted from the beginning of the line. In either case, the line is accepted as if a newline had been typed. The default value of **comment-begin** causes this command to make the current line a shell comment. If a numeric argument causes the comment character to be removed, the line will be executed by the shell.

**glob-complete-word (M-g)**

The word before point is treated as a pattern for pathname expansion, with an asterisk implicitly appended. This pattern is used to generate a list of matching file names for possible completions.

**glob-expand-word (C-x \*)**

The word before point is treated as a pattern for pathname expansion, and the list of matching file names is inserted, replacing the word. If a numeric argument is supplied, an asterisk is appended before pathname expansion.

**glob-list-expansions (C-x g)**

The list of expansions that would have been generated by **glob-expand-word** is displayed, and the line is redrawn. If a numeric argument is supplied, an asterisk is appended before pathname expansion.

**dump-functions**

Print all of the functions and their key bindings to the readline output stream. If a numeric argument is supplied, the output is formatted in such a way that it can be made part of an *inputrc* file.

**dump-variables**

Print all of the settable readline variables and their values to the readline output stream. If a numeric argument is supplied, the output is formatted in such a way that it can be made part of an *inputrc* file.

**dump-macros**

Print all of the readline key sequences bound to macros and the strings they output. If a numeric argument is supplied, the output is formatted in such a way that it can be made part of an *inputrc* file.

**display-shell-version (C-x C-v)**

Display version information about the current instance of **bash**.

**Programmable Completion**

When word completion is attempted for an argument to a command for which a completion specification (a *compspec*) has been defined using the **complete** builtin (see **SHELL BUILTIN COMMANDS** below), the programmable completion facilities are invoked.

First, the command name is identified. If a *compspec* has been defined for that command, the *compspec* is used to generate the list of possible completions for the word. If the command word is a full pathname, a *compspec* for the full pathname is searched for first. If no *compspec* is found for the full pathname, an attempt is made to find a *compspec* for the portion following the final slash.

Once a *compspec* has been found, it is used to generate the list of matching words. If a *compspec* is not found, the default **bash** completion as described above under **Completing** is performed.

First, the actions specified by the *compspec* are used. Only matches which are prefixed by the word being completed are returned. When the **-f** or **-d** option is used for filename or directory name completion, the shell variable **FIGNORE** is used to filter the matches.

Any completions specified by a filename expansion pattern to the **-G** option are generated next. The words generated by the pattern need not match the word being completed. The **GLOBIGNORE** shell variable is not used to filter the matches, but the **FIGNORE** variable is used.

Next, the string specified as the argument to the **-W** option is considered. The string is first split using the characters in the **IFS** special variable as delimiters. Shell quoting is honored. Each word is then expanded using brace expansion, tilde expansion, parameter and variable expansion, command substitution, and arithmetic expansion, as described above under **EXPANSION**. The results are split using the rules described above under **Word Splitting**. The results of the expansion are prefix-matched against the word being completed, and the matching words become the possible completions.

After these matches have been generated, any shell function or command specified with the **-F** and **-C** options is invoked. When the command or function is invoked, the **COMP\_LINE** and **COMP\_POINT** variables are assigned values as described above under **Shell Variables**. If a shell function is being invoked, the **COMP\_WORDS** and **COMP\_CWORD** variables are also set. When the function or command is invoked, the first argument is the name of the command whose arguments are being completed, the second argument is the word being completed, and the third argument is the word preceding the word being

completed on the current command line. No filtering of the generated completions against the word being completed is performed; the function or command has complete freedom in generating the matches.

Any function specified with **-F** is invoked first. The function may use any of the shell facilities, including the **compgen** builtin described below, to generate the matches. It must put the possible completions in the **COMPREPLY** array variable.

Next, any command specified with the **-C** option is invoked in an environment equivalent to command substitution. It should print a list of completions, one per line, to the standard output. Backslash may be used to escape a newline, if necessary.

After all of the possible completions are generated, any filter specified with the **-X** option is applied to the list. The filter is a pattern as used for pathname expansion; a **&** in the pattern is replaced with the text of the word being completed. A literal **&** may be escaped with a backslash; the backslash is removed before attempting a match. Any completion that matches the pattern will be removed from the list. A leading **!** negates the pattern; in this case any completion not matching the pattern will be removed.

Finally, any prefix and suffix specified with the **-P** and **-S** options are added to each member of the completion list, and the result is returned to the readline completion code as the list of possible completions.

If the previously-applied actions do not generate any matches, and the **-o dirnames** option was supplied to **complete** when the compspec was defined, directory name completion is attempted.

If the **-o plusdirs** option was supplied to **complete** when the compspec was defined, directory name completion is attempted and any matches are added to the results of the other actions.

By default, if a compspec is found, whatever it generates is returned to the completion code as the full set of possible completions. The default **bash** completions are not attempted, and the readline default of filename completion is disabled. If the **-o bashdefault** option was supplied to **complete** when the compspec was defined, the **bash** default completions are attempted if the compspec generates no matches. If the **-o default** option was supplied to **complete** when the compspec was defined, readline's default completion will be performed if the compspec (and, if attempted, the default **bash** completions) generate no matches.

When a compspec indicates that directory name completion is desired, the programmable completion functions force readline to append a slash to completed names which are symbolic links to directories, subject to the value of the **mark-directories** readline variable, regardless of the setting of the **mark-symlinked-directories** readline variable.

## HISTORY

When the **-o history** option to the **set** builtin is enabled, the shell provides access to the *command history*, the list of commands previously typed. The value of the **HISTSIZE** variable is used as the number of commands to save in a history list. The text of the last **HISTSIZE** commands (default 500) is saved. The shell stores each command in the history list prior to parameter and variable expansion (see **EXPANSION** above) but after history expansion is performed, subject to the values of the shell variables **HISTIGNORE** and **HISTCONTROL**.

On startup, the history is initialized from the file named by the variable **HISTFILE** (default **~/.bash\_history**). The file named by the value of **HISTFILE** is truncated, if necessary, to contain no more than the number of lines specified by the value of **HISTFILESIZE**. When an interactive shell exits, the last **HISTSIZE** lines are copied from the history list to **\$HISTFILE**. If the **histappend** shell option is enabled (see the description of **shopt** under **SHELL BUILTIN COMMANDS** below), the lines are appended to the history file, otherwise the history file is overwritten. If **HISTFILE** is unset, or if the history file is unwritable, the history is not saved. After saving the history, the history file is truncated to contain no more than **HISTFILESIZE** lines. If **HISTFILESIZE** is not set, no truncation is performed.

The builtin command **fc** (see **SHELL BUILTIN COMMANDS** below) may be used to list or edit and re-execute a portion of the history list. The **history** builtin may be used to display or modify the history list and manipulate the history file. When using command-line editing, search commands are available in each editing mode that provide access to the history list.

The shell allows control over which commands are saved on the history list. The **HISTCONTROL** and **HISTIGNORE** variables may be set to cause the shell to save only a subset of the commands entered. The

**cmdhist** shell option, if enabled, causes the shell to attempt to save each line of a multi-line command in the same history entry, adding semicolons where necessary to preserve syntactic correctness. The **lithist** shell option causes the shell to save the command with embedded newlines instead of semicolons. See the description of the **shopt** builtin below under **SHELL BUILTIN COMMANDS** for information on setting and unsetting shell options.

## HISTORY EXPANSION

The shell supports a history expansion feature that is similar to the history expansion in **csh**. This section describes what syntax features are available. This feature is enabled by default for interactive shells, and can be disabled using the **+H** option to the **set** builtin command (see **SHELL BUILTIN COMMANDS** below). Non-interactive shells do not perform history expansion by default.

History expansions introduce words from the history list into the input stream, making it easy to repeat commands, insert the arguments to a previous command into the current input line, or fix errors in previous commands quickly.

History expansion is performed immediately after a complete line is read, before the shell breaks it into words. It takes place in two parts. The first is to determine which line from the history list to use during substitution. The second is to select portions of that line for inclusion into the current one. The line selected from the history is the *event*, and the portions of that line that are acted upon are *words*. Various *modifiers* are available to manipulate the selected words. The line is broken into words in the same fashion as when reading input, so that several *metacharacter*-separated words surrounded by quotes are considered one word. History expansions are introduced by the appearance of the history expansion character, which is **!** by default. Only backslash (**\**) and single quotes can quote the history expansion character.

Several characters inhibit history expansion if found immediately following the history expansion character, even if it is unquoted: space, tab, newline, carriage return, and **=**. If the **extglob** shell option is enabled, ( will also inhibit expansion.

Several shell options settable with the **shopt** builtin may be used to tailor the behavior of history expansion. If the **histverify** shell option is enabled (see the description of the **shopt** builtin), and **readline** is being used, history substitutions are not immediately passed to the shell parser. Instead, the expanded line is reloaded into the **readline** editing buffer for further modification. If **readline** is being used, and the **histreedit** shell option is enabled, a failed history substitution will be reloaded into the **readline** editing buffer for correction. The **-p** option to the **history** builtin command may be used to see what a history expansion will do before using it. The **-s** option to the **history** builtin may be used to add commands to the end of the history list without actually executing them, so that they are available for subsequent recall.

The shell allows control of the various characters used by the history expansion mechanism (see the description of **histchars** above under **Shell Variables**).

### Event Designators

An event designator is a reference to a command line entry in the history list.

- !** Start a history substitution, except when followed by a **blank**, newline, carriage return, **=** or ( (when the **extglob** shell option is enabled using the **shopt** builtin).
- !n** Refer to command line *n*.
- !-n** Refer to the current command line minus *n*.
- !!** Refer to the previous command. This is a synonym for **!-1**.
- !string** Refer to the most recent command starting with *string*.
- !?string[?]** Refer to the most recent command containing *string*. The trailing **?** may be omitted if *string* is followed immediately by a newline.
- ^string1^string2^** Quick substitution. Repeat the last command, replacing *string1* with *string2*. Equivalent to **“!!:s/string1/string2”** (see **Modifiers** below).
- !#** The entire command line typed so far.

### Word Designators

Word designators are used to select desired words from the event. A **:** separates the event specification from the word designator. It may be omitted if the word designator begins with a **^**, **\$**, **\***, **-**, or **%**. Words are numbered from the beginning of the line, with the first word being denoted by 0 (zero). Words are inserted into the current line separated by single spaces.

#### 0 (zero)

The zeroth word. For the shell, this is the command word.

*n* The *n*th word.

**^** The first argument. That is, word 1.

**\$** The last argument.

**%** The word matched by the most recent *'?string?'* search.

*x-y* A range of words; *'-y'* abbreviates *'0-y'*.

**\*** All of the words but the zeroth. This is a synonym for *'1-\$'*. It is not an error to use **\*** if there is just one word in the event; the empty string is returned in that case.

**x\*** Abbreviates *x-\$*.

**x-** Abbreviates *x-\$* like **x\***, but omits the last word.

If a word designator is supplied without an event specification, the previous command is used as the event.

### Modifiers

After the optional word designator, there may appear a sequence of one or more of the following modifiers, each preceded by a **:**.

**h** Remove a trailing file name component, leaving only the head.

**t** Remove all leading file name components, leaving the tail.

**r** Remove a trailing suffix of the form *.xxx*, leaving the basename.

**e** Remove all but the trailing suffix.

**p** Print the new command but do not execute it.

**q** Quote the substituted words, escaping further substitutions.

**x** Quote the substituted words as with **q**, but break into words at **blanks** and newlines.

**/oldnew/**

Substitute *new* for the first occurrence of *old* in the event line. Any delimiter can be used in place of */*. The final delimiter is optional if it is the last character of the event line. The delimiter may be quoted in *old* and *new* with a single backslash. If **&** appears in *new*, it is replaced by *old*. A single backslash will quote the **&**. If *old* is null, it is set to the last *old* substituted, or, if no previous history substitutions took place, the last *string* in a *!?string[?]* search.

**&** Repeat the previous substitution.

**g** Cause changes to be applied over the entire event line. This is used in conjunction with **'s'** (e.g., **'gsloldnew/')** or **':&'**. If used with **'s'**, any delimiter can be used in place of */*, and the final delimiter is optional if it is the last character of the event line. An **a** may be used as a synonym for **g**.

**G** Apply the following **'s'** modifier once to each word in the event line.

### SHELL BUILTIN COMMANDS

Unless otherwise noted, each builtin command documented in this section as accepting options preceded by **-** accepts **--** to signify the end of the options. For example, the **:**, **true**, **false**, and **test** builtins do not accept options.

**:** [*arguments*]

No effect; the command does nothing beyond expanding *arguments* and performing any specified redirections. A zero exit code is returned.

**.** *filename* [*arguments*]

**source** *filename* [*arguments*]

Read and execute commands from *filename* in the current shell environment and return the exit status of the last command executed from *filename*. If *filename* does not contain a slash, file names in **PATH** are used to find the directory containing *filename*. The file searched for in **PATH** need not be executable. When **bash** is not in *posix mode*, the current directory is searched if no

file is found in **PATH**. If the **sourcepath** option to the **shopt** builtin command is turned off, the **PATH** is not searched. If any *arguments* are supplied, they become the positional parameters when *filename* is executed. Otherwise the positional parameters are unchanged. The return status is the status of the last command exited within the script (0 if no commands are executed), and false if *filename* is not found or cannot be read.

**alias** [-p] [*name*[=*value*] ...]

**Alias** with no arguments or with the **-p** option prints the list of aliases in the form **alias name=value** on standard output. When arguments are supplied, an alias is defined for each *name* whose *value* is given. A trailing space in *value* causes the next word to be checked for alias substitution when the alias is expanded. For each *name* in the argument list for which no *value* is supplied, the name and value of the alias is printed. **Alias** returns true unless a *name* is given for which no alias has been defined.

**bg** [*jobspec* ...]

Resume each suspended job *jobspec* in the background, as if it had been started with **&**. If *jobspec* is not present, the shell's notion of the *current job* is used. **bg jobspec** returns 0 unless run when job control is disabled or, when run with job control enabled, any specified *jobspec* was not found or was started without job control.

**bind** [-m *keymap*] [-lpsvPSV]

**bind** [-m *keymap*] [-q *function*] [-u *function*] [-r *keyseq*]

**bind** [-m *keymap*] -f *filename*

**bind** [-m *keymap*] -x *keyseq:shell-command*

**bind** [-m *keymap*] *keyseq:function-name*

**bind** *readline-command*

Display current **readline** key and function bindings, bind a key sequence to a **readline** function or macro, or set a **readline** variable. Each non-option argument is a command as it would appear in *.inputrc*, but each binding or command must be passed as a separate argument; e.g., '"\C-x\C-r": re-read-init-file'. Options, if supplied, have the following meanings:

**-m keymap**

Use *keymap* as the keymap to be affected by the subsequent bindings. Acceptable *keymap* names are *emacs*, *emacs-standard*, *emacs-meta*, *emacs-ctlx*, *vi*, *vi-move*, *vi-command*, and *vi-insert*. *vi* is equivalent to *vi-command*; *emacs* is equivalent to *emacs-standard*.

**-l** List the names of all **readline** functions.

**-p** Display **readline** function names and bindings in such a way that they can be re-read.

**-P** List current **readline** function names and bindings.

**-v** Display **readline** variable names and values in such a way that they can be re-read.

**-V** List current **readline** variable names and values.

**-s** Display **readline** key sequences bound to macros and the strings they output in such a way that they can be re-read.

**-S** Display **readline** key sequences bound to macros and the strings they output.

**-f filename**

Read key bindings from *filename*.

**-q function**

Query about which keys invoke the named *function*.

**-u function**

Unbind all keys bound to the named *function*.

**-r keyseq**

Remove any current binding for *keyseq*.

**-x keyseq:shell-command**

Cause *shell-command* to be executed whenever *keyseq* is entered.

The return value is 0 unless an unrecognized option is given or an error occurred.

**break** [*n*]

Exit from within a **for**, **while**, **until**, or **select** loop. If *n* is specified, break *n* levels. *n* must be  $\geq 1$ . If *n* is greater than the number of enclosing loops, all enclosing loops are exited. The return value is 0 unless the shell is not executing a loop when **break** is executed.

**builtin** *shell-builtin* [*arguments*]

Execute the specified shell builtin, passing it *arguments*, and return its exit status. This is useful when defining a function whose name is the same as a shell builtin, retaining the functionality of the builtin within the function. The **cd** builtin is commonly redefined this way. The return status is false if *shell-builtin* is not a shell builtin command.

**cd** [-L|-P] [*dir*]

Change the current directory to *dir*. The variable **HOME** is the default *dir*. The variable **CDPATH** defines the search path for the directory containing *dir*. Alternative directory names in **CDPATH** are separated by a colon (:). A null directory name in **CDPATH** is the same as the current directory, i.e., ".". If *dir* begins with a slash (/), then **CDPATH** is not used. The **-P** option says to use the physical directory structure instead of following symbolic links (see also the **-P** option to the **set** builtin command); the **-L** option forces symbolic links to be followed. An argument of **-** is equivalent to **\$OLDPWD**. If a non-empty directory name from **CDPATH** is used, or if **-** is the first argument, and the directory change is successful, the absolute pathname of the new working directory is written to the standard output. The return value is true if the directory was successfully changed; false otherwise.

**caller** [*expr*]

Returns the context of any active subroutine call (a shell function or a script executed with the **.** or **source** builtins. Without *expr*, **caller** displays the line number and source filename of the current subroutine call. If a non-negative integer is supplied as *expr*, **caller** displays the line number, subroutine name, and source file corresponding to that position in the current execution call stack. This extra information may be used, for example, to print a stack trace. The current frame is frame 0. The return value is 0 unless the shell is not executing a subroutine call or *expr* does not correspond to a valid position in the call stack.

**command** [-pVv] *command* [*arg* ...]

Run *command* with *args* suppressing the normal shell function lookup. Only builtin commands or commands found in the **PATH** are executed. If the **-p** option is given, the search for *command* is performed using a default value for **PATH** that is guaranteed to find all of the standard utilities. If either the **-V** or **-v** option is supplied, a description of *command* is printed. The **-v** option causes a single word indicating the command or file name used to invoke *command* to be displayed; the **-V** option produces a more verbose description. If the **-V** or **-v** option is supplied, the exit status is 0 if *command* was found, and 1 if not. If neither option is supplied and an error occurred or *command* cannot be found, the exit status is 127. Otherwise, the exit status of the **command** builtin is the exit status of *command*.

**compgen** [*option*] [*word*]

Generate possible completion matches for *word* according to the *options*, which may be any option accepted by the **complete** builtin with the exception of **-p** and **-r**, and write the matches to the standard output. When using the **-F** or **-C** options, the various shell variables set by the programmable completion facilities, while available, will not have useful values.

The matches will be generated in the same way as if the programmable completion code had generated them directly from a completion specification with the same flags. If *word* is specified, only those completions matching *word* will be displayed.

The return value is true unless an invalid option is supplied, or no matches were generated.

**complete** [-*abcdefghijklmnopqrstuvwxyz*] [-o *comp-option*] [-A *action*] [-G *globpat*] [-W *wordlist*] [-P *prefix*] [-S *suffix*]

[-X *filterpat*] [-F *function*] [-C *command*] *name* [*name* ...]

**complete -pr** [*name* ...]

Specify how arguments to each *name* should be completed. If the **-p** option is supplied, or if no options are supplied, existing completion specifications are printed in a way that allows them to be reused as input. The **-r** option removes a completion specification for each *name*, or, if no *names* are supplied, all completion specifications.

The process of applying these completion specifications when word completion is attempted is described above under **Programmable Completion**.

Other options, if specified, have the following meanings. The arguments to the **-G**, **-W**, and **-X** options (and, if necessary, the **-P** and **-S** options) should be quoted to protect them from expansion before the **complete** builtin is invoked.

**-o** *comp-option*

The *comp-option* controls several aspects of the compspec's behavior beyond the simple generation of completions. *comp-option* may be one of:

**bashdefault**

Perform the rest of the default **bash** completions if the compspec generates no matches.

**default** Use readline's default filename completion if the compspec generates no matches.

**dirnames**

Perform directory name completion if the compspec generates no matches.

**filenames**

Tell readline that the compspec generates filenames, so it can perform any file-name-specific processing (like adding a slash to directory names or suppressing trailing spaces). Intended to be used with shell functions.

**nospace** Tell readline not to append a space (the default) to words completed at the end of the line.

**plusdirs** After any matches defined by the compspec are generated, directory name completion is attempted and any matches are added to the results of the other actions.

**-A** *action*

The *action* may be one of the following to generate a list of possible completions:

**alias** Alias names. May also be specified as **-a**.

**arrayvar**

Array variable names.

**binding** Readline key binding names.

**builtin** Names of shell builtin commands. May also be specified as **-b**.

**command**

Command names. May also be specified as **-c**.

**directory**

Directory names. May also be specified as **-d**.

**disabled**

Names of disabled shell builtins.

**enabled** Names of enabled shell builtins.

**export** Names of exported shell variables. May also be specified as **-e**.

**file** File names. May also be specified as **-f**.

**function**

Names of shell functions.

**group** Group names. May also be specified as **-g**.

**helptopic**

Help topics as accepted by the **help** builtin.

**hostname**

Hostnames, as taken from the file specified by the **HOSTFILE** shell variable.

**job** Job names, if job control is active. May also be specified as **-j**.

**keyword**

Shell reserved words. May also be specified as **-k**.

**running** Names of running jobs, if job control is active.

**service** Service names. May also be specified as **-s**.

**setopt** Valid arguments for the **-o** option to the **set** builtin.

**shopt** Shell option names as accepted by the **shopt** builtin.

**signal** Signal names.

**stopped** Names of stopped jobs, if job control is active.

**user** User names. May also be specified as **-u**.

**variable** Names of all shell variables. May also be specified as **-v**.

**-G globpat**

The filename expansion pattern *globpat* is expanded to generate the possible completions.

**-W wordlist**

The *wordlist* is split using the characters in the **IFS** special variable as delimiters, and each resultant word is expanded. The possible completions are the members of the resultant list which match the word being completed.

**-C command**

*command* is executed in a subshell environment, and its output is used as the possible completions.

**-F function**

The shell function *function* is executed in the current shell environment. When it finishes, the possible completions are retrieved from the value of the **COMPREPLY** array variable.

**-X filterpat**

*filterpat* is a pattern as used for filename expansion. It is applied to the list of possible completions generated by the preceding options and arguments, and each completion matching *filterpat* is removed from the list. A leading **!** in *filterpat* negates the pattern; in this case, any completion not matching *filterpat* is removed.

**-P prefix**

*prefix* is added at the beginning of each possible completion after all other options have been applied.

**-S suffix**

*suffix* is appended to each possible completion after all other options have been applied.

The return value is true unless an invalid option is supplied, an option other than **-p** or **-r** is supplied without a *name* argument, an attempt is made to remove a completion specification for a *name* for which no specification exists, or an error occurs adding a completion specification.

**continue** [*n*]

Resume the next iteration of the enclosing **for**, **while**, **until**, or **select** loop. If *n* is specified, resume at the *n*th enclosing loop. *n* must be  $\geq 1$ . If *n* is greater than the number of enclosing loops, the last enclosing loop (the “top-level” loop) is resumed. The return value is 0 unless the shell is not executing a loop when **continue** is executed.

**declare** [**-afFirtx**] [**-p**] [*name*[=*value*] ...]**typeset** [**-afFirtx**] [**-p**] [*name*[=*value*] ...]

Declare variables and/or give them attributes. If no *names* are given then display the values of variables. The **-p** option will display the attributes and values of each *name*. When **-p** is used, additional options are ignored. The **-F** option inhibits the display of function definitions; only the function name and attributes are printed. If the **extdebug** shell option is enabled using **shopt**, the source file name and line number where the function is defined are displayed as well. The **-F** option implies **-f**. The following options can be used to restrict output to variables with the specified attribute or to give variables attributes:

- a** Each *name* is an array variable (see **Arrays** above).
- f** Use function names only.
- i** The variable is treated as an integer; arithmetic evaluation (see **ARITHMETIC EVALUATION**) is performed when the variable is assigned a value.
- r** Make *names* readonly. These names cannot then be assigned values by subsequent assignment statements or unset.
- t** Give each *name* the *trace* attribute. Traced functions inherit the **DEBUG** and **RETURN** traps from the calling shell. The trace attribute has no special meaning for variables.
- x** Mark *names* for export to subsequent commands via the environment.

Using **+** instead of **-** turns off the attribute instead, with the exception that **+a** may not be used to destroy an array variable. When used in a function, makes each *name* local, as with the **local** command. If a variable name is followed by **=value**, the value of the variable is set to *value*. The return value is 0 unless an invalid option is encountered, an attempt is made to define a function using **-f foo=bar**, an attempt is made to assign a value to a readonly variable, an attempt is made to assign a value to an array variable without using the compound assignment syntax (see **Arrays** above), one of the *names* is not a valid shell variable name, an attempt is made to turn off readonly status for a readonly variable, an attempt is made to turn off array status for an array variable, or an attempt is made to display a non-existent function with **-f**.

#### **dirs [-clpv] [+n] [-n]**

Without options, displays the list of currently remembered directories. The default display is on a single line with directory names separated by spaces. Directories are added to the list with the **pushd** command; the **popd** command removes entries from the list.

- +n** Displays the *n*th entry counting from the left of the list shown by **dirs** when invoked without options, starting with zero.
- n** Displays the *n*th entry counting from the right of the list shown by **dirs** when invoked without options, starting with zero.
- c** Clears the directory stack by deleting all of the entries.
- l** Produces a longer listing; the default listing format uses a tilde to denote the home directory.
- p** Print the directory stack with one entry per line.
- v** Print the directory stack with one entry per line, prefixing each entry with its index in the stack.

The return value is 0 unless an invalid option is supplied or *n* indexes beyond the end of the directory stack.

#### **disown [-ar] [-h] [jobspec ...]**

Without options, each *jobspec* is removed from the table of active jobs. If the **-h** option is given, each *jobspec* is not removed from the table, but is marked so that **SIGHUP** is not sent to the job if the shell receives a **SIGHUP**. If no *jobspec* is present, and neither the **-a** nor the **-r** option is supplied, the *current job* is used. If no *jobspec* is supplied, the **-a** option means to remove or mark all jobs; the **-r** option without a *jobspec* argument restricts operation to running jobs. The return value is 0 unless a *jobspec* does not specify a valid job.

#### **echo [-neE] [arg ...]**

Output the *args*, separated by spaces, followed by a newline. The return status is always 0. If **-n** is specified, the trailing newline is suppressed. If the **-e** option is given, interpretation of the following backslash-escaped characters is enabled. The **-E** option disables the interpretation of these escape characters, even on systems where they are interpreted by default. The **xpg\_echo** shell option may be used to dynamically determine whether or not **echo** expands these escape characters by default. **echo** does not interpret **--** to mean the end of options. **echo** interprets the following escape sequences:

- \a** alert (bell)
- \b** backspace

|                    |                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------|
| <code>\c</code>    | suppress trailing newline                                                                      |
| <code>\e</code>    | an escape character                                                                            |
| <code>\f</code>    | form feed                                                                                      |
| <code>\n</code>    | new line                                                                                       |
| <code>\r</code>    | carriage return                                                                                |
| <code>\t</code>    | horizontal tab                                                                                 |
| <code>\v</code>    | vertical tab                                                                                   |
| <code>\\</code>    | backslash                                                                                      |
| <code>\0nnn</code> | the eight-bit character whose value is the octal value <i>nnn</i> (zero to three octal digits) |
| <code>\xHH</code>  | the eight-bit character whose value is the hexadecimal value <i>HH</i> (one or two hex digits) |

**enable** [**-adnps**] [**-f** *filename*] [*name* ...]

Enable and disable builtin shell commands. Disabling a builtin allows a disk command which has the same name as a shell builtin to be executed without specifying a full pathname, even though the shell normally searches for builtins before disk commands. If **-n** is used, each *name* is disabled; otherwise, *names* are enabled. For example, to use the **test** binary found via the **PATH** instead of the shell builtin version, run **enable -n test**. The **-f** option means to load the new builtin command *name* from shared object *filename*, on systems that support dynamic loading. The **-d** option will delete a builtin previously loaded with **-f**. If no *name* arguments are given, or if the **-p** option is supplied, a list of shell builtins is printed. With no other option arguments, the list consists of all enabled shell builtins. If **-n** is supplied, only disabled builtins are printed. If **-a** is supplied, the list printed includes all builtins, with an indication of whether or not each is enabled. If **-s** is supplied, the output is restricted to the POSIX *special* builtins. The return value is 0 unless a *name* is not a shell builtin or there is an error loading a new builtin from a shared object.

**eval** [*arg* ...]

The *args* are read and concatenated together into a single command. This command is then read and executed by the shell, and its exit status is returned as the value of **eval**. If there are no *args*, or only null arguments, **eval** returns 0.

**exec** [**-cl**] [**-a** *name*] [*command* [*arguments*]]

If *command* is specified, it replaces the shell. No new process is created. The *arguments* become the arguments to *command*. If the **-l** option is supplied, the shell places a dash at the beginning of the zeroth arg passed to *command*. This is what **login(1)** does. The **-c** option causes *command* to be executed with an empty environment. If **-a** is supplied, the shell passes *name* as the zeroth argument to the executed command. If *command* cannot be executed for some reason, a non-interactive shell exits, unless the shell option **execfail** is enabled, in which case it returns failure. An interactive shell returns failure if the file cannot be executed. If *command* is not specified, any redirections take effect in the current shell, and the return status is 0. If there is a redirection error, the return status is 1.

**exit** [*n*] Cause the shell to exit with a status of *n*. If *n* is omitted, the exit status is that of the last command executed. A trap on **EXIT** is executed before the shell terminates.

**export** [**-fn**] [*name*[=*word*]] ...

**export -p**

The supplied *names* are marked for automatic export to the environment of subsequently executed commands. If the **-f** option is given, the *names* refer to functions. If no *names* are given, or if the **-p** option is supplied, a list of all names that are exported in this shell is printed. The **-n** option causes the export property to be removed from each *name*. If a variable name is followed by *=word*, the value of the variable is set to *word*. **export** returns an exit status of 0 unless an invalid option is encountered, one of the *names* is not a valid shell variable name, or **-f** is supplied with a *name* that is not a function.

**fc** [**-e** *ename*] [**-nlr**] [*first*] [*last*]

**fc** **-s** [*pat=rep*] [*cmd*]

Fix Command. In the first form, a range of commands from *first* to *last* is selected from the history list. *First* and *last* may be specified as a string (to locate the last command beginning with that string) or as a number (an index into the history list, where a negative number is used as an offset from the current command number). If *last* is not specified it is set to the current command for listing (so that `fc -l -10` prints the last 10 commands) and to *first* otherwise. If *first* is not specified it is set to the previous command for editing and `-16` for listing.

The **-n** option suppresses the command numbers when listing. The **-r** option reverses the order of the commands. If the **-l** option is given, the commands are listed on standard output. Otherwise, the editor given by *ename* is invoked on a file containing those commands. If *ename* is not given, the value of the **FCEDIT** variable is used, and the value of **EDITOR** if **FCEDIT** is not set. If neither variable is set, *vi* is used. When editing is complete, the edited commands are echoed and executed.

In the second form, *command* is re-executed after each instance of *pat* is replaced by *rep*. A useful alias to use with this is `r='fc -s'`, so that typing `r cc` runs the last command beginning with `cc` and typing `r` re-executes the last command.

If the first form is used, the return value is 0 unless an invalid option is encountered or *first* or *last* specify history lines out of range. If the **-e** option is supplied, the return value is the value of the last command executed or failure if an error occurs with the temporary file of commands. If the second form is used, the return status is that of the command re-executed, unless *cmd* does not specify a valid history line, in which case **fc** returns failure.

**fg** [*jobspec*]

Resume *jobspec* in the foreground, and make it the current job. If *jobspec* is not present, the shell's notion of the *current job* is used. The return value is that of the command placed into the foreground, or failure if run when job control is disabled or, when run with job control enabled, if *jobspec* does not specify a valid job or *jobspec* specifies a job that was started without job control.

**getopts** *optstring name* [*args*]

**getopts** is used by shell procedures to parse positional parameters. *optstring* contains the option characters to be recognized; if a character is followed by a colon, the option is expected to have an argument, which should be separated from it by white space. The colon and question mark characters may not be used as option characters. Each time it is invoked, **getopts** places the next option in the shell variable *name*, initializing *name* if it does not exist, and the index of the next argument to be processed into the variable **OPTIND**. **OPTIND** is initialized to 1 each time the shell or a shell script is invoked. When an option requires an argument, **getopts** places that argument into the variable **OPTARG**. The shell does not reset **OPTIND** automatically; it must be manually reset between multiple calls to **getopts** within the same shell invocation if a new set of parameters is to be used.

When the end of options is encountered, **getopts** exits with a return value greater than zero. **OPTIND** is set to the index of the first non-option argument, and **name** is set to `?`.

**getopts** normally parses the positional parameters, but if more arguments are given in *args*, **getopts** parses those instead.

**getopts** can report errors in two ways. If the first character of *optstring* is a colon, *silent* error reporting is used. In normal operation diagnostic messages are printed when invalid options or missing option arguments are encountered. If the variable **OPTERR** is set to 0, no error messages will be displayed, even if the first character of *optstring* is not a colon.

If an invalid option is seen, **getopts** places `?` into *name* and, if not silent, prints an error message and unsets **OPTARG**. If **getopts** is silent, the option character found is placed in **OPTARG** and no

diagnostic message is printed.

If a required argument is not found, and **getopts** is not silent, a question mark (?) is placed in *name*, **OPTARG** is unset, and a diagnostic message is printed. If **getopts** is silent, then a colon (:) is placed in *name* and **OPTARG** is set to the option character found.

**getopts** returns true if an option, specified or unspecified, is found. It returns false if the end of options is encountered or an error occurs.

**hash** [-lr] [-p *filename*] [-dt] [*name*]

For each *name*, the full file name of the command is determined by searching the directories in **\$PATH** and remembered. If the **-p** option is supplied, no path search is performed, and *filename* is used as the full file name of the command. The **-r** option causes the shell to forget all remembered locations. The **-d** option causes the shell to forget the remembered location of each *name*. If the **-t** option is supplied, the full pathname to which each *name* corresponds is printed. If multiple *name* arguments are supplied with **-t**, the *name* is printed before the hashed full pathname. The **-l** option causes output to be displayed in a format that may be reused as input. If no arguments are given, or if only **-l** is supplied, information about remembered commands is printed. The return status is true unless a *name* is not found or an invalid option is supplied.

**help** [-s] [*pattern*]

Display helpful information about builtin commands. If *pattern* is specified, **help** gives detailed help on all commands matching *pattern*; otherwise help for all the builtins and shell control structures is printed. The **-s** option restricts the information displayed to a short usage synopsis. The return status is 0 unless no command matches *pattern*.

**history** [*n*]

**history** -c

**history** -d *offset*

**history** -anrw [*filename*]

**history** -p *arg* [*arg* ...]

**history** -s *arg* [*arg* ...]

With no options, display the command history list with line numbers. Lines listed with a \* have been modified. An argument of *n* lists only the last *n* lines. If the shell variable **HISTTIMEFORMAT** is set and not null, it is used as a format string for *strftime*(3) to display the time stamp associated with each displayed history entry. No intervening blank is printed between the formatted time stamp and the history line. If *filename* is supplied, it is used as the name of the history file; if not, the value of **HISTFILE** is used. Options, if supplied, have the following meanings:

**-c** Clear the history list by deleting all the entries.

**-d** *offset*

Delete the history entry at position *offset*.

**-a** Append the “new” history lines (history lines entered since the beginning of the current **bash** session) to the history file.

**-n** Read the history lines not already read from the history file into the current history list. These are lines appended to the history file since the beginning of the current **bash** session.

**-r** Read the contents of the history file and use them as the current history.

**-w** Write the current history to the history file, overwriting the history file’s contents.

**-p** Perform history substitution on the following *args* and display the result on the standard output. Does not store the results in the history list. Each *arg* must be quoted to disable normal history expansion.

**-s** Store the *args* in the history list as a single entry. The last command in the history list is removed before the *args* are added.

If the **HISTTIMEFORMAT** is set, the time stamp information associated with each history entry is written to the history file. The return value is 0 unless an invalid option is encountered, an error occurs while reading or writing the history file, an invalid *offset* is supplied as an argument to **-d**,

or the history expansion supplied as an argument to **-p** fails.

**jobs** [**-lnprs**] [*jobspec* ...]

**jobs** **-x** *command* [*args* ...]

The first form lists the active jobs. The options have the following meanings:

- l** List process IDs in addition to the normal information.
- p** List only the process ID of the job's process group leader.
- n** Display information only about jobs that have changed status since the user was last notified of their status.
- r** Restrict output to running jobs.
- s** Restrict output to stopped jobs.

If *jobspec* is given, output is restricted to information about that job. The return status is 0 unless an invalid option is encountered or an invalid *jobspec* is supplied.

If the **-x** option is supplied, **jobs** replaces any *jobspec* found in *command* or *args* with the corresponding process group ID, and executes *command* passing it *args*, returning its exit status.

**kill** [**-s** *sigspec* | **-n** *signum* | **-sigspec**] [*pid* | *jobspec*] ...

**kill** **-l** [*sigspec* | *exit\_status*]

Send the signal named by *sigspec* or *signum* to the processes named by *pid* or *jobspec*. *sigspec* is either a case-insensitive signal name such as **SIGKILL** (with or without the **SIG** prefix) or a signal number; *signum* is a signal number. If *sigspec* is not present, then **SIGTERM** is assumed. An argument of **-l** lists the signal names. If any arguments are supplied when **-l** is given, the names of the signals corresponding to the arguments are listed, and the return status is 0. The *exit\_status* argument to **-l** is a number specifying either a signal number or the exit status of a process terminated by a signal. **kill** returns true if at least one signal was successfully sent, or false if an error occurs or an invalid option is encountered.

**let** *arg* [*arg* ...]

Each *arg* is an arithmetic expression to be evaluated (see **ARITHMETIC EVALUATION**). If the last *arg* evaluates to 0, **let** returns 1; 0 is returned otherwise.

**local** [*option*] [*name*[=*value*] ...]

For each argument, a local variable named *name* is created, and assigned *value*. The *option* can be any of the options accepted by **declare**. When **local** is used within a function, it causes the variable *name* to have a visible scope restricted to that function and its children. With no operands, **local** writes a list of local variables to the standard output. It is an error to use **local** when not within a function. The return status is 0 unless **local** is used outside a function, an invalid *name* is supplied, or *name* is a readonly variable.

**logout** Exit a login shell.

**popd** [**-n**] [**+n**] [**-n**]

Removes entries from the directory stack. With no arguments, removes the top directory from the stack, and performs a **cd** to the new top directory. Arguments, if supplied, have the following meanings:

- +n** Removes the *n*th entry counting from the left of the list shown by **dirs**, starting with zero. For example: **popd +0** removes the first directory, **popd +1** the second.
- n** Removes the *n*th entry counting from the right of the list shown by **dirs**, starting with zero. For example: **popd -0** removes the last directory, **popd -1** the next to last.
- n** Suppresses the normal change of directory when removing directories from the stack, so that only the stack is manipulated.

If the **popd** command is successful, a **dirs** is performed as well, and the return status is 0. **popd** returns false if an invalid option is encountered, the directory stack is empty, a non-existent directory stack entry is specified, or the directory change fails.

**printf** [-v *var*] *format* [*arguments*]

Write the formatted *arguments* to the standard output under the control of the *format*. The *format* is a character string which contains three types of objects: plain characters, which are simply copied to standard output, character escape sequences, which are converted and copied to the standard output, and format specifications, each of which causes printing of the next successive *argument*. In addition to the standard *printf*(1) formats, **%b** causes **printf** to expand backslash escape sequences in the corresponding *argument* (except that **\c** terminates output, backslashes in **\'**, **\''**, and **\?** are not removed, and octal escapes beginning with **\0** may contain up to four digits), and **%q** causes **printf** to output the corresponding *argument* in a format that can be reused as shell input.

The **-v** option causes the output to be assigned to the variable *var* rather than being printed to the standard output.

The *format* is reused as necessary to consume all of the *arguments*. If the *format* requires more *arguments* than are supplied, the extra format specifications behave as if a zero value or null string, as appropriate, had been supplied. The return value is zero on success, non-zero on failure.

**pushd** [-n] [*dir*]**pushd** [-n] [+n] [-n]

Adds a directory to the top of the directory stack, or rotates the stack, making the new top of the stack the current working directory. With no arguments, exchanges the top two directories and returns 0, unless the directory stack is empty. Arguments, if supplied, have the following meanings:

- +n** Rotates the stack so that the *n*th directory (counting from the left of the list shown by **dirs**, starting with zero) is at the top.
- n** Rotates the stack so that the *n*th directory (counting from the right of the list shown by **dirs**, starting with zero) is at the top.
- n** Suppresses the normal change of directory when adding directories to the stack, so that only the stack is manipulated.
- dir* Adds *dir* to the directory stack at the top, making it the new current working directory.

If the **pushd** command is successful, a **dirs** is performed as well. If the first form is used, **pushd** returns 0 unless the **cd** to *dir* fails. With the second form, **pushd** returns 0 unless the directory stack is empty, a non-existent directory stack element is specified, or the directory change to the specified new current directory fails.

**pwd** [-LP]

Print the absolute pathname of the current working directory. The pathname printed contains no symbolic links if the **-P** option is supplied or the **-o physical** option to the **set** builtin command is enabled. If the **-L** option is used, the pathname printed may contain symbolic links. The return status is 0 unless an error occurs while reading the name of the current directory or an invalid option is supplied.

**read** [-ers] [-u *fd*] [-t *timeout*] [-a *aname*] [-p *prompt*] [-n *nchars*] [-d *delim*] [*name* ...]

One line is read from the standard input, or from the file descriptor *fd* supplied as an argument to the **-u** option, and the first word is assigned to the first *name*, the second word to the second *name*, and so on, with leftover words and their intervening separators assigned to the last *name*. If there are fewer words read from the input stream than names, the remaining names are assigned empty values. The characters in **IFS** are used to split the line into words. The backslash character (**\**) may be used to remove any special meaning for the next character read and for line continuation. Options, if supplied, have the following meanings:

**-a aname**

The words are assigned to sequential indices of the array variable *aname*, starting at 0. *aname* is unset before any new values are assigned. Other *name* arguments are ignored.

**-d *delim***

The first character of *delim* is used to terminate the input line, rather than newline.

**-e**

If the standard input is coming from a terminal, **readline** (see **README** above) is used to obtain the line.

**-n *nchars***

**read** returns after reading *nchars* characters rather than waiting for a complete line of input.

**-p *prompt***

Display *prompt* on standard error, without a trailing newline, before attempting to read any input. The prompt is displayed only if input is coming from a terminal.

**-r**

Backslash does not act as an escape character. The backslash is considered to be part of the line. In particular, a backslash-newline pair may not be used as a line continuation.

**-s**

Silent mode. If input is coming from a terminal, characters are not echoed.

**-t *timeout***

Cause **read** to time out and return failure if a complete line of input is not read within *timeout* seconds. This option has no effect if **read** is not reading input from the terminal or a pipe.

**-u *fd***

Read input from file descriptor *fd*.

If no *names* are supplied, the line read is assigned to the variable **REPLY**. The return code is zero, unless end-of-file is encountered, **read** times out, or an invalid file descriptor is supplied as the argument to **-u**.

**readonly [-apf] [*name*[=*word*] ...]**

The given *names* are marked readonly; the values of these *names* may not be changed by subsequent assignment. If the **-f** option is supplied, the functions corresponding to the *names* are so marked. The **-a** option restricts the variables to arrays. If no *name* arguments are given, or if the **-p** option is supplied, a list of all readonly names is printed. The **-p** option causes output to be displayed in a format that may be reused as input. If a variable name is followed by *=word*, the value of the variable is set to *word*. The return status is 0 unless an invalid option is encountered, one of the *names* is not a valid shell variable name, or **-f** is supplied with a *name* that is not a function.

**return [*n*]**

Causes a function to exit with the return value specified by *n*. If *n* is omitted, the return status is that of the last command executed in the function body. If used outside a function, but during execution of a script by the **.** (**source**) command, it causes the shell to stop executing that script and return either *n* or the exit status of the last command executed within the script as the exit status of the script. If used outside a function and not during execution of a script by **.**, the return status is false. Any command associated with the **RETURN** trap is executed before execution resumes after the function or script.

**set [--abefhkmnptuvxBCHP] [--o *option*] [*arg* ...]**

Without options, the name and value of each shell variable are displayed in a format that can be reused as input for setting or resetting the currently-set variables. Read-only variables cannot be reset. In *posix mode*, only shell variables are listed. The output is sorted according to the current locale. When options are specified, they set or unset shell attributes. Any arguments remaining after the options are processed are treated as values for the positional parameters and are assigned, in order, to **\$1**, **\$2**, ... **\$n**. Options, if specified, have the following meanings:

**-a**

Automatically mark variables and functions which are modified or created for export to the environment of subsequent commands.

**-b**

Report the status of terminated background jobs immediately, rather than before the next primary prompt. This is effective only when job control is enabled.

**-e**

Exit immediately if a *simple command* (see **SHELL GRAMMAR** above) exits with a non-zero status. The shell does not exit if the command that fails is part of the command list immediately following a **while** or **until** keyword, part of the test in an *if* statement, part of a **&&** or **||** list, or if the command's return value is being inverted via **!**. A trap

- on **ERR**, if set, is executed before the shell exits.
- f** Disable pathname expansion.
  - h** Remember the location of commands as they are looked up for execution. This is enabled by default.
  - k** All arguments in the form of assignment statements are placed in the environment for a command, not just those that precede the command name.
  - m** Monitor mode. Job control is enabled. This option is on by default for interactive shells on systems that support it (see **JOB CONTROL** above). Background processes run in a separate process group and a line containing their exit status is printed upon their completion.
  - n** Read commands but do not execute them. This may be used to check a shell script for syntax errors. This is ignored by interactive shells.
  - o option-name**  
The *option-name* can be one of the following:
    - allexport** Same as **-a**.
    - braceexpand** Same as **-B**.
    - emacs** Use an emacs-style command line editing interface. This is enabled by default when the shell is interactive, unless the shell is started with the **--noediting** option.
    - errtrace** Same as **-E**.
    - functrace** Same as **-T**.
    - errexit** Same as **-e**.
    - hashall** Same as **-h**.
    - histexpand** Same as **-H**.
    - history** Enable command history, as described above under **HISTORY**. This option is on by default in interactive shells.
    - ignoreeof**  
The effect is as if the shell command `IGNOREEOF=10` had been executed (see **Shell Variables** above).
    - keyword** Same as **-k**.
    - monitor** Same as **-m**.
    - noclobber** Same as **-C**.
    - noexec** Same as **-n**.
    - noglob** Same as **-f**. **nolog** Currently ignored.
    - notify** Same as **-b**.
    - nounset** Same as **-u**.
    - onecmd** Same as **-t**.
    - physical** Same as **-P**.
    - pipefail** If set, the return value of a pipeline is the value of the last (rightmost) command to exit with a non-zero status, or zero if all commands in the pipeline exit successfully. This option is disabled by default.
    - posix** Change the behavior of **bash** where the default operation differs from the POSIX standard to match the standard (*posix mode*).
    - privileged** Same as **-p**.
    - verbose** Same as **-v**.
    - vi** Use a vi-style command line editing interface.

**xtrace** Same as **-x**.

If **-o** is supplied with no *option-name*, the values of the current options are printed. If **+o** is supplied with no *option-name*, a series of **set** commands to recreate the current option settings is displayed on the standard output.

- p** Turn on *privileged* mode. In this mode, the **\$ENV** and **\$BASH\_ENV** files are not processed, shell functions are not inherited from the environment, and the **SHELLOPTS** variable, if it appears in the environment, is ignored. If the shell is started with the effective user (group) id not equal to the real user (group) id, and the **-p** option is not supplied, these actions are taken and the effective user id is set to the real user id. If the **-p** option is supplied at startup, the effective user id is not reset. Turning this option off causes the effective user and group ids to be set to the real user and group ids.
- t** Exit after reading and executing one command.
- u** Treat unset variables as an error when performing parameter expansion. If expansion is attempted on an unset variable, the shell prints an error message, and, if not interactive, exits with a non-zero status.
- v** Print shell input lines as they are read.
- x** After expanding each *simple command*, **for** command, **case** command, **select** command, or arithmetic **for** command, display the expanded value of **PS4**, followed by the command and its expanded arguments or associated word list.
- B** The shell performs brace expansion (see **Brace Expansion** above). This is on by default.
- C** If set, **bash** does not overwrite an existing file with the **>**, **>&**, and **<>** redirection operators. This may be overridden when creating output files by using the redirection operator **>|** instead of **>**.
- E** If set, any trap on **ERR** is inherited by shell functions, command substitutions, and commands executed in a subshell environment. The **ERR** trap is normally not inherited in such cases.
- H** Enable **!** style history substitution. This option is on by default when the shell is interactive.
- P** If set, the shell does not follow symbolic links when executing commands such as **cd** that change the current working directory. It uses the physical directory structure instead. By default, **bash** follows the logical chain of directories when performing commands which change the current directory.
- T** If set, any traps on **DEBUG** and **RETURN** are inherited by shell functions, command substitutions, and commands executed in a subshell environment. The **DEBUG** and **RETURN** traps are normally not inherited in such cases.
- If no arguments follow this option, then the positional parameters are unset. Otherwise, the positional parameters are set to the *args*, even if some of them begin with a **-**.
- Signal the end of options, cause all remaining *args* to be assigned to the positional parameters. The **-x** and **-v** options are turned off. If there are no *args*, the positional parameters remain unchanged.

The options are off by default unless otherwise noted. Using **+** rather than **-** causes these options to be turned off. The options can also be specified as arguments to an invocation of the shell. The current set of options may be found in **\$-**. The return status is always true unless an invalid option is encountered.

#### **shift** [*n*]

The positional parameters from *n*+1 ... are renamed to **\$1** .... Parameters represented by the numbers **\$#** down to **\$#-n+1** are unset. *n* must be a non-negative number less than or equal to **\$#**. If *n* is 0, no parameters are changed. If *n* is not given, it is assumed to be 1. If *n* is greater than **\$#**, the positional parameters are not changed. The return status is greater than zero if *n* is greater than **\$#** or less than zero; otherwise 0.

**shopt** [-pqsu] [-o] [*optname* ...]

Toggle the values of variables controlling optional shell behavior. With no options, or with the **-p** option, a list of all settable options is displayed, with an indication of whether or not each is set. The **-p** option causes output to be displayed in a form that may be reused as input. Other options have the following meanings:

- s** Enable (set) each *optname*.
- u** Disable (unset) each *optname*.
- q** Suppresses normal output (quiet mode); the return status indicates whether the *optname* is set or unset. If multiple *optname* arguments are given with **-q**, the return status is zero if all *optnames* are enabled; non-zero otherwise.
- o** Restricts the values of *optname* to be those defined for the **-o** option to the **set** builtin.

If either **-s** or **-u** is used with no *optname* arguments, the display is limited to those options which are set or unset, respectively. Unless otherwise noted, the **shopt** options are disabled (unset) by default.

The return status when listing options is zero if all *optnames* are enabled, non-zero otherwise. When setting or unsetting options, the return status is zero unless an *optname* is not a valid shell option.

The list of **shopt** options is:

**cdable\_vars**

If set, an argument to the **cd** builtin command that is not a directory is assumed to be the name of a variable whose value is the directory to change to.

**cdspell** If set, minor errors in the spelling of a directory component in a **cd** command will be corrected. The errors checked for are transposed characters, a missing character, and one character too many. If a correction is found, the corrected file name is printed, and the command proceeds. This option is only used by interactive shells.

**checkhash**

If set, **bash** checks that a command found in the hash table exists before trying to execute it. If a hashed command no longer exists, a normal path search is performed.

**checkwinsize**

If set, **bash** checks the window size after each command and, if necessary, updates the values of **LINES** and **COLUMNS**.

**cmdhist** If set, **bash** attempts to save all lines of a multiple-line command in the same history entry. This allows easy re-editing of multi-line commands.

**compat31**

If set, **bash** changes its behavior to that of version 3.1 with respect to quoted arguments to the conditional command's **=~** operator.

**dotglob** If set, **bash** includes filenames beginning with a **.** in the results of pathname expansion.

**execfail** If set, a non-interactive shell will not exit if it cannot execute the file specified as an argument to the **exec** builtin command. An interactive shell does not exit if **exec** fails.

**expand\_aliases**

If set, aliases are expanded as described above under **ALIASES**. This option is enabled by default for interactive shells.

**extdebug**

If set, behavior intended for use by debuggers is enabled:

1. The **-F** option to the **declare** builtin displays the source file name and line number corresponding to each function name supplied as an argument.
2. If the command run by the **DEBUG** trap returns a non-zero value, the next command is skipped and not executed.
3. If the command run by the **DEBUG** trap returns a value of 2, and the shell is executing in a subroutine (a shell function or a shell script executed by the **.** or **source** builtins), a call to **return** is simulated.
4. **BASH\_ARGC** and **BASH\_ARGV** are updated as described in their descriptions above.

5. Function tracing is enabled: command substitution, shell functions, and subshells invoked with ( *command* ) inherit the **DEBUG** and **RETURN** traps.
  6. Error tracing is enabled: command substitution, shell functions, and subshells invoked with ( *command* ) inherit the **ERROR** trap.
- extglob** If set, the extended pattern matching features described above under **Pathname Expansion** are enabled.
- extquote** If set, `'string'` and `"string"` quoting is performed within `${parameter}` expansions enclosed in double quotes. This option is enabled by default.
- failglob** If set, patterns which fail to match filenames during pathname expansion result in an expansion error.
- force\_ignore** If set, the suffixes specified by the **FIGNORE** shell variable cause words to be ignored when performing word completion even if the ignored words are the only possible completions. See **SHELL VARIABLES** above for a description of **FIGNORE**. This option is enabled by default.
- gnu\_errfmt** If set, shell error messages are written in the standard GNU error message format.
- histappend** If set, the history list is appended to the file named by the value of the **HISTFILE** variable when the shell exits, rather than overwriting the file.
- histreedit** If set, and **readline** is being used, a user is given the opportunity to re-edit a failed history substitution.
- histverify** If set, and **readline** is being used, the results of history substitution are not immediately passed to the shell parser. Instead, the resulting line is loaded into the **readline** editing buffer, allowing further modification.
- hostcomplete** If set, and **readline** is being used, **bash** will attempt to perform hostname completion when a word containing a `@` is being completed (see **Completing** under **READLINE** above). This is enabled by default.
- huponexit** If set, **bash** will send **SIGHUP** to all jobs when an interactive login shell exits.
- interactive\_comments** If set, allow a word beginning with `#` to cause that word and all remaining characters on that line to be ignored in an interactive shell (see **COMMENTS** above). This option is enabled by default.
- lithist** If set, and the **cmdhist** option is enabled, multi-line commands are saved to the history with embedded newlines rather than using semicolon separators where possible.
- login\_shell** The shell sets this option if it is started as a login shell (see **INVOCATION** above). The value may not be changed.
- mailwarn** If set, and a file that **bash** is checking for mail has been accessed since the last time it was checked, the message “The mail in *mailfile* has been read” is displayed.
- no\_empty\_cmd\_completion** If set, and **readline** is being used, **bash** will not attempt to search the **PATH** for possible completions when completion is attempted on an empty line.
- nocaseglob** If set, **bash** matches filenames in a case-insensitive fashion when performing pathname expansion (see **Pathname Expansion** above).

**nocasematch**

If set, **bash** matches patterns in a case-insensitive fashion when performing matching while executing **case** or **[[** conditional commands.

**nullglob**

If set, **bash** allows patterns which match no files (see **Pathname Expansion** above) to expand to a null string, rather than themselves.

**progcomp**

If set, the programmable completion facilities (see **Programmable Completion** above) are enabled. This option is enabled by default.

**promptvars**

If set, prompt strings undergo parameter expansion, command substitution, arithmetic expansion, and quote removal after being expanded as described in **PROMPTING** above. This option is enabled by default.

**restricted\_shell**

The shell sets this option if it is started in restricted mode (see **RESTRICTED SHELL** below). The value may not be changed. This is not reset when the startup files are executed, allowing the startup files to discover whether or not a shell is restricted.

**shift\_verbose**

If set, the **shift** builtin prints an error message when the shift count exceeds the number of positional parameters.

**sourcepath**

If set, the **source** (.) builtin uses the value of **PATH** to find the directory containing the file supplied as an argument. This option is enabled by default.

**xpg\_echo**

If set, the **echo** builtin expands backslash-escape sequences by default.

**suspend** [-f]

Suspend the execution of this shell until it receives a **SIGCONT** signal. The **-f** option says not to complain if this is a login shell; just suspend anyway. The return status is 0 unless the shell is a login shell and **-f** is not supplied, or if job control is not enabled.

**test** *expr*

[ *expr* ] Return a status of 0 or 1 depending on the evaluation of the conditional expression *expr*. Each operator and operand must be a separate argument. Expressions are composed of the primaries described above under **CONDITIONAL EXPRESSIONS**. **test** does not accept any options, nor does it accept and ignore an argument of **--** as signifying the end of options.

Expressions may be combined using the following operators, listed in decreasing order of precedence.

**! *expr*** True if *expr* is false.

**( *expr* )** Returns the value of *expr*. This may be used to override the normal precedence of operators.

***expr1* -a *expr2***

True if both *expr1* and *expr2* are true.

***expr1* -o *expr2***

True if either *expr1* or *expr2* is true.

**test** and [ evaluate conditional expressions using a set of rules based on the number of arguments.

0 arguments

The expression is false.

1 argument

The expression is true if and only if the argument is not null.

2 arguments

If the first argument is **!**, the expression is true if and only if the second argument is null. If the first argument is one of the unary conditional operators listed above under **CONDITIONAL EXPRESSIONS**, the expression is true if the unary test is true. If the first argument is not a valid unary conditional operator, the expression is false.

## 3 arguments

If the second argument is one of the binary conditional operators listed above under **CONDITIONAL EXPRESSIONS**, the result of the expression is the result of the binary test using the first and third arguments as operands. If the first argument is **!**, the value is the negation of the two-argument test using the second and third arguments. If the first argument is exactly **(** and the third argument is exactly **)**, the result is the one-argument test of the second argument. Otherwise, the expression is false. The **-a** and **-o** operators are considered binary operators in this case.

## 4 arguments

If the first argument is **!**, the result is the negation of the three-argument expression composed of the remaining arguments. Otherwise, the expression is parsed and evaluated according to precedence using the rules listed above.

## 5 or more arguments

The expression is parsed and evaluated according to precedence using the rules listed above.

**times** Print the accumulated user and system times for the shell and for processes run from the shell. The return status is 0.

**trap** **[-lp]** **[[arg] sigspec ...]**

The command *arg* is to be read and executed when the shell receives signal(s) *sigspec*. If *arg* is absent (and there is a single *sigspec*) or **-**, each specified signal is reset to its original disposition (the value it had upon entrance to the shell). If *arg* is the null string the signal specified by each *sigspec* is ignored by the shell and by the commands it invokes. If *arg* is not present and **-p** has been supplied, then the trap commands associated with each *sigspec* are displayed. If no arguments are supplied or if only **-p** is given, **trap** prints the list of commands associated with each signal. The **-l** option causes the shell to print a list of signal names and their corresponding numbers. Each *sigspec* is either a signal name defined in *<signal.h>*, or a signal number. Signal names are case insensitive and the SIG prefix is optional. If a *sigspec* is **EXIT** (0) the command *arg* is executed on exit from the shell. If a *sigspec* is **DEBUG**, the command *arg* is executed before every *simple command*, *for* command, *case* command, *select* command, every arithmetic *for* command, and before the first command executes in a shell function (see **SHELL GRAMMAR** above). Refer to the description of the **extdebug** option to the **shopt** builtin for details of its effect on the **DEBUG** trap. If a *sigspec* is **ERR**, the command *arg* is executed whenever a simple command has a non-zero exit status, subject to the following conditions. The **ERR** trap is not executed if the failed command is part of the command list immediately following a **while** or **until** keyword, part of the test in an *if* statement, part of a **&&** or **||** list, or if the command's return value is being inverted via **!**. These are the same conditions obeyed by the **errexit** option. If a *sigspec* is **RETURN**, the command *arg* is executed each time a shell function or a script executed with the **.** or **source** builtins finishes executing. Signals ignored upon entry to the shell cannot be trapped or reset. Trapped signals that are not being ignored are reset to their original values in a child process when it is created. The return status is false if any *sigspec* is invalid; otherwise **trap** returns true.

**type** **[-aftpP]** *name* [*name* ...]

With no options, indicate how each *name* would be interpreted if used as a command name. If the **-t** option is used, **type** prints a string which is one of *alias*, *keyword*, *function*, *builtin*, or *file* if *name* is an alias, shell reserved word, function, builtin, or disk file, respectively. If the *name* is not found, then nothing is printed, and an exit status of false is returned. If the **-p** option is used, **type** either returns the name of the disk file that would be executed if *name* were specified as a command name, or nothing if `type -t name` would not return *file*. The **-P** option forces a **PATH** search for each *name*, even if `type -t name` would not return *file*. If a command is hashed, **-p** and **-P** print the hashed value, not necessarily the file that appears first in **PATH**. If the **-a** option is used, **type** prints all of the places that contain an executable named *name*. This includes aliases and functions, if and only if the **-p** option is not also used. The table of hashed commands is not consulted when using **-a**. The **-f** option suppresses shell function lookup, as with the **command**

builtin. **type** returns true if any of the arguments are found, false if none are found.

**ulimit** [**-SHacdefilmnpqrstuvx** [*limit*]]

Provides control over the resources available to the shell and to processes started by it, on systems that allow such control. The **-H** and **-S** options specify that the hard or soft limit is set for the given resource. A hard limit cannot be increased once it is set; a soft limit may be increased up to the value of the hard limit. If neither **-H** nor **-S** is specified, both the soft and hard limits are set. The value of *limit* can be a number in the unit specified for the resource or one of the special values **hard**, **soft**, or **unlimited**, which stand for the current hard limit, the current soft limit, and no limit, respectively. If *limit* is omitted, the current value of the soft limit of the resource is printed, unless the **-H** option is given. When more than one resource is specified, the limit name and unit are printed before the value. Other options are interpreted as follows:

- a** All current limits are reported
- c** The maximum size of core files created
- d** The maximum size of a process's data segment
- e** The maximum scheduling priority ("nice")
- f** The maximum size of files written by the shell and its children
- i** The maximum number of pending signals
- l** The maximum size that may be locked into memory
- m** The maximum resident set size
- n** The maximum number of open file descriptors (most systems do not allow this value to be set)
- p** The pipe size in 512-byte blocks (this may not be set)
- q** The maximum number of bytes in POSIX message queues
- r** The maximum real-time scheduling priority
- s** The maximum stack size
- t** The maximum amount of cpu time in seconds
- u** The maximum number of processes available to a single user
- v** The maximum amount of virtual memory available to the shell
- x** The maximum number of file locks

If *limit* is given, it is the new value of the specified resource (the **-a** option is display only). If no option is given, then **-f** is assumed. Values are in 1024-byte increments, except for **-t**, which is in seconds, **-p**, which is in units of 512-byte blocks, and **-n** and **-u**, which are unscaled values. The return status is 0 unless an invalid option or argument is supplied, or an error occurs while setting a new limit.

**umask** [**-p**] [**-S**] [*mode*]

The user file-creation mask is set to *mode*. If *mode* begins with a digit, it is interpreted as an octal number; otherwise it is interpreted as a symbolic mode mask similar to that accepted by *chmod*(1). If *mode* is omitted, the current value of the mask is printed. The **-S** option causes the mask to be printed in symbolic form; the default output is an octal number. If the **-p** option is supplied, and *mode* is omitted, the output is in a form that may be reused as input. The return status is 0 if the mode was successfully changed or if no *mode* argument was supplied, and false otherwise.

**unalias** [**-a**] [*name* ...]

Remove each *name* from the list of defined aliases. If **-a** is supplied, all alias definitions are removed. The return value is true unless a supplied *name* is not a defined alias.

**unset** [**-fv**] [*name* ...]

For each *name*, remove the corresponding variable or function. If no options are supplied, or the **-v** option is given, each *name* refers to a shell variable. Read-only variables may not be unset. If **-f** is specified, each *name* refers to a shell function, and the function definition is removed. Each unset variable or function is removed from the environment passed to subsequent commands. If any of **RANDOM**, **SECONDS**, **LINENO**, **HISTCMD**, **FUNCNAME**, **GROUPS**, or **DIRSTACK** are unset, they lose their special properties, even if they are subsequently reset. The exit status is true unless a *name* is readonly.

**wait** [*n* ...]

Wait for each specified process and return its termination status. Each *n* may be a process ID or a job specification; if a job spec is given, all processes in that job's pipeline are waited for. If *n* is not given, all currently active child processes are waited for, and the return status is zero. If *n* specifies a non-existent process or job, the return status is 127. Otherwise, the return status is the exit status of the last process or job waited for.

**RESTRICTED SHELL**

If **bash** is started with the name **rbash**, or the **-r** option is supplied at invocation, the shell becomes restricted. A restricted shell is used to set up an environment more controlled than the standard shell. It behaves identically to **bash** with the exception that the following are disallowed or not performed:

- changing directories with **cd**
- setting or unsetting the values of **SHELL**, **PATH**, **ENV**, or **BASH\_ENV**
- specifying command names containing /
- specifying a file name containing a / as an argument to the **.** builtin command
- Specifying a filename containing a slash as an argument to the **-p** option to the **hash** builtin command
- importing function definitions from the shell environment at startup
- parsing the value of **SHELLOPTS** from the shell environment at startup
- redirecting output using the **>**, **>|**, **<>**, **>&**, **&>**, and **>>** redirection operators
- using the **exec** builtin command to replace the shell with another command
- adding or deleting builtin commands with the **-f** and **-d** options to the **enable** builtin command
- Using the **enable** builtin command to enable disabled shell builtins
- specifying the **-p** option to the **command** builtin command
- turning off restricted mode with **set +r** or **set +o restricted**.

These restrictions are enforced after any startup files are read.

When a command that is found to be a shell script is executed (see **COMMAND EXECUTION** above), **rbash** turns off any restrictions in the shell spawned to execute the script.

## BUG REPORTS

If you find a bug in **bash**, you should report it. But first, you should make sure that it really is a bug, and that it appears in the latest version of **bash**. The latest version is always available from <ftp://ftp.gnu.org/pub/bash/>.

Once you have determined that a bug actually exists, use the *bashbug* command to submit a bug report. If you have a fix, you are encouraged to mail that as well! Suggestions and ‘philosophical’ bug reports may be mailed to [bug-bash@gnu.org](mailto:bug-bash@gnu.org) or posted to the Usenet newsgroup **gnu.bash.bug**.

ALL bug reports should include:

The version number of **bash**

The hardware and operating system

The compiler used to compile

A description of the bug behaviour

A short script or ‘recipe’ which exercises the bug

*bashbug* inserts the first three items automatically into the template it provides for filing a bug report.

Comments and bug reports concerning this manual page should be directed to [chet@po.cwru.edu](mailto:chet@po.cwru.edu).

## BUGS

It’s too big and too slow.

There are some subtle differences between **bash** and traditional versions of **sh**, mostly because of the **POSIX** specification.

Aliases are confusing in some uses.

Shell builtin commands and functions are not stoppable/restartable.

Compound commands and command sequences of the form ‘a ; b ; c’ are not handled gracefully when process suspension is attempted. When a process is stopped, the shell immediately executes the next command in the sequence. It suffices to place the sequence of commands between parentheses to force it into a subshell, which may be stopped as a unit.

Commands inside of  $\$(...)$  command substitution are not parsed until substitution is attempted. This will delay error reporting until some time after the command is entered. For example, unmatched parentheses, even inside shell comments, will result in error messages while the construct is being read.

Array variables may not (yet) be exported.

**NAME**

**batteryalert** – monitor battery capacity and alert to terminals on low charge

**SYNOPSIS**

root user:

**edrc/bin/batteryalert [ -h | -s | -i | -a ]**

non-root user:

**edrc/bin/batteryalert -h | -i | -a**

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

the **batteryalert** command runs in the background, monitors the power supply battery capacity and alerts (using **wall**) to all terminals on low charge.

**OPTIONS**

start **batteryalert** background process.

**-h** usage.

**-s** stop **batteryalert** background process.

**-i** print battery and **batteryalert** information.

**-a** check if battery capacity id below threshold and discharging. If so the exit status is **8**.

**ENVIRONMENT**

**\$BATTERYALERT\_THRESHOLD**

battery charge threshold in %.

The default threshold is **20** percent.

**\$BATTERYALERT\_INTERVAL**

battery charge check interval in seconds.

The default interval is **120** seconds.

**EXIT STATUS**

- 0** no error.
- 1** no battery information found.
- 2** operating system not supported.
- 4** usage printed.
- 6** cannot stop **batteryalert**.
- 7** **batteryalert** not running.
- 8** **batteryalert** is in ALERT state (when using **-a**).

**FILES**

- /sys/class/power\_supply/BAT\*/capacity**  
current battery charge level.
- /sys/class/power\_supply/BAT\*/status**  
status (**Charging/Discharging**) of the battery.
- edrc/var/settings/batteryalert.threshold**  
holds the battery alert threshold during **batteryalert** run if not default.

**EXAMPLES**

-

**SEE ALSO**

**edrcintro(1), edrcinit(1m), acpi(1), wall(1)**

**NOTES**

A service handler (**WA2Ledrc.batteryalert**) for **edrcinit(1m)** is provided.

**BUGS**

The first battery found is used for alerting and information display.

**AUTHOR**

batteryalert was developed by Christian Walther. Send suggestions and bug reports to [wa2l@users.sourceforge.net](mailto:wa2l@users.sourceforge.net).

**NAME**

**bc** - An arbitrary precision calculator language

**SYNTAX**

**bc** [ **-hlwsqv** ] [long-options] [ *file* ... ]

**DESCRIPTION**

**bc** is a language that supports arbitrary precision numbers with interactive execution of statements. There are some similarities in the syntax to the C programming language. A standard math library is available by command line option. If requested, the math library is defined before processing any files. **bc** starts by processing code from all the files listed on the command line in the order listed. After all files have been processed, **bc** reads from the standard input. All code is executed as it is read. (If a file contains a command to halt the processor, **bc** will never read from the standard input.)

This version of **bc** contains several extensions beyond traditional **bc** implementations and the POSIX draft standard. Command line options can cause these extensions to print a warning or to be rejected. This document describes the language accepted by this processor. Extensions will be identified as such.

**OPTIONS**

- h, --help  
Print the usage and exit.
- i, --interactive  
Force interactive mode.
- l, --mathlib  
Define the standard math library.
- w, --warn  
Give warnings for extensions to POSIX **bc**.
- s, --standard  
Process exactly the POSIX **bc** language.
- q, --quiet  
Do not print the normal GNU **bc** welcome.
- v, --version  
Print the version number and copyright and quit.

**NUMBERS**

The most basic element in **bc** is the number. Numbers are arbitrary precision numbers. This precision is both in the integer part and the fractional part. All numbers are represented internally in decimal and all computation is done in decimal. (This version truncates results from divide and multiply operations.) There are two attributes of numbers, the length and the scale. The length is the total number of decimal digits used by **bc** to represent a number and the scale is the total number of decimal digits after the decimal point. For example:

.000001 has a length of 6 and scale of 6.  
1935.000 has a length of 7 and a scale of 3.

**VARIABLES**

Numbers are stored in two types of variables, simple variables and arrays. Both simple variables and array variables are named. Names begin with a letter followed by any number of letters, digits and underscores. All letters must be lower case. (Full alpha-numeric names are an extension. In POSIX **bc** all names are a single lower case letter.) The type of variable is clear by the context because all array variable names will be followed by brackets ([]).

There are four special variables, **scale**, **ibase**, **obase**, and **last**. **scale** defines how some operations use digits after the decimal point. The default value of **scale** is 0. **ibase** and **obase** define the conversion base for input and output numbers. The default for both input and output is base 10. **last** (an extension) is a variable that has the value of the last printed number. These will be discussed in further detail where appropriate. All of these variables may have values assigned to them as well as used in expressions.

## COMMENTS

Comments in **bc** start with the characters **/\*** and end with the characters **\*/**. Comments may start anywhere and appear as a single space in the input. (This causes comments to delimit other input items. For example, a comment can not be found in the middle of a variable name.) Comments include any newlines (end of line) between the start and the end of the comment.

To support the use of scripts for **bc**, a single line comment has been added as an extension. A single line comment starts at a **#** character and continues to the next end of the line. The end of line character is not part of the comment and is processed normally.

## EXPRESSIONS

The numbers are manipulated by expressions and statements. Since the language was designed to be interactive, statements and expressions are executed as soon as possible. There is no "main" program. Instead, code is executed as it is encountered. (Functions, discussed in detail later, are defined when encountered.)

A simple expression is just a constant. **bc** converts constants into internal decimal numbers using the current input base, specified by the variable **ibase**. (There is an exception in functions.) The legal values of **ibase** are 2 through 36. (Bases greater than 16 are an extension.) Assigning a value outside this range to **ibase** will result in a value of 2 or 36. Input numbers may contain the characters 0–9 and A–Z. (Note: They must be capitals. Lower case letters are variable names.) Single digit numbers always have the value of the digit regardless of the value of **ibase**. (i.e. A = 10.) For multi-digit numbers, **bc** changes all input digits greater or equal to **ibase** to the value of **ibase-1**. This makes the number **ZZZ** always be the largest 3 digit number of the input base.

Full expressions are similar to many other high level languages. Since there is only one kind of number, there are no rules for mixing types. Instead, there are rules on the scale of expressions. Every expression has a scale. This is derived from the scale of original numbers, the operation performed and in many cases, the value of the variable **scale**. Legal values of the variable **scale** are 0 to the maximum number representable by a C integer.

In the following descriptions of legal expressions, "expr" refers to a complete expression and "var" refers to a simple or an array variable. A simple variable is just a

*name*

and an array variable is specified as

*name[expr]*

Unless specifically mentioned the scale of the result is the maximum scale of the expressions involved.

- expr    The result is the negation of the expression.

++ var    The variable is incremented by one and the new value is the result of the expression.

-- var    The variable is decremented by one and the new value is the result of the expression.

var ++

          The result of the expression is the value of the variable and then the variable is incremented by one.

var --    The result of the expression is the value of the variable and then the variable is decremented by one.

expr + expr

          The result of the expression is the sum of the two expressions.

expr - expr

          The result of the expression is the difference of the two expressions.

expr \* expr

          The result of the expression is the product of the two expressions.

expr / expr

          The result of the expression is the quotient of the two expressions. The scale of the result is the value of the variable **scale**.

`expr % expr`

The result of the expression is the "remainder" and it is computed in the following way. To compute `a%b`, first `a/b` is computed to **scale** digits. That result is used to compute `a-(a/b)*b` to the scale of the maximum of **scale**+`scale(b)` and `scale(a)`. If **scale** is set to zero and both expressions are integers this expression is the integer remainder function.

`expr ^ expr`

The result of the expression is the value of the first raised to the second. The second expression must be an integer. (If the second expression is not an integer, a warning is generated and the expression is truncated to get an integer value.) The scale of the result is **scale** if the exponent is negative. If the exponent is positive the scale of the result is the minimum of the scale of the first expression times the value of the exponent and the maximum of **scale** and the scale of the first expression. (e.g. `scale(a^b) = min(scale(a)*b, max( scale, scale(a)))`.) It should be noted that `expr^0` will always return the value of 1.

( `expr` ) This alters the standard precedence to force the evaluation of the expression.

`var = expr`

The variable is assigned the value of the expression.

`var <op>= expr`

This is equivalent to "`var = var <op> expr`" with the exception that the "`var`" part is evaluated only once. This can make a difference if "`var`" is an array.

Relational expressions are a special kind of expression that always evaluate to 0 or 1, 0 if the relation is false and 1 if the relation is true. These may appear in any legal expression. (POSIX `bc` requires that relational expressions are used only in `if`, `while`, and `for` statements and that only one relational test may be done in them.) The relational operators are

`expr1 < expr2`

The result is 1 if `expr1` is strictly less than `expr2`.

`expr1 <= expr2`

The result is 1 if `expr1` is less than or equal to `expr2`.

`expr1 > expr2`

The result is 1 if `expr1` is strictly greater than `expr2`.

`expr1 >= expr2`

The result is 1 if `expr1` is greater than or equal to `expr2`.

`expr1 == expr2`

The result is 1 if `expr1` is equal to `expr2`.

`expr1 != expr2`

The result is 1 if `expr1` is not equal to `expr2`.

Boolean operations are also legal. (POSIX `bc` does NOT have boolean operations). The result of all boolean operations are 0 and 1 (for false and true) as in relational expressions. The boolean operators are:

`!expr` The result is 1 if `expr` is 0.

`expr && expr`

The result is 1 if both expressions are non-zero.

`expr || expr`

The result is 1 if either expression is non-zero.

The expression precedence is as follows: (lowest to highest)

- `||` operator, left associative
- `&&` operator, left associative
- `!` operator, nonassociative
- Relational operators, left associative
- Assignment operator, right associative

+ and - operators, left associative  
 \*, / and % operators, left associative  
 ^ operator, right associative  
 unary - operator, nonassociative  
 ++ and -- operators, nonassociative

This precedence was chosen so that POSIX compliant **bc** programs will run correctly. This will cause the use of the relational and logical operators to have some unusual behavior when used with assignment expressions. Consider the expression:

```
a = 3 < 5
```

Most C programmers would assume this would assign the result of "3 < 5" (the value 1) to the variable "a". What this does in **bc** is assign the value 3 to the variable "a" and then compare 3 to 5. It is best to use parenthesis when using relational and logical operators with the assignment operators.

There are a few more special expressions that are provided in **bc**. These have to do with user defined functions and standard functions. They all appear as "*name(parameters)*". See the section on functions for user defined functions. The standard functions are:

length ( expression )

The value of the length function is the number of significant digits in the expression.

read ( ) The read function (an extension) will read a number from the standard input, regardless of where the function occurs. Beware, this can cause problems with the mixing of data and program in the standard input. The best use for this function is in a previously written program that needs input from the user, but never allows program code to be input from the user. The value of the read function is the number read from the standard input using the current value of the variable **ibase** for the conversion base.

scale ( expression )

The value of the scale function is the number of digits after the decimal point in the expression.

sqrt ( expression )

The value of the sqrt function is the square root of the expression. If the expression is negative, a run time error is generated.

## STATEMENTS

Statements (as in most algebraic languages) provide the sequencing of expression evaluation. In **bc** statements are executed "as soon as possible." Execution happens when a newline is encountered and there is one or more complete statements. Due to this immediate execution, newlines are very important in **bc**. In fact, both a semicolon and a newline are used as statement separators. An improperly placed newline will cause a syntax error. Because newlines are statement separators, it is possible to hide a newline by using the backslash character. The sequence "\<nl>", where <nl> is the newline appears to **bc** as whitespace instead of a newline. A statement list is a series of statements separated by semicolons and newlines. The following is a list of **bc** statements and what they do: (Things enclosed in brackets []) are optional parts of the statement.)

expression

This statement does one of two things. If the expression starts with "<variable> <assignment> ...", it is considered to be an assignment statement. If the expression is not an assignment statement, the expression is evaluated and printed to the output. After the number is printed, a newline is printed. For example, "a=1" is an assignment statement and "(a=1)" is an expression that has an embedded assignment. All numbers that are printed are printed in the base specified by the variable **obase**. The legal values for **obase** are 2 through BC\_BASE\_MAX. (See the section LIMITS.) For bases 2 through 16, the usual method of writing numbers is used. For bases greater than 16, **bc** uses a multi-character digit method of printing the numbers where each higher base digit is printed as a base 10 number. The multi-character digits are separated by spaces. Each digit contains the number of characters required to represent the base ten value of "obase-1". Since numbers are of arbitrary precision, some numbers may not be printable on a single output line. These long numbers will be split across lines using the "\" as the last character on a line. The maximum

number of characters printed per line is 70. Due to the interactive nature of **bc**, printing a number causes the side effect of assigning the printed value to the special variable **last**. This allows the user to recover the last value printed without having to retype the expression that printed the number. Assigning to **last** is legal and will overwrite the last printed value with the assigned value. The newly assigned value will remain until the next number is printed or another value is assigned to **last**. (Some installations may allow the use of a single period (.) which is not part of a number as a short hand notation for for **last**.)

**string** The string is printed to the output. Strings start with a double quote character and contain all characters until the next double quote character. All characters are take literally, including any newline. No newline character is printed after the string.

#### **print list**

The print statement (an extension) provides another method of output. The "list" is a list of strings and expressions separated by commas. Each string or expression is printed in the order of the list. No terminating newline is printed. Expressions are evaluated and their value is printed and assigned to the variable **last**. Strings in the print statement are printed to the output and may contain special characters. Special characters start with the backslash character (\). The special characters recognized by **bc** are "a" (alert or bell), "b" (backspace), "f" (form feed), "n" (newline), "r" (carriage return), "q" (double quote), "t" (tab), and "\" (backslash). Any other character following the backslash will be ignored.

**{ statement\_list }**

This is the compound statement. It allows multiple statements to be grouped together for execution.

**if ( expression ) statement1 [else statement2]**

The if statement evaluates the expression and executes statement1 or statement2 depending on the value of the expression. If the expression is non-zero, statement1 is executed. If statement2 is present and the value of the expression is 0, then statement2 is executed. (The else clause is an extension.)

**while ( expression ) statement**

The while statement will execute the statement while the expression is non-zero. It evaluates the expression before each execution of the statement. Termination of the loop is caused by a zero expression value or the execution of a break statement.

**for ( [expression1] ; [expression2] ; [expression3] ) statement**

The for statement controls repeated execution of the statement. Expression1 is evaluated before the loop. Expression2 is evaluated before each execution of the statement. If it is non-zero, the statement is evaluated. If it is zero, the loop is terminated. After each execution of the statement, expression3 is evaluated before the reevaluation of expression2. If expression1 or expression3 are missing, nothing is evaluated at the point they would be evaluated. If expression2 is missing, it is the same as substituting the value 1 for expression2. (The optional expressions are an extension. POSIX **bc** requires all three expressions.) The following is equivalent code for the for statement:

```
expression1;
while (expression2) {
 statement;
 expression3;
}
```

**break** This statement causes a forced exit of the most recent enclosing while statement or for statement.

#### **continue**

The continue statement (an extension) causes the most recent enclosing for statement to start the next iteration.

#### **halt**

The halt statement (an extension) is an executed statement that causes the **bc** processor to quit only when it is executed. For example, "if (0 == 1) halt" will not cause **bc** to terminate because the halt is not executed.

**return** Return the value 0 from a function. (See the section on functions.)

**return** ( expression )

Return the value of the expression from a function. (See the section on functions.) As an extension, the parenthesis are not required.

## PSEUDO STATEMENTS

These statements are not statements in the traditional sense. They are not executed statements. Their function is performed at "compile" time.

**limits** Print the local limits enforced by the local version of **bc**. This is an extension.

**quit** When the quit statement is read, the **bc** processor is terminated, regardless of where the quit statement is found. For example, "if (0 == 1) quit" will cause **bc** to terminate.

**warranty**

Print a longer warranty notice. This is an extension.

## FUNCTIONS

Functions provide a method of defining a computation that can be executed later. Functions in **bc** always compute a value and return it to the caller. Function definitions are "dynamic" in the sense that a function is undefined until a definition is encountered in the input. That definition is then used until another definition for the same name is encountered. The new definition then replaces the older definition. A function is defined as follows:

```
define name (parameters) { newline
 auto_list statement_list }
```

A function call is just an expression of the form "*name(parameters)*".

Parameters are numbers or arrays (an extension). In the function definition, zero or more parameters are defined by listing their names separated by commas. All parameters are call by value parameters. Arrays are specified in the parameter definition by the notation "*name*[]". In the function call, actual parameters are full expressions for number parameters. The same notation is used for passing arrays as for defining array parameters. The named array is passed by value to the function. Since function definitions are dynamic, parameter numbers and types are checked when a function is called. Any mismatch in number or types of parameters will cause a runtime error. A runtime error will also occur for the call to an undefined function.

The *auto\_list* is an optional list of variables that are for "local" use. The syntax of the auto list (if present) is "**auto** *name*, ... ;". (The semicolon is optional.) Each *name* is the name of an auto variable. Arrays may be specified by using the same notation as used in parameters. These variables have their values pushed onto a stack at the start of the function. The variables are then initialized to zero and used throughout the execution of the function. At function exit, these variables are popped so that the original value (at the time of the function call) of these variables are restored. The parameters are really auto variables that are initialized to a value provided in the function call. Auto variables are different than traditional local variables because if function A calls function B, B may access function A's auto variables by just using the same name, unless function B has called them auto variables. Due to the fact that auto variables and parameters are pushed onto a stack, **bc** supports recursive functions.

The function body is a list of **bc** statements. Again, statements are separated by semicolons or newlines. Return statements cause the termination of a function and the return of a value. There are two versions of the return statement. The first form, "**return**", returns the value 0 to the calling expression. The second form, "**return** ( *expression* )", computes the value of the expression and returns that value to the calling expression. There is an implied "**return** (0)" at the end of every function. This allows a function to terminate and return 0 without an explicit return statement.

Functions also change the usage of the variable **ibase**. All constants in the function body will be converted using the value of **ibase** at the time of the function call. Changes of **ibase** will be ignored during the execution of the function except for the standard function **read**, which will always use the current value of **ibase** for conversion of numbers.

Several extensions have been added to functions. First, the format of the definition has been slightly

relaxed. The standard requires the opening brace be on the same line as the **define** keyword and all other parts must be on following lines. This version of **bc** will allow any number of newlines before and after the opening brace of the function. For example, the following definitions are legal.

```
define d (n) { return (2*n); }
define d (n)
{ return (2*n); }
```

Functions may be defined as **void**. A void function returns no value and thus may not be used in any place that needs a value. A void function does not produce any output when called by itself on an input line. The key word **void** is placed between the key word **define** and the function name. For example, consider the following session.

```
define py (y) { print "---->", y, "<---", "\n"; }
define void px (x) { print "---->", x, "<---", "\n"; }
py(1)
---->1<---
0
px(1)
---->1<---
```

Since **py** is not a void function, the call of **py(1)** prints the desired output and then prints a second line that is the value of the function. Since the value of a function that is not given an explicit return statement is zero, the zero is printed. For **px(1)**, no zero is printed because the function is a void function.

Also, call by variable for arrays was added. To declare a call by variable array, the declaration of the array parameter in the function definition looks like **"\*name[]"**. The call to the function remains the same as call by value arrays.

## MATH LIBRARY

If **bc** is invoked with the **-l** option, a math library is preloaded and the default scale is set to 20. The math functions will calculate their results to the scale set at the time of their call. The math library defines the following functions:

- s (x)** The sine of x, x is in radians.
- c (x)** The cosine of x, x is in radians.
- a (x)** The arctangent of x, arctangent returns radians.
- l (x)** The natural logarithm of x.
- e (x)** The exponential function of raising e to the value x.
- j (n,x)** The Bessel function of integer order n of x.

## EXAMPLES

In **/bin/sh**, the following will assign the value of "pi" to the shell variable **pi**.

```
pi=$(echo "scale=10; 4*a(1)" | bc -l)
```

The following is the definition of the exponential function used in the math library. This function is written in POSIX **bc**.

```
scale = 20

/* Uses the fact that e^x = (e^(x/2))^2
 When x is small enough, we use the series:
 e^x = 1 + x + x^2/2! + x^3/3! + ...
*/

define e(x) {
 auto a, d, e, f, i, m, v, z

 /* Check the sign of x. */
 if (x<0) {
```

```

 m = 1
 x = -x
}

/* Precondition x. */
z = scale;
scale = 4 + z + .44*x;
while (x > 1) {
 f += 1;
 x /= 2;
}

/* Initialize the variables. */
v = 1+x
a = x
d = 1

for (i=2; 1; i++) {
 e = (a *= x) / (d *= i)
 if (e == 0) {
 if (f>0) while (f--) v = v*v;
 scale = z
 if (m) return (1/v);
 return (v/1);
 }
 v += e
}
}

```

The following is code that uses the extended features of **bc** to implement a simple program for calculating checkbook balances. This program is best kept in a file so that it can be used many times without having to retype it at every use.

```

scale=2
print "\nCheck book program!\n"
print " Remember, deposits are negative transactions.\n"
print " Exit by a 0 transaction.\n\n"

print "Initial balance? "; bal = read()
bal /= 1
print "\n"
while (1) {
 "current balance = "; bal
 "transaction? "; trans = read()
 if (trans == 0) break;
 bal -= trans
 bal /= 1
}
quit

```

The following is the definition of the recursive factorial function.

```

define f (x) {
 if (x <= 1) return (1);
 return (f(x-1) * x);
}

```

## READLINE AND LIBEDIT OPTIONS

GNU **bc** can be compiled (via a configure option) to use the GNU **readline** input editor library or the BSD **libedit** library. This allows the user to do editing of lines before sending them to **bc**. It also allows for a history of previous lines typed. When this option is selected, **bc** has one more special variable. This special variable, **history** is the number of lines of history retained. For **readline**, a value of `-1` means that an unlimited number of history lines are retained. Setting the value of **history** to a positive number restricts the number of history lines to the number given. The value of `0` disables the history feature. The default value is `100`. For more information, read the user manuals for the GNU **readline**, **history** and BSD **libedit** libraries. One can not enable both **readline** and **libedit** at the same time.

## DIFFERENCES

This version of **bc** was implemented from the POSIX P1003.2/D11 draft and contains several differences and extensions relative to the draft and traditional implementations. It is not implemented in the traditional way using *dc(1)*. This version is a single process which parses and runs a byte code translation of the program. There is an "undocumented" option (`-c`) that causes the program to output the byte code to the standard output instead of running it. It was mainly used for debugging the parser and preparing the math library.

A major source of differences is extensions, where a feature is extended to add more functionality and additions, where new features are added. The following is the list of differences and extensions.

### LANG environment

This version does not conform to the POSIX standard in the processing of the LANG environment variable and all environment variables starting with `LC_`.

**names** Traditional and POSIX **bc** have single letter names for functions, variables and arrays. They have been extended to be multi-character names that start with a letter and may contain letters, numbers and the underscore character.

**Strings** Strings are not allowed to contain NUL characters. POSIX says all characters must be included in strings.

**last** POSIX **bc** does not have a **last** variable. Some implementations of **bc** use the period (`.`) in a similar way.

### comparisons

POSIX **bc** allows comparisons only in the if statement, the while statement, and the second expression of the for statement. Also, only one relational operation is allowed in each of those statements.

### if statement, else clause

POSIX **bc** does not have an else clause.

### for statement

POSIX **bc** requires all expressions to be present in the for statement.

### &&, ||, !

POSIX **bc** does not have the logical operators.

### read function

POSIX **bc** does not have a read function.

### print statement

POSIX **bc** does not have a print statement.

### continue statement

POSIX **bc** does not have a continue statement.

### return statement

POSIX **bc** requires parentheses around the return expression.

**array parameters**

POSIX **bc** does not (currently) support array parameters in full. The POSIX grammar allows for arrays in function definitions, but does not provide a method to specify an array as an actual parameter. (This is most likely an oversight in the grammar.) Traditional implementations of **bc** have only call by value array parameters.

**function format**

POSIX **bc** requires the opening brace on the same line as the **define** key word and the **auto** statement on the next line.

**==+, ==-, ==\*, ==/, ==%, ==^**

POSIX **bc** does not require these "old style" assignment operators to be defined. This version may allow these "old style" assignments. Use the limits statement to see if the installed version supports them. If it does support the "old style" assignment operators, the statement "a ==- 1" will decrement **a** by 1 instead of setting **a** to the value -1.

**spaces in numbers**

Other implementations of **bc** allow spaces in numbers. For example, "x=1 3" would assign the value 13 to the variable **x**. The same statement would cause a syntax error in this version of **bc**.

**errors and execution**

This implementation varies from other implementations in terms of what code will be executed when syntax and other errors are found in the program. If a syntax error is found in a function definition, error recovery tries to find the beginning of a statement and continue to parse the function. Once a syntax error is found in the function, the function will not be callable and becomes undefined. Syntax errors in the interactive execution code will invalidate the current execution block. The execution block is terminated by an end of line that appears after a complete sequence of statements. For example,

```
a = 1
b = 2
```

has two execution blocks and

```
{ a = 1
 b = 2 }
```

has one execution block. Any runtime error will terminate the execution of the current execution block. A runtime warning will not terminate the current execution block.

**Interrupts**

During an interactive session, the SIGINT signal (usually generated by the control-C character from the terminal) will cause execution of the current execution block to be interrupted. It will display a "runtime" error indicating which function was interrupted. After all runtime structures have been cleaned up, a message will be printed to notify the user that **bc** is ready for more input. All previously defined functions remain defined and the value of all non-auto variables are the value at the point of interruption. All auto variables and function parameters are removed during the clean up process. During a non-interactive session, the SIGINT signal will terminate the entire run of **bc**.

**LIMITS**

The following are the limits currently in place for this **bc** processor. Some of them may have been changed by an installation. Use the limits statement to see the actual values.

**BC\_BASE\_MAX**

The maximum output base is currently set at 999. The maximum input base is 16.

**BC\_DIM\_MAX**

This is currently an arbitrary limit of 65535 as distributed. Your installation may be different.

**BC\_SCALE\_MAX**

The number of digits after the decimal point is limited to INT\_MAX digits. Also, the number of digits before the decimal point is limited to INT\_MAX digits.

**BC\_STRING\_MAX**

The limit on the number of characters in a string is INT\_MAX characters.

**exponent**

The value of the exponent in the raise operation (\*\*) is limited to LONG\_MAX.

**variable names**

The current limit on the number of unique names is 32767 for each of simple variables, arrays and functions.

**ENVIRONMENT VARIABLES**

The following environment variables are processed by **bc**:

**POSIXLY\_CORRECT**

This is the same as the **-s** option.

**BC\_ENV\_ARGS**

This is another mechanism to get arguments to **bc**. The format is the same as the command line arguments. These arguments are processed first, so any files listed in the environment arguments are processed before any command line argument files. This allows the user to set up "standard" options and files to be processed at every invocation of **bc**. The files in the environment variables would typically contain function definitions for functions the user wants defined every time **bc** is run.

**BC\_LINE\_LENGTH**

This should be an integer specifying the number of characters in an output line for numbers. This includes the backslash and newline characters for long numbers. As an extension, the value of zero disables the multi-line feature. Any other value of this variable that is less than 3 sets the line length to 70.

**DIAGNOSTICS**

If any file on the command line can not be opened, **bc** will report that the file is unavailable and terminate. Also, there are compile and run time diagnostics that should be self-explanatory.

**BUGS**

Error recovery is not very good yet.

Email bug reports to **bug-bc@gnu.org**. Be sure to include the word "bc" somewhere in the "Subject:" field.

**AUTHOR**

Philip A. Nelson  
philnelson@acm.org

**ACKNOWLEDGEMENTS**

The author would like to thank Steve Sommars (Steve.Sommars@att.com) for his extensive help in testing the implementation. Many great suggestions were given. This is a much better product due to his involvement.

**NAME**

bget – basic HTTP get tool

**DESCRIPTION**

Basic tool to make HTTP GET requests and monitor the results. Unlike LWP GET, it does not require special Perl modules, and by virtue of being cruder makes HTTP headers easier to spy on.

Only URLs of the forms

```
http://hostname/[localpart]
http://hostname:port/[localpart]
```

are supported.

Options:

- `-a --autoname`

Save output automatically based on URI. Will not warn if the file already exists. This overrides the `-o` (`--out`) option. The preferred output name is everything after the last `/` in the URL, or `'dir-default'` if the URL ends with a `/`.

- `-B --no-body`

Don't print the body of the response.

- `-b --browser NAME`

What browser to emulate. Use `--emulations` to list available browser headers.

- `-c --cookie VALUE`

Set the cookie header with VALUE.

- `-d --dontdechunk`

As of version 1.2, when the response headers indicate a Transfer-Encoding of 'chunked', bget will rename the header (prefixing it with 'Xbget-') and unchunk the response. This is desirable so that chunked responses from HTTP/1.1 servers look right. In some cases it may be desirable to see raw output from the server however, so this behavior can be turned off.

- `-e --head`

Make a HEAD request instead of a GET. Note that this does not imply `-h` (`--heads`) to print the headers, nor `-B` (`--no-body`) to suppress printing any body content. (Some servers, eg `www.yahoo.com`, treat HEAD like a GET.)

- `-F --file FILE`

Read URLs from FILE (one per line) instead of from command line. Use filename `-` for standard input.

If there are two URLs on a line, the first one is used as the referer URL. The referer will remain unused until the next line with two URLs.

If there is an additional field after the URL, that will be used as an `-o` (`--out`) output file until the next line with an output file. An output file should not begin with `"http:/"` or `"https:/"`.

Fields on each line of the URL file are whitespace separated.

- `-f --follow`

Follow redirects. If printing headers, the redirecting headers and the destination headers will be printed. (No loop detection is attempted.) If printing bodies and not saving via `autoname`, the redirecting body and the destination body will be printed. If saving via `autoname`, a new file will be opened for each request made. Some redirects (eg loops) may cause the `autoname` to pick the same filename as a previous request, which will cause the earlier file to be clobbered.

- `-H --host HOST[:P]`  
Connect to HOST for request (useful for testing virtual hosts before a DNS change or use with `-l` for proxies).
- `-h --heads`  
Print the response headers.
- `-L --language LANG`  
Use LANG for Accept-Language: header. See `--languages` for a small list.
- `-l --long`  
Use long address on GET line (using the full `http://...` format, a MUST for HTTP/1.1 server compliance but handy with `-H` for proxies).
- `-o --out FILE`  
Write output to FILE. Unlike `-a` (`--autoname`) this will not use a different file for each request. The autoname option has precedence over this option. Filenames in a `-F` (`--file`) URL file will also override this.
- `-p --post STRING`  
Use STRING as a post form contents (forms of type `application/x-www-form-urlencoded` only).
- `-P --filepost FILE`  
Use contents of FILE as a post form contents. If the first line is of the form “Content-Type: foo/bar” it will be used to set the Content-Type: header. More than just the MIME type is allowed, but it must be all on one line. Typical POST content types are  

```
application/x-www-form-urlencoded
 Encoded like a typical CGI URL.
multipart/form-data
 Each form element is in a separate MIME part; needed for
 file uploads. This type requires a boundary parameter on
 the Content-Type: header.
```

There is a similar allowance for setting the Transfer-Encoding: header. This must be on the second line if Content-Type: is set, and on the first line if not. When Transfer-Encoding: contains the string ‘chunked’, Content-Length: will not be set for a post. Note that apache 1.3.x (at least) does not allow chunked POST requests.

You may find the tool `mkpost` (available in the scripts section of CPAN) to be helpful in creating CGI interface files for this option. For other content types, like “text/xml” for XML-RPC interface requests, other tools will be needed.
- `-R --refer VALUE`  
Set the (initial) referer header with VALUE.
- `-r --request`  
Print the request headers.
- `-s --status CODE`  
After fetching a page — including following redirects and printing bits of the response as controlled by other options — if the HTTP status code is not exactly the one given, bget will exit (returning code 3 to the shell). Useful for looping until one hits a 404 or the like.

- `-t --time N`  
Use Benchmark module to time making the command line request(s) N times.
- `-C --count N`  
Just like `-t/--time`, but optimizations apply: if neither heads nor bodies are requested, nothing will be fetched. If body is not requested only heads will be fetched.
- `-u --user USER:PW`  
Basic authentication in the form {username}:{password}.
- `-w --wait N`  
Wait N seconds between fetching each URL.
- `-w --wait A,D`  
Waits a random number of seconds, average A standard deviation D, between fetching each URL. Requires the Math::Random module. Useful for being subtle when fetching a lot of pages, along with emulating a browser and using per-page referer headers via the `-F (--file)` method.
- `--help`  
Show a help message and exit.
- `--version`  
Print version and exit.
- `--emulations`  
Print list of available browser emulations.
- `--languages`  
Print a sample of language codes.

#### Note

If `-H (--host)` is used with multiple URLs, all connections are made to the specified HOST (and port) even if different hosts are used in the URLs. This can be used to fetch files through a HTTP proxy if `-l (--long)` is also used.

With `-L (--langauge)` the Accept-Language: header will not be added if the browser has not been observed to use it.

## EMULATIONS

The following browsers are recognized for header emulation. This might not be the definitive list. Check `--emulations` for that. Some have comments to help identify them.

- Amaya-8.1  
Amaya is the W3C's combination browser page editor.
- links-0.84  
Text mode browser for Unix. <http://artax.karlin.mff.cuni.cz/~mikulas/links> Version 0.84 does not do cookies or referer headers, so we might misemulate it that way.
- elinks-0.5pre4-linux  
Forked from links, this is another text mode browser. Quirks include giving a bunch away about the system, including window size, in the User-Agent: and including a 'Referer' header in URLs entered by hand. The User-Agent for this is from a Redhat 7.1 x86 system in an 80x24 window. <http://elinks.or.cz/>
- w3c-5.2.8

Command line web tool that uses libwww. <<http://www.w3.org/ComLine/>>

- w3m-beta99

Text mode browser for Unix. <<http://ei5nazha.yz.yamagata-u.ac.jp/~aito/w3m/>>

- Dillo-0.8.4

Dillo is Linux browser, under current development, that focuses on speed, small size, and protocol correctness. It can do cookies, but it defaults to not accepting them. It does not do Referer: headers, but bget may misemulate it on that point. <<http://www.dillo.org/>>

- Linux-Mosaic-2.6

The browser that started the rush, compiled for Linux. This is an archaic browser. It doesn't do Host: headers or Cookies:. bget can misemulate the Cookies: part, but won't do the Host: header. Many modern sites require this for proper operation, so expect problems. The headers this thing spits out are longer even than the Lynx ones.

- Qweb-1.3

Qweb was an early X11 style-sheet capable browser. Too bad it didn't do javascript (needed for some stylesheets) or even Host: headers. bget will misemulate this if you use Cookies, but won't supply a Host: header.

- X11-Chimera-1.70

The name 'Chimera' has been used by two different browsers. This is the X11 Chimera developed at the University of Las Vegas, not the Mac Mozilla derivative Chimera. In authentic use this browser does not have cookies or use Referer: headers.

- ApacheBench-1.3

ab, the benchmark tool that comes with the Apache httpd package.

- Opera-3.60

An old version of a popular alternative browser for Windows.

- Windows-Opera-7beta

More modern (2003) version of Opera.

- Linux-Opera-6.11

As of Opera 6.x there is a linux version.

- lwp-request-1.38

Lib WWW Perl module (these are the default headers).

- wget-1.6

Command-line bulk page downloading tool for Unix.

- NetBSD-curl-7.10.4-HTTP1.1

Command-line page upload/download tool for Unix. Prefers HTTP/1.1 but can do HTTP/1.0 upon request. Can do PUTs and DELETes and other obscure things, too.

- NetBSD-curl-7.10.4-HTTP1.0

Curl in HTTP/1.0 mode.

- iCab-pre1.7

Popular alternative browser for Macs.

- junkbuster-2

Once popular ad- and cookie-filtering proxy. Junkbuster does a bunch of header editing from the

actual browser headers, and thus the headers out of it can vary considerably from this. It looks like Accept-\* headers are not edited, allowing identification of the underlying browser sometimes. The Accept-\* headers here come from a Netscape 4.7. By default, Junkbuster masquerades as Netscape 3.01 (GOLD) for Mac PPC.

- **Lynx-2.8.1**  
Popular text mode browser, predominately unix.
- **Linux-Mozilla-1.0.0**  
Mozilla is the open source version of Netscape 7. It exists for many platforms.
- **Linux-Phoenix-0.6-beta**  
Phoenix (formerly Firebird) is Mozilla with a different user-interface library. There are unix, windows and mac variants.
- **Konqueror-2.1.1**  
Konqueror is a mostly-Linux browser based on KDE.
- **OpenOffice-1.0.0**  
OpenOffice is a StarOffice relation, intended to be a free Unix "Office" compatible software bundle. It includes an HTML editor that can download pages to edit, but as such it does things like issue PROPFIND requests that are not emulated here.
- **WindowsNT-Explorer-5.0-as-4.0**  
Explorer 5.0 can be installed with a compatibility mode that emulates (or claims to emulate) Explorer 4.0.
- **Windows98-Explorer-5.5**
- **WindowsNT-ActiveDesktop**  
This is on a system with IE5.5 installed, but this identifies itself as IE4.01. This one is hard to do right, since in my tests I saw two requests for the test file. The first came with this UA, the second had this instead:  
User-Agent: Mozilla/4.0 (compatible; MSIE 4.01; MSIECrawler; Windows NT)  
The crawler version had an 'Accept-Language: us-en' as well as a different order to the headers (Accept: User-Agent:, Accept-Language: Accept-Encoding, Host:).
- **WindowsNT-Netscape6**
- **WindowsNT-Explorer-5.5**
- **Windows98-Explorer-4.0**
- **WindowsNT-Explorer-5.0**  
Normal mode Windows NT IE 5.0.
- **WindowsNT-ExplorerOffline-5.0**  
IE can optionally crawl pages to cache them for offline browsing. This is Windows NT IE 5.01 in crawl mode.
- **WindowsNT-Netscape-4.6**
- **MacPPC-Explorer-4.0**  
Mac PPC is System 7, 8 or 9 on PowerPC computers.
- **MacPPC-Netscape-4.0**
- **MacPPC-Netscape-4.6**

- MacOSX-Safari-1.2.4  
Safari is a Mozilla derivative that ships with OS X.
- MacOSX-Explorer-5.2  
Internet Explorer for OS X. (Comes with OS X?)
- Linux-Netscape-3.0
- Linux-Netscape-4.51

## LANGUAGES

In HTTP standard languages use the ISO 639 two letter code, but can have an optional two letter country code for national variants. Generic English is 'en', American English is 'en-us', Irish English is 'en-ie', Australian English is 'en-au'.

Some other lanuages:

|       |                    |
|-------|--------------------|
| af    | Afrikaans          |
| sq    | Albanian           |
| eu    | Basque             |
| bg    | Bulgarian          |
| be    | Byelorussian       |
| ca    | Catalan            |
| zh    | Chinese            |
| zh-cn | Chinese/China      |
| zh-tw | Chinese/Taiwan     |
| hr    | Croatian           |
| cs    | Czech              |
| da    | Danish             |
| nl    | Dutch              |
| nl-be | Dutch/Belgium      |
| fo    | Faeroese           |
| fi    | Finnish            |
| fr    | French             |
| fr-be | French/Belgium     |
| fr-ca | French/Canada      |
| fr-fr | French/France      |
| fr-ch | French/Switzerland |
| gl    | Galician           |
| de    | German             |
| de-at | German/Austria     |
| de-de | German/Germany     |
| de-ch | German/Switzerland |
| el    | Greek              |
| hu    | Hungarian          |
| is    | Icelandic          |
| id    | Indonesian         |
| ga    | Irish              |
| it    | Italian            |
| ja    | Japanese           |
| ko    | Korean             |
| mk    | Macedonian         |
| no    | Norwegian          |
| pl    | Polish             |
| pt    | Portuguese         |
| pt-br | Portuguese/Brazil  |
| ro    | Romanian           |
| ru    | Russian            |
| gd    | Scots Gaelic       |
| sr    | Serbian            |
| sk    | Slovak             |
| sl    | Slovenian          |
| es    | Spanish            |
| es-ar | Spanish/Argentina  |
| es-co | Spanish/Colombia   |
| ex-mx | Spanish/Mexico     |
| es-es | Spanish/Spain      |
| sv    | Swedish            |
| tr    | Turkish            |
| uk    | Ukrainian          |

This list is from the default set of languages in Netscape 4.5. IE has a different set, including more country

variations. Note that the country variations are frequently misused. A request with a language header like:

```
Accept-Language: en-us, es-mx; q=0.7, fr-ca; q=0.3
```

Would specify a first choice language of US English, second choice Mexican Spanish, third choice Canadian French. If a content-negotiating server only has generic English, generic Spanish, and generic French, then by specification it should return a “406 Not Acceptable” error, since it has no languages that match. This could be seen as a deficiency of the spec, but that’s the way it is.

## REVISION HISTORY

NEW IN VERSION 1.2

By supporting chunked transfer encodings, the author considers bget to be HTTP/1.1 compliant now. A word of warning, some emulations specify various allowed other encodings, like gzipped content. You should be prepared to deal with these outside of bget.

## README

bget – basic HTTP get tool

## PREREQUISITES

This uses the `strict`, `vars`, `Socket`, and `Carp` modules.

## COREQUISITES

This will try to use the `Benchmark` and `Math::Random` modules when run with certain options.

## OSNAMES

Should not be OS dependent. The `autoname` feature (`-a / --autoname`) assumes that `/` separates directories, however this should have minimal impact since it always tries to save in the current directory. Problems will likely only ensue if the automatically chosen name contains a directory separator for the current OS.

**NAME**

binprobe – probe compiled binaries and perl scripts

**SYNOPSIS**

**edrc/bin/binprobe** [ **-h** ]

**binprobe** [ **-l** | **-v** ]

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

probe (compiled) executables and perl scripts if they are able to start on the current operating system.

**OPTIONS**

- h**           usage message.
- l**           list all binaries that are probed.
- v**           verbose output of additional information.

**ENVIRONMENT**

-

**EXIT STATUS**

- 0**           no error.
- 2**           operating system not supported. See **osid**(3) if you get this error.
- 4**           usage displayed.

**FILES**

**etc/binprobe.dat**  
configuration file for **binprobe**(1m).

**EXAMPLES**

**NAME**

binprobe.dat – binary probe configuration for binprobe

**SYNOPSIS**

edrc/etc/binprobe.dat

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

This is the binary probe definition for the **binprobe** command.

**FILEFORMAT**

The fileformat is a list of definitions that have the format

*COMMAND;TYPE;OPTIONS;EXITCODE;TESTCMD;COMMENT;*

Rows starting with a # are considered as comments. Empty lines are allowed, too.

**OPTIONS**

*COMMAND*

command to probe.

*TYPE*

command type as in **compatibility**(1).

*OPTIONS*

probe options.

*EXITCODE*

expected exit code.

*TESTCMD*

test command if it is different from *COMMAND OPTIONS*.

When the *TESTCMD* is set to **MANUAL** the *COMMAND* is not executed, but the status is set to [ **MANL** ] to indicate that a manual check is needed. This is to document GUI programs.

**COMMENT**

free text comment.

**EXAMPLES**

```

**NAME**

**bzip2**, **bunzip2** – a block-sorting file compressor, v1.0.3  
**bzcat** – decompresses files to stdout  
**bzip2recover** – recovers data from damaged bzip2 files

**SYNOPSIS**

**bzip2** [ **-cdfkqstvwVL123456789** ] [ *filenames ...* ]  
**bunzip2** [ **-fkvsVL** ] [ *filenames ...* ]  
**bzcat** [ **-s** ] [ *filenames ...* ]  
**bzip2recover** *filename*

**DESCRIPTION**

*bzip2* compresses files using the Burrows-Wheeler block sorting text compression algorithm, and Huffman coding. Compression is generally considerably better than that achieved by more conventional LZ77/LZ78-based compressors, and approaches the performance of the PPM family of statistical compressors.

The command-line options are deliberately very similar to those of *GNU gzip*, but they are not identical.

*bzip2* expects a list of file names to accompany the command-line flags. Each file is replaced by a compressed version of itself, with the name "original\_name.bz2". Each compressed file has the same modification date, permissions, and, when possible, ownership as the corresponding original, so that these properties can be correctly restored at decompression time. File name handling is naive in the sense that there is no mechanism for preserving original file names, permissions, ownerships or dates in filesystems which lack these concepts, or have serious file name length restrictions, such as MS-DOS.

*bzip2* and *bunzip2* will by default not overwrite existing files. If you want this to happen, specify the **-f** flag.

If no file names are specified, *bzip2* compresses from standard input to standard output. In this case, *bzip2* will decline to write compressed output to a terminal, as this would be entirely incomprehensible and therefore pointless.

*bunzip2* (or *bzip2 -d*) decompresses all specified files. Files which were not created by *bzip2* will be detected and ignored, and a warning issued. *bzip2* attempts to guess the filename for the decompressed file from that of the compressed file as follows:

```
filename.bz2 becomes filename
filename.bz becomes filename
filename.tbz2 becomes filename.tar
filename.tbz becomes filename.tar
anyothername becomes anyothername.out
```

If the file does not end in one of the recognised endings, *.bz2*, *.bz*, *.tbz2* or *.tbz*, *bzip2* complains that it cannot guess the name of the original file, and uses the original name with *.out* appended.

As with compression, supplying no filenames causes decompression from standard input to standard output.

*bunzip2* will correctly decompress a file which is the concatenation of two or more compressed files. The result is the concatenation of the corresponding uncompressed files. Integrity testing (**-t**) of concatenated compressed files is also supported.

You can also compress or decompress files to the standard output by giving the **-c** flag. Multiple files may be compressed and decompressed like this. The resulting outputs are fed sequentially to stdout.

Compression of multiple files in this manner generates a stream containing multiple compressed file representations. Such a stream can be decompressed correctly only by *bzip2* version 0.9.0 or later. Earlier versions of *bzip2* will stop after decompressing the first file in the stream.

*bzcat* (or *bzip2 -dc*) decompresses all specified files to the standard output.

*bzip2* will read arguments from the environment variables *BZIP2* and *BZIP*, in that order, and will process them before any arguments read from the command line. This gives a convenient way to supply default arguments.

Compression is always performed, even if the compressed file is slightly larger than the original. Files of less than about one hundred bytes tend to get larger, since the compression mechanism has a constant overhead in the region of 50 bytes. Random data (including the output of most file compressors) is coded at about 8.05 bits per byte, giving an expansion of around 0.5%.

As a self-check for your protection, *bzip2* uses 32-bit CRCs to make sure that the decompressed version of a file is identical to the original. This guards against corruption of the compressed data, and against undetected bugs in *bzip2* (hopefully very unlikely). The chances of data corruption going undetected is microscopic, about one chance in four billion for each file processed. Be aware, though, that the check occurs upon decompression, so it can only tell you that something is wrong. It can't help you recover the original uncompressed data. You can use *bzip2recover* to try to recover data from damaged files.

Return values: 0 for a normal exit, 1 for environmental problems (file not found, invalid flags, I/O errors, &c), 2 to indicate a corrupt compressed file, 3 for an internal consistency error (eg, bug) which caused *bzip2* to panic.

## OPTIONS

### **-c --stdout**

Compress or decompress to standard output.

### **-d --decompress**

Force decompression. *bzip2*, *bunzip2* and *bzcat* are really the same program, and the decision about what actions to take is done on the basis of which name is used. This flag overrides that mechanism, and forces *bzip2* to decompress.

### **-z --compress**

The complement to *-d*: forces compression, regardless of the invocation name.

### **-t --test**

Check integrity of the specified file(s), but don't decompress them. This really performs a trial decompression and throws away the result.

### **-f --force**

Force overwrite of output files. Normally, *bzip2* will not overwrite existing output files. Also forces *bzip2* to break hard links to files, which it otherwise wouldn't do.

*bzip2* normally declines to decompress files which don't have the correct magic header bytes. If forced (*-f*), however, it will pass such files through unmodified. This is how GNU *gzip* behaves.

### **-k --keep**

Keep (don't delete) input files during compression or decompression.

### **-s --small**

Reduce memory usage, for compression, decompression and testing. Files are decompressed and tested using a modified algorithm which only requires 2.5 bytes per block byte. This means any file can be decompressed in 2300k of memory, albeit at about half the normal speed.

During compression, *-s* selects a block size of 200k, which limits memory use to around the same

figure, at the expense of your compression ratio. In short, if your machine is low on memory (8 megabytes or less), use `-s` for everything. See MEMORY MANAGEMENT below.

**-q --quiet**

Suppress non-essential warning messages. Messages pertaining to I/O errors and other critical events will not be suppressed.

**-v --verbose**

Verbose mode -- show the compression ratio for each file processed. Further `-v`'s increase the verbosity level, spewing out lots of information which is primarily of interest for diagnostic purposes.

**-L --license -V --version**

Display the software version, license terms and conditions.

**-1 (or --fast) to -9 (or --best)**

Set the block size to 100 k, 200 k .. 900 k when compressing. Has no effect when decompressing. See MEMORY MANAGEMENT below. The `--fast` and `--best` aliases are primarily for GNU gzip compatibility. In particular, `--fast` doesn't make things significantly faster. And `--best` merely selects the default behaviour.

**--**

Treats all subsequent arguments as file names, even if they start with a dash. This is so you can handle files with names beginning with a dash, for example: `bzip2 -- -myfilename`.

**--repetitive-fast --repetitive-best**

These flags are redundant in versions 0.9.5 and above. They provided some coarse control over the behaviour of the sorting algorithm in earlier versions, which was sometimes useful. 0.9.5 and above have an improved algorithm which renders these flags irrelevant.

## MEMORY MANAGEMENT

*bzip2* compresses large files in blocks. The block size affects both the compression ratio achieved, and the amount of memory needed for compression and decompression. The flags `-1` through `-9` specify the block size to be 100,000 bytes through 900,000 bytes (the default) respectively. At decompression time, the block size used for compression is read from the header of the compressed file, and *bunzip2* then allocates itself just enough memory to decompress the file. Since block sizes are stored in compressed files, it follows that the flags `-1` to `-9` are irrelevant to and so ignored during decompression.

Compression and decompression requirements, in bytes, can be estimated as:

Compression:  $400k + (8 \times \text{block size})$

Decompression:  $100k + (4 \times \text{block size})$ , or  
 $100k + (2.5 \times \text{block size})$

Larger block sizes give rapidly diminishing marginal returns. Most of the compression comes from the first two or three hundred k of block size, a fact worth bearing in mind when using *bzip2* on small machines. It is also important to appreciate that the decompression memory requirement is set at compression time by the choice of block size.

For files compressed with the default 900k block size, *bunzip2* will require about 3700 kbytes to decompress. To support decompression of any file on a 4 megabyte machine, *bunzip2* has an option to decompress using approximately half this amount of memory, about 2300 kbytes. Decompression speed is also halved, so you should use this option only where necessary. The relevant flag is `-s`.

In general, try and use the largest block size memory constraints allow, since that maximises the compression achieved. Compression and decompression speed are virtually unaffected by block size.

Another significant point applies to files which fit in a single block -- that means most files you'd encounter using a large block size. The amount of real memory touched is proportional to the size of the file, since

the file is smaller than a block. For example, compressing a file 20,000 bytes long with the flag -9 will cause the compressor to allocate around 7600k of memory, but only touch 400k + 20000 \* 8 = 560 kbytes of it. Similarly, the decompressor will allocate 3700k but only touch 100k + 20000 \* 4 = 180 kbytes.

Here is a table which summarises the maximum memory usage for different block sizes. Also recorded is the total compressed size for 14 files of the Calgary Text Compression Corpus totalling 3,141,622 bytes. This column gives some feel for how compression varies with block size. These figures tend to understate the advantage of larger block sizes for larger files, since the Corpus is dominated by smaller files.

| Flag | Compress<br>usage | Decompress<br>usage | Decompress<br>-s usage | Corpus<br>Size |
|------|-------------------|---------------------|------------------------|----------------|
| -1   | 1200k             | 500k                | 350k                   | 914704         |
| -2   | 2000k             | 900k                | 600k                   | 877703         |
| -3   | 2800k             | 1300k               | 850k                   | 860338         |
| -4   | 3600k             | 1700k               | 1100k                  | 846899         |
| -5   | 4400k             | 2100k               | 1350k                  | 845160         |

| -7   | 6100k             | 2900k               | 1850k                  | 834096         |
| -8   | 6800k             | 3300k               | 2100k                  | 828642         |
| -9   | 7600k             | 3700k               | 2350k                  | 828642         |

## RECOVERING DATA FROM DAMAGED FILES

*bzip2* compresses files in blocks, usually 900kbytes long. Each block is handled independently. If a media or transmission error causes a multi-block .bz2 file to become damaged, it may be possible to recover data from the undamaged blocks in the file.

The compressed representation of each block is delimited by a 48-bit pattern, which makes it possible to find the block boundaries with reasonable certainty. Each block also carries its own 32-bit CRC, so damaged blocks can be distinguished from undamaged ones.

*bzip2recover* is a simple program whose purpose is to search for blocks in .bz2 files, and write each block out into its own .bz2 file. You can then use *bzip2* -t to test the integrity of the resulting files, and decompress those which are undamaged.

*bzip2recover* takes a single argument, the name of the damaged file, and writes a number of files "rec00001file.bz2", "rec00002file.bz2", etc, containing the extracted blocks. The output filenames are designed so that the use of wildcards in subsequent processing -- for example, "bzip2 -dc rec\*file.bz2 > recovered\_data" -- processes the files in the correct order.

*bzip2recover* should be of most use dealing with large .bz2 files, as these will contain many blocks. It is clearly futile to use it on damaged single-block files, since a damaged block cannot be recovered. If you wish to minimise any potential data loss through media or transmission errors, you might consider compressing with a smaller block size.

## PERFORMANCE NOTES

The sorting phase of compression gathers together similar strings in the file. Because of this, files containing very long runs of repeated symbols, like "aabaabaabaab ..." (repeated several hundred times) may compress more slowly than normal. Versions 0.9.5 and above fare much better than previous versions in this respect. The ratio between worst-case and average-case compression time is in the region of 10:1. For previous versions, this figure was more like 100:1. You can use the -vvvv option to monitor progress in great detail, if you want.

Decompression speed is unaffected by these phenomena.

*bzip2* usually allocates several megabytes of memory to operate in, and then charges all over it in a fairly random fashion. This means that performance, both for compressing and decompressing, is largely determined by the speed at which your machine can service cache misses. Because of this, small changes to the code to reduce the miss rate have been observed to give disproportionately large performance improvements. I imagine *bzip2* will perform best on machines with very large caches.

## CAVEATS

I/O error messages are not as helpful as they could be. *bzip2* tries hard to detect I/O errors and exit cleanly, but the details of what the problem is sometimes seem rather misleading.

This manual page pertains to version 1.0.3 of *bzip2*. Compressed data created by this version is entirely forwards and backwards compatible with the previous public releases, versions 0.1pl2, 0.9.0, 0.9.5, 1.0.0, 1.0.1 and 1.0.2, but with the following exception: 0.9.0 and above can correctly decompress multiple concatenated compressed files. 0.1pl2 cannot do this; it will stop after decompressing just the first file in the stream.

*bzip2recover* versions prior to 1.0.2 used 32-bit integers to represent bit positions in compressed files, so they could not handle compressed files more than 512 megabytes long. Versions 1.0.2 and above use 64-bit ints on some platforms which support them (GNU supported targets, and Windows). To establish whether or not *bzip2recover* was built with such a limitation, run it without arguments. In any event you can build yourself an unlimited version if you can recompile it with `MaybeUInt64` set to be an unsigned 64-bit integer.

## AUTHOR

Julian Seward, [jsewardbzip.org](http://jsewardbzip.org).

<http://www.bzip.org>

The ideas embodied in *bzip2* are due to (at least) the following people: Michael Burrows and David Wheeler (for the block sorting transformation), David Wheeler (again, for the Huffman coder), Peter Fenwick (for the structured coding model in the original *bzip*, and many refinements), and Alistair Moffat, Radford Neal and Ian Witten (for the arithmetic coder in the original *bzip*). I am much indebted for their help, support and advice. See the manual in the source distribution for pointers to sources of documentation. Christian von Roques encouraged me to look for faster sorting algorithms, so as to speed up compression. Bela Lubkin encouraged me to improve the worst-case compression performance. Donna Robinson XMLised the documentation. The *bz\** scripts are derived from those of GNU *gzip*. Many people sent patches, helped with portability problems, lent machines, gave advice and were generally helpful.

**NAME**

busy – keep the terminal busy

**SYNOPSIS**

**edrc/bin/busy**

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

This command does nothing productive. It is used to keep a TCP/IP connection open. Using this command you will prevent a connection loss caused by a firewall which disconnects a session after a certain TCP timeout is reached.

To end type *Ctrl+C* .

**OPTIONS**

-

**ENVIRONMENT****\$BUSY\_TURNING\_INTERVAL**

define the speed of the rotating slash in seconds.

Sometimes the default speed of 1 second might not be feasible, for example when old output has to be checked in the terminal scrolling the window up, the output of **busy** will cause the terminal to jump back to the line where the **busy** slash is turning.

**\$BUSY\_ANIMATION**

set the animation to display. Possible settings are *inflate*, *spin*, *snip*, *snap*, *blink*, *cross*, *target*, *jump* and *slash*.

**EXIT STATUS**

**0** always.

**FILES**

-

**EXAMPLES**

-

**SEE ALSO**

**edrcintro(1)**, **edrc(1)**

**NOTES**

-

**BUGS**

-

**AUTHOR**

busy was developed by Christian Walther. Send suggestions and bug reports to [wa2l@users.sourceforge.net](mailto:wa2l@users.sourceforge.net)

**NAME**

**bwcreate** – create a BarbedWire file

**SYNOPSIS**

**edrc/bin/bwcreate** [ **-h** ]

**bwcreate** **-s** [ **-f** ] [ **-p** *profile* ] [ **-c** *config\_file* ] [ **-o** *outputfile* ]

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

Create a BarbedWire file that contains file properties and checksum of files on filesystems defined in the **bwcreate.cfg**(4) file. The BarbedWire file is used to track changes on (operating system) files.

The intention is to create a BarbedWire file for a system files in regular intervals. Doing this it is possible to track for files whose credentials changed. This might help to detect system intrusion or to find causes of system problems.

**bwcreate** saves all information in a compressed format to the BarbedWire file. The contents of the BarbedWire file can be listed using the **lscomp**(1), **llcomp**(1) and **catcomp**(1) commands.

**OPTIONS**

**-h** usage message.

**-s** start BarbedWire file creation

**-f** force overwriting of output file

**-l** list all profiles defined in the configuration file.

**-c** *config\_file*  
configuration file for **bwcreate**. Default configuration file is **edrc/etc/bwcreate.cfg**.

**-o** *output\_file*  
output filename, the BarbedWire file, without the **.bw** suffix.

**-p** *profile* Profile (=set of options) to be used to create the BarbedWire file. If this option is not specified the profile with the name *default* is used.

## FILE FORMAT

The BarbedWire file version 100 consists of a **HEADER** and a **FILELIST** section. Use **lscomp(1)**, **llcomp(1)** and **catcomp(1)** to display the contents of a BarbedWire ( **.bw** ) file.

### HEADER

The header of the BarbedWire file consists of the entries explained below. The fileformat is **OPTION=VALUE** . Between the **OPTION**, the = and the **VALUE** are no spaces. Each **OPTION** is on a separate line. The sequence of the **OPTION** entries is as explained below, but can change without notice. Therefore, if you write programs that resolve the **OPTION** do not rely on the sequence.

### APPLICATION

Name of the application that created the file. This setting is set to *BarbedWire*.

### FILEVERSION

Version of the BarbedWire file format.

### HOSTNAME

Hostname where the BarbedWire file has been created.

**PROFILE** Profile specified with the **-p** option.

### DESCRIPTION

Description text of the profile.

### CREATED

Date and time when the BarbedWire file has been created. The Format is: YYYYMMDDhh-mmss.

### CREATED\_BY

Command that created the BarbedWire file. This setting is set to *bwcreate*.

### ENVIRONMENT

Server environment where the BarbedWire file has been created. This setting is resolved by **bwcreate** using the **server\_environment** command.

### ENVIRONMENT\_DESCRIPTION

Detail description of the **ENVIRONMENT**. This setting is resolved by **bwcreate** using the **server\_environment -d** command.

**OSID** Osid, see **osid(3)**, of the system where the BarbedWire file has been created.

**UNAME** System information of the system where the BarbedWire file has been created. This setting equals to the **uname -a** command output.

**USER** User that created the BarbedWire file.

**CONFIGFILE**

Configuration file used to create the BarbedWire file.

**FILESYSTEMS**

List of filesystems whose files are resolved and part of the **FILELIST**.

**OUTPUT\_DIRECTORY**

Output directory where the BarbedWire file has been written to during creation.

**OUTPUT\_FILE**

Output file name (BarbedWire file name) during creation.

**FILELIST**

The file list section of the Barbed Wire file consists of the lines explained below. The first line in the **FILELIST** section is a header listing all fields that are present for all files in the filelist separated by a ; . All following lines are file entries. The filelist header defines the sequence and the name of the fields. Therefore, if you write programs that resolve the **FILELIST** of a BarbedWire file use the filelist header entry to resolve the fields of the filelist entries and do not rely on the sequence documented here, due to the fact that this sequence can change without notice.

**TYPE** File type:

**f** file

**d**  
directory

**c** Character oriented device file (special file)

**b**  
Block oriented device file (special file)

**PERM\_OWNER**

Symbolic permission representation for the file owner. See **chmod(1)** for more information.

**PERM\_GROUP**

Symbolic permission representation for the file group. See **chmod(1)** for more information.

**PERM\_OTHER**

Symbolic permission representation for the others file permissions. See **chmod(1)** or **ls(1)** for more information.

**CHECKSUM**

MD5 checksum of the file. See **md5sum(1)** for more information.

**INODE**

Inode number of the file. See **ls(1)** or **stat(1)** for more information.

**BLOCKS**

Number of blocks on the filesystem used by the file. See **ls(1)** or **stat(1)** for more information.

**PERM\_ALL**

Complete file permission settings of the file. See **chmod**(1) or **ls**(1) for more information.

**REF**

Number of references to a file. See **ls**(1) or **stat**(1) for more information.

**OWNER**

Owner of the file. See **chown**(1) or **ls**(1) for more information.

**GROUP**

Group of the file. See **chgrp**(1) or **ls**(1) for more information.

**BITES**

Size of the file in bytes. See **ls**(1) or **stat**(1) for more information.

**NODE**

Node of the file. This applies to special files only. See **mknod**(1) or **ls**(1) for more information.

**MTIME**

Modification time of the file. See **ls**(1) or **stat**(1) for more information.

**FILE**

File name.

**ENVIRONMENT**

-

**EXIT STATUS**

- 0** no error.
- 2** operating system is not supported. See **osid**(3) if you get this error.
- 3** profile specified in the **-p** option is not defined in the configuration file.
- 4** usage listed.
- 5** **bwcreate** has been aborted pressing Ctrl+C or by issuing **kill bwcreate\_pid**.
- 6** configuration file **edrc/etc/bwcreate.cfg** does not exist.
- 7** output file already exists.
- 8** cannot write to the logfile.

**FILES****edrc/etc/bwcreate.cfg**

default configuration file for **bwcreate**.

**edrc/var/log/**

default logfile location of **bwcreate**.

**edrc/var/barbedwire/cache/bwcreate.duration**

record of durations of past runs of **bwcreate** to calculate the completion estimation.

**.bw**

BarbedWire output file suffix. The content of a BarbedWire file can be listed using **lscomp**, **llcomp** and **catcomp**.

**EXAMPLES****1) display contents of a BarbedWire file****Display contents:**

```

**NAME**

bwcreate.cfg – configuration file for bwcreate

**SYNOPSIS**

edrc/etc/bwcreate.cfg

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

This is the configuration file for the **bwcreate** command.

**FILEFORMAT**

The format for options is **OPTION=VALUE** .

The format of a profile definition is:

```
PROFILE_name(){
 OPTION1=VALUE
 OPTION2=VALUE
 :
 OPTIONn=VALUE
}
```

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION**. If you like to use default settings simply do not specify a *VALUE*.

Normally there are multiple profiles defined in one configuration file.

**OPTIONS****GLOBAL OPTIONS**

This options influence the general behavior of the **bwcreate** command.

**LOG**      Log output dir of **bwcreate**. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation.

Example: LOG=/var/opt/edrc/log

Default: LOG=var/log

## PROFILE OPTIONS

A profile has the following structure:

```
PROFILE_name(){
 DESCRIPTION='Text'
 FILESYSTEMS=" filesystems"
 OUTPUT_DIRECTORY=directory
 OUTPUT_FILE=filename
 OUTPUT_FILE_PERMISSIONS=perm
 PARALLEL_EXECUTION=True|False
}
```

The options recognized in a profile are:

*name* Name of the profile. The name defined here has to be specified in the **-p** option in the **bwcreate** command. The profile with the name *default* is called when the **-p** option is not specified when using the **bwcreate** command. Therefore each **bwcreate.cfg** file should at least define a profile with the name *default*.

## DESCRIPTION

Profile description. The description text has to be enclosed in *\*single\** quotes.

Example: DESCRIPTION='common Unix/Linux'

Default: DESCRIPTION=""

## FILESYSTEMS

Filesystems to be listed in the BarbedWire file. It is also possible to define directories within a filesystem. If there are extra filesystems for **/opt**, **/usr** it is not sufficient to list only the root filesystem / here, due to the fact that the file search is local to a filesystem.

Example: FILESYSTEMS="/ /var /usr /opt"

Default: FILESYSTEMS=""

## OUTPUT\_DIRECTORY

Existing directory where the BarbedWire file is created. This directory should have at least twice the space available as the resulting BarbedWire file size.

Example: OUTPUT\_DIRECTORY=/dat/report/barbedwire

Default: OUTPUT\_DIRECTORY=/var/tmp

**OUTPUT\_FILE**

Filename of BarbedWire file in OUTPUT\_DIRECTORY without suffix. A BarbedWire file has the suffix **.bw**.

Example: OUTPUT\_FILE=\$HOSTNAME\_\$NOW

Default: OUTPUT\_FILE=barbedwire\_outfile\_\$HOSTNAME\_\$TODAY

**OUTPUT\_FILE\_PERMISSIONS**

File permissions of BarbedWire file produced.

Example: OUTPUT\_FILE\_PERMISSIONS=400

Default: OUTPUT\_FILE\_PERMISSIONS=444

**PARALLEL\_EXECUTION**

Execute the resolution of the fileproperties for all filesystems or directories listed in **FILESYSTEMS** in parallel.

Example: PARALLEL\_EXECUTION=False

Default: PARALLEL\_EXECUTION=True

**VARIABLES**

The following variables can be used in profiles. Do not use other variables in a **bwcreate.cfg** file seen by **bwcreate** due to the fact that the existence and/or contents can change without notice.

**\$HOSTNAME**

The hostname of the system where the **bwcreate** command is executed.

**\$SERVER\_ENVIRONMENT**

The name of the server environment as returned by the **server\_environment** command. See also **server\_environment(3)** for more information about this command.

**\$TODAY** Date in the format YYYYMMDD (e.g. 20061206).

**\$NOW** Date and time in the format YYYYMMDDHHmm (e.g. 200612062307).

**SEE ALSO**

**bwcreate(1)**, **edrcintro(1)**, **server\_environment(3)**

**NOTES**

**NAME**

**bzip2**, **bunzip2** – a block-sorting file compressor, v1.0.3  
**bzcat** – decompresses files to stdout  
**bzip2recover** – recovers data from damaged bzip2 files

**SYNOPSIS**

**bzip2** [ **-cdfkqstvwVL123456789** ] [ *filenames ...* ]  
**bunzip2** [ **-fkvsVL** ] [ *filenames ...* ]  
**bzcat** [ **-s** ] [ *filenames ...* ]  
**bzip2recover** *filename*

**DESCRIPTION**

*bzip2* compresses files using the Burrows-Wheeler block sorting text compression algorithm, and Huffman coding. Compression is generally considerably better than that achieved by more conventional LZ77/LZ78-based compressors, and approaches the performance of the PPM family of statistical compressors.

The command-line options are deliberately very similar to those of *GNU gzip*, but they are not identical.

*bzip2* expects a list of file names to accompany the command-line flags. Each file is replaced by a compressed version of itself, with the name "original\_name.bz2". Each compressed file has the same modification date, permissions, and, when possible, ownership as the corresponding original, so that these properties can be correctly restored at decompression time. File name handling is naive in the sense that there is no mechanism for preserving original file names, permissions, ownerships or dates in filesystems which lack these concepts, or have serious file name length restrictions, such as MS-DOS.

*bzip2* and *bunzip2* will by default not overwrite existing files. If you want this to happen, specify the **-f** flag.

If no file names are specified, *bzip2* compresses from standard input to standard output. In this case, *bzip2* will decline to write compressed output to a terminal, as this would be entirely incomprehensible and therefore pointless.

*bunzip2* (or *bzip2 -d*) decompresses all specified files. Files which were not created by *bzip2* will be detected and ignored, and a warning issued. *bzip2* attempts to guess the filename for the decompressed file from that of the compressed file as follows:

```
filename.bz2 becomes filename
filename.bz becomes filename
filename.tbz2 becomes filename.tar
filename.tbz becomes filename.tar
anyothername becomes anyothername.out
```

If the file does not end in one of the recognised endings, *.bz2*, *.bz*, *.tbz2* or *.tbz*, *bzip2* complains that it cannot guess the name of the original file, and uses the original name with *.out* appended.

As with compression, supplying no filenames causes decompression from standard input to standard output.

*bunzip2* will correctly decompress a file which is the concatenation of two or more compressed files. The result is the concatenation of the corresponding uncompressed files. Integrity testing (**-t**) of concatenated compressed files is also supported.

You can also compress or decompress files to the standard output by giving the **-c** flag. Multiple files may be compressed and decompressed like this. The resulting outputs are fed sequentially to stdout.

Compression of multiple files in this manner generates a stream containing multiple compressed file representations. Such a stream can be decompressed correctly only by *bzip2* version 0.9.0 or later. Earlier versions of *bzip2* will stop after decompressing the first file in the stream.

*bzcat* (or *bzip2 -dc*) decompresses all specified files to the standard output.

*bzip2* will read arguments from the environment variables *BZIP2* and *BZIP*, in that order, and will process them before any arguments read from the command line. This gives a convenient way to supply default arguments.

Compression is always performed, even if the compressed file is slightly larger than the original. Files of less than about one hundred bytes tend to get larger, since the compression mechanism has a constant overhead in the region of 50 bytes. Random data (including the output of most file compressors) is coded at about 8.05 bits per byte, giving an expansion of around 0.5%.

As a self-check for your protection, *bzip2* uses 32-bit CRCs to make sure that the decompressed version of a file is identical to the original. This guards against corruption of the compressed data, and against undetected bugs in *bzip2* (hopefully very unlikely). The chances of data corruption going undetected is microscopic, about one chance in four billion for each file processed. Be aware, though, that the check occurs upon decompression, so it can only tell you that something is wrong. It can't help you recover the original uncompressed data. You can use *bzip2recover* to try to recover data from damaged files.

Return values: 0 for a normal exit, 1 for environmental problems (file not found, invalid flags, I/O errors, &c), 2 to indicate a corrupt compressed file, 3 for an internal consistency error (eg, bug) which caused *bzip2* to panic.

## OPTIONS

### **-c --stdout**

Compress or decompress to standard output.

### **-d --decompress**

Force decompression. *bzip2*, *bunzip2* and *bzcat* are really the same program, and the decision about what actions to take is done on the basis of which name is used. This flag overrides that mechanism, and forces *bzip2* to decompress.

### **-z --compress**

The complement to *-d*: forces compression, regardless of the invocation name.

### **-t --test**

Check integrity of the specified file(s), but don't decompress them. This really performs a trial decompression and throws away the result.

### **-f --force**

Force overwrite of output files. Normally, *bzip2* will not overwrite existing output files. Also forces *bzip2* to break hard links to files, which it otherwise wouldn't do.

*bzip2* normally declines to decompress files which don't have the correct magic header bytes. If forced (*-f*), however, it will pass such files through unmodified. This is how GNU *gzip* behaves.

### **-k --keep**

Keep (don't delete) input files during compression or decompression.

### **-s --small**

Reduce memory usage, for compression, decompression and testing. Files are decompressed and tested using a modified algorithm which only requires 2.5 bytes per block byte. This means any file can be decompressed in 2300k of memory, albeit at about half the normal speed.

During compression, *-s* selects a block size of 200k, which limits memory use to around the same

figure, at the expense of your compression ratio. In short, if your machine is low on memory (8 megabytes or less), use `-s` for everything. See MEMORY MANAGEMENT below.

**-q --quiet**

Suppress non-essential warning messages. Messages pertaining to I/O errors and other critical events will not be suppressed.

**-v --verbose**

Verbose mode -- show the compression ratio for each file processed. Further `-v`'s increase the verbosity level, spewing out lots of information which is primarily of interest for diagnostic purposes.

**-L --license -V --version**

Display the software version, license terms and conditions.

**-1 (or --fast) to -9 (or --best)**

Set the block size to 100 k, 200 k .. 900 k when compressing. Has no effect when decompressing. See MEMORY MANAGEMENT below. The `--fast` and `--best` aliases are primarily for GNU gzip compatibility. In particular, `--fast` doesn't make things significantly faster. And `--best` merely selects the default behaviour.

**--**

Treats all subsequent arguments as file names, even if they start with a dash. This is so you can handle files with names beginning with a dash, for example: `bzip2 -- -myfilename`.

**--repetitive-fast --repetitive-best**

These flags are redundant in versions 0.9.5 and above. They provided some coarse control over the behaviour of the sorting algorithm in earlier versions, which was sometimes useful. 0.9.5 and above have an improved algorithm which renders these flags irrelevant.

## MEMORY MANAGEMENT

*bzip2* compresses large files in blocks. The block size affects both the compression ratio achieved, and the amount of memory needed for compression and decompression. The flags `-1` through `-9` specify the block size to be 100,000 bytes through 900,000 bytes (the default) respectively. At decompression time, the block size used for compression is read from the header of the compressed file, and *bunzip2* then allocates itself just enough memory to decompress the file. Since block sizes are stored in compressed files, it follows that the flags `-1` to `-9` are irrelevant to and so ignored during decompression.

Compression and decompression requirements, in bytes, can be estimated as:

Compression:  $400k + (8 \times \text{block size})$

Decompression:  $100k + (4 \times \text{block size})$ , or  
 $100k + (2.5 \times \text{block size})$

Larger block sizes give rapidly diminishing marginal returns. Most of the compression comes from the first two or three hundred k of block size, a fact worth bearing in mind when using *bzip2* on small machines. It is also important to appreciate that the decompression memory requirement is set at compression time by the choice of block size.

For files compressed with the default 900k block size, *bunzip2* will require about 3700 kbytes to decompress. To support decompression of any file on a 4 megabyte machine, *bunzip2* has an option to decompress using approximately half this amount of memory, about 2300 kbytes. Decompression speed is also halved, so you should use this option only where necessary. The relevant flag is `-s`.

In general, try and use the largest block size memory constraints allow, since that maximises the compression achieved. Compression and decompression speed are virtually unaffected by block size.

Another significant point applies to files which fit in a single block -- that means most files you'd encounter using a large block size. The amount of real memory touched is proportional to the size of the file, since

the file is smaller than a block. For example, compressing a file 20,000 bytes long with the flag -9 will cause the compressor to allocate around 7600k of memory, but only touch 400k + 20000 \* 8 = 560 kbytes of it. Similarly, the decompressor will allocate 3700k but only touch 100k + 20000 \* 4 = 180 kbytes.

Here is a table which summarises the maximum memory usage for different block sizes. Also recorded is the total compressed size for 14 files of the Calgary Text Compression Corpus totalling 3,141,622 bytes. This column gives some feel for how compression varies with block size. These figures tend to understate the advantage of larger block sizes for larger files, since the Corpus is dominated by smaller files.

| Flag | Compress<br>usage | Decompress<br>usage | Decompress<br>-s usage | Corpus<br>Size |
|------|-------------------|---------------------|------------------------|----------------|
| -1   | 1200k             | 500k                | 350k                   | 914704         |
| -2   | 2000k             | 900k                | 600k                   | 877703         |
| -3   | 2800k             | 1300k               | 850k                   | 860338         |
| -4   | 3600k             | 1700k               | 1100k                  | 846899         |
| -5   | 4400k             | 2100k               | 1350k                  | 845160         |
| -6   | 5200k             | 2500k               | 1600k                  | 838626         |
| -7   | 6100k             | 2900k               | 1850k                  | 834096         |
| -8   | 6800k             | 3300k               | 2100k                  | 828642         |
| -9   | 7600k             | 3700k               | 2350k                  | 828642         |

## RECOVERING DATA FROM DAMAGED FILES

*bzip2* compresses files in blocks, usually 900kbytes long. Each block is handled independently. If a media or transmission error causes a multi-block .bz2 file to become damaged, it may be possible to recover data from the undamaged blocks in the file.

The compressed representation of each block is delimited by a 48-bit pattern, which makes it possible to find the block boundaries with reasonable certainty. Each block also carries its own 32-bit CRC, so damaged blocks can be distinguished from undamaged ones.

*bzip2recover* is a simple program whose purpose is to search for blocks in .bz2 files, and write each block out into its own .bz2 file. You can then use *bzip2* -t to test the integrity of the resulting files, and decompress those which are undamaged.

*bzip2recover* takes a single argument, the name of the damaged file, and writes a number of files "rec00001file.bz2", "rec00002file.bz2", etc, containing the extracted blocks. The output filenames are designed so that the use of wildcards in subsequent processing -- for example, "bzip2 -dc rec\*file.bz2 > recovered\_data" -- processes the files in the correct order.

*bzip2recover* should be of most use dealing with large .bz2 files, as these will contain many blocks. It is clearly futile to use it on damaged single-block files, since a damaged block cannot be recovered. If you wish to minimise any potential data loss through media or transmission errors, you might consider compressing with a smaller block size.

## PERFORMANCE NOTES

The sorting phase of compression gathers together similar strings in the file. Because of this, files containing very long runs of repeated symbols, like "aabaabaabaab ..." (repeated several hundred times) may compress more slowly than normal. Versions 0.9.5 and above fare much better than previous versions in this respect. The ratio between worst-case and average-case compression time is in the region of 10:1. For previous versions, this figure was more like 100:1. You can use the -vvvv option to monitor progress in great detail, if you want.

Decompression speed is unaffected by these phenomena.

*bzip2* usually allocates several megabytes of memory to operate in, and then charges all over it in a fairly random fashion. This means that performance, both for compressing and decompressing, is largely determined by the speed at which your machine can service cache misses. Because of this, small changes to the code to reduce the miss rate have been observed to give disproportionately large performance improvements. I imagine *bzip2* will perform best on machines with very large caches.

## CAVEATS

I/O error messages are not as helpful as they could be. *bzip2* tries hard to detect I/O errors and exit cleanly, but the details of what the problem is sometimes seem rather misleading.

This manual page pertains to version 1.0.3 of *bzip2*. Compressed data created by this version is entirely forwards and backwards compatible with the previous public releases, versions 0.1pl2, 0.9.0, 0.9.5, 1.0.0, 1.0.1 and 1.0.2, but with the following exception: 0.9.0 and above can correctly decompress multiple concatenated compressed files. 0.1pl2 cannot do this; it will stop after decompressing just the first file in the stream.

*bzip2recover* versions prior to 1.0.2 used 32-bit integers to represent bit positions in compressed files, so they could not handle compressed files more than 512 megabytes long. Versions 1.0.2 and above use 64-bit ints on some platforms which support them (GNU supported targets, and Windows). To establish whether or not *bzip2recover* was built with such a limitation, run it without arguments. In any event you can build yourself an unlimited version if you can recompile it with `MaybeUInt64` set to be an unsigned 64-bit integer.

## AUTHOR

Julian Seward, [jsewardbzip.org](http://jsewardbzip.org).

<http://www.bzip.org>

The ideas embodied in *bzip2* are due to (at least) the following people: Michael Burrows and David Wheeler (for the block sorting transformation), David Wheeler (again, for the Huffman coder), Peter Fenwick (for the structured coding model in the original *bzip*, and many refinements), and Alistair Moffat, Radford Neal and Ian Witten (for the arithmetic coder in the original *bzip*). I am much indebted for their help, support and advice. See the manual in the source distribution for pointers to sources of documentation. Christian von Roques encouraged me to look for faster sorting algorithms, so as to speed up compression. Bela Lubkin encouraged me to improve the worst-case compression performance. Donna Robinson XMLised the documentation. The *bz\** scripts are derived from those of GNU *gzip*. Many people sent patches, helped with portability problems, lent machines, gave advice and were generally helpful.

**NAME**

**bzcmp**, **bzdiff** – compare bzip2 compressed files

**SYNOPSIS**

**bzcmp** [ *cmp\_options* ] *file1* [ *file2* ]

**bzdiff** [ *diff\_options* ] *file1* [ *file2* ]

**DESCRIPTION**

*Bzcmp* and *bzdiff* are used to invoke the *cmp* or the *diff* program on bzip2 compressed files. All options specified are passed directly to *cmp* or *diff*. If only 1 file is specified, then the files compared are *file1* and an uncompressed *file1.bz2*. If two files are specified, then they are uncompressed if necessary and fed to *cmp* or *diff*. The exit status from *cmp* or *diff* is preserved.

**SEE ALSO**

*cmp*(1), *diff*(1), *bzmore*(1), *bzless*(1), *bzgrep*(1), *bzip2*(1)

**BUGS**

Messages from the *cmp* or *diff* programs refer to temporary filenames instead of those specified.

**NAME**

**bzgrep**, **bzfgrep**, **bzegrep** – search possibly bzip2 compressed files for a regular expression

**SYNOPSIS**

**bzgrep** [ *grep\_options* ] [ **-e** ] *pattern filename...*

**bzegrep** [ *egrep\_options* ] [ **-e** ] *pattern filename...*

**bzfgrep** [ *fgrep\_options* ] [ **-e** ] *pattern filename...*

**DESCRIPTION**

*Bzgrep* is used to invoke the *grep* on bzip2-compressed files. All options specified are passed directly to *grep*. If no file is specified, then the standard input is decompressed if necessary and fed to *grep*. Otherwise the given files are uncompressed if necessary and fed to *grep*.

If *bzgrep* is invoked as *bzegrep* or *bzfgrep* then *egrep* or *fgrep* is used instead of *grep*. If the GREP environment variable is set, *bzgrep* uses it as the *grep* program to be invoked. For example:

for sh: GREP=fgrep bzgrep string files

for csh: (setenv GREP fgrep; bzgrep string files)

**SEE ALSO**

*grep*(1), *egrep*(1), *fgrep*(1), *bzdiff*(1), *bzmore*(1), *bzless*(1), *bzip2*(1)

**NAME**

**bzip2**, **bunzip2** – a block-sorting file compressor, v1.0.3  
**bzcat** – decompresses files to stdout  
**bzip2recover** – recovers data from damaged bzip2 files

**SYNOPSIS**

**bzip2** [ **-cdfkqstvwVL123456789** ] [ *filenames ...* ]  
**bunzip2** [ **-fkvsVL** ] [ *filenames ...* ]  
**bzcat** [ **-s** ] [ *filenames ...* ]  
**bzip2recover** *filename*

**DESCRIPTION**

*bzip2* compresses files using the Burrows-Wheeler block sorting text compression algorithm, and Huffman coding. Compression is generally considerably better than that achieved by more conventional LZ77/LZ78-based compressors, and approaches the performance of the PPM family of statistical compressors.

The command-line options are deliberately very similar to those of *GNU gzip*, but they are not identical.

*bzip2* expects a list of file names to accompany the command-line flags. Each file is replaced by a compressed version of itself, with the name "original\_name.bz2". Each compressed file has the same modification date, permissions, and, when possible, ownership as the corresponding original, so that these properties can be correctly restored at decompression time. File name handling is naive in the sense that there is no mechanism for preserving original file names, permissions, ownerships or dates in filesystems which lack these concepts, or have serious file name length restrictions, such as MS-DOS.

*bzip2* and *bunzip2* will by default not overwrite existing files. If you want this to happen, specify the **-f** flag.

If no file names are specified, *bzip2* compresses from standard input to standard output. In this case, *bzip2* will decline to write compressed output to a terminal, as this would be entirely incomprehensible and therefore pointless.

*bunzip2* (or *bzip2 -d*) decompresses all specified files. Files which were not created by *bzip2* will be detected and ignored, and a warning issued. *bzip2* attempts to guess the filename for the decompressed file from that of the compressed file as follows:

```
filename.bz2 becomes filename
filename.bz becomes filename
filename.tbz2 becomes filename.tar
filename.tbz becomes filename.tar
anyothername becomes anyothername.out
```

If the file does not end in one of the recognised endings, *.bz2*, *.bz*, *.tbz2* or *.tbz*, *bzip2* complains that it cannot guess the name of the original file, and uses the original name with *.out* appended.

As with compression, supplying no filenames causes decompression from standard input to standard output.

*bunzip2* will correctly decompress a file which is the concatenation of two or more compressed files. The result is the concatenation of the corresponding uncompressed files. Integrity testing (**-t**) of concatenated compressed files is also supported.

You can also compress or decompress files to the standard output by giving the **-c** flag. Multiple files may be compressed and decompressed like this. The resulting outputs are fed sequentially to stdout.

Compression of multiple files in this manner generates a stream containing multiple compressed file representations. Such a stream can be decompressed correctly only by *bzip2* version 0.9.0 or later. Earlier versions of *bzip2* will stop after decompressing the first file in the stream.

*bzcat* (or *bzip2 -dc*) decompresses all specified files to the standard output.

*bzip2* will read arguments from the environment variables *BZIP2* and *BZIP*, in that order, and will process them before any arguments read from the command line. This gives a convenient way to supply default arguments.

Compression is always performed, even if the compressed file is slightly larger than the original. Files of less than about one hundred bytes tend to get larger, since the compression mechanism has a constant overhead in the region of 50 bytes. Random data (including the output of most file compressors) is coded at about 8.05 bits per byte, giving an expansion of around 0.5%.

As a self-check for your protection, *bzip2* uses 32-bit CRCs to make sure that the decompressed version of a file is identical to the original. This guards against corruption of the compressed data, and against undetected bugs in *bzip2* (hopefully very unlikely). The chances of data corruption going undetected is microscopic, about one chance in four billion for each file processed. Be aware, though, that the check occurs upon decompression, so it can only tell you that something is wrong. It can't help you recover the original uncompressed data. You can use *bzip2recover* to try to recover data from damaged files.

Return values: 0 for a normal exit, 1 for environmental problems (file not found, invalid flags, I/O errors, &c), 2 to indicate a corrupt compressed file, 3 for an internal consistency error (eg, bug) which caused *bzip2* to panic.

## OPTIONS

### **-c --stdout**

Compress or decompress to standard output.

### **-d --decompress**

Force decompression. *bzip2*, *bunzip2* and *bzcat* are really the same program, and the decision about what actions to take is done on the basis of which name is used. This flag overrides that mechanism, and forces *bzip2* to decompress.

### **-z --compress**

The complement to *-d*: forces compression, regardless of the invocation name.

### **-t --test**

Check integrity of the specified file(s), but don't decompress them. This really performs a trial decompression and throws away the result.

### **-f --force**

Force overwrite of output files. Normally, *bzip2* will not overwrite existing output files. Also forces *bzip2* to break hard links to files, which it otherwise wouldn't do.

*bzip2* normally declines to decompress files which don't have the correct magic header bytes. If forced (*-f*), however, it will pass such files through unmodified. This is how GNU *gzip* behaves.

### **-k --keep**

Keep (don't delete) input files during compression or decompression.

### **-s --small**

Reduce memory usage, for compression, decompression and testing. Files are decompressed and tested using a modified algorithm which only requires 2.5 bytes per block byte. This means any file can be decompressed in 2300k of memory, albeit at about half the normal speed.

During compression, *-s* selects a block size of 200k, which limits memory use to around the same

figure, at the expense of your compression ratio. In short, if your machine is low on memory (8 megabytes or less), use `-s` for everything. See MEMORY MANAGEMENT below.

**-q --quiet**

Suppress non-essential warning messages. Messages pertaining to I/O errors and other critical events will not be suppressed.

**-v --verbose**

Verbose mode -- show the compression ratio for each file processed. Further `-v`'s increase the verbosity level, spewing out lots of information which is primarily of interest for diagnostic purposes.

**-L --license -V --version**

Display the software version, license terms and conditions.

**-1 (or --fast) to -9 (or --best)**

Set the block size to 100 k, 200 k .. 900 k when compressing. Has no effect when decompressing. See MEMORY MANAGEMENT below. The `--fast` and `--best` aliases are primarily for GNU gzip compatibility. In particular, `--fast` doesn't make things significantly faster. And `--best` merely selects the default behaviour.

**--**

Treats all subsequent arguments as file names, even if they start with a dash. This is so you can handle files with names beginning with a dash, for example: `bzip2 -- -myfilename`.

**--repetitive-fast --repetitive-best**

These flags are redundant in versions 0.9.5 and above. They provided some coarse control over the behaviour of the sorting algorithm in earlier versions, which was sometimes useful. 0.9.5 and above have an improved algorithm which renders these flags irrelevant.

## MEMORY MANAGEMENT

*bzip2* compresses large files in blocks. The block size affects both the compression ratio achieved, and the amount of memory needed for compression and decompression. The flags `-1` through `-9` specify the block size to be 100,000 bytes through 900,000 bytes (the default) respectively. At decompression time, the block size used for compression is read from the header of the compressed file, and *bunzip2* then allocates itself just enough memory to decompress the file. Since block sizes are stored in compressed files, it follows that the flags `-1` to `-9` are irrelevant to and so ignored during decompression.

Compression and decompression requirements, in bytes, can be estimated as:

Compression:  $400k + (8 \times \text{block size})$

Decompression:  $100k + (4 \times \text{block size})$ , or  
 $100k + (2.5 \times \text{block size})$

Larger block sizes give rapidly diminishing marginal returns. Most of the compression comes from the first two or three hundred k of block size, a fact worth bearing in mind when using *bzip2* on small machines. It is also important to appreciate that the decompression memory requirement is set at compression time by the choice of block size.

For files compressed with the default 900k block size, *bunzip2* will require about 3700 kbytes to decompress. To support decompression of any file on a 4 megabyte machine, *bunzip2* has an option to decompress using approximately half this amount of memory, about 2300 kbytes. Decompression speed is also halved, so you should use this option only where necessary. The relevant flag is `-s`.

In general, try and use the largest block size memory constraints allow, since that maximises the compression achieved. Compression and decompression speed are virtually unaffected by block size.

Another significant point applies to files which fit in a single block -- that means most files you'd encounter using a large block size. The amount of real memory touched is proportional to the size of the file, since

the file is smaller than a block. For example, compressing a file 20,000 bytes long with the flag -9 will cause the compressor to allocate around 7600k of memory, but only touch 400k + 20000 \* 8 = 560 kbytes of it. Similarly, the decompressor will allocate 3700k but only touch 100k + 20000 \* 4 = 180 kbytes.

Here is a table which summarises the maximum memory usage for different block sizes. Also recorded is the total compressed size for 14 files of the Calgary Text Compression Corpus totalling 3,141,622 bytes. This column gives some feel for how compression varies with block size. These figures tend to understate the advantage of larger block sizes for larger files, since the Corpus is dominated by smaller files.

| Flag | Compress<br>usage | Decompress<br>usage | Decompress<br>-s usage | Corpus<br>Size |
|------|-------------------|---------------------|------------------------|----------------|
| -1   | 1200k             | 500k                | 350k                   | 914704         |
| -2   | 2000k             | 900k                | 600k                   | 877703         |
| -3   | 2800k             | 1300k               | 850k                   | 860338         |
| -4   | 3600k             | 1700k               | 1100k                  | 846899         |
| -5   | 4400k             | 2100k               | 1350k                  | 845160         |
| -6   | 5200k             | 2500k               | 1600k                  | 838626         |
| -7   | 6100k             | 2900k               | 1850k                  | 834096         |
| -8   | 6800k             | 3300k               | 2100k                  | 828642         |
| -9   | 7600k             | 3700k               | 2350k                  | 828642         |

## RECOVERING DATA FROM DAMAGED FILES

*bzip2* compresses files in blocks, usually 900kbytes long. Each block is handled independently. If a media or transmission error causes a multi-block .bz2 file to become damaged, it may be possible to recover data from the undamaged blocks in the file.

The compressed representation of each block is delimited by a 48-bit pattern, which makes it possible to find the block boundaries with reasonable certainty. Each block also carries its own 32-bit CRC, so damaged blocks can be distinguished from undamaged ones.

*bzip2recover* is a simple program whose purpose is to search for blocks in .bz2 files, and write each block out into its own .bz2 file. You can then use *bzip2* -t to test the integrity of the resulting files, and decompress those which are undamaged.

*bzip2recover* takes a single argument, the name of the damaged file, and writes a number of files "rec00001file.bz2", "rec00002file.bz2", etc, containing the extracted blocks. The output filenames are designed so that the use of wildcards in subsequent processing -- for example, "bzip2 -dc rec\*file.bz2 > recovered\_data" -- processes the files in the correct order.

*bzip2recover* should be of most use dealing with large .bz2 files, as these will contain many blocks. It is clearly futile to use it on damaged single-block files, since a damaged block cannot be recovered. If you wish to minimise any potential data loss through media or transmission errors, you might consider compressing with a smaller block size.

## PERFORMANCE NOTES

The sorting phase of compression gathers together similar strings in the file. Because of this, files containing very long runs of repeated symbols, like "aabaabaabaab ..." (repeated several hundred times) may compress more slowly than normal. Versions 0.9.5 and above fare much better than previous versions in this respect. The ratio between worst-case and average-case compression time is in the region of 10:1. For previous versions, this figure was more like 100:1. You can use the -vvvv option to monitor progress in great detail, if you want.

Decompression speed is unaffected by these phenomena.

*bzip2* usually allocates several megabytes of memory to operate in, and then charges all over it in a fairly random fashion. This means that performance, both for compressing and decompressing, is largely determined by the speed at which your machine can service cache misses. Because of this, small changes to the code to reduce the miss rate have been observed to give disproportionately large performance improvements. I imagine *bzip2* will perform best on machines with very large caches.

## CAVEATS

I/O error messages are not as helpful as they could be. *bzip2* tries hard to detect I/O errors and exit cleanly, but the details of what the problem is sometimes seem rather misleading.

This manual page pertains to version 1.0.3 of *bzip2*. Compressed data created by this version is entirely forwards and backwards compatible with the previous public releases, versions 0.1pl2, 0.9.0, 0.9.5, 1.0.0, 1.0.1 and 1.0.2, but with the following exception: 0.9.0 and above can correctly decompress multiple concatenated compressed files. 0.1pl2 cannot do this; it will stop after decompressing just the first file in the stream.

*bzip2recover* versions prior to 1.0.2 used 32-bit integers to represent bit positions in compressed files, so they could not handle compressed files more than 512 megabytes long. Versions 1.0.2 and above use 64-bit ints on some platforms which support them (GNU supported targets, and Windows). To establish whether or not *bzip2recover* was built with such a limitation, run it without arguments. In any event you can build yourself an unlimited version if you can recompile it with `MaybeUInt64` set to be an unsigned 64-bit integer.

## AUTHOR

Julian Seward, [jsewardbzip.org](http://jsewardbzip.org).

<http://www.bzip.org>

The ideas embodied in *bzip2* are due to (at least) the following people: Michael Burrows and David Wheeler (for the block sorting transformation), David Wheeler (again, for the Huffman coder), Peter Fenwick (for the structured coding model in the original *bzip*, and many refinements), and Alistair Moffat, Radford Neal and Ian Witten (for the arithmetic coder in the original *bzip*). I am much indebted for their help, support and advice. See the manual in the source distribution for pointers to sources of documentation. Christian von Roques encouraged me to look for faster sorting algorithms, so as to speed up compression. Bela Lubkin encouraged me to improve the worst-case compression performance. Donna Robinson XMLised the documentation. The *bz\** scripts are derived from those of GNU *gzip*. Many people sent patches, helped with portability problems, lent machines, gave advice and were generally helpful.

**NAME**

**bzip2**, **bunzip2** – a block-sorting file compressor, v1.0.3  
**bzcat** – decompresses files to stdout  
**bzip2recover** – recovers data from damaged bzip2 files

**SYNOPSIS**

**bzip2** [ **-cdfkqstvwVL123456789** ] [ *filenames ...* ]  
**bunzip2** [ **-fkvsVL** ] [ *filenames ...* ]  
**bzcat** [ **-s** ] [ *filenames ...* ]  
**bzip2recover** *filename*

**DESCRIPTION**

*bzip2* compresses files using the Burrows-Wheeler block sorting text compression algorithm, and Huffman coding. Compression is generally considerably better than that achieved by more conventional LZ77/LZ78-based compressors, and approaches the performance of the PPM family of statistical compressors.

The command-line options are deliberately very similar to those of *GNU gzip*, but they are not identical.

*bzip2* expects a list of file names to accompany the command-line flags. Each file is replaced by a compressed version of itself, with the name "original\_name.bz2". Each compressed file has the same modification date, permissions, and, when possible, ownership as the corresponding original, so that these properties can be correctly restored at decompression time. File name handling is naive in the sense that there is no mechanism for preserving original file names, permissions, ownerships or dates in filesystems which lack these concepts, or have serious file name length restrictions, such as MS-DOS.

*bzip2* and *bunzip2* will by default not overwrite existing files. If you want this to happen, specify the **-f** flag.

If no file names are specified, *bzip2* compresses from standard input to standard output. In this case, *bzip2* will decline to write compressed output to a terminal, as this would be entirely incomprehensible and therefore pointless.

*bunzip2* (or *bzip2 -d*) decompresses all specified files. Files which were not created by *bzip2* will be detected and ignored, and a warning issued. *bzip2* attempts to guess the filename for the decompressed file from that of the compressed file as follows:

```
filename.bz2 becomes filename
filename.bz becomes filename
filename.tbz2 becomes filename.tar
filename.tbz becomes filename.tar
anyothername becomes anyothername.out
```

If the file does not end in one of the recognised endings, *.bz2*, *.bz*, *.tbz2* or *.tbz*, *bzip2* complains that it cannot guess the name of the original file, and uses the original name with *.out* appended.

As with compression, supplying no filenames causes decompression from standard input to standard output.

*bunzip2* will correctly decompress a file which is the concatenation of two or more compressed files. The result is the concatenation of the corresponding uncompressed files. Integrity testing (**-t**) of concatenated compressed files is also supported.

You can also compress or decompress files to the standard output by giving the **-c** flag. Multiple files may be compressed and decompressed like this. The resulting outputs are fed sequentially to stdout.

Compression of multiple files in this manner generates a stream containing multiple compressed file representations. Such a stream can be decompressed correctly only by *bzip2* version 0.9.0 or later. Earlier versions of *bzip2* will stop after decompressing the first file in the stream.

*bzcat* (or *bzip2 -dc*) decompresses all specified files to the standard output.

*bzip2* will read arguments from the environment variables *BZIP2* and *BZIP*, in that order, and will process them before any arguments read from the command line. This gives a convenient way to supply default arguments.

Compression is always performed, even if the compressed file is slightly larger than the original. Files of less than about one hundred bytes tend to get larger, since the compression mechanism has a constant overhead in the region of 50 bytes. Random data (including the output of most file compressors) is coded at about 8.05 bits per byte, giving an expansion of around 0.5%.

As a self-check for your protection, *bzip2* uses 32-bit CRCs to make sure that the decompressed version of a file is identical to the original. This guards against corruption of the compressed data, and against undetected bugs in *bzip2* (hopefully very unlikely). The chances of data corruption going undetected is microscopic, about one chance in four billion for each file processed. Be aware, though, that the check occurs upon decompression, so it can only tell you that something is wrong. It can't help you recover the original uncompressed data. You can use *bzip2recover* to try to recover data from damaged files.

Return values: 0 for a normal exit, 1 for environmental problems (file not found, invalid flags, I/O errors, &c), 2 to indicate a corrupt compressed file, 3 for an internal consistency error (eg, bug) which caused *bzip2* to panic.

## OPTIONS

### **-c --stdout**

Compress or decompress to standard output.

### **-d --decompress**

Force decompression. *bzip2*, *bunzip2* and *bzcat* are really the same program, and the decision about what actions to take is done on the basis of which name is used. This flag overrides that mechanism, and forces *bzip2* to decompress.

### **-z --compress**

The complement to *-d*: forces compression, regardless of the invocation name.

### **-t --test**

Check integrity of the specified file(s), but don't decompress them. This really performs a trial decompression and throws away the result.

### **-f --force**

Force overwrite of output files. Normally, *bzip2* will not overwrite existing output files. Also forces *bzip2* to break hard links to files, which it otherwise wouldn't do.

*bzip2* normally declines to decompress files which don't have the correct magic header bytes. If forced (*-f*), however, it will pass such files through unmodified. This is how GNU *gzip* behaves.

### **-k --keep**

Keep (don't delete) input files during compression or decompression.

### **-s --small**

Reduce memory usage, for compression, decompression and testing. Files are decompressed and tested using a modified algorithm which only requires 2.5 bytes per block byte. This means any file can be decompressed in 2300k of memory, albeit at about half the normal speed.

During compression, *-s* selects a block size of 200k, which limits memory use to around the same

figure, at the expense of your compression ratio. In short, if your machine is low on memory (8 megabytes or less), use `-s` for everything. See MEMORY MANAGEMENT below.

**-q --quiet**

Suppress non-essential warning messages. Messages pertaining to I/O errors and other critical events will not be suppressed.

**-v --verbose**

Verbose mode -- show the compression ratio for each file processed. Further `-v`'s increase the verbosity level, spewing out lots of information which is primarily of interest for diagnostic purposes.

**-L --license -V --version**

Display the software version, license terms and conditions.

**-1 (or --fast) to -9 (or --best)**

Set the block size to 100 k, 200 k .. 900 k when compressing. Has no effect when decompressing. See MEMORY MANAGEMENT below. The `--fast` and `--best` aliases are primarily for GNU gzip compatibility. In particular, `--fast` doesn't make things significantly faster. And `--best` merely selects the default behaviour.

**--**

Treats all subsequent arguments as file names, even if they start with a dash. This is so you can handle files with names beginning with a dash, for example: `bzip2 -- -myfilename`.

**--repetitive-fast --repetitive-best**

These flags are redundant in versions 0.9.5 and above. They provided some coarse control over the behaviour of the sorting algorithm in earlier versions, which was sometimes useful. 0.9.5 and above have an improved algorithm which renders these flags irrelevant.

## MEMORY MANAGEMENT

*bzip2* compresses large files in blocks. The block size affects both the compression ratio achieved, and the amount of memory needed for compression and decompression. The flags `-1` through `-9` specify the block size to be 100,000 bytes through 900,000 bytes (the default) respectively. At decompression time, the block size used for compression is read from the header of the compressed file, and *bunzip2* then allocates itself just enough memory to decompress the file. Since block sizes are stored in compressed files, it follows that the flags `-1` to `-9` are irrelevant to and so ignored during decompression.

Compression and decompression requirements, in bytes, can be estimated as:

Compression:  $400k + (8 \times \text{block size})$

Decompression:  $100k + (4 \times \text{block size})$ , or  
 $100k + (2.5 \times \text{block size})$

Larger block sizes give rapidly diminishing marginal returns. Most of the compression comes from the first two or three hundred k of block size, a fact worth bearing in mind when using *bzip2* on small machines. It is also important to appreciate that the decompression memory requirement is set at compression time by the choice of block size.

For files compressed with the default 900k block size, *bunzip2* will require about 3700 kbytes to decompress. To support decompression of any file on a 4 megabyte machine, *bunzip2* has an option to decompress using approximately half this amount of memory, about 2300 kbytes. Decompression speed is also halved, so you should use this option only where necessary. The relevant flag is `-s`.

In general, try and use the largest block size memory constraints allow, since that maximises the compression achieved. Compression and decompression speed are virtually unaffected by block size.

Another significant point applies to files which fit in a single block -- that means most files you'd encounter using a large block size. The amount of real memory touched is proportional to the size of the file, since

the file is smaller than a block. For example, compressing a file 20,000 bytes long with the flag -9 will cause the compressor to allocate around 7600k of memory, but only touch 400k + 20000 \* 8 = 560 kbytes of it. Similarly, the decompressor will allocate 3700k but only touch 100k + 20000 \* 4 = 180 kbytes.

Here is a table which summarises the maximum memory usage for different block sizes. Also recorded is the total compressed size for 14 files of the Calgary Text Compression Corpus totalling 3,141,622 bytes. This column gives some feel for how compression varies with block size. These figures tend to understate the advantage of larger block sizes for larger files, since the Corpus is dominated by smaller files.

| Flag | Compress<br>usage | Decompress<br>usage | Decompress<br>-s usage | Corpus<br>Size |
|------|-------------------|---------------------|------------------------|----------------|
| -1   | 1200k             | 500k                | 350k                   | 914704         |
| -2   | 2000k             | 900k                | 600k                   | 877703         |
| -3   | 2800k             | 1300k               | 850k                   | 860338         |
| -4   | 3600k             | 1700k               | 1100k                  | 846899         |
| -5   | 4400k             | 2100k               | 1350k                  | 845160         |
| -6   | 5200k             | 2500k               | 1600k                  | 838626         |
| -7   | 6100k             | 2900k               | 1850k                  | 834096         |
| -8   | 6800k             | 3300k               | 2100k                  | 828642         |
| -9   | 7600k             | 3700k               | 2350k                  | 828642         |

## RECOVERING DATA FROM DAMAGED FILES

*bzip2* compresses files in blocks, usually 900kbytes long. Each block is handled independently. If a media or transmission error causes a multi-block .bz2 file to become damaged, it may be possible to recover data from the undamaged blocks in the file.

The compressed representation of each block is delimited by a 48-bit pattern, which makes it possible to find the block boundaries with reasonable certainty. Each block also carries its own 32-bit CRC, so damaged blocks can be distinguished from undamaged ones.

*bzip2recover* is a simple program whose purpose is to search for blocks in .bz2 files, and write each block out into its own .bz2 file. You can then use *bzip2* -t to test the integrity of the resulting files, and decompress those which are undamaged.

*bzip2recover* takes a single argument, the name of the damaged file, and writes a number of files "rec00001file.bz2", "rec00002file.bz2", etc, containing the extracted blocks. The output filenames are designed so that the use of wildcards in subsequent processing -- for example, "bzip2 -dc rec\*file.bz2 > recovered\_data" -- processes the files in the correct order.

*bzip2recover* should be of most use dealing with large .bz2 files, as these will contain many blocks. It is clearly futile to use it on damaged single-block files, since a damaged block cannot be recovered. If you wish to minimise any potential data loss through media or transmission errors, you might consider compressing with a smaller block size.

## PERFORMANCE NOTES

The sorting phase of compression gathers together similar strings in the file. Because of this, files containing very long runs of repeated symbols, like "aabaabaabaab ..." (repeated several hundred times) may compress more slowly than normal. Versions 0.9.5 and above fare much better than previous versions in this respect. The ratio between worst-case and average-case compression time is in the region of 10:1. For previous versions, this figure was more like 100:1. You can use the -vvvv option to monitor progress in great detail, if you want.

Decompression speed is unaffected by these phenomena.

*bzip2* usually allocates several megabytes of memory to operate in, and then charges all over it in a fairly random fashion. This means that performance, both for compressing and decompressing, is largely determined by the speed at which your machine can service cache misses. Because of this, small changes to the code to reduce the miss rate have been observed to give disproportionately large performance improvements. I imagine *bzip2* will perform best on machines with very large caches.

## CAVEATS

I/O error messages are not as helpful as they could be. *bzip2* tries hard to detect I/O errors and exit cleanly, but the details of what the problem is sometimes seem rather misleading.

This manual page pertains to version 1.0.3 of *bzip2*. Compressed data created by this version is entirely forwards and backwards compatible with the previous public releases, versions 0.1pl2, 0.9.0, 0.9.5, 1.0.0, 1.0.1 and 1.0.2, but with the following exception: 0.9.0 and above can correctly decompress multiple concatenated compressed files. 0.1pl2 cannot do this; it will stop after decompressing just the first file in the stream.

*bzip2recover* versions prior to 1.0.2 used 32-bit integers to represent bit positions in compressed files, so they could not handle compressed files more than 512 megabytes long. Versions 1.0.2 and above use 64-bit ints on some platforms which support them (GNU supported targets, and Windows). To establish whether or not *bzip2recover* was built with such a limitation, run it without arguments. In any event you can build yourself an unlimited version if you can recompile it with `MaybeUInt64` set to be an unsigned 64-bit integer.

**NAME**

*bzmore*, *bzless* – file perusal filter for crt viewing of bzip2 compressed text

**SYNOPSIS**

**bzmore** [ name ... ]

**bzless** [ name ... ]

**NOTE**

In the following description, *bzless* and *less* can be used interchangeably with *bzmore* and *more*.

**DESCRIPTION**

*Bzmore* is a filter which allows examination of compressed or plain text files one screenful at a time on a soft-copy terminal. *bzmore* works on files compressed with *bzip2* and also on uncompressed files. If a file does not exist, *bzmore* looks for a file of the same name with the addition of a .bz2 suffix.

*Bzmore* normally pauses after each screenful, printing --More-- at the bottom of the screen. If the user then types a carriage return, one more line is displayed. If the user hits a space, another screenful is displayed. Other possibilities are enumerated later.

*Bzmore* looks in the file */etc/termcap* to determine terminal characteristics, and to determine the default window size. On a terminal capable of displaying 24 lines, the default window size is 22 lines. Other sequences which may be typed when *bzmore* pauses, and their effects, are as follows (*i* is an optional integer argument, defaulting to 1) :

- i* <space> display *i* more lines, (or another screenful if no argument is given)
- ^D display 11 more lines (a “scroll”). If *i* is given, then the scroll size is set to *i*.
- d same as ^D (control-D)
- i* z same as typing a space except that *i*, if present, becomes the new window size. Note that the window size reverts back to the default at the end of the current file.
- i* s skip *i* lines and print a screenful of lines
- i* f skip *i* screenfuls and print a screenful of lines
- q or Q quit reading the current file; go on to the next (if any)
- e or q When the prompt --More--(Next file: *file*) is printed, this command causes *bzmore* to exit.
- s When the prompt --More--(Next file: *file*) is printed, this command causes *bzmore* to skip the next file and continue.
- = Display the current line number.
- i* /*expr* search for the *i*-th occurrence of the regular expression *expr*. If the pattern is not found, *bzmore* goes on to the next file (if any). Otherwise, a screenful is displayed, starting two lines before the place where the expression was found. The user's erase and kill characters may be used to edit the regular expression. Erasing back past the first column cancels the search command.
- i* n search for the *i*-th occurrence of the last regular expression entered.
- !*command* invoke a shell with *command*. The character '!' in "*command*" are replaced with the previous shell command. The sequence "\!" is replaced by "!".
- :q or :Q quit reading the current file; go on to the next (if any) (same as q or Q).
- . (dot) repeat the previous command.

The commands take effect immediately, i.e., it is not necessary to type a carriage return. Up to the time when the command character itself is given, the user may hit the line kill character to cancel the numerical argument being formed. In addition, the user may hit the erase character to redisplay the --More-- message.

At any time when output is being sent to the terminal, the user can hit the quit key (normally control-\\).

*Bzmore* will stop sending output, and will display the usual --More-- prompt. The user may then enter one of the above commands in the normal manner. Unfortunately, some output is lost when this is done, due to the fact that any characters waiting in the terminal's output queue are flushed when the quit signal occurs.

The terminal is set to *noecho* mode by this program so that the output can be continuous. What you type will thus not show on your terminal, except for the / and ! commands.

If the standard output is not a teletype, then *bzmore* acts just like *bzcat*, except that a header is printed before each file.

**NAME**

catcomp – cat a file to stdout out of a compressed archive file

**SYNOPSIS**

**edrc/bin/catcomp** [ **-h** ]

**catcomp** *file path*

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

With **catcomp** you cat a file out of a compressed archive without decompressing the whole archive file. To list the contents of an archive file use the **lscomp** or **llcomp** command.

**OPTIONS**

**-h**           usage message

*file*           filename of the compressed archive file. This file is a file with the suffixes **.tgz**, **.tar.gz**, **.tar.bz**, **.tar.bz2**, **.tar.Z**, **.tar.zip**, **.cpio**, **.cpio.gz**, **.cpio.bz**, **.cpio.bz2**, **.cpio.xz**, **.cpio.Z**, **.cpio.zip**, **.depot.gz**, **.depot**, **.epub**, **.zip**, **.jar**, **.whl**, **.rock**, **.rpm**, **.deb** or **.bw**.

*path*           complete path and filename of the file inside the archive you like to display.

**ENVIRONMENT**

The following environment variables influence the behavior of the **catcomp** command:

**\$TMPDIR**

if you like to display files that are bigger then the free disk space available in **/tmp** this variable has to be set to a directory with sufficient disk space available. You have to ensure that the directory you specify exists and is writeable by the user invoking the **catcomp** command.

**EXIT STATUS**

**1**           specified archive file not found.

- 2** file format of specified archive file not recognized. The file format is determined by the file suffix only.
- 4** usage displayed.
- 5** file not found in archive. If this error occurs, try also **lscomp** *filename* to figure out if the archive is probably corrupt.
- 6** error while decompressing a compressed archive. This error occurs if the file is not compressed with the command that is normally assigned with the file suffix.  
For instance: the file **my\_archive.tar.gz** was not really compressed with **gzip** or the file is corrupt.

**NAME**

**ccrypt** – encrypt and decrypt files and streams

**SYNOPSIS**

```
ccrypt [mode] [options] [file...]
ccencrypt [options] [file...]
ccdecrypt [options] [file...]
ccat [options] file...
```

**DESCRIPTION**

**ccrypt** is a utility for encrypting and decrypting files and streams. It was designed to replace the standard unix **crypt** utility, which is notorious for using a very weak encryption algorithm. **ccrypt** is based on the Rijndael block cipher, which was also chosen by the U.S. government as the Advanced Encryption Standard (AES, see <http://www.nist.gov/aes>). This cipher is believed to provide very strong cryptographic security.

Unlike unix **crypt**, the algorithm provided by **ccrypt** is not symmetric, i.e., one must specify whether to encrypt or decrypt. The most common way to invoke **ccrypt** is via the commands **ccencrypt** and **ccdecrypt**.

Encryption and decryption depends on a keyword (or key phrase) supplied by the user. By default, the user is prompted to enter a keyword from the terminal. Keywords can consist of any number of characters, and all characters are significant (although **ccrypt** internally hashes the key to 256 bits). Longer keywords provide better security than short ones, since they are less likely to be discovered by exhaustive search.

**MODES**

**ccrypt** can operate in five different modes. If more than one mode is specified, the last one specified takes precedence. The aliases **ccencrypt**, **ccdecrypt**, and **ccat** are provided as a convenience; they are equivalent to **ccrypt -e**, **ccrypt -d**, and **ccrypt -c**, respectively.

- e, --encrypt**      Encrypt. This is the default mode. If filename arguments are given, encrypt the files and append the suffix **.cpt** to their names. Otherwise, run as a filter.
- d, --decrypt**      Decrypt. If filename arguments are given, decrypt the files and strip the suffix **.cpt** from the filenames, if present. Otherwise, run as a filter.
- c, --cat**          Decrypt one or more files to standard output. If no filename arguments are given, decrypt as a filter. Implies **-l**.
- x, --keychange**    Change the key of encrypted data. In this mode, **ccrypt** prompts for two passwords: the old one and the new one. If filename arguments are given, modify the files. Otherwise, run as a filter.
- u, --unixcrypt**    Simulate the old unix crypt command. Note: the cipher used by unix crypt has been broken and is not secure. Please use this option only to decrypt existing files. If filename arguments are given, decrypt the files to stdout. Otherwise, run as a filter. Note that for the unix crypt format, there is no easy way to detect whether a given key matches or not; thus, for safety, this mode does not overwrite files.

**OPTIONS**

The following options are supported in addition to the modes described above:

- b, --brave**        When reading an encryption key from the terminal, ask the user only once for the key. By default, **ccrypt** will ask the user to enter such keys twice, as a safeguard against accidentally destroying data due to a mistyped key. Using the **--brave** option disables this safety check. Never use it, unless you know what you are doing. See also **--timid**.
- E var, --envvar var**    Read the keyword from the environment variable *var*. Note that this might be unsafe on certain systems, namely where users can use the **ps** command to see the environment of a process owner by another user. On most modern systems, however, such behavior of **ps**

- is disabled and the **-E** option should be safe there. Also, as an added security measure, **ccrypt** erases the keyword from its environment immediately after reading it.
- f, --force** Overwrite existing files or operate on write-protected files without asking any questions. Also, override **ccrypt**'s reluctance to write or read encrypted data to or from a terminal.
  - F var, --envvar2 var** Same as **-E**, except for second keyword (in keychange mode).
  - h, --help** Help. Print usage information and exit.
  - H key, --key2 key** Same as **-K**, except for second keyword (in keychange mode).
  - k file, --keyfile file** Read the keyword as the first line from the named file. In keychange mode, two keywords are read as the first two lines of the file. The filename "-" may be given for reading keywords from standard input. Using the **-k** option and sending the keyword on stdin is probably the safest way to pass a keyword to **ccrypt** from another program or script.
  - K key, --key key** Specify the keyword on the command line. This is unsafe, because any other user can see the command line by running the **ps** command. Only use this option for testing purposes, and never with a real keyword.
  - l, --symlinks** Force encryption/decryption of symbolic links. By default, symbolic links are ignored except in cat or unixcrypt mode. Note that with the **-l** option, encryption/decryption of a symbolic link causes the suffix **.cpt** to be added/removed from the name of the link, not the name of the file pointed to.
  - L, --license** Print license info and exit.
  - m, --mismatch** Normally, **ccrypt** refuses to decrypt data with a key that does not seem to match. The **-m** option overrides this restriction. This can sometimes be useful in recovering data from a corrupted file (see RECOVERING DATA FROM CORRUPTED FILES). To avoid irretrievable loss of data when decrypting with a wrong key, this option cannot be used with modes that overwrite the input file.
  - P prompt, --prompt prompt** Use *prompt* instead of the default prompt "Enter encryption/decryption key: ". This may be useful in some shell scripts.
  - q, --quiet** Suppress most warnings.
  - Q prompt, --prompt2 prompt** Same as **-P**, except for second keyword (in keychange mode).
  - r, --recursive** Traverse subdirectories recursively.
  - R, --rec-symlinks** Traverse subdirectories recursively, and also follow symbolic links to subdirectories.
  - s, --strictsuffix** Refuse to encrypt files which already have the **.cpt** suffix (or that selected with **-S**). This can be useful when adding some files to a directory of already encrypted files. This option has no effect in decryption or keychange mode.
  - S .suf, --suffix .suf** Use the suffix *.suf* instead of the default suffix **.cpt**.
  - t, --timid** When reading an encryption key from the terminal, ask the user to enter the key twice. If the two entered keys are not identical, abort. This is a safeguard against accidentally destroying data by encrypting it with a mistyped key. Note: this behavior is now the default, and can be overridden with the **--brave** option.
  - T, --tmpfiles** This option causes **ccrypt** to use temporary files during encryption/decryption, rather than overwriting the file contents destructively. This method leaves the original file

contents lying around in unused sectors of the file system, and thus is less secure than the default behavior. However, in situations where this loss of security is not important, the **--tmpfiles** option can provide a measure of protection against data being corrupted due to a system crash in the middle of overwriting a file.

- v, --verbose** Print progress information to stderr.
- V, --version** Print version info and exit.
- End of options. Any remaining arguments are interpreted as filenames. This also turns off filter mode, even if zero filenames follow. This might be useful in the context of shell pattern expansion; **ccrypt -- \*** will behave correctly even if no files match the pattern **\***.

## NOTES ON USAGE

The user interface of **ccrypt** intentionally resembles that of GNU **gzip**, although it is not identical. When invoked with filename arguments, **ccrypt** normally modifies the files in place, overwriting their old content. Unlike **gzip**, the output is not first written to a temporary file; instead, the data is literally overwritten. For encryption, this is usually the desired behavior, since one does not want copies of the unencrypted data to remain in hidden places in the file system. The disadvantage is that if **ccrypt** is interrupted in the middle of writing to a file, the file will end up in a corrupted, partially encrypted state. However, in such cases it is possible to recover most of the data; see RECOVERING DATA FROM CORRUPTED FILES below. If you want to force **ccrypt** to use temporary files, use the **--tmpfiles** option.

When **ccrypt** receives an interrupt signal (Ctrl-C) while updating a file in place, it does not exit immediately, but rather delays the exit until after it finishes writing to the current file. This is to prevent files from being partially overwritten and thus corrupted. If you want to force **ccrypt** to exit immediately, just press Ctrl-C twice quickly.

The encryption algorithm used by **ccrypt** uses a random seed which is different each time. As a result, encrypting the same file twice will never yield the same result. The advantage of this method is that similarities in plaintext do not lead to similarities in ciphertext; there is no way of telling whether the content of two encrypted files is similar or not.

Because of the use of a random seed, decrypting and re-encrypting a file with the same key will not lead to an identical file. It is primarily for this reason that **ccrypt** refuses to decrypt files with a non-matching key; if this were allowed, there would be no way afterwards to restore the original file, and the data would be irretrievably lost.

When overwriting files, special care is taken with hard links and symbolic links. Each physical file (i.e., each inode) is processed at most once, no matter how many paths to it are encountered on the command line or in subdirectories traversed recursively. For each file which has multiple hard links, a warning is printed, to alert the user that not all paths to the file might have been properly renamed. Symbolic links are ignored except in cat mode, or unless the **-I** or **-R** option is given.

Unlike **gzip**, **ccrypt** does not complain about files that have improper suffixes. It is legal to doubly encrypt a file. It is also legal to decrypt a file which does not have the **.cpt** suffix, provided the file contains valid data for the given decryption key. Use the **--strictsuffix** option if you want to prevent **ccrypt** from encrypting files which already have a **.cpt** suffix.

Regarding encryption and compression: encrypted data is statistically indistinguishable from random data, and thus it cannot be compressed. But of course it is possible to compress the data first, then encrypt it. Suggested file suffixes are **.gz.cpt** or **.gzc**.

## RECOVERING DATA FROM CORRUPTED FILES

Encrypted data might be corrupted for a number of reasons. For instance, a file might have been partially encrypted or decrypted if **ccrypt** was interrupted while processing the file. Or data might be corrupted by a software or hardware error, or during transmission over a network. The encryption algorithm used by

**ccrypt** is designed to allow recovery from errors. In general, only a few bytes of data will be lost near where the error occurred.

Data encrypted by **ccrypt** can be thought of as a sequence of 32-byte blocks. To decrypt a particular block, **ccrypt** only needs to know the decryption key, the data of the block itself, and the data of the block immediately preceding it. **ccrypt** cannot tell whether a block is corrupted or not, except the very first block, which is special. Thus, if the encrypted data has been altered in the middle or near the end of a file, **ccrypt** can be run to decrypt it as usual, and most of the data will be decrypted correctly, except near where the corruption occurred.

The very first block of encrypted data is special, because it does not actually correspond to any plaintext data; this block holds the random seed generated at encryption time. **ccrypt** also uses the very first block to decide whether the given keyword matches the data or not. If the first block has been corrupted, **ccrypt** will likely decide that the keyword does not match; in such cases, the **-m** option can be used to force **ccrypt** to decrypt the data anyway.

If a file contains some encrypted and some unencrypted data, or data encrypted with two different keys, one should decrypt the entire file with each applicable key, and then piece together the meaningful parts manually.

Finally, decryption will only produce meaningful results if the data is aligned correctly along block boundaries. If the block boundary information has been lost, one has to try all 32 possibilities.

## DESCRIPTION OF THE CIPHER

*Block ciphers* operate on data segments of a fixed length. For instance, the Rijndael block cipher used in **ccrypt** has a block length of 32 bytes or 256 bits. Thus, this cipher encrypts 32 bytes at a time.

*Stream ciphers* operate on data streams of any length. There are several standard modes for operating a block cipher as a stream cipher. One such standard is *Cipher Feedback (CFB)*, defined in FIPS 81 and ANSI X3.106-1983. **ccrypt** implements a stream cipher by operating the Rijndael block cipher in CFB mode.

Let  $P[i]$  and  $C[i]$  be the  $i$ th block of the plaintext and ciphertext, respectively. CFB mode specifies that

$$C[i] = P[i] \oplus E(k, C[i-1])$$

Here  $\oplus$  denotes the bitwise exclusive or function, and  $E(k, x)$  denotes the encryption of the block  $x$  under the key  $k$  using the block cipher. Thus, each block of the ciphertext is calculated from the corresponding block of plaintext and the previous block of ciphertext. Note that in fact, each byte of  $P[i]$  can be calculated from the corresponding byte of  $C[i]$ , so that the stream cipher can be applied to one byte at a time. In particular, the stream length need not be a multiple of the block size.

Assuming that blocks are numbered starting from 0, a special "initial" ciphertext block  $C[-1]$  is needed to provide the base case for the above formula. This value  $C[-1]$  is called the *initialization vector* or *seed*. The seed is chosen at encryption time and written as the first block of the encrypted stream. It is important never to use the same seed more than once; otherwise, the two resulting ciphertext blocks  $C[0]$  could be related by a simple xor to obtain information about the corresponding plaintext blocks  $P[0]$ . If the same seed is never reused, CFB is provably as secure as the underlying block cipher.

In **ccrypt**, the seed is constructed as follows: first, a combination of the host name, current time, process id, and an internal counter are hashed into a 28-byte value, using a cryptographic hash function. A fixed four-byte "magic number" is combined with this value, and the resulting 32-byte value is encrypted by one round of the Rijndael block cipher with the given key. The result is used as the seed and appended to the beginning of the ciphertext. The use of the magic number allows **ccrypt** to detect non-matching keys before decryption.

## SECURITY

**ccrypt** is believed to provide very strong cryptographic security, equivalent to that of the Rijndael cipher with 256-bit block size and 256-bit key size. Another version of the Rijndael cipher (with a smaller block size) is used in the U.S. government's Advanced Encryption Standard (AES, see <http://www.nist.gov/aes>). Therefore, this cipher is very well studied and subject to intensive public scrutiny. This scrutiny has a positive effect on the cipher's security. In particular, if an exploitable weakness in this cipher were ever discovered, this would become widely publicized.

In practical terms, the security of **ccrypt** means that, without knowledge of the encryption key, it is effectively impossible to obtain any information about the plaintext from a given ciphertext. This is true even if a large number of plaintext-ciphertext pairs are already known for the same key. Moreover, because **ccrypt** uses a key size of 256 bits, an exhaustive search of the key space is not feasible, at least as long as sufficiently long keys are actually used in practice. No cipher is secure if users choose insecure keywords.

On the other hand, **ccrypt** does not attempt to provide *data integrity*, i.e., it will not attempt to detect whether the ciphertext was modified after encryption. In particular, encrypted data can be truncated, leaving the corresponding decrypted data also truncated, but otherwise consistent. If one needs to ensure data integrity as well as secrecy, this can be achieved by other methods. The recommended method is to prepend a cryptographic hash (for instance, an MD5 or SHA-1 hash) to the data before encryption.

**ccrypt** does not claim to provide any particular safeguards against information leaking via the local operating system. While reasonable precautions are taken, there is no guarantee that keywords and plaintexts have been physically erased after encryption is completed; parts of such data might still exist in memory or on disk. **ccrypt** does not currently use privileged memory pages.

When encrypting files, **ccrypt** by default accesses them in read-write mode. This normally causes the original file to be physically overwritten, but on some file systems, this might not be the case.

Note that the use of the **-K** option is unsafe in a multiuser environment, because the command line of a process is visible to other users running the **ps** command. The use of the **-E** option is potentially unsafe for the same reason, although recent versions of **ps** don't tend to display environment information to other users. The use of the **-T** option is unsafe for encryption because the original plaintext will remain in unused sectors of the file system.

## EMACS PACKAGE

There is an emacs package for reading and writing encrypted files. (Note that this package currently only works with emacs, not with xemacs.) This package hooks into the low-level file I/O functions of emacs, prompting the user for a password where appropriate. It is implemented in much the same way as support for compressed files; in fact, the package, whose name is `jka-compr-ccrypt`, is based directly on the `jka-compr` package which is part of GNU Emacs. It handles both encrypted and compressed files (although currently not encrypted compressed files).

To use the package, simply load `jka-compr-ccrypt`, then edit as usual. When you open a file with the `".cpt"` extension, emacs will prompt you for a password for the file. It will remember the password for the buffer, and when you save the file later, it will be automatically encrypted again (provided you save it with a `".cpt"` extension). Except for the password prompt, the operation of the package should be transparent to the user. The package also handles compressed `".gz"`, `".bz2"`, and `".Z"` files, and it should be used instead of, not in addition to, `jka-compr`. The command `M-x ccrypt-set-buffer-password` can be used to change the current password of a buffer.

The simplest way to use this package is to include the lines

```
(setq load-path (cons "path" load-path))
(require 'jka-compr-ccrypt "jka-compr-ccrypt.el")
```

in your `.emacs` file, where *path* is the directory which holds the file `jka-compr-ccrypt.el`. You may also need

to disable loading of the old jka-compr package, since the two packages are not compatible with each other (and in any case, jka-compr-ccrypt contains all the functionality of jka-compr).

Limitations of the emacs package: there is no guarantee that unencrypted information cannot leak to the file system; in fact, the package sometimes writes unencrypted data to temporary files. However, auto-saved files are normally treated correctly (i.e., encrypted). For details, see the comments in the file jka-compr-ccrypt.el.

## EXIT STATUS

The exit status is 0 on successful completion, and non-zero otherwise. An exit status of 1 means illegal command line, 2 is out of memory, 3 is a fatal i/o error, 4 is a non-matching key or wrong file format, 6 is interrupt, 7 is mistyped key in **--timid** mode, and 8 is a non-fatal i/o error.

Fatal i/o errors are those which occur while processing a file which is already open. Such errors cause ccrypt to abort its operation immediately with an exit status of 3. Non-fatal i/o errors are those which occur while handling files which are not already open; typically, such errors are caused by files that are missing, not readable, or can't be created. When encountering a non-fatal i/o error, ccrypt simply continues to process the next available input file. The exit status of 8 is delayed until after all the files have been processed.

Non-matching keys and wrong file formats are also considered non-fatal errors, and cause ccrypt to continue with processing the next available input file. In this case, an exit status of 4 is given after all the files have been processed. If there is a conflict between exit status 4 and 8, then 8 is returned.

The former exit status 5 ("wrong file format") has been eliminated, and is now covered under exit status 4 ("non-matching key or wrong file format"). Note that ccrypt does not really have a "file format" in the proper sense of the word; any file of length at least 32 bytes is potentially a valid encrypted file.

## BUGS

While **ccrypt** can handle keywords of arbitrary length, some operating systems limit the length of an input line to 1024 characters.

The renaming of files (adding or removing the **.cpt** suffix) can go wrong if a filename is repeated on the command line. In this case, the file is only encrypted/decrypted once, but the suffix may be added or removed several times. This is because **ccrypt** thinks it encountered different hardlinks for the same file.

The **--strictsuffix** option can behave in unexpected ways if one file has several hardlinks of which some have the suffix and some don't. In this case, the inode will be encrypted/decrypted, but the suffix will be changed only for those filenames that allow it. Similarly, if a file cannot be renamed because a file of the given name already exists, the file may still be encrypted/decrypted if it has another hardlink.

cfg2html is a little utility program that can be used to collect the necessary system configuration files and system set-up information to both an ASCII and an HTML file. Simple to use and very helpful when preparing for disaster recovery situations.

## NAME

cfg2html – creates nice HTML and plain ASCII documentation of your GNU/Linux systems.

**WARNING, use this script AT YOUR OWN RISK.**

## SYNOPSIS

**cfg2html** [**-oshxOcSTflkenaHLvhpPA210**] *option...*

## DESCRIPTION

**cfg2html** collects the system configuration details into a webpage and a text file. **cfg2html** is the âSwiss army knifeâ for sysadmins. It was written to get the necessary information to plan an update, to perform basic troubleshooting or do performance analysis.

This includes the collection of Cron and At jobs, installed Hardware, installed Software, Filesystems, Dump- and Swap-configuration, LVM, Network Settings, Kernel, System enhancements and Applications, and Subsystems.

If you like, you can add a description of the system into **/etc/cfg2html/systeminfo**

example:

Main database server using special software.

Contact: Micky Mouse <admin@foo.bar>

Location: Mars Moon

and so on.

If file **/etc/cfg2html/files** exists, you can add your own list of files to collect - see example included.

## Switches

The following switches are available from the command line:

- o** *dir*  
Override the default Logfile output location for the generated HTML and text output (e.g. **/var/log/cfg2html**) to the specified directory  
Alternatively, you can specify the location of the logfile by setting the environment variable **OUTDIR="/path/to/dir"**  
Specifying the **-o** option supercedes the definition of the OUTDIR environment variable
- 0** append the datestamp to the Logfile (OUTDIR) with format Day-Month-Year-HourMinute, e.g. 28-Oct-2020-2212
- 1** append the datestamp to the Logfile (OUTDIR) with format Day-Month-Year, e.g. 28-Oct-2020
- 2** append the datestamp to the Logfile (OUTDIR) with the date format of your own choosing. e.g specifying **%Y%m%d-%H%M** would append the date with a format of 20201028-2212 to the log file name.
- v** output cfg2html version information, kernel information and exit

**-h** output usage information and exit

By default, information in each of the following categories will be collected. Use the following options to disable the collection of the indicated configuration information:

**-s** disable: System  
**-c** disable: Cron  
**-S** disable: Software  
**-f** disable: Filesystem  
**-l** disable: LVM  
**-k** disable: Kernel  
**-e** disable: Enhancements  
**-n** disable: Network  
**-a** disable: Applications  
**-H** disable: Hardware  
**-x** disable listing the executable files in the PATH  
 This switch has no effect if -s is specified.  
**-O** disable listing open files that have been deleted  
 This switch has no effect if -s is specified.  
**-A** disable collecting the Altiris ADL Agent files, if present

Other options

**-p** enable collecting the system's Log files. If running on an HP PROLIANT SERVER, collect additional relevant logs.  
**-P** enable the processing of the custom plugins that you may have configured  
**-L** disable showing the command that was executed to generate the html output in each section  
**-T** enable showing performance information regarding the execution of cfg2html

## VARIABLES

### OUTDIR

defines the folder where the generated reports are saved. The -o switch overrides the setting of this environment variable.

A useful technique is to specify it on the command line when executed. E.g.

OUTDIR=/path/to/dir ./cfg2html

Note that using the -0 -1 or -2 switches append the indicated date stamp to the log files created in OUTDIR.

### LOCALPATH

If not specified, cfg2html will by default display all of the executable files in the deemed to be optimal PATH as stated in

<http://security.stackexchange.com/questions/117535/ordering-of-the-path-environment-variable>

defined at the beginning of the path, followed by specific additional directories that cfg2html has found to be installed.

**LOCALPATH** provides a means for the Sysadmin to specify the PATH for which they want to see the contents. If defined, the variable should be set to a colon-separated list of directories, which do

not need to exist.  
 e.g. LOCALPATH=/operator/bin:/sbin:/bin:/usr/sbin:/usr/bin  
 The best location for setting this variable is in  
 /etc/cfg2html/local.conf  
 but like **OUTDIR**, can also be specified on the command line, if so desired.

## FILES

After installation, the following files will exist:

### **/etc/cfg2html/systeminfo**

The system description you can update

### **/etc/cfg2html/files**

The contents of the files listed will be collected into the report

### **/etc/cfg2html/local.conf**

Can contain local switch over-rides and local variable definitions

After cfg2html is run, the following files will be generated in OUTDIR:

### **<hostname>.html**

the generated documentation in HTML form

### **<hostname>.txt**

the generated documentation in ASCII form

### **<hostname>.err**

error logfile (if any errors are generated)

### **<hostname>.partitions.save**

Disk Partitions to restore from

### **<hostname>.\_xpio.csv**

(only on systems connected to HP Disk Arrays): the output of the xpinfo command

Other files:

### **README**

Additional documentation and installation instructions.

### **changelog**

Revision history for cfg2html and associated files. Also, see the git log.

## SEE ALSO

**README**, **License.txt** and **changelog** files in the source directory.

**NOTES**

Only **root** can run the **cfg2html** wrapper script.

For security reasons, it is best to store the HTML and ASCII files in a safe place where only the root user has access, or remove the files from your file system.

**CONTACTING**

If you like the script, want to learn more about it, or want to see a feature added to it that isn't already here, then please subscribe to the project mailing list. The project web page is at **<http://www.cfg2html.com>** and the source code is hosted on github at: **<https://github.com/cfg2html/cfg2html>**

**WARNINGS**

use the **cfg2html** script at your own risk! See the file License.txt for details!

**DIAGNOSTICS**

**cfg2html** writes errors to <hostname>.err

**BUGS**

There are probably a lot of bugs. We are currently using this script successfully for our own systems, but there are many features included that we don't have any way to test right now. If you find a bug or have a comment or suggestion about the script, please submit an issue at <https://github.com/cfg2html/cfg2html/issues> or you can also email bugs and issues to the authors. You can find the address in the *AUTHORS* section. We'd love to hear from you. :-)

**AUTHORS**

Original cfg2html HP-UX version written by Ralph Roth <cfg2html@hotmail.com> and ported to Linux by Michael Meifert, maintained by Gratien D'haese and Ralph Roth on github.com.

See the source code and ChangeLog file for the complete history and credits.

**NAME**

checkopt – check used options in shellscripts

**SYNOPSIS**

**edrc/lib/checkopt -h**

**checkopt** "*used\_opts*" "*truthtable*"

```
checkopt "used_opts" "header
row_1
row_2
.....
row_n
"
```

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

check if a list of used options matches against a table of allowed option combinations.

This command is intended to be used to efficiently parse arguments in a script.

**OPTIONS**

"*used\_options*"

continuous or space separated string of options that were used. The characters `._:;=+|` are considered as separators and therefore cannot be part of a list of used options.

The order of the options provided in *used\_options* is not significant.

"*truthtable*"

truth table of the format "*header row\_1 row\_2 row\_3 ... row\_n* " :

*header*

the header line defines the meaning of the fields defined in the row settings. Only single-character options can be checked by the **checkopt** command.

The characters `._:;=+|` can be used to format the *header* content.

*row* in the *row* settings the possible correct option combinations are defined. The following settings are recognized as 'option is used': *I*, *T*, *True*, *Y*, *Yes*, the settings *O*, *F*, *False*, *N*, *No* are recognized as 'option not used'.

The *used\_options* are checked against each *row* in the *truthtable*. If the used options

match against a *row*, the **checkopt** command exits with exit code **0**, if no *row* matches, the exit code is **1**.

The characters `._::;=+|-` can be used to format the *row* content.

## ENVIRONMENT

-

## EXIT STATUS

- 0**        used option combination is correct.
- 1**        used option combination is not correct.
- 4**        usage printed.

## FILES

-

## EXAMPLES

### 1) example usage in a shellscript

Parsing of a command having the usage:

**my\_script -h | -f *file* [ -n | -v ]**

```
#!/bin/sh
:
:
parse_args() { args=$*
 debug=False
 Patchfile=""
 Noexecute=False
 Verbose=False

 getopt xhf:n $* > /dev/null 2>&1
 if [$? -ne 0]; then
 usage
 fi

 opts=""
 while [$# -ge 1]; do
 opts="$opts $1"
 case $1 in
 -x) debug=True ;;
 -f) Patchfile=`rel2abs $2`
 shift ;;
 esac
 done
```

```

 -n) Noexecute=True ;;
 -v) Verbose=True ;;
 -h|*) usage ;;
 esac
 shift
done

checkopt "$opts" "
 fnv
 100
 101
 110
 " || usage
} # parse_args

main() {
 parse_args $*
 :
 :
} # main
main $*

```

## 2) alternate checkopt usage

alternate use of **checkopt**. This usage is equal to example 1).

```

checkopt "$opts" "
 fnv
 YNN
 YNY
 YYN
"

```

## 3) alternate checkopt usage

alternate use of **checkopt**. This usage is equal to example 1).

```

checkopt "$opts" "
 fnv
 TFF
 TFT
 TTF
"

```

## 4) alternate checkopt usage

alternate use of **checkopt**. This usage is equal to example 1).

```

checkopt "$opts" "
 f-----n-----v-----
"

```

```
True--False-False
True--False-True
True--True--False
"
```

**NAME**

setopt, checkopt, CHECKOPT – check used command line options

**SYNOPSIS**

```
#include "checkopt.h"

char *setopt(char opt);

bool checkopt(char *head, int *table);

bool CHECKOPT(char *head, int_1, int_2, ..., int_n);
```

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

**checkopt.h** provides functionality to efficiently check the correct use of command line switch combinations.

The definition of correct command line option combinations is done by a binary truth table that is more easy to maintain than combinations of logical and/or expressions.

**setopt()**

record all used command line options.

Example:

```
#define USAGE "Usage: mycmd [-l | -m][-z][-n | -f filename]\n"

int opt;
while ((opt = getopt(argc, argv, "f:nlmz")) != -1) {
 switch (opt) {
 case 'f':
 file = true;
 filename = strdup(optarg);
 break;
 case 'n':
 file = false;
 break;
 case 'l':
 low = true;
 break;
 case 'm':
 medium = true;
 break;
 case 'z':
```

```

 zero = true;
 break;
 case '?':
 printf(USAGE);
 return 4;
 break;
 }
 setopt(opt);
 }
 for (int i=optind; i<argc; i++){
 printf(USAGE);
 return 4;
 }

```

**checkopt()**

check all options recorded by **setopt()** against a truth table.

The *header* is a string with all options to be checked in the truth table.

In the truth *table* (=integer array) all allowed (good) option combinations are set by setting the related bit in the integer value list in the same order as the options given in the *header* string.

The last entry in the truth *table* needs to be set to **-1**.

Example:

```

int table[] = {
 0b00000000,
 0b00000100,
 0b00001000,

 0b00000001,
 0b00000101,
 0b00001001,

 0b00000010,
 0b00000110,
 0b00001010,

 -1
};

if (!checkopt("mlnf", table)){
 printf(USAGE);
 return 4;
};

```

**CHECKOPT()**

check all options recorded by **setopt()** against a truth table.

The *header* is a string with all options to be checked in the truth table.

In the truth *table* (=integer array) all allowed (good) option combinations are set by setting the related bit in the integer value list in the same order as the options given in the *header* string.

The **CHECKOPT** macro is suited to more conveniently define the truth *table*.

Example:

```

if (!CHECKOPT (
 "mlnf",
 0b00000000,
 0b00000100,
 0b00001000,

 0b00000001,
 0b00000101,
 0b00001001,

 0b00000010,
 0b00000110,
 0b00001010
)) {
 printf(USAGE);
 return 4;
};

```

## RETURN VALUE

the return value of **checkopt()** and **CHECKOPT()** is **true**, if the option combination is correct (respectively found in the truth table) and **false** if the option combination is not correct (respectively not found in the truth table).

## ENVIRONMENT

-

## FILES

lib/\$OSID/includes/checkopt.h

**NAME**

choice – prompt for a key to be pressed

**SYNOPSIS**

**edrc/lib/choice** "*prompt*" *keylist* [ *default\_key* [ *options* ] ]

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

This command is used in scripts to prompt a user to press a key.

As long as a key is pressed that is not specified as valid in the *keylist* the **choice** prompt is repeated.

It is also possible to specify a default key that takes in effect when <ENTER> or <RETURN> without entering a key is pressed.

All input is logged to a logfile if the environment variable **\$EDRC\_LOGFILE** is set and the **NO\_LOG** option isn't set.

**OPTIONS**

*prompt*      prompt to be displayed.

*keylist*      a string of keys which are accepted by **choice**. If a key is entered the **choice** prompt is re-displayed and the user is requested to enter a valid key. The *keylist* is case-sensitive.

*default\_key*      default key. This key will be returned if the <ENTER> key is pressed.

*options*

**NOT\_NULL**

null input is not accepted.

**NO\_LOG**

do not record the input to the logfile.

**LOG\_STARS**

log a star (\*) to the logfile instead of the real input.

**ENVIRONMENT****\$EDRC\_LOGFILE**

the accepted input read by **choice** is logged to the file specified in this environment variable (if set).

**EXIT STATUS**

- 0** no error.
- 4** usage listed.

**EXAMPLES**

The following examples are script cut-outs of Bourne-, Korn- or Bash shell scripts:

**1) Yes/No user prompt**

```
answer=`choice "remove file? <yn>" yn n`
if [$answer = y]; then
 \rm -f $file
 echo "File removed"
else
 echo "File not removed"
fi
```

**2) A menu**

```
cat <<EOM
p) print user credentials
a) create user account
h) create home directory

q) quit
EOM

ans=`choice "?" pahq q`
case $ans in
p) print_users ;;
a) create_account ;;
h) create_homedir ;;
q) exit ;;
esac
```

**3) A menu including logging all actions**

```
Logfile=/var/log/user_management.log

EDRC_LOGFILE=$Logfile; export EDRC_LOGFILE

{
```

```

cat <<EOM
p) print user credentials
a) create user account
h) create home directory

q) quit
EOM

ans=`choice "?" pahq q`
case $ans in
p) print_users ;;
a) create_account ;;
h) create_homedir ;;
q) exit ;;
esac
} >> $Logfile

```

#### 4) Run a command until 'n' is pressed

```

while [`choice "count? <yn>" yn y` = y]; do
 echo "number of processes: `ps -ef | wc -l`"
done

```

**NAME**

cltrash – tidy up global trash and \*.TRASHED files

**SYNOPSIS**

**edrc/bin/cltrash** [ **-h** ]

**cltrash -a purge** [ **-d days** ]

**cltrash -a remove** [ **-d days** ] [ **-r rootdir** ]

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

The **cltrash** command is used to tidy up the global trash and the file systems after the use of the **trash** command.

To tidy up the global trash properly the **cltrash** command supports two actions:

**purge**        purge (remove) files which were trashed a certain number of days ago from the trash.

**remove**      remove the *filename.TRASHED* "information and instruction files" which are generated a certain number of days ago from the system.

Therefore the **cltrash** command has to be started once to purge the global trash with the **purge** action and once on each system participating on the global trash with the **remove** action to remove the related "information and instruction files" from the system. If you don't, the user thinks that a file can still be retrieved from the trash, even it has been purged or a trashed file still uses disk space even if the "information and instruction file" does not exist and the user has no hint any more that the file could still be retrieved.

**OPTIONS**

**-h**            usage message.

**-a purge**     purge (remove) files which were trashed a number of days, optionally to be specified with the **-d** option, ago from the trash.

**-a remove**    remove the *filename.TRASHED* "information and instruction files" which are generated a number of days, optionally to be specified with the **-d** option, ago from the system.

**-d days**      number of days. If not specified this option defaults to 30 days.

**-r rootdir**    start dir to search for *filename.TRASHED* files on the system. If not specified this option defaults to /.

**EXIT STATUS**

- 0** no error.
- 1** LOGDIR or TRASHDIR does not exist. See **trash.cfg**(4) if you get this error.
- 2** operating system is not supported. See **osid**(3) if you get this error.
- 3** rootdir does not exist.
- 4** usage listed.
- 6** configuration file **edrc/etc/trash.cfg** does not exist.

**FILES**

**edrc/etc/trash.cfg**  
configuration file for **trash**, **untrash** and **cltrash**.

**edrc/var/trash/log/**  
default logfile location of **trash** , **untrash** and **cltrash**.

**edrc/var/trash/files/**  
default location for trashed files.

*filename*.**TRASHED**  
information and instruction file to document the file trashing and to give instructions how to recover ( **untrash** ) the trashed file.

**EXAMPLES**

- 1) automated tidy up of a global trash using cron

In this example the **cron** entry of all participating systems is identical and the global trash is physically located in the directory **/data\_adm1/dat/trash**. This is why the **purge** action is only executed if the directory exists on the system (important to check in a clustered environment where the global trash should resist on a cluster package, too).

## 1.1) trash.cfg configuration file

```
#
trash.cfg - trash/untrash/cltrash configuration file
#
[00] 15.02.2005 CWa Initial Version
#

#
Fileformat:
#
OPTION=<VALUE>
#
```

```
Trash basedir. This directory holds all trashed files.
#
TRASHDIR=/dat/trash/files

Logdir.
#
LOGDIR=/dat/trash/logs
```

#### 1.2) needed cron entries to purge the global trash and remove the trash info files

```
[/data_adm1/dat]
[root@adm_db1_prod][ksh]: crontab -l

:
#
purge trash (see also: cltrash -a remove)
#
0 2 * * * [-d /data_adm1/dat/trash] && /opt/edrc/bin/cltrash \
-a purge -d 14 > /dev/null 2>&1
:

:
#
remove trash info files (see also: cltrash -a purge)
#
0 2 * * * [-x /opt/edrc/bin/cltrash] && /opt/edrc/bin/cltrash \
-a remove -r / -d 14 > /dev/null 2>&1
:
```

#### SEE ALSO

**edrcintro(1)**, **trash(1)**, **trash.cfg(4)**, **untrash(1)**

#### NOTES

**cltrash** travels thru all filesystems if the rootdir is specified as / ( **-r** / ), therefore if NFS mounted filesystems are used, those filesystems are searched multiple times.

#### BUGS

-

#### AUTHOR

cltrash was developed by Christian Walther. Send suggestions and bug reports to [wa2l@users.sourceforge.net](mailto:wa2l@users.sourceforge.net).

**NAME**

cmdlist – list all WA2L/edrc commands

**SYNOPSIS**

**edrc/bin/cmdlist** [ **-h** ]

**cmdlist** [ **-l** ] [ *selection* ]

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

list all commands available in the WA2L/edrc package providing additional credential information.

A user of the WA2L/edrc package is advised to use the **usage**(1) command to get a list of all commands with a short usage.

The **cmdlist** command is intended to be used by a WA2L/edrc developer needing a quick information about implementation details.

Beside **cmdlist**, see also the **binprobe** command to check which binaries (**TYPE**: **BIN**, **JBIN**, **LSCR**, **PSCR**, **YSCR**) are able to run on the operating system where currently logged in.

The output of **cmdlist** consists of a table having the following columns:

**COMMAND**

*command* executable name.

**TYPE** indicator of *command* realization (the same **TYPE** indicator is used in the **compatibility**(1) manual page):

**BIN** machine binary file. A compiled source code.

**JBIN** Java binary files. A compiled \*.**java** source code.

**SCR** Bourne shell script.

**KSCR** Korn (or Bourne-Again) shell script.

**LSCR** Lua script or program.

|             |                                                                                              |
|-------------|----------------------------------------------------------------------------------------------|
| <b>PSCR</b> | Perl script.                                                                                 |
| <b>YSCR</b> | Python script.                                                                               |
| <b>LINK</b> | symbolic link to an other <i>command</i> providing an alternate name for an executable file. |

## DIRECTORY

directory in which the *command* is located (see also: **edrc**(1m)):

### **bin** (=edrc/bin/)

executables planned to be used mostly from the command line.

This directory is in **\$PATH** when using **edrc**, **shell** or **eshell**.

### **lib** (=edrc/lib/)

executables planned to be used mostly from within scripts because this *commands* often have the character of supporting functions and need often more initialization.

This directory is in **\$PATH** when using **edrc**, **shell** or **eshell**.

### **sbin** (=edrc/sbin/)

executables planned to be used from the command line.

This directory is not in **\$PATH** when using **edrc**, **shell** or **eshell**.

### **pbin** (=edrc/pbin/)

executables to be used mostly from the command line as normal (unprivileged) user but with elevated permissions. Depending on the system, *commands* in this directory use automatically **sudo** or **pfexec** to elevate the permissions without the need to manually call **sudo command** or **pfexec command**.

This directory is not in **\$PATH** when using **edrc**, **shell** or **eshell**, but should be added to the **\$PATH** of the normal (unprivileged) user.

## STARTMODE

mode how the *command* is started. In general it can be distinguished between tree categories. However the user does not note a difference (and does not need to know the **STARTMODE**) when using the *commands* of any of the categories (sometimes such a behaviour is called "transparent"):

**direct** direct start of a command where **TYPE** is **SCR**.

*command* a command is started thru an alternate name (**TYPE** is **LINK**) provoking a different behaviour.

This method of calling the same command thru different names is a common concept on UNIX like systems to save implementation effort.

**.name\_wrapper**

start thru a wrapper (see related *name\_wrapper*(1) manual page), where before the real start additional checks are executed and specific settings are automatically applied:

**.os\_wrapper**

start of operating system dependent binaries.

**.java\_wrapper**

start Java binary code using a system-wide installed Java RE (JRE, Java Runtime Environment).

Note: There is no JRE distributed/bundled with WA2L/edrc and needs to be installed somewhere on the system.

**.perl\_wrapper**

start Perl script using a system-wide installed Perl interpreter.

**.python\_wrapper**

start Python script using a system-wide installed Python interpreter.

**.ksh\_wrapper**

start Korn- or Bourne-Again (**bash**) script using **ksh** or **bash** depending on availability on the system.

**.pf\_wrapper**

start executable using **sudo** or **pfexec** depending on availability/configuration on the system.

**.daemon\_wrapper**

start a daemon-like executable.

**daemon** start a daemon-like executable exceptionally not using the **.daemon\_wrapper**.

## OPERATINGSYSTEM

a list of operating systems (**osid**) for which distinct binaries are provided/bundled in/with WA2L/edrc.

This does not necessarily mean, that on operating systems for which the WA2L/edrc does not provide a binary file, the related command cannot be started from within WA2L/edrc.

For a description of this concept in WA2L/edrc, see **os\_wrapper**(1) manual page.

OPTIONS

- h usage message.
- l provide list as CSV file format.

ENVIRONMENT

-

EXIT STATUS

- 0 no error.
- 4 usage displayed.

FILES

WA2L/edrc

**DESCRIPTION**

switch a MC/SG package to a node. Using this interactive command is much faster then entering all commands needed for a cluster package switch from one to an other node. You can restart a package if you specify the host where the package is currently running as the target node.

Be aware that the **cmswitch** command does not check if it is possible to switch the package to the specified target node, therefore you should check the possible package switch positions first using the **cmmon** command.

This command is ideal to be used while efficiently testing the correct functionality of the configuration of the cluster package configuration because also timing information is printed. Therefore the command output is well suited for test protocol usage.

**OPTIONS**

-

**ENVIRONMENT**

-

**EXIT STATUS**

**0** no error.

**4** operating system not supported.

**FILES**

**edrc/var/log/cmswitch.log**

log file of the **cmswitch** command.

**EXAMPLES**

-

**SEE ALSO**

**edrcintro(1)**, **cmhaltpkg(1m)**, **cmmodpkg(1m)**, **cmmon(1m)**, **cmrunpkg(1m)**

**NOTES**

This command only runs on HP-UX systems having MC/ServiceGuard installed.

**BUGS**

-

**AUTHOR**

cmswitch was developed by Christian Walther. Send suggestions and bug reports to [wa2l@users.sourceforge.net](mailto:wa2l@users.sourceforge.net).

**NAME**

comm – compare two sorted files line by line

**SYNOPSIS**

**comm** [*OPTION*]... *FILE1 FILE2*

**DESCRIPTION**

Compare sorted files *FILE1* and *FILE2* line by line.

When *FILE1* or *FILE2* (not both) is –, read standard input.

With no options, produce three-column output. Column one contains lines unique to *FILE1*, column two contains lines unique to *FILE2*, and column three contains lines common to both files.

**-1** suppress column 1 (lines unique to *FILE1*)

**-2** suppress column 2 (lines unique to *FILE2*)

**-3** suppress column 3 (lines that appear in both files)

**--check-order**

check that the input is correctly sorted, even if all input lines are pairable

**--nocheck-order**

do not check that the input is correctly sorted

**--output-delimiter=STR**

separate columns with *STR*

**--total** output a summary

**-z, --zero-terminated**

line delimiter is NUL, not newline

**--help** display this help and exit

**--version**

output version information and exit

Note, comparisons honor the rules specified by 'LC\_COLLATE'.

**EXAMPLES**

comm -12 file1 file2

Print only lines present in both file1 and file2.

comm -3 file1 file2

Print lines in file1 not in file2, and vice versa.

**AUTHOR**

Written by Richard M. Stallman and David MacKenzie.

NAME

compatibility – WA2L/edrc command compatibility overview (compatibility matrix)

SYNOPSIS

–

AVAILABILITY

WA2L/edrc

DESCRIPTION

This matrix shows for which OSID or group of OSIDs a command has been developed or is available.

COMPATIBILITY MATRIX

All commands of type **BIN** are started thru the **os\_wrapper(1)**. If such a command is not distributed with the WA2L/edrc package for a certain OSID, but it is available on the operating system, it will be started, and is therefore also available for an OSID not listed here. This is often the case for commands that are installed by standard on certain operating systems only.

The *X* entry for a command indicates for which OSID it is able to run, respectively on which operating system ID the command has been tested.

The *e* entry for a command indicates for which OSID it is expected to run, but has not been tested.

Always use the **binprobe(1m)** command to test binaries and Perl programs.

## NOTES

Description of startup of the command **TYPES**:

**BIN** started thru the **.os\_wrapper**. See **os\_wrapper**(1) for more information.

**JBIN** started thru the **.java\_wrapper**. See **java\_wrapper**(1) for more information.

**SCR** direct startup or start thru the **.daemon\_wrapper**, depending on the functionality. See **daemon\_wrapper**(1) for more information.

- PSCR** started thru the **.perl\_wrapper**. See **perl\_wrapper(1)** for more information.
- PM** Perl modules are used using the **use <Module>;** statement in a Perl script. The modules bundled with WA2L/edrc are available when the Perl script is started thru the **.perl\_wrapper**. If a certain bundled Perl module is not available for a certain OS-Id, but it is installed on the system, the module is available for the calling Perl script. See **perl\_wrapper(1)** and **perlenv(3)** for more information.
- KSCR** started thru the **.ksh\_wrapper**. See **ksh\_wrapper(1)** for more information.
- LSCR** started thru the **.lua\_wrapper**. See **lua\_wrapper(1)** for more information.
- YSCR** started thru the **.python\_wrapper**. See **python\_wrapper(1)** for more information.

## BUGS

**NAME**

**connect** – Make socket connection using SOCKS4/5 and HTTP tunnel

**SYNOPSIS**

```
connect [-dnhst45] [-R resolve] [-p local-port] [-w seconds]
 [-H [user@] proxy-server [:port]]
 [-S [user@] socks-server [:port]]
 [-T proxy-server [:port]]
 [-c telnet proxy command]
 host port
```

**DESCRIPTION**

*Connect* is a proxy tool to enable *OpenSSH* and other TCP/IP utilities to run through SOCKS4/5 and HTTP proxy gateways. The arguments *host* and *port* are for the target hostname and port number to connect to.

The **-H** option specifies the hostname and port number of the HTTP proxy server to be used as the relay. If *port* is omitted, the default value of 80 will be used. This value can also be specified using the environment variable HTTP\_PROXY and pass the **-h** option to use it.

The **-S** option specifies the hostname and port number of the SOCKS server to be used as the relay. As with **-H**, the port number can be omitted, in which case the default value is 1080. This value pair can also be specified in the environment variable SOCKS5\_SERVER and use it with the **-s** option.

The **-4** and **-5** options are for specifying the SOCKS relaying and indicates which protocol version to use. The options are valid only when used with **-s** or **-S**. The default is **-5** (protocol version 5).

The **-R** option is for specifying method to resolve the hostname. Three keywords (*local*, *remote* and *both*) or an IP address in dot-notation are acceptable. The keyword *both* means, “Try local first, then remote”. If a dot-notation IP address is specified, use *IP address* as the name server. The default is *remote* for SOCKS5 or *local* for others. On SOCKS4 protocol, remote resolving method (*remote* and *both*) requires a protocol 4a supported server.

The **-p** option will forward a local TCP port instead of using standard input and output.

The **-P** option is the same as **-p** except that it will keep the remote session open. The program will wait the port and hold the remote session without disconnecting. To disconnect the remote session, send EOF to stdin or kill the program.

The **-w** option specifies timeout *seconds* for opening a connection with the target *host*.

The **-d** option is used for debugging connections. If you fail to connect to a host, use this option to check requests to and responses from server.

**EXAMPLES**

You can omit the *port* argument when program name is special format containing port number itself. For example,

```
$ ln -s connect connect-25
```

means this connect-25 command is specifying port number 25 already, thus the second argument is not needed and it will be ignored if specified.

To use proxy, this example is for SOCKS5 connection to connect to *host* at port 25 via SOCKS5 server on *firewall* host.

```
$ connect -S firewall host 25
```

or

```
$ SOCKS5_SERVER=firewall; export SOCKS5_SERVER
$ connect -s host 25
```

For a HTTP-PROXY connection:

```
$ connect -H proxy-server:8080 host 25
```

or

```
$ HTTP_PROXY=proxy-server:8080; export HTTP_PROXY
$ connect -h host 25
```

To forward a local port, for example to use ssh:

```
$ connect -p 5550 -H proxy-server:8080 host 22
($ ssh -l user -p 5550 localhost)
```

When used with OpenSSH, e.g. *ssh*(1), connect can be used with *ProxyCommand* in *ssh\_config*(5) to inter-operate with SOCKS gateways.

Host destinationhost

```
ProxyCommand connect -R local -S proxygw destinationhost %p
```

## ENVIRONMENT

User name for authentication is passed to *connect* in an environment variable and if none defined, the system login name will be used. Similarly, the password can be specified by using an environment variable, external program, specified in **\$SSH\_ASKPASS**, or from tty.

Following environment variables are used for specifying user name. SOCKS: **\$SOCKS5\_USER**, **\$LOGNAME**, **\$USER**

HTTP Proxy: **\$HTTP\_PROXY\_USER**, **\$LOGNAME**, **\$USER**

## LIMITATIONS

Only USER/PASS authentication is supported in SOCKS5 authentication.

Only HTTP Basic Authentication is supported in HTTP proxy authentication.

## SEE ALSO

*ssh*(1), *ssh\_config*(5)

**NAME**

consolidate – filter to consolidate unix file content

**SYNOPSIS**

**edrc/bin/consolidate** [ **-h** ]

**consolidate** *structure*

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

filter to consolidate structured unix file content from multiple input.

After using the **consolidate** command, the output should be verified, to ensure it matches to the conventions in your environment.

**OPTIONS**

**-h**           usage message.

*structure*   data structure to consolidate:

**services**

internet network services list as known from the **/etc/services** file.

The consolidated output is sorted by the service number field and not by the service name.

See **services(5)** for more information.

**ENVIRONMENT**

-

**EXIT STATUS**

**0**           no error.

**4**           usage printed.

**FILES**

-

**EXAMPLES****1) consolidate multiple services files**

```
cat services.host1 services.host2 |\
consolidate services > services.out
```

**2) consolidate multiple services files using rcmd**

```
rcmd -n -t host1,host2 -c "cat /etc/services" |\
consolidate services > services.out
```

**NAME**

contrib – writing contributed commands for edrc

**SYNOPSIS**

**edrc/contrib/edrc**

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

If you miss a general command in **edrc** that is available in all menus, do not change the **edrc** program.

It is possible to write this commands as a separate program (a contributed command) and place it into the **edrc/contrib/edrc** directory. From then on the new contributed command can be called as if it is an **edrc** internal command. It is then listed in the section **CONTRIBUTED COMMANDS** when the **help** command in **edrc** is invoked.

This will protect you from loosing your work after an upgrade of **edrc**, simplifies the development of additional functionality for **edrc** and will keep the **edrc** command itself stable.

**CONVENTIONS**

A contributed command has to comply with some conventions:

- If the command is limited to be started on certain operating systems only, use **osid(3)** or **is\_osid(3)** to ensure the startup on the designated operating systems only.
- Don't use absolute pathnames. If you have to resolve something within WA2L/edrc, use **approot(3)** and the environment variables provided. See also section **ENVIRONMENT**.
- To save persistent information, use the **\$EDRC\_CONTRIB\_VARDIR** environment variable to do so. You should add the name of the contributed command as prefix to ensure a unique filename.

Example:

```
date > $EDRC_CONTRIB_VARDIR/my_command.begin
```

- If a man page is written for a contributed command, the manpage name convention is **contrib.my\_command.1m** and it has to be placed into the man page directory **man/all/man1m**.
- If a contributed command provides functionalities that can be denied from execution, the **@PROVIDES@** tag has to be used in the file header and the functionality has to be listed.

Example:

```
@PROVIDES@ view display more grep tail head
```

This results in the contributed functionality being listed in the output of the **edrcperm** command within **edrc** in the form **contrib.my\_command.functionality**.

Example:

```
EDRC PERMISSIONS / FUNCTIONALITIES
```

```
All:
 :
 contrib.logs.display contrib.logs.grep contrib.logs.head
 contrib.logs.more contrib.logs.tail contrib.logs.view
 :
```

To handle the denial of a functionality startup in a contributed command, the **is\_permitted(3)** command has to be used.

Example:

```
if [`is_permitted view` = True]; then
 view $log >`tty`
fi
```

## FILE STRUCTURE

A contributed command consists of the following file structure:

*my\_command*

The new contributed command. This file has to have appropriate execute permissions.

*my\_command.nolog*

This is a flagfile. If this file exists the output sent to stdout is not saved to a designated logfile in **var/log**. This file should only be created if the contributed command creates a continuous output that ends only by user intervention. This is to avoid file system fill ups.

## OPTIONS

As all **edrc** commands, the contributed commands do not receive command line options. All options have to be queried by the contributed command using for example the **input(3)** or **choice(3)** commands. See example 2) in the **EXAMPLES** section to see how to query user input.

## ENVIRONMENT

All environment variables exported to a recovery script are exported to a contributed command, too. In addition the **\$EDRC\_CONTRIB\_VARDIR** is exported.

See section **ENVIRONMENT** in the **edrc(1m)** manpage for a complete explanation of all exported environment variables.

## EXIT STATUS

-

## FILES

### **contrib/edrc/**

location of all contributed commands to **edrc**.

### **contrib/edrc/my\_command**

the executable of a contributed command. This file has to have appropriate execute permissions.

### **contrib/edrc/my\_command.nolog**

if this file exists, the output sent to stdout is not logged in a logfile in **var/log**. This file should only be present for contributed commands creating a permanent output to avoid filesystem fill up caused by endless growing logfiles. This is the case if the contributed command monitors a certain system state and only stops monitoring after a user intervention. If the contributed command creates no such continuous output the **my\_command.nolog** should not be created.

### **man/all/man1m/contrib.my\_command.1m**

man page of a contributed command.

## EXAMPLES

See also existing contributed commands in **contrib/edrc**.

### 1) the logtail contributed command

This contributed command provides the **logtail(1)** functionality within **edrc**.

The contributed command **logtail** :

```
#!/bin/sh
#
logtail - start logtail
#
[00] 08.08.2004 CWa Initial Version
[01] 25.01.2006 CWa chg: command name ltail -> logtail
#

test "$DEBUG" = True && set -x

logtail
```

The nolog file **logtail.nolog** (the content of the **logtail.nolog** is not important. **edrc** only checks if the **logtail.nolog** file exists or not):

```
#
logtail.nolog - flag file to prevent output logging
#
```

```
[00] 26.01.2006 CWa Initial Version
#
If this file exists, the output of the relating
contributed command is not logged to a logfile.
#
This make sense if the contributed command
generates continuous output which would generate
very large logfiles.
#
```

## 2) the cmviewcl contributed command

This contributed command provides the **cmviewcl(1)** functionality to **edrc**. **cmviewcl** is a command to display the state of a **MC/ServiceGuard** cluster as available on HP-UX. Therefore it only makes sense to allow the startup of this command on HP-UX.

The contributed command **cmviewcl** :

```
#!/bin/sh
#
cmviewcl - MC/ServiceGuard state
#
[00] 08.02.2003 CWa Initial Version
[01] 18.03.2003 CWa +opt
[02] 10.05.2003 CWa fix: DEBUG
[03] 24.07.2003 CWa +is_osid
#

test "$DEBUG" = True && set -x

is_osid -s $0 -o HP-11,HP-11i || exit $?

opt=`input "options" "" `

msg INFO "MC/ServiceGuard state:"

cmviewcl $opt | more
```

## SEE ALSO

**contrib.edrc(1m)**, **contrib.<contributed\_command>(1m)**, **edrcintro(1)**, **edrc(1m)**, **edrc.cfg(4)**, **edrcenv(1)**, **choice(1m)**, **input(1m)**, **is\_permitted(3)**, **log(3)**

## NOTES

As you might notice already a number of contributed commands are distributed with the WA2L/edrc package. The reason for this is that all operating system dependent commands were moved in an early version of **edrc** to contributed commands and only the core non operating system dependent functionality remained in **edrc**. This should support the concept of **edrc** to be compatible to a wide range of operating systems without modifications.

In addition some additional functionality that does not support the basic **edrc** functionality is first implemented as a contributed command and probably later integrated if all bugs are fixed and the decision is made to include it. In general there is no disadvantage to have some functionality available as contributed commands and not as a core **edrc** command.

The complete list of all contributed commands distributed with WA2L/edrc is given in the man page **contrib.edrc(1m)**.

## BUGS

-

## AUTHOR

contrib was developed by Christian Walther. Send suggestions and bug reports to [wa2l@users.sourceforge.net](mailto:wa2l@users.sourceforge.net).

**NAME**

contrib.doc – display recovery script and menu documentation

**SYNOPSIS**

**doc** (contributed WA2L/edrc command)

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

All menu points and menus can be documented. The documentation is displayed using the **doc** contributed **edrc** command.

The documentation is compiled out of commented sections of a recovery script or menu title.

A documentation is structured into several sections similar to Unix man pages. To place text into a documentation section, each line has to be preceded by a section tag consisting of a capital letter and a colon.

To write text for the **DESCRIPTION** section, the recovery script looks like this:

```
:
#
D: This is an example that is displayed as
D: justified text in the DESCRIPTION section
D: of the documentation when displayed
D: with the 'doc' contributed command.
#
:
```

It is not necessary that all your documentation is done at the beginning of a recovery script. Suppose your script conducts several steps; it might make sense that you enter the documentation near the single steps to ensure an update if the code changes in the future.

**PREDEFINED DOCUMENTATION SECTIONS**

The following documentation sections with the given documentation tags are predefined. The tag sequence in the recovery script is not important, the output will be in the sequence as the sections are explained below. Note, that only sections that contain information will be displayed, therefore if you do not enter text for a certain section, it won't be printed.

**NAME**     The name and short description of a menu point as shown when the menu is displayed using the **menu** command in **edrc**. This section is dynamically generated.

**AVAILABILITY**

This section contains information about the **SCRIPTS\_BASEDIR** you are currently in.

A second line prints the logical menu path where you are in, i.e. which menus you have to enter to go to the menu or menupoint. This section is dynamically generated.

**D: DESCRIPTION**

Description text. The output format is justified. If you want to set an empty line, simply enter a **D:** without text.

Example:

```
#
D: The database to be refreshed has been
D: stopped and removed by the Storage Mgmt group.
D:
D: If the "oracle server" or "oracle instance" is
D: "up", contact the Storage Mgmt group.
#
```

**R: RE-RUN ALLOWED?**

The intention of this sections is to either enter *YES* or *NO* or some other text to document if a menu point can be restarted immediately without side effects.

Example:

```
#
R: YES
#
```

**O: OUTPUT-EXAMPLE**

Verbatim output of entered text. Here no text formatting takes place.

Example 1:

```
#
O: PERMISSION OWNER GROUP DIRECTORY
O: drwxr-x--- oracle dba /ora01/oradata/DWHPROD
O: drwxr-x--- oracle dba /ora02/oradata/DWHPROD
O: drwxr-x--- oracle dba /ora03/oradata/DWHPROD
#
```

Example 2 (using **.SS SubSection Title** to create two output sub-sections):

```
#
O: .SS If host acme007 is up:
O: 22:26:53 up 3:51, 1 user, load average: 0.09, 0.15, 0.22
#
O: .SS If host acme007 is not up:
O: ssh-exec-ERROR: remote system 'acme007' is not up, aborting.
#
```

To efficiently get data from a log file, use the **outex(1)** command from within the **vi** session,

using:

```
#
#
~
~
~
: . !outex 2009-09-22_13.10.22__list_db_files.log
```

## L: LIMITATIONS

Document limitations (or bugs) of the recovery script. The output format is justified. If you want to set an empty line, simply enter a **L:** without text.

Example:

```
#
L: The UID (User-ID) and UNAME (User-name)
L: cannot be changed in this tool.
#
```

## N: NOTES

Additional information to the menu point that is not to be documented in the **DESCRIPTION** section. If you want to set an empty line, simply enter a **N:** without text.

Example

```
#
N: Special character input is not
N: allowed (Control-Characters, Umlaut, etc.)
#
```

**F: FILES** List of files. Each text line in this section is printed on a separate line.

Example:

```
#
F: /etc/passwd
F: /etc/nsswitch.conf
F: /var/spool/cron/atjobs/<at-job-file>
#
```

## S: SEE ALSO

Reference to other documentation etc. If the first element of the line is a reference in square brackets (as: [REFER], [1], etc.), it is taken as a reference marker, the following text until the next reference is taken as the reference text.

It is not needed to indent the text as done in the example below for the [AWK] and [CHA] references. The text following a reference can be written as shown for [SSP], the output will be identical for all.

Example:

```
#
S: [AWK] The AWK Programming Language, October 1988,
```

```
S: Aho Alfred V., Weinberger Peter J.,
S: Kernighan Brian W., ISBN 0-201-07981-X
S: [CHA] Clusters, For High Availability,
S: 2nd Edition 2001, Weygant Peter S.,
S: HP-Part No: B3936-90047, ISBN 0-13-089355-2
S: [SSP] Shellscript Programmierung, Sun Service,
S: Revision C21 February 1994, Sun Microsystems Inc.,
S: Sun Part No: 8xx-xxxx-xx
#
```

### T: DURATION

Document the approximate runtime duration of the menu point.

Example:

```
#
T: ~7 minutes
#
```

If using the **scripttitle(3)** command, the duration text given here is displayed as expected duration in braces.

### SPECIAL BEHAVIOR

To speed up documentation writing some special behavior is implemented based on the content written.

- If you start a line with a dash ( - ) the line containing the dash and following text not preceded by a dash are set with an indent of 2 characters. I.e. an unsorted list is created.

Example:

```
#
D: Why go fishing in Canada?
D: - vast area of wild nature where
D: the big fish can be caught.
D: - peaceful lakes and streams invite to
D: relax and recover from daily hassles.
#
```

- /- End an unordered list started with the dash ( - ). This is needed if you like to quit the indented text because the following text does not relate to the list point any more. If the next text you write is assigned to another section, it is not needed to add an /- at the end of the list.

Example:

```
#
D: Why go fishing in Canada?
D: - vast area of non touched nature where
D: the big fish can be caught.
D: - peaceful lakes and streams invite to
D: relax and recover from daily problems.
D: /-
D: Of course there are other places to
D: experience similar landscape as ...
#
```

**preformatted text**

```
<pre>
text
</pre>
```

unformatted output of *text*.

Example:

```
#
D: To efficiently rename many menu points, use:
D: <pre>
D: lsmv > a; vi a; sh ./a; rm a; \
D: scriptheadersync -execute
D: </pre>
D: This loads the 'mv' commands into 'vi' and
#
```

**section tag without text**

If any section tag without text is set, a line break with a line feed occurs. Therefore in the example below, between the whale and the bear part of the text will be a one line gap in the output.

Example:

```
#
D: Beside orcas you can see humpback whales and
D: if you are lucky you will catch a view of a
D: gray whale.
D:
D: It might be the case that you are more
D: interested in bears, those fellows can be
D: seen near ...
#
```

**<br>** force a line break without setting a whole empty line.

Example:

```
#
D: Hint:
D:

D: The 'Be Bear Aware Campaign' is a national,
D: non-profit conservation organization ...
#
```

**<b>text</b>**

set *text* in bold font.

This formatting cannot be used in sections: **F: FILES**, **O: OUTPUT-EXAMPLE**, **F: FILES** and **S: SEE ALSO**.

Example:

```
#
D: Bears are not mean or malicious - they
D: are wild - and all wild animals need
D: their space.
#
```

**<i>text</i>**

set *text* underlined on the terminal and in italic font when producing a HTML output.

This formatting cannot be used in sections: **F: FILES**, **O: OUTPUT-EXAMPLE**, **F: FILES** and **S: SEE ALSO**.

Example:

```
#
D: Blackbears, grizzly bears, polar bears,
D: oh <i>wonderful</i> bears!
#
```

**<u>text</u>**

set *text* underlined on the terminal and in italic font when producing a HTML output.

Basically the **<u>text</u>** is identical to the **<i>text</i>** specification, but to show that the underlining is important to your documenting, this control can be used.

The **<u>text</u>** can be used to "document" that a text is underlined.

This formatting cannot be used in sections: **F: FILES**, **O: OUTPUT-EXAMPLE**, **F: FILES** and **S: SEE ALSO**.

Example:

```
#
D: To see more information about bears,
D: visit the 'Be Bear Aware Campaign':
D:
D: <u>https://bebearaware.org</u>
#
```

## USER DEFINED DOCUMENTATION SECTIONS

It might be the case that the predefined sections as explained above do not fulfill all your needs.

However, it is possible to define additional sections and documentation tags.

To do so you have to list it using the **&:** tag in each recovery script or menu title where you need special sections.

A section definition has the format:

**# &:** *specification* [{ *specification* }]

**specification::= tag:section**

The *tag* is a lowercase letter (a-z), the *section* is the section title. Spaces and tabs are not allowed between the *tag*, the colon ( : ) and the *section* and within the *section* text. If spaces in the *section* title output are needed, they have to be replaced by a % character in the definition.

Example:

```
#
&: e:EMERGENCY%CONTACTS w:WORKAROUNDS
#
#
```

The sections can then be used:

```
#
e: +41 12 345 67 89, 7x24 hour operations
#
w: If you cannot log on to the host dcdbsi20 any more
w: try to connect via the lan console dcdbsi20cons from
w: another server in the farm.
#
```

The new defined sections **EMERGENCY CONTACTS** and **WORKAROUNDS** will be listed after the predefined sections. The output is justified.

**ENVIRONMENT**

-

**EXIT STATUS**

-

**FILES****Recovery Script (=menupoint)**

The recovery script can contain the documentation tags as explained above.

**Menu Title (=menu)**

The title files of menus can contain documentation tags as explained above to add documentation to a menu.

Be aware that the first line of a menu title file contains the title of the menu which is displayed when you invoke the **menu** command in **edrc**. The following lines can contain the documentation tags.

Create/edit/remove the menu title file using the **title** command in **edrc**.

**EXAMPLES**

See documentation of "recovery" script trees distributed with the WA2L/edrc package.

**NAME**

contrib.edrc – list of all contributed commands distributed with WA2L/edrc

**SYNOPSIS**

-

**AVAILABILITY**

WA2L/edrc

**DESCRIPTION**

This man page lists all contributed commands that are part of the core WA2L/edrc package and distributed with it.

If you write own contributed commands do not list it in this man page, due to the fact that your change would be lost after an upgrade of WA2L/edrc. If you send your contributed command to the author of WA2L/edrc your command will be added to this list.

To see where to place manual pages of your own contributed commands, see **contrib(1m)**.

**CONTRIBUTED COMMANDS OF CORE WA2L/edrc**

To see a list of all contributed commands available in your WA2L/edrc installation invoke **help** within **edrc**.

**contrib.apropos(1m)** search the whatis database for strings. See **apropos(1)** for a detail description.

**contrib.bc(1)** An arbitrary precision calculator language that supports arbitrary precision numbers with interactive execution of statements.

There are some similarities in the syntax to the C programming language.

The standard math library is enabled.

See also: **bc(1)**, **contrib.calc(1)**, **contrib.kalc(1)**.

**contrib.calc(1m)** single row calculator using awk. All calculations as possible in **awk(1)** can be performed. Be aware that this command will be denied from startup if *shell* is listed in the **DENY\_LIST**.

See also: **contrib.kalc(1)**, **contrib.bc(1)**.

**contrib.checklist**(1m) print a checklist that can be used to track the disaster recovery progress based on the recovery script tree.

The **checklist** command can also be started from a recovery script.

In this case the environment variable **\$EDRC\_CONTRIB\_CHECKLIST\_ROOTDIR** can be set to produce a checklist for a part of a recovery script tree if needed, as:

```
export EDRC_CONTRIB_CHECKLIST_ROOTDIR=$EDRC_ENTRY_DIR
```

This example produces a checklist starting in the current menu and descending.

In a restricted environment the functionality *contrib.checklist.setrootdir* can be added to the **DENY\_LIST** of the **edrc.cfg**(4) file to deny the corresponding functionality.

**contrib.clock**(1m) display a running clock banner in military format.

In a restricted environment the functionality *contrib.clock.start* can be added to the **DENY\_LIST** of the **edrc.cfg**(4) file to deny the corresponding functionality.

**contrib.clonemenu**(1m)

clone (copy) an existing submenu. Pre-requirements for cloning a submenu are, that the source and the clone submenus exist and the clone menu does not have contents (except a title). Therefore ahead of cloning an existing menu it is needed to create a new menu with the **newmenu edrc** command that will be the clone of the existing submenu.

**contrib.cmmon**(1m) monitor of all MC/SG packages on HP-UX systems having MC/ServiceGuard installed. If an interval of 0 is specified a one time output is provided, else the output is continuously.

**contrib.cmswitch**(1m) switch a MC/SG package to a node. Using this interactive command is much faster then entering all commands needed for a cluster package switch from one to another node. You can restart a package if you specify the host where the package is currently running as the target node. Be aware that the **cmswitch** command does not check if it is possible to switch the package to the specified target node, therefore you should check the possible package switch positions first using the **cmmon** contributed command.

**contrib.cmviewcl**(1m) MC/ServiceGuard state. This is the presentation of the standard **cmviewcl**(1) command available on HP-UX with installed MC/ServiceGuard to **edrc**.

**contrib.countdown(1m)**

countdown control (a stopwatch). The values are stored persistently, therefore after a system reboot the countdown figures are still valid.

In a restricted environment the functionality *contrib.countdown.init*, *contrib.countdown.pause*, *contrib.countdown.resume*, *contrib.countdown.end* and *contrib.countdown.start* can be added to the **DENY\_LIST** of the **edrc.cfg(4)** file to deny the corresponding functionality.

The fore- and background colors can optionally be defined in the global config file **etc/contrib.edrc.countdown.cfg** with the settings **COUNTDOWN\_FOREGROUND\_COLOR=***color* and **COUNTDOWN\_BACKGROUND\_COLOR=***color* where the *color* values are numbers between 0 and 7 (black= 0, red= 1, green= 2, yellow= 3, blue= 4, magenta= 5, cyan= 6, white= 7).

To set the character used to display the big counter (that is normally composed out of "#" characters, use the **COUNTDOWN\_COUNTER\_CHARACTER="***character***"** setting to define a single character to be used instead. You can also use a block character, as: "â" to produce a more prominent counter effect.

The countdown state can also be viewed thru **wa2ledrc\_report(1)**.

**contrib.dirwatch(1m)**

watch and summarize restore progress. With this command directory sizes are monitored and the average size difference over time is calculated. Therefore this command can be used to monitor restore, removal or file copy progress and do an estimation when it would be completed.

**contrib.doc(1m)**

display recovery script documentation. All menu points can contain a documentation that is displayed using this command. If no documentation tags are found in a menu point, only the dynamic documentation header is displayed.

**contrib.drstat(1m)**

LTO library drive status. This command is useful to display the tape drive states of a tape library on HP-UX systems where HP DataProtector (former OmniBack) is installed.

**contrib.edrcenv(1m)**

print the official WA2L/edrc environment variables as the **edrcenv** command. See also **edrcenv(1m)**.

**contrib.edrcupgrade(1m)**

an easy to use interface to efficiently download WA2L/edrc patches from **sourceforge.net**.

In addition the downloaded patches can be deployed and installed. If a direct internet connection is not permitted from the system the connection via a http proxy is also supported. Furthermore the patches could also be provided on a internal web server or locally on the filesystem from where the patch installation should be performed.

In a restricted environment the functionality *contrib.edrcupgrade.start*, *contrib.edrcupgrade.download*, *contrib.edrcupgrade.install*, *contrib.edrcupgrade.setagent*, *contrib.edrcupgrade.setdir*, *contrib.edrcupgrade.useproxy*, *contrib.edrcupgrade.setproxy*, *contrib.edrcupgrade.setproxyauth*, *contrib.edrcupgrade.sethttpauth* and *contrib.edrcupgrade.settargets* can be added to the **DENY\_LIST** of the **edrc.cfg**(4) file to deny the corresponding functionality.

**contrib.find**(1m) find text in recovery scripts header and documentation and print a list of matched menu points. The text to find is a non case sensitive regular expression. See also: **contrib.search**(1m).

**contrib.kalc**(1) A programmable scientific calculator, using RPN (Reverse Polish Notation). It includes over 200 functions and a built-in help system. **kalc** works with real numbers, complex numbers and also integers in other numeric bases. Its has a complete programming language, with control-flow structures such as if and while. It has "unlimited" memory for you to store objects.

See also: **bc**(1), **contrib.bc**(1), **contrib.calc**(1m).

**contrib.leo**(1m) execute dictionary queries to **http://dict.leo.org**. The input defaults and options can optionally be defined in the global config file **etc/contrib.edrc.leo.cfg** which has the identical format as the file **var/contrib/edrc/leo.<session name>** where the inputs are persistently saved in an **edrc** session.

To change the translation language or **leo** options, enter **!** in the **'term to translate'** prompt.

See **leo**(1) for possible language and options settings.

In a restricted environment the functionality *contrib.leo.setlang*, *contrib.leo.setproxy* and *contrib.leo.setopts* can be added to the **DENY\_LIST** of the **edrc.cfg**(4) file to deny the corresponding functionality.

**contrib.license**(1m) print the WA2L/edrc license terms.

**contrib.locations**(1m) print a list of corporate locations with local time.

**contrib.logs**(1m) view any session log file of **edrc**. This is an enhanced log viewer compared to the internal **log** command of **edrc** which displays the log file of the last script run. It is possible to select the logfiles by date or session and to "scroll" efficiently thru a sequence of logs.

In a restricted environment the functionality *contrib.logs.view* should be added to the **DENY\_LIST** of the **edrc.cfg**(4) file.

**contrib.logtail(1m)** give a selection of common logfiles to be displayed with **tail -f** *<selected logfile>* . This is the presentation of the **logtail(1)** command to **edrc**.

**contrib.logview(1m)** give a selection of common logfiles to be displayed with **view** *<selected logfile>* . This is the presentation of the **logview(1)** command to **edrc**.

**contrib.logviewer(1m)** create a browseable LogViewer HTML archive containing all log files between two selected dates. The generated **.zip** file should be encrypted due to the fact that there might be a chance that a logfile could contain passwords.

In **\$EDRC\_SCRIPTS\_BASEDIR/logviewer.fl** a list of extra log files also to be included to the LogViewer archive can be defined. Relative path names are relative to the WA2L/edrc installation.

In a restricted environment the functionality *contrib.logviewer.sendpassword*, *contrib.logviewer.setaddress*, *contrib.logviewer.setdates*, *contrib.logviewer.setdir*, *contrib.logviewer.setemptyxlogs*, *contrib.logviewer.setmode* and *contrib.logviewer.setpassword* can be added to the **DENY\_LIST** of the **edrc.cfg(4)** file to deny the related functionality in the command.

**contrib.motd(1m)** print system wide message of the day (*/etc/motd*).

**contrib.newscripttree(1m)** create a new script tree based on a template.

**contrib.notepad(1m)** a notepad to quickly save ad hoc notes locally.

If the setting **TIMESTAMPS=ON** is set within the notepad file, automatically a timestamp in the military format is added when opening the file for editing.

In a restricted environment the functionality *contrib.notepad.edit*, *contrib.notepad.view*, *contrib.notepad.display*, *contrib.notepad.more* and *contrib.countdown.grep* can be added to the **DENY\_LIST** of the **edrc.cfg(4)** file to deny the corresponding functionality.

The notepad has the name **notepad.<edrc\_config>.txt** and is saved to the **\$EDRC\_CONTRIB\_VARDIR** by default. The save directory can optionally be defined in the global config file **etc/contrib.edrc.notepad.cfg** with the settings **NOTEPAD\_NOTESDIR=directory** .

**contrib.oerr(1m)** resolve Oracle error numbers. This is the presentation of the **oerr(1)** command available on systems where Oracle is installed to **edrc**.

**contrib.omnimon(1m)** OmniBack Session Monitor. With this commands the status of HP DataProtector (former OmniBack) can be continuously displayed on cell servers where

DataProtector is installed.

**contrib.omnistat**(1m) OmniBack Status (running sessions).

**contrib.pwsafe**(1m) interactive password safe that allows also to protect the password data file with a master password if needed.

To change the master password, invoke: **pwsafe -> edit -> change some content -> save**

The password data file is saved in the **\$EDRC\_SCRIPTS\_BASEDIR/pwsafe.dat** file which will be newly created from a template when **pwsafe** is initially called.

The only compulsory field in the password data file is **HANDLE**; which has to be the leftmost one.

If the direct query functionality **pwsafe user@system** is used the **PASSWORD**;, **USER**;, and **SYSTEM\_OR\_APPLICATION**;; fields must also exist.

All other columns are optional and can be changed.

In a restricted environment the functionality *contrib.pwsafe.edit* can be added to the **DENY\_LIST** of the **edrc.cfg**(4) file to deny the functionality to edit the password data file and *contrib.pwsafe.directquery* to deny direct **pwsafe user@system** query within recovery scripts.

Because the **pwsafe** saves the data as semicolon (;) separated file that allows tabs and spaces to format the file, a semicolon, space and tabulator cannot be entered plain in the **PASSWORD** field. Therefore if your password contains a semicolon, replace it with **[:SEMICOLON:]**, if it contains a space, replace it with **[:SPACE:]** and replace a tabulator with **[:TAB:]**.

So if your password is **'my;secret '** the password has to be defined as **my[:SEMICOLON:]secret[:SPACE:]** in the **PASSWORD** field of the **pwsafe**.

The replacement strings **[:SEMICOLON:]**, **[:SPACE:]** and **[:TAB:]** can be changed in the optional configuration file **etc/contrib.edrc.pwsafe.cfg** using the **SEMICOLON=string**, **SPACE=string** and **TAB=string** settings.

The encryption mode default is **AES** which uses **ccrypt**(1).

The encryption mode can be defined in the optional configuration file **etc/contrib.edrc.pwsafe.cfg** using the setting **CRYPT\_MODE=mode** (example: **CRYPT\_MODE=AES256**).

Possible encryption modes are:

**AES** uses **ccrypt**(1) by Peter Selinger.

It is based on the Rijndael block cipher, a version of which is also used in the Advanced Encryption Standard (AES, see <http://www.nist.gov/aes>). This cipher is believed to provide very strong security.

**AES256**

uses **openssl(1)**

The openssl program is a command line tool for using the various cryptography functions of OpenSSL's crypto library from the shell. This cipher is believed to provide very strong security.

**ZIP** uses **zip(1)**

Where security is truly important, use strong encryption such as **AES** or **AES256** instead of the relatively weak standard encryption provided by zip-file utilities.

**ENIGMA**

uses **crypt(1)**

Where security is truly important, use strong encryption such as **AES** or **AES256** instead of the relatively weak encryption provided by the enigma encryption of **crypt(1)**.

**ENIGMA** is provided to handle password safe files produced in early versions of WA2L/edrc but should not be used for new setups.

**NO** uses no encryption even if you answer the dialog to encrypt the file with **y** (yes).

This mode could be used for intermediate solutions where none of the commands needed by the other modes are working on a system.

In general a **pwsafe.nolog** file should exist in the **edrc/contrib/edrc** directory to avoid output logging for this command. This is especially important if you decide to protect the password data file with a master password because else the clear text passwords will be seen in the corresponding log files.

The **pwsafe(3)** command that can be called from outside of **edrc** ( using the command: **edrc/lib/pwsafe [ -c config\_file ] user@system** ) allows also to access the password safe of a recovery script tree.

In this case the master password has to be provided thru the environment variable **\$PWSAFE\_MASTERPASSWORD**.

Of course one using this command should be careful about how to handle the master password.

See **pwsafe(3)** for more information.

**contrib.pid(1m)**

UNIX process list. Select processes from the system. See **pid(1)** for a detail description.

**contrib.ping(1m)**

send ICMP ECHO\_REQUEST packets to network hosts. This interactive command guides thru a more advanced usage of **ping(8)**.

**contrib.pstree**(1m) UNIX process tree. The processes of an optionally specified root process is displayed in a tree form.

**contrib.sane**(1m) reset the tty issuing **stty sane** internally.

**contrib.scriptdocbook**(1m)

create a document book in WA2L/DocBrowser of the current recovery script tree. This command travels thru the whole script tree and generates a HTML page for each menu point. The information in the HTML page is as the **doc** contributed command is called.

In a restricted environment the functionality *contrib.scriptdocbook.checklist*, *contrib.scriptdocbook.setdir*, *contrib.scriptdocbook.setmode*, *contrib.scriptdocbook.setpassword*, *contrib.scriptdocbook.sendpassword* and *contrib.scriptdocbook.setaddress* can be added to the **DENY\_LIST** of the **edrc.cfg**(4) file to deny the related functionality in the command.

A BIBLIOGRAPHY entry is added as the very end of the menu, if the file **scriptdocbook.bib** is created in the **\$EDRC\_SCRIPTS\_BASEDIR** directory. The entries must have the following format:

```
[EDRC]
TITLE= EDRC
SUBTITLE= Enterprise Disaster Recovery Console
VERSION= 1.5.32
DATE= 30.01.2010
COMPANY= ACME Switzerland
AUTHOR= Walther Christian
ISBN= ISBN 0-330-35169-9
FILE= File: edrc_manpages-1.5.32.pdf
PATH= doc/edrc_manpages-1.*.pdf
URL= http://www.acme.ch/doc/edrc.html
```

The compulsory entry is *[reference]*, all other entries are optional.

If the *[----]* reference is used, a horizontal line is inserted. For this special reference no other fields should be set.

The **PATH=***path/filename* defines the path- and filename of the file referenced in the **FILE** entry.

The *path/filename* can be specified as follows:

*/path/filename*  
absolute file location on the system.

*~user/path/filename*  
file located in a **\$HOME** directory of a *user*.

*./path/filename*

file located in the **\$EDRC\_SCRIPTS\_BASEDIR**

*path/filename*

file located relatively to the WA2L/edrc package installation directory.

If the file in **PATH** exists, it is copied to the ScriptDocBook and the entry in **FILE** is a hyperlink pointing to that included file.

If **TODAY** is specified in *date* of **DATE=date**, the current date will be printed. This might be useful when including configuration files into the ScriptDocBook.

When **EDRCREVISION** is specified in *version* of **VERSION=version** the current WA2L/edrc release is printed.

The input defaults can optionally be defined in the global config file **etc/contrib.edrc.scriptdocbook.cfg** and/or the local "recovery" script tree config file **\$EDRC\_SCRIPTS\_BASEDIR/scriptdocbook.cfg** which has the identical format as the file **var/contrib/edrc/scriptdocbook.<session name>** where the inputs are persistently saved in an **edrc** session.

#### **contrib.scriptinstall(1m)**

install a script tree package created with the **contrib.scriptpack(1m)** contributed command into the current script tree.

The current script tree contents is removed (and backed up to the **\$EDRC\_SCRIPTS\_BASEDIR/.sav/scriptinstall/<timestamp>/** directory) before the installation of the script tree package file.

In a restricted environment the functionality *contrib.scriptinstall.install*, *contrib.scriptinstall.list* and *contrib.scriptinstall.patch* can be added to the **DENY\_LIST** of the **edrc.cfg(4)** file to deny the related functionality of the **scriptinstall** contributed command.

#### **contrib.scriptpack(1m)**

pack the current recovery script tree to an archive package (= \*.cpio.gz file).

It is supported to stripe out the passwords stored in **\_env** files and to exclude an existing **pwsafe.dat** file from the script package based on dialog input. Furthermore it can be selected if the recovery script tree package should be saved into a directory or if it should be mailed to a list of recipients.

The generated package can be shared among other system administrators, can be used as a backup snapshot of a recovery tree at a certain point in time (e.g. as proof after a disaster recovery (test)) or to transport a script tree from one environment to another (if a direct **distribute** is not possible or the code transport between environments needs to be carried out by other personnel due to segregation of duty requirements).

The generated package can be installed most efficiently on the target system using the **contrib.scriptinstall(1m)** contributed command.

To easily list/cat the contents of the generated package file, the **llcomp**(1), **lscomp**(1) and **catcomp**(1) can be used.

In a restricted environment the functionality *contrib.scriptpack.cpconfig*, *contrib.scriptpack.cpfiles*, *contrib.scriptpack.setdir*, *contrib.scriptpack.passwdstrip*, *contrib.scriptpack.pwsaferm*, *contrib.scriptpack.setmode*, *contrib.scriptpack.setaddress*, *contrib.scriptpack.sendpassword* and *contrib.scriptpack.setpassword* can be added to the **DENY\_LIST** of the **edrc.cfg**(4) file to deny the related functionality of the **scriptpack** contributed command.

The input defaults can optionally be defined in the config file **etc/contrib.edrc.scriptpack.cfg** which has the identical format as the file **var/contrib/edrc/scriptpack.<session name>** where the inputs are persistently saved in an **edrc** session.

In **\$EDRC\_SCRIPTS\_BASEDIR/scriptpack.fl** a list of other files (one per line) and directories also to be saved to the script package can be defined. Relative path names are relative to the WA2L/edrc installation.

The (include) list can contain wildcards as known from the **ls** and **find** commands. To test an entry run the '**find entry**' command.

To exclude files from the resulting list of (included) files, list it in the **[EXCLUDE]** section, whereas the list entries are treated as regular expressions.

All files before a **[EXCLUDE]** section are treated as includes. If the includes shall be defined after the **[EXCLUDE]** section, an **[INCLUDE]** section has to be defined, else the **[INCLUDE]** keyword is optional.

The files listed in **scriptpack.fl** are packed to the **\$EDRC\_SCRIPTS\_BASEDIR/.sav/scriptpack/file/** directory and the WA2L/edrc configuration files (if chosen in the **scriptpack** dialog) to **\$EDRC\_SCRIPTS\_BASEDIR/.sav/scriptpack/conf/** in the script tree package file.

#### **contrib.scriptsequence**(1m)

globally control the **scriptsequence**(3) command used in **\_env** files or recovery scripts during a session without changing the related file.

When the (m)ode is set to **dynamic** (=default) the action as defined in the **scriptsequence -a action** command line option is used as specified, therefore if **scriptsequence** is used with other actions in other menus, the related action is used.

If the (m)ode is set to **query**, **inform** or **cancel** the setting specified in the contributed command overrides the command line options of **scriptsequence** for the whole session.

When it is chosen to (d)isable and the script sequence checking, the auditing of the direct ascending menu point starts is set on hold as long as it is chosen to (e)nable the checking again (or the session is newly started).

In a restricted environment the functionality *contrib.scriptsequence.print*, *contrib.scriptsequence.disable*, *contrib.scriptsequence.enable*, *contrib.scriptsequence.init* and *contrib.scriptsequence.setmode* can be added to the **DENY\_LIST**

of the **edrc.cfg**(4) file to deny the related functionality of the **scriptsequence** contributed command.

**contrib.scripttree**(1m) print recovery script menu tree. A tree of all scripts and menus in a "Recovery" script tree configuration is printed. If you are looking for a certain menupoint in a big recovery script tree, this command might help.

**contrib.scriptstats**(1m)  
print recovery script menu statistics.

**contrib.search**(1m) search text in recovery scripts. The text to search is a case sensitive regular expression. See also: **contrib.find**(1m).

In a restricted environment the functionality *contrib.search.all*, *contrib.search.code*, *contrib.search.doc*, *contrib.search.file*, and *contrib.search.header*, can be added to the **DENY\_LIST** of the **edrc.cfg**(4) file to deny the related functionality.

**contrib.sessions**(1m) display currently running **edrc**(1m) sessions on the local host. It is also possible to end possibly existing inactive **edrc** sessions.

In a restricted environment the functionality *contrib.sessions.end* can be added to the **DENY\_LIST** of the **edrc.cfg**(4) file to deny the functionality to end inactive sessions.

**contrib.tail**(1m) monitor the growth of a local or remote file using **tail -f file** internally.

To monitor a local file, specify */var/log/mylogfile.log* at the '**file to monitor:**' prompt.

To monitor a remote file specify *hostname:/var/log/mylogfile.log* or *remoteuser@hostname:/var/log/mylogfile.log* at the '**file to monitor:**' prompt.

In a restricted environment the functionality *contrib.tail.remote* can be added to the **DENY\_LIST** of the **edrc.cfg**(4) file to deny the functionality to **tail -f** a remote file.

**contrib.whatis**(1m) search the **whatis** database for strings. See **whatis**(1) for a detail description.

**contrib.whereami**(1m) server environment where logged on. Print the server environment where you are currently logged on. This command helps if you are unsure if you are really logged on to the TEST environment, for instance.

**ENVIRONMENT**

See **contrib(1m)** and **edrc(1m)** section **ENVIRONMENT**.

**EXIT STATUS**

-

**FILES**

See **contrib(1m)** and **contrib.<contributed\_command>(1m)**.

**NAME**

**cpanm** – get, unpack build and install modules from CPAN

**SYNOPSIS**

```

cpanm Test::More # install Test::More
cpanm MIYAGAWA/Plack-0.99_05.tar.gz # full distribution path
cpanm http://example.org/LDS/CGI.pm-3.20.tar.gz # install from URL
cpanm ~/dists/MyCompany-Enterprise-1.00.tar.gz # install from a local file
cpanm --interactive Task::Kensho # Configure interactively
cpanm . # install from local directory
cpanm --installdeps . # install all the deps for the
cpanm -L extlib Plack # install Plack and all non-co.
cpanm --mirror http://cpan.cpantesters.org/ DBI # use the fast-syncing mirror
cpanm --from https://cpan.metacpan.org/ Plack # use only the HTTPS mirror

```

**COMMANDS**

(arguments)

Command line arguments can be either a module name, distribution file, local file path, HTTP URL or git repository URL. Following commands will all work as you expect.

```

cpanm Plack
cpanm Plack/Request.pm
cpanm MIYAGAWA/Plack-1.0000.tar.gz
cpanm /path/to/Plack-1.0000.tar.gz
cpanm http://cpan.metacpan.org/authors/id/M/MI/MIYAGAWA/Plack-0.9990.tar.g
cpanm git://github.com/plack/Plack.git

```

Additionally, you can use the notation using `~` and `@` to specify version for a given module. `~` specifies the version requirement in the CPAN::Meta::Spec format, while `@` pins the exact version, and is a shortcut for `~"== VERSION"`.

```

cpanm Plack~1.0000 # 1.0000 or later
cpanm Plack~">= 1.0000, < 2.0000" # latest of 1.xxxx
cpanm Plack@0.9990 # specific version. same as Plack~"== 0

```

The version query including specific version or range will be sent to MetaCPAN to search for previous releases. The query will search for BackPAN archives by default, unless you specify `--dev` option, in which case, archived versions will be filtered out.

For a git repository, you can specify a branch, tag, or commit SHA to build. The default is master

```

cpanm git://github.com/plack/Plack.git@1.0000 # tag
cpanm git://github.com/plack/Plack.git@devel # branch

```

**-i, --install**

Installs the modules. This is a default behavior and this is just a compatibility option to make it work like `cpan` or `cpanp`.

**--self-upgrade**

Upgrades itself. It's just an alias for:

```
cpanm App::cpanminus
```

**--info**

Displays the distribution information in `AUTHOR/Dist-Name-ver.tar.gz` format in the standard out.

**--installdeps**

Installs the dependencies of the target distribution but won't build itself. Handy if you want to try the application from a version controlled repository such as git.

- ```
cpanm --installdeps .
```
- `--look`
Download and unpack the distribution and then open the directory with your shell. Handy to poke around the source code or do manual testing.
 - `-h, --help`
Displays the help message.
 - `-V, --version`
Displays the version number.

OPTIONS

You can specify the default options in `PERL_CPANM_OPT` environment variable.

- `-f, --force`
Force install modules even when testing failed.
- `-n, --notest`
Skip the testing of modules. Use this only when you just want to save time for installing hundreds of distributions to the same perl and architecture you've already tested to make sure it builds fine.

Defaults to false, and you can say `--no-notest` to override when it is set in the default options in `PERL_CPANM_OPT`.
- `--test-only`
Run the tests only, and do not install the specified module or distributions. Handy if you want to verify the new (or even old) releases pass its unit tests without installing the module.

Note that if you specify this option with a module or distribution that has dependencies, these dependencies will be installed if you don't currently have them.
- `-S, --sudo`
Switch to the root user with `sudo` when installing modules. Use this if you want to install modules to the system perl include path.

Defaults to false, and you can say `--no-sudo` to override when it is set in the default options in `PERL_CPANM_OPT`.
- `-v, --verbose`
Makes the output verbose. It also enables the interactive configuration. (See `--interactive`)
- `-q, --quiet`
Makes the output even more quiet than the default. It only shows the successful/failed dependencies to the output.
- `-l, --local-lib`
Sets the `local::lib` compatible path to install modules to. You don't need to set this if you already configure the shell environment variables using `local::lib`, but this can be used to override that as well.
- `-L, --local-lib-contained`
Same with `--local-lib` but with `--self-contained` set. All non-core dependencies will be installed even if they're already installed.

For instance,

```
cpanm -L extlib Plack
```

would install Plack and all of its non-core dependencies into the directory `extlib`, which can be loaded from your application with:

```
use local::lib '/path/to/extlib';
```

Note that this option does **NOT** reliably work with perl installations supplied by operating system vendors that strips standard modules from perl, such as RHEL, Fedora and CentOS, **UNLESS** you also install packages supplying all the modules that have been stripped. For these systems you will

probably want to install the `perl-core` meta-package which does just that.

--self-contained

When examining the dependencies, assume no non-core modules are installed on the system. Handy if you want to bundle application dependencies in one directory so you can distribute to other machines.

--exclude-vendor

Don't include modules installed under the 'vendor' paths when searching for core modules when the `--self-contained` flag is in effect. This restores the behaviour from before version 1.7023

--mirror

Specifies the base URL for the CPAN mirror to use, such as `http://cpan.cpantesters.org/` (you can omit the trailing slash). You can specify multiple mirror URLs by repeating the command line option.

You can use a local directory that has a CPAN mirror structure (created by tools such as OrePAN or Pinto) by using a special URL scheme `file:///`. If the given URL begins with '/' (without any scheme), it is considered as a file scheme as well.

```
cpanm --mirror file:///path/to/mirror
cpanm --mirror ~/minicpan          # Because shell expands ~ to /home/user
```

Defaults to `http://www.cpan.org/`.

--mirror-only

Download the mirror's `02packages.details.txt.gz` index file instead of querying the CPAN Meta DB. This will also effectively opt out sending your local perl versions to backend database servers such as CPAN Meta DB and MetaCPAN.

Select this option if you are using a local mirror of CPAN, such as minicpan when you're offline, or your own CPAN index (a.k.a darkpan).

--from, -M

```
cpanm -M https://cpan.metacpan.org/
cpanm --from https://cpan.metacpan.org/
```

Use the given mirror URL and its index as the *only* source to search and download modules from.

It works similar to `--mirror` and `--mirror-only` combined, with a small difference: unlike `--mirror` which *appends* the URL to the list of mirrors, `--from` (or `-M` for short) uses the specified URL as its *only* source to download index and modules from. This makes the option always override the default mirror, which might have been set via global options such as the one set by `PERL_CPANM_OPT` environment variable.

Tip: It might be useful if you name these options with your shell aliases, like:

```
alias minicpanm='cpanm --from ~/minicpan'
alias darkpan='cpanm --from http://mycompany.example.com/DPAN'
```

--mirror-index

EXPERIMENTAL: Specifies the file path to `02packages.details.txt` for module search index.

--cpanmetadb

EXPERIMENTAL: Specifies an alternate URI for CPAN MetaDB index lookups.

--metacpan

Prefers MetaCPAN API over CPAN MetaDB.

--cpanfile

EXPERIMENTAL: Specified an alternate path for `cpanfile` to search for, when `--installdeps` command is in use. Defaults to `cpanfile`.

--prompt

Prompts when a test fails so that you can skip, force install, retry or look in the shell to see what's going wrong. It also prompts when one of the dependency failed if you want to proceed the installation.

Defaults to false, and you can say `--no-prompt` to override if it's set in the default options in `PERL_CPANM_OPT`.

--dev

EXPERIMENTAL: search for a newer developer release as well. Defaults to false.

--reinstall

`cpanm`, when given a module name in the command line (i.e. `cpanm Plack`), checks the locally installed version first and skips if it is already installed. This option makes it skip the check, so:

```
cpanm --reinstall Plack
```

would reinstall `Plack` even if your locally installed version is latest, or even newer (which would happen if you install a developer release from version control repositories).

Defaults to false.

--interactive

Makes the configuration (such as `Makefile.PL` and `Build.PL`) interactive, so you can answer questions in the distribution that requires custom configuration or `Task::distributions`.

Defaults to false, and you can say `--no-interactive` to override when it's set in the default options in `PERL_CPANM_OPT`.

--pp, --pureperl

Prefer Pure perl build of modules by setting `PUREPERL_ONLY=1` for `MakeMaker` and `--pureperl-only` for `Build.PL` based distributions. Note that not all of the CPAN modules support this convention yet.

--with-recommends, --with-suggests

EXPERIMENTAL: Installs dependencies declared as `recommends` and `suggests` respectively, per META spec. When these dependencies fail to install, `cpanm` continues the installation, since they're just recommendation/suggestion.

Enabling this could potentially make a circular dependency for a few modules on CPAN, when `recommends` adds a module that `recommends` back the module in return.

There's also `--without-recommend` and `--without-suggests` to override the default decision made earlier in `PERL_CPANM_OPT`.

Defaults to false for both.

--with-develop

EXPERIMENTAL: Installs develop phase dependencies in META files or `cpanfile` when used with `--installdeps`. Defaults to false.

--with-configure

EXPERIMENTAL: Installs configure phase dependencies in `cpanfile` when used with `--installdeps`. Defaults to false.

--with-feature, --without-feature, --with-all-features

EXPERIMENTAL: Specifies the feature to enable, if a module supports optional features per META spec 2.0.

```
cpanm --with-feature=opt_csv Spreadsheet::Read
```

the features can also be interactively chosen when `--interactive` option is enabled.

`--with-all-features` enables all the optional features, and `--without-feature` can select a feature to disable.

`--configure-timeout`, `--build-timeout`, `--test-timeout`

Specify the timeout length (in seconds) to wait for the configure, build and test process. Current default values are: 60 for configure, 3600 for build and 1800 for test.

`--configure-args`, `--build-args`, `--test-args`, `--install-args`

EXPERIMENTAL: Pass arguments for configure/build/test/install commands respectively, for a given module to install.

```
cpanm DBD:mysql --configure-args="--cflags=... --libs=..."
```

The argument is only enabled for the module passed as a command line argument, not dependencies.

`--scandeps`

DEPRECATED: Scans the dependencies of given modules and output the tree in a text format. (See `--format` below for more options)

Because this command doesn't actually install any distributions, it will be useful that by typing:

```
cpanm --scandeps Catalyst::Runtime
```

you can make sure what modules will be installed.

This command takes into account which modules you already have installed in your system. If you want to see what modules will be installed against a vanilla perl installation, you might want to combine it with `-L` option.

`--format`

DEPRECATED: Determines what format to display the scanned dependency tree. Available options are `tree`, `json`, `yaml` and `dists`.

`tree` Displays the tree in a plain text format. This is the default value.

`json`, `yaml`

Outputs the tree in a JSON or YAML format. JSON and YAML modules need to be installed respectively. The output tree is represented as a recursive tuple of:

```
[ distribution, dependencies ]
```

and the container is an array containing the root elements. Note that there may be multiple root nodes, since you can give multiple modules to the `--scandeps` command.

`dists` `dists` is a special output format, where it prints the distribution filename in the *depth first order* after the dependency resolution, like:

```
GAAS/MIME-Base64-3.13.tar.gz
GAAS/URI-1.58.tar.gz
PETDANCE/HTML-Tagset-3.20.tar.gz
GAAS/HTML-Parser-3.68.tar.gz
GAAS/libwww-perl-5.837.tar.gz
```

which means you can install these distributions in this order without extra dependencies. When combined with `-L` option, it will be useful to replay installations on other machines.

`--save-dists`

Specifies the optional directory path to copy downloaded tarballs in the CPAN mirror compatible directory structure i.e. `authors/id/A/AU/AUTHORS/Foo-Bar-version.tar.gz`

If the distro tarball did not come from CPAN, for example from a local file or from GitHub, then it will be saved under `vendor/Foo-Bar-version.tar.gz`.

`--uninst-shadows`

Uninstalls the shadow files of the distribution that you're installing. This eliminates the confusion if you're trying to install core (dual-life) modules from CPAN against perl 5.10 or older, or modules that used to be XS-based but switched to pure perl at some version.

If you run `cpanm` as root and use `INSTALL_BASE` or equivalent to specify custom installation path, you **SHOULD** disable this option so you won't accidentally uninstall dual-life modules from the core include path.

Defaults to true if your perl version is smaller than 5.12, and you can disable that with `--no-uninst-shadows`.

NOTE: Since version 1.3000 this flag is turned off by default for perl newer than 5.12, since with 5.12 `@INC` contains `site_perl` directory *before* the perl core library path, and uninstalling shadows is not necessary anymore and does more harm by deleting files from the core library path.

`--uninstall, -U`

Uninstalls a module from the library path. It finds a packlist for given modules, and removes all the files included in the same distribution.

If you enable `local::lib`, it only removes files from the `local::lib` directory.

If you try to uninstall a module in `perl` directory (i.e. core module), an error will be thrown.

A dialog will be prompted to confirm the files to be deleted. If you pass `-f` option as well, the dialog will be skipped and uninstallation will be forced.

`--cascade-search`

EXPERIMENTAL: Specifies whether to cascade search when you specify multiple mirrors and a mirror doesn't have a module or has a lower version of the module than requested. Defaults to false.

`--skip-installed`

Specifies whether a module given in the command line is skipped if its latest version is already installed. Defaults to true.

NOTE: The `PERL5LIB` environment variable have to be correctly set for this to work with modules installed using `local::lib`, unless you always use the `-l` option.

`--skip-satisfied`

EXPERIMENTAL: Specifies whether a module (and version) given in the command line is skipped if it's already installed.

If you run:

```
cpanm --skip-satisfied CGI DBI~1.2
```

`cpanm` won't install them if you already have `CGI` (for whatever versions) or have `DBI` with version higher than 1.2. It is similar to `--skip-installed` but while `--skip-installed` checks if the *latest* version of CPAN is installed, `--skip-satisfied` checks if a requested version (or not, which means any version) is installed.

Defaults to false.

`--verify`

Verify the integrity of distribution files retrieved from CPAN using `CHECKSUMS` file, and `SIGNATURES` file (if found in the distribution). Defaults to false.

Using this option does not verify the integrity of the `CHECKSUMS` file, and it's unsafe to rely on this option if you're using a CPAN mirror that you do not trust.

`--report-perl-version`

Whether it reports the locally installed perl version to the various web server as part of User-Agent. Defaults to true unless CI related environment variables such as `TRAVIS`, `CI` or `AUTOMATED_TESTING` is enabled. You can disable it by using `--no-report-perl-version`.

`--auto-cleanup`

Specifies the number of days in which `cpanm`'s work directories expire. Defaults to 7, which means old work directories will be cleaned up in one week.

You can set the value to 0 to make `cpan` never cleanup those directories.

--man-pages

Generates man pages for executables (man1) and libraries (man3).

Defaults to true (man pages generated) unless `-L|--local-lib-contained` option is supplied in which case it's set to false. You can disable it with `--no-man-pages`.

--lwp

Uses LWP module to download stuff over HTTP. Defaults to true, and you can say `--no-lwp` to disable using LWP, when you want to upgrade LWP from CPAN on some broken perl systems.

--wget

Uses GNU Wget (if available) to download stuff. Defaults to true, and you can say `--no-wget` to disable using Wget (versions of Wget older than 1.9 don't support the `--retry-connrefused` option used by cpanm).

--curl

Uses cURL (if available) to download stuff. Defaults to true, and you can say `--no-curl` to disable using cURL.

Normally with `--lwp`, `--wget` and `--curl` options set to true (which is the default) cpanm tries LWP, Wget, cURL and HTTP::Tiny (in that order) and uses the first one available.

ENVIRONMENT VARIABLES**PERL_CPANM_HOME**

The directory cpanm should use to store downloads and build and test modules. Defaults to the `.cpanm` directory in your user's home directory.

PERL_CPANM_OPT

If set, adds a set of default options to every cpanm command. These options come first, and so are overridden by command-line options.

DESCRIPTION

This manual page documents the GNU version of **cpio**. **cpio** copies files into or out of a cpio or tar archive, which is a file that contains other files plus information about them, such as their file name, owner, time-stamps, and access permissions. The archive can be another file on the disk, a magnetic tape, or a pipe. **cpio** has three operating modes.

In copy-out mode, **cpio** copies files into an archive. It reads a list of filenames, one per line, on the standard input, and writes the archive onto the standard output. A typical way to generate the list of filenames is with the **find** command; you should give **find** the **-depth** option to minimize problems with permissions on directories that are unwritable or not searchable.

In copy-in mode, **cpio** copies files out of an archive or lists the archive contents. It reads the archive from the standard input. Any non-option command line arguments are shell globbing patterns; only files in the archive whose names match one or more of those patterns are copied from the archive. Unlike in the shell, an initial **'.'** in a filename does match a wildcard at the start of a pattern, and a **'/'** in a filename can match wildcards. If no patterns are given, all files are extracted.

In copy-pass mode, **cpio** copies files from one directory tree to another, combining the copy-out and copy-in steps without actually using an archive. It reads the list of files to copy from the standard input; the directory into which it will copy them is given as a non-option argument.

cpio supports the following archive formats: binary, old ASCII, new ASCII, crc, HPUX binary, HPUX old ASCII, old tar, and POSIX.1 tar. The binary format is obsolete because it encodes information about the files in a way that is not portable between different machine architectures. The old ASCII format is portable between different machine architectures, but should not be used on file systems with more than 65536 i-nodes. The new ASCII format is portable between different machine architectures and can be used on any size file system, but is not supported by all versions of **cpio**; currently, it is only supported by GNU and Unix System V R4. The crc format is like the new ASCII format, but also contains a checksum for each file which **cpio** calculates when creating an archive and verifies when the file is extracted from the archive. The HPUX formats are provided for compatibility with HPUX's **cpio** which stores device files differently.

The tar format is provided for compatability with the **tar** program. It can not be used to archive files with names longer than 100 characters, and can not be used to archive "special" (block or character devices) files. The POSIX.1 tar format can not be used to archive files with names longer than 255 characters (less unless they have a **'/'** in just the right place).

By default, **cpio** creates binary format archives, for compatibility with older **cpio** programs. When extracting from archives, **cpio** automatically recognizes which kind of archive it is reading and can read archives created on machines with a different byte-order.

Some of the options to **cpio** apply only to certain operating modes; see the SYNOPSIS section for a list of which options are allowed in which modes.

OPTIONS

-0, --null

In copy-out and copy-pass modes, read a list of filenames terminated by a null character instead of a newline, so that files whose names contain newlines can be archived. GNU **find** is one way to produce a list of null-terminated filenames.

-a, --reset-access-time

Reset the access times of files after reading them, so that it does not look like they have just been read.

-A, --append

Append to an existing archive. Only works in copy-out mode. The archive must be a disk file specified with the **-O** or **-F (--file)** option.

-b, --swap

In copy-in mode, swap both halfwords of words and bytes of halfwords in the data. Equivalent to **-sS**. Use this option to convert 32-bit integers between big-endian and little-endian machines.

-B

Set the I/O block size to 5120 bytes. Initially the block size is 512 bytes.

--block-size=BLOCK-SIZE

Set the I/O block size to BLOCK-SIZE * 512 bytes.

-c

Use the old portable (ASCII) archive format.

-C IO-SIZE, --io-size=IO-SIZE

Set the I/O block size to IO-SIZE bytes.

-d, --make-directories

Create leading directories where needed.

-E FILE, --pattern-file=FILE

In copy-in mode, read additional patterns specifying filenames to extract or list from FILE. The lines of FILE are treated as if they had been non-option arguments to **cpio**.

-f, --nonmatching

Only copy files that do not match any of the given patterns.

-F, --file=archive

Archive filename to use instead of standard input or output. To use a tape drive on another machine as the archive, use a filename that starts with 'HOSTNAME:'. The hostname can be preceded by a username and an '@' to access the remote tape drive as that user, if you have permission to do so (typically an entry in that user's '~/.rhosts' file).

--force-local

With **-F**, **-I**, or **-O**, take the archive file name to be a local file even if it contains a colon, which would ordinarily indicate a remote host name.

-H FORMAT, --format=FORMAT

Use archive format FORMAT. The valid formats are listed below; the same names are also recognized in all-caps. The default in copy-in mode is to automatically detect the archive format, and in copy-out mode is "bin".

bin The obsolete binary format.

odc The old (POSIX.1) portable format.

- `newc` The new (SVR4) portable format, which supports file systems having more than 65536 i-nodes.
- `crc` The new (SVR4) portable format with a checksum added.
- `tar` The old tar format.
- `ustar` The POSIX.1 tar format. Also recognizes GNU **tar** archives, which are similar but not identical.
- `hpbm` The obsolete binary format used by HP-UX's `cpio` (which stores device files differently).
- `hpdc` The portable format used by HP-UX's `cpio` (which stores device files differently).
- `-i, --extract`
Run in copy-in mode.
- `-I archive`
Archive filename to use instead of standard input. To use a tape drive on another machine as the archive, use a filename that starts with 'HOSTNAME:'. The hostname can be preceded by a username and an '@' to access the remote tape drive as that user, if you have permission to do so (typically an entry in that user's '~/.rhosts' file).
- `-k` Ignored; for compatibility with other versions of **cpio**.
- `-l, --link`
Link files instead of copying them, when possible.
- `-L, --dereference`
Dereference symbolic links (copy the files that they point to instead of copying the links).
- `-m, --preserve-modification-time`
Retain previous file modification times when creating files.
- `-M MESSAGE, --message=MESSAGE`
Print MESSAGE when the end of a volume of the backup media (such as a tape or a floppy disk) is reached, to prompt the user to insert a new volume. If MESSAGE contains the string "%d", it is replaced by the current volume number (starting at 1).
- `-n, --numeric-uid-gid`
In the verbose table of contents listing, show numeric UID and GID instead of translating them into names. Also extracts tar archives using the numeric UID and GID instead of the user/group names. (**cpio** archives are always extracted using the numeric UID and GID.)
- `--no-absolute-filenames`
In copy-in mode, create all files relative to the current directory, even if they have an absolute file name in the archive.
- `--no-preserve-owner`
In copy-in mode and copy-pass mode, do not change the ownership of the files; leave them owned by the user extracting them. This is the default for non-root users, so that users on System V don't inadvertently give away files.
- `-o, --create`
Run in copy-out mode.
- `-O archive`
Archive filename to use instead of standard output. To use a tape drive on another machine as the archive, use a filename that starts with 'HOSTNAME:'. The hostname can be preceded by a username and an '@' to access the remote tape drive as that user, if you have permission to do so (typically an entry in that user's '~/.rhosts' file).
- `--only-verify-crc`
When reading a CRC format archive in copy-in mode, only verify the CRC's of each file in the archive, don't actually extract the files.

- p, --pass-through*
Run in copy-pass mode.
- quiet*
Do not print the number of blocks copied.
- r, --rename*
Interactively rename files.
- R [user][:][group], --owner [user][:][group]*
In copy-out and copy-pass modes, set the ownership of all files created to the specified user and/or group. Either the user or the group, or both, must be present. If the group is omitted but the ":" or "." separator is given, use the given user's login group. Only the super-user can change files' ownership.
- rsh-command=COMMAND*
Notifies **mt** that it should use **COMMAND** to communicate with remote devices instead of **/usr/bin/ssh** or **/usr/bin/rsh**.
- sparse*
In copy-in and copy-pass modes, write files with large blocks of zeros as sparse files.
- s, --swap-bytes*
In copy-in mode, swap the bytes of each halfword (pair of bytes) in the files.
- S, --swap-halfwords*
In copy-in mode, swap the halfwords of each word (4 bytes) in the files.
- t, --list*
Print a table of contents of the input.
- u, --unconditional*
Replace all files, without asking whether to replace existing newer files with older files.
- v, --verbose*
List the files processed, or with *-t*, give an 'ls -l' style table of contents listing. In a verbose table of contents of a ustar archive, user and group names in the archive that do not exist on the local system are replaced by the names that correspond locally to the numeric UID and GID stored in the archive.
- V --dot*
Print a "." for each file processed.
- version*
Print the **cpio** program version number and exit.

NAME

crfile – create a dump file with a certain size

SYNOPSIS

edrc/bin/crfile [**-h**]

crfile { **-k** | **-m** | **-g** } *size* **-f** *filename*

AVAILABILITY

WA2L/edrc

DESCRIPTION

Create a dump file with a size to be specified.

Ahead of writing the file, it is checked if the file size does not exceed the available space on the file system.

OPTIONS

-h usage message.

-k file *size* specified in kilobytes.

-m file *size* specified in megabytes.

-g file *size* specified in gigabytes.

size file size.

-f *filename*
 name of the dump file to be created.

ENVIRONMENT

-

EXIT STATUS

0 no error.

1 **crfile** cannot write to the file specified in the **-f** option.

- 2** operating system not supported, yet. See **osid(3)** if you get this error.
- 3** file size of dump file exceeds available filesystem space.
- 4** usage listed.
- 5** file creation aborted.
- 6** the **size** specified was not greater than 0.
- 7** file specified in the **-f** option already exists.
- 11** a temporary directory could not be claimed or created in **/tmp**. Check the system temporary directory **/tmp** if you get this error, it is an indicator of system intrusion.

NAME

crond – daemon to execute scheduled commands (cron in WA2L/edrc)

SYNOPSIS

edrc/lib/crond [**-h** | **-i** | **-n** | **-p** | **-P** | **-s** | **-m** *mail-command*]

crond -x [ext,sch,proc,pars,load,misc,test,bit]

crond -V

DESCRIPTION

Crond is started from **edrcinit**(1m).

Crond searches **edrc/var/spool/cron/** for crontab files which are named after accounts in **/etc/passwd**. The found crontabs are loaded into the memory. **Crond** also searches for any files in the **edrc/var/spool/cron.d/** directory, which have a different format (see **crontab**(4)). **Crond** examines all stored crontabs and checks each job to see if it needs to be run in the current minute. When executing commands, any output is mailed to the owner of the crontab (or to the user specified in the **MAILTO** environment variable in the crontab, if such exists). Any job output can also be sent to syslog by using the **-s** option.

Crond checks its crontables' modtimes every minute to check for any changes and reloads the crontables which have changed. There is no need to restart **Crond** after some of the crontables were modified.

Crond checks these files and directories:

edrc/etc/crontab

system crontab. The file is empty/not used by default.

edrc/var/spool/cron.d/

directory that contains system cronjobs stored for different users.

edrc/var/spool/cron/

directory that contains user crontables created by the **ecrontab** command (this is the most commonly used job scheduling method).

Note that the **ecrontab**(1) command updates the modtime of the spool directory whenever it changes a crontab.

Daylight Saving Time and other time changes

Local time changes of less than three hours, such as those caused by the Daylight Saving Time changes, are handled in a special way. This only applies to jobs that run at a specific time and jobs that run with a granularity greater than one hour. Jobs that run more frequently are scheduled normally.

If time was adjusted one hour forward, those jobs that would have run in the interval that has been skipped will be run immediately. Conversely, if time was adjusted backward, running the same job twice is avoided.

Time changes of more than 3 hours are considered to be corrections to the clock or the timezone, and the new time is used immediately.

It is possible to use different time zones for crontables. See **crontab**(4) for more information.

OPTIONS

- h** Prints a help message and exits.
- i** Disables inotify support (inotify is not compiled in).
- m** This option allows you to specify a shell command to use for sending **Crond** mail output instead of using **sendmail(8)**. This command must accept a fully formatted mail message (with headers) on standard input and send it as a mail message to the recipients specified in the mail headers. Specifying the string **off** (i.e., **crond -m off**) will disable the sending of mail.
- n** Tells the daemon to run in the foreground. This can be useful when starting it out of init.
- f** the same as **-n**, consistent with other crond implementations.
- p** Allows **Crond** to accept any user set crontables.
- P** Don't set PATH. PATH is instead inherited from the environment.
- s** This option will direct **Crond** to send the job output to the system log using **syslog(3)**. This is useful if your system does not have **sendmail(8)**, installed or if mail is disabled.
- x** This option allows you to set debug flags.
- V** Print version and exit.

SIGNALS

When the *SIGHUP* is received, the **Crond** daemon will close and reopen its log file. This proves to be useful in scripts which rotate and age log files. Naturally, this is not relevant if **Crond** was built to use **syslog(3)**.

CAVEATS

All crontab files have to be regular files or symlinks to regular files, they must not be executable or writable for anyone else but the owner. This requirement can be overridden by using the **-p** option on the crond command line. If inotify support is in use, changes in the symlinked crontabs are not automatically noticed by the cron daemon. The cron daemon must receive a SIGHUP signal to reload the crontabs. This is a limitation of the inotify API.

The syslog output will be used instead of mail, when sendmail is not installed.

NAME

cronhandler – handle cron and at in a cluster environment

SYNOPSIS

edrc/bin/cronhandler [**-h**]

cronhandler -a { save | load | start } -s *save_dir* -u { *userlist* | *homedir* }

cronhandler -a stop -s *save_dir*

AVAILABILITY

WA2L/edrc

DESCRIPTION

With **cronhandler** it is possible to transfer **crontab** and **at** entries from one cluster node to another. This is important if users related to a MC/ServiceGuard package are allowed to use **cron** and **at**.

cronhandler takes care of the user's **crontab** entries and transfers even defined **at** jobs to the other cluster node. Furthermore all **cron** and **at** control files (**cron.allow**, **cron.deny**, **at.allow**, **at.deny**) are maintained properly. Therefore it is ensured that a user related to a package can only define **crontab** and **at** entries if this user logs on to the node where the package is up and running (i.e. where the **crontab** entries and **at** jobs are loaded).

The basic concept of **cronhandler** is to save all **crontab** and **at** entries to a set of files located on a filesystem related to a MC/ServiceGuard package.

After the package switch the saved files are loaded and applied to the system where the package is starting. **crontab** entries are loaded like they were defined on the source node. If the execution of an **at** job falls into the short period of time between the package stop and a restart, the job will be rescheduled (current time + 60 seconds contingency time) on the target node. If there is a job planned on the target node at the same time a job from the source node likes to run, the job from the source node will be rescheduled one second after an already existing job.

Failover mechanism:

Preparation

- + permanently write cron/at entries to the *save_dir*
(**cronhandler** started as daemon)

Failover situation

- (1) save cron/at entries to the *save_dir*
(**cronhandler -a save ...**).
- (2) stop cluster package on current node
- 3 start cluster package on alternate node
- 4 load cron/at entries from *save_dir*
(**cronhandler -a load ...**)

() = step will only happen if the cluster node can be shut down properly.

After a **save** or **load** the **cron** daemon is restarted to ensure that all possibly changed **crontab** definitions and **at** jobs are recognized again.

OPTIONS

-h usage message.

-a action:

save

save **crontab** entries and current **at** jobs of user(s) specified with the **-u** option to the directory specified with the **-s** option. After a save of the **crontab** entries and all current **at** jobs, the **crontab** and **at** jobs are removed from the system and the related user is no longer allowed to define **crontab** and **at** entries on the node. **save** is normally used to save **crontab** and **at** entries during a controlled cluster switch while halting the cluster package. After invoking **-a save** the **cronhandler** daemon is stopped.

load

load a previous saved **crontab** and **at** specification and allow the related user **crontab** and **at** definition where granted. After loading the saved jobs **cronhandler** enters into daemon mode and continues to run in the background. In daemon mode **cronhandler** writes all **crontab** entries and current **at** jobs of user(s) specified with the **-u** option in a regular interval to the directory specified with the **-s** option. The write interval can be specified in the config file **edrc/etc/cronhandler.cfg** with the setting **WRITE_INTERVAL**.

stop

stop the **cronhandler** daemon. Normally you don't have to stop the daemon by hand, it is stopped automatically after the **save** action has been invoked. The **stop** option is provided for ease of administration during maintenance tasks on the system when you don't want to have the **cronhandler** daemon running, but all **cron** and **at** jobs must continue to run.

start

start the **cronhandler** daemon. Normally you don't have to start the daemon by hand, it is started automatically after the **load** action has been invoked. The **start** option is provided for ease of administration during maintenance tasks on the system when you don't want to have the **cronhandler** daemon running, but all **cron** and **at** jobs must continue to run.

write

this action does no longer exist as command line option and is ignored if issued. It has no side effects (except for a logfile entry) if this option is still used.

-s *save_dir*

directory where to save all **crontab** and **at** data. See section **FILES** for the recommended permissions of this directory.

-u

userlist a list of users separated by commas. The **crontab** and **at** entries of those users will be saved to the directory specified by the **-s** option.

homedir

if you have many users or if you like to react **cronhandler** dynamically on new/removed users you should use the definition of a \$HOME directory. All subdirectories of the *homedir* will be considered as users. Therefore the username has to match with the \$HOME (what is normally the case). See section **EXAMPLES** for a common setup.

SIGNALS

The following signals are handled by **cronhandler**. Do not use other signals as those listed below, as long as you do not really know what you are doing and what the consequences are. In general there is no need to invoke those signals by your own, this signals are used for inter process communication of **cronhandler**.

- INT** kill the process with **kill -SIGINT PID** . Issuing this signal, the daemon will end.
- TERM** kill the process without an argument (**kill PID**). Issuing this signal, the daemon will end.

EXIT STATUS

- 0** no error.
- 2** operating system is not supported. See **osid(3)** if you get this error.
- 4** usage listed.
- 7** the **cronhandler** has been started with the depreciated command line option **-a write**. This option is ignored from command line.
- 11** a temporary directory could not be claimed or created in **/var/tmp**. Check the system temporary directory **/var/tmp** if you get this error, it is an indicator of system intrusion.

FILES**etc/cronhandler.cfg**

configuration file of **cronhandler**, see **cronhandler(4)** for more information. The configfile is reloaded in the interval defined in **WRITE_INTERVAL**, therefore all settings (except **LOCKDIR**) can be changed without stopping the **cronhandler** daemon.

var/log/cronhandler.log

logfile of **cronhandler**.

<save_dir>/

directory where to save the **cron** and **at** definitions. Due to security reasons the directory permissions should be root:sys, 0751 . You should not use this directory to save other data because it is maintained completely by **cronhandler**.

<save_dir>/cronhandler/action=save

flagfile if the last **cronhandler** action was **save**. This file contains the nodename where the action has been executed.

<save_dir>/cronhandler/action=write

flagfile if the last **cronhandler** action was **write**. This file contains the nodename where the action has been executed.

<save_dir>/cronhandler/<username>/cron/<username>

saved crontab.

<save_dir>/cronhandler/<username>/cron.allow=YES

flagfile if user was defined in **cron.allow** on source node.

<save_dir>/cronhandler/<username>/cron.allow=NO

flagfile if user was not defined in **cron.allow** on source node.

<save_dir>/cronhandler/<username>/at.allow=YES

flagfile if user was defined in **at.allow** on source node.

<save_dir>/cronhandler/<username>/at.allow=NO

flagfile if user was not defined in **at.allow** on source node.

<save_dir>/cronhandler/<username>/at/

directory to save currently defined **at** jobs for the user.

<homedir>/

user's \$HOME directory.

/usr/lib/cron/cron.allow /usr/lib/cron/cron.deny

List of users which are allowed/denied to create a **crontab**(1) on HP-UX and Solaris.

/etc/cron.allow /etc/cron.deny

List of users which are allowed/denied to create a **crontab**(1) on Linux.

/sbin/init.d/cron

Start/Stop script for **cron**(1m) on HP-UX.

/etc/init.d/crond

Start/Stop script for **cron**(8) on Linux and on Solaris.

/var/spool/cron/atjobs

at job spool dir accessed on Solaris only.

EXAMPLES

1) Common setup using MC/ServiceGuard

In this example the users `sys_asys` and `ora_asys` are related to a MC/ServiceGuard (see also <http://www.hp.com>) package. Both users are allowed to create at jobs, but only the user `ora_asys` is allowed to have an own crontab. The filesystem `/data_asys1` goes with the package (=moving disks) and is therefore used to carry the cron entries and at jobs from one to the other node.

1.1) `/etc/passwd` (on all nodes):

```
:
:
ora_asys:adSKflweIRsdf:253:101::/data_asys1/home/ora_asys:/bin/ksh
sys_asys:Wm9MyTyKtRI2c:106:104::/data_asys1/home/sys_asys:/sbin/sh
:
:
```

1.2) `/usr/lib/cron/cron.allow` (on active node):

```
:
ora_asys
:
```

1.3) `/usr/lib/cron/at.allow` (on active node):

```
:
ora_asys
sys_asys
:
```

1.4) `cd /data_asys1/home; ls -ald` (on active node):

```
drwxr-xr-x  6 ora_asys oinstall ... ora_asys/
drwxrwxr-x 10 sys_asys autosys  ... sys_asys/
```

HINT: `/data_asys1` goes with the asys package.

1.5) `/etc/cmcluster/asys_sv1_prod/asys_sv1_prod.cntl` (on all nodes):

```
:
:

function customer_defined_run_cmds
{
    # ADD customer defined run commands.

    :
    :

    /opt/edrc/bin/cronhandler -a load \
        -s /data_asys1/pkg_cron -u /data_asys1/home

    test_return 51
}
```

```

:
:

function customer_defined_halt_cmds
{
    # ADD customer defined halt commands.

    /opt/edrc/bin/cronhandler -a save \
        -s /data_asys1/pkg_cron -u /data_asys1/home

    :
    :

    test_return 52
}

:
:

```

1.6) Initial steps to initiate the daemon to work (on active node):

Save the current **crontab** definitions and **at** jobs to disk:

/opt/edrc/bin/cronhandler -a save -s /data_asys1/pkg_cron -u /data_asys1/home

```

cronhandler - handle cron and at entries in a cluster environment,

stop cronhandler daemon for '/data_asys1/pkg_cron' ...(not running)
save crontab and at entries ...
user: asys_sv1 ...
    clear old cron/at saves ... done.
    disable cron execution ... done.
    save at jobs ...
    done.
    disable at execution ... done.
done.
user: ora_sys ...
    clear old cron/at saves ... done.
    save cron entries ... done.
    remove cron entries ... done.
    disable cron execution ... done.
    save at jobs ...
        save at job 1189778400.a ... done.
        remove at job 1189778400.a ... done.
    done.
    disable at execution ... done.
done.
user: sys_asys ...
    clear old cron/at saves ... done.
    disable cron execution ... done.
    save at jobs ...
        save at job 1189778500.a ... done.
        remove at job 1189778500.a ... done.

```

```

        save at job 1189779100.a ... done.
        remove at job 1189779100.a ... done.
    done.
    disable at execution ... done.
done.
clean up remaining saves (corpses) ...
done.
restart cron ...(wait 5 seconds)... done.
done.

```

Immediately load the saved **crontab** definitions and **at** jobs from disk back into the system:

/opt/edrc/bin/cronhandler -a load -s /data_asys1/pkg_cron -u /data_asys1/home

```

cronhandler - handle cron and at entries in a cluster environment,

load crontab and at entries ...
    asys_sv1 ...
        cron usage not authorized
        at usage not authorized
    done.
    ora_sys ...
        enable cron execution ... done.
        load cron entries ... done.
        enable at execution ... done.
        load at jobs ...
            load at job 1189778400.a ... done.
        done.
    done.
    sys_asys ...
        cron usage not authorized
        enable at execution ... done.
        load at jobs ...
            load at job 1189778500.a ... done.
            load at job 1189779100.a ... done.
        done.
    done.
    restart cron ...(wait 5 seconds)... done.
done.
start cronhandler daemon for '/data_asys1/pkg_cron' ...(PID=18790).

```

From now on the **cronhandler** daemon writes **crontab** definitions and defined **at** jobs in a regular interval to disk and no manual interventions are needed. The correct stop and start is handled via the MC/ServiceGuard control script (**/etc/cmcluster/asys_sv1_prod/asys_sv1_prod.cntl**).

SEE ALSO

edrcintro(1), **osid(3)**, **cron(1m)**, **at(1)**, **crontab(1)**, **cronhandler.cfg(4)**,
Managing MC/ServiceGuard, March 2002, Hewlett-Packard Company, Part No: B3936-90055"

NOTES

Currently **cronhandler** runs on HP-UX (tested on 11.00 and 11.11), Linux (tested on RedHat 7.2) Solaris (tested on SunOS 5.6). Enhancements to support other operating systems might be realized on request (please ask the author).

In an earlier version of **cronhandler** a root **crontab** entry was needed to write the **crontab** definitions and the **at** jobs to disk - this is no longer the case. Eventually existing **/opt/edrc/bin/cronhandler -a write ...** calls are ignored and do not influence the **cronhandler**. To avoid logfile entries, the old **crontab** entries should be removed eventually.

Use **cron.allow** and **at.allow** to control **crontab** and **at** job definition.

BUGS

-

AUTHOR

cronhandler was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

cronhandler.cfg – configuration file for cronhandler

SYNOPSIS

edrc/etc/cronhandler.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **cronhandler** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS

LOG Log output dir of **cronhandler**. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation.

Example: LOG=/var/opt/edrc/log

Default: LOG=var/log

LOCKDIR

Lock dir of **cronhandler**. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation. In General it is not recommended to set the lockdir within EDRC, locate it in a system own directory. This is the only setting that is ignored when the **cronhandler.cfg** file is reloaded.

Example: LOCKDIR=/var/run/cronhandler

Default: LOCKDIR=var/lock

WRITE_INTERVAL

Interval in seconds of writing the **crontab** definitions and **at** jobs to disk. This is also the interval in which the configfile is reloaded.

Example: WRITE_INTERVAL=120

Default: WRITE_INTERVAL=60

CRON_START_DELAY

Delay in seconds between **cron** stop and **cron** start after a **save** or **load** action.

Example: CRON_START_DELAY=10

Default: CRON_START_DELAY=5

CONTINGENCY

Contingency time in seconds when a **at** job has to be rescheduled. A reschedule occurs when a **at** job falls into the time between a package stop (**save** action) and restart (**load** action).

Example: CONTINGENCY=90

Default: CONTINGENCY=60

NAME

crontab – files used to schedule the execution of programs (cron in WA2L/edrc)

DESCRIPTION

A **crontab** file contains instructions for the **crond**(3) daemon in the following simplified manner: "run this command at this time on this date". Each user can define their own crontab. Commands defined in any given crontab are executed under the user who owns that particular crontab. Uucp and News usually have their own crontabs, eliminating the need for explicitly running **su**(1) as part of a cron command.

Blank lines, leading spaces, and tabs are ignored. Lines whose first non-white space character is a pound-sign (#) are comments, and are not processed. Note that comments are not allowed on the same line as cron commands, since they are considered a part of the command. Similarly, comments are not allowed on the same line as environment variable settings.

An active line in a crontab is either an environment setting or a cron command. An environment setting is of the form:

```
name = value
```

where the white spaces around the equal-sign (=) are optional, and any subsequent non-leading white spaces in *value* is a part of the value assigned to *name*. The *value* string may be placed in quotes (single or double, but matching) to preserve leading or trailing white spaces.

Several environment variables are set up automatically by the **crond**(3) daemon. *SHELL* is set to **/bin/sh**, and *LOGNAME* and *HOME* are set from the **/etc/passwd** line of the crontab's owner. *HOME* and *SHELL* can be overridden by settings in the crontab; *LOGNAME* can not.

(Note: the *LOGNAME* variable is sometimes called *USER* on BSD systems and is also automatically set).

In addition to *LOGNAME*, *HOME*, and *SHELL*, **crond**(3) looks at the *MAILTO* variable if a mail needs to be sent as a result of running any commands in that particular crontab. If *MAILTO* is defined (and non-empty), mail is sent to the specified address. If *MAILTO* is defined but empty (*MAILTO=""*), no mail is sent. Otherwise, mail is sent to the owner of the crontab. This option is useful if you decide to use **/bin/mail** instead of **/usr/lib/sendmail** as your mailer. Note that **/bin/mail** does not provide aliasing and UUCP usually does not read its mail. If *MAILFROM* is defined (and non-empty), it is used as the envelope sender address, otherwise, "root" is used.

(Note: Both *MAILFROM* and *MAILTO* variables are expanded, so setting them as in the following example works as expected: *MAILFROM=cron-\$USER@cron.com* (*\$USER* is replaced by the system user))

By default, cron sends a mail using the 'Content-Type:' header of 'text/plain' with the 'charset=' parameter set to the 'charmap/codeset' of the locale in which **crond**(3) is started up, i.e., either the default system locale, if no *LC_** environment variables are set, or the locale specified by the *LC_** environment variables (see *locale*(7)). Different character encodings can be used for mailing cron job outputs by setting the *CONTENT_TYPE* and *CONTENT_TRANSFER_ENCODING* variables in a crontab to the correct values of the mail headers of those names.

The *CRON_TZ* variable specifies the time zone specific for the cron table. The user should enter a time according to the specified time zone into the table. The time used for writing into a log file is taken from the local time zone, where the daemon is running.

The *RANDOM_DELAY* variable allows delaying job startups by random amount of minutes with upper limit specified by the variable. The random scaling factor is determined during the cron daemon startup so it remains constant for the whole run time of the daemon.

The format of a cron command is similar to the V7 standard, with a number of upward-compatible extensions. Each line has five time-and-date fields followed by a **username** (if this is the **system** crontab file), and followed by a command. Commands are executed by **crond**(3) when the 'minute', 'hour', and 'month of the year' fields match the current time, *and* at least one of the two 'day' fields ('day of month', or 'day of

week') match the current time (see "Note" below).

Note that this means that non-existent times, such as the "missing hours" during the daylight savings time conversion, will never match, causing jobs scheduled during the "missing times" not to be run. Similarly, times that occur more than once (again, during the daylight savings time conversion) will cause matching jobs to be run twice.

crond(3) examines cron entries every minute.

The time and date fields are:

| field | allowed values |
|--------------|--------------------------------------|
| ----- | ----- |
| minute | 0-59 |
| hour | 0-23 |
| day of month | 1-31 |
| month | 1-12 (or names, see below) |
| day of week | 0-7 (0 or 7 is Sunday, or use names) |

A field may contain an asterisk (*), which always stands for "first-last".

Ranges of numbers are allowed. Ranges are two numbers separated with a hyphen. The specified range is inclusive. For example, 8-11 for an 'hours' entry specifies execution at hours 8, 9, 10, and 11. The first number must be less than or equal to the second one.

Randomization of the execution time within a range can be used. A random number within a range specified as two numbers separated with a tilde is picked. The specified range is inclusive. For example, 6~15 for a 'minutes' entry picks a random minute within 6 to 15 range. The random number is picked when crontab file is parsed. The first number must be less than or equal to the second one. You might omit one or both of the numbers specifying the range. For example, ~ for a 'minutes' entry picks a random minute within 0 to 59 range.

Lists are allowed. A list is a set of numbers (or ranges) separated by commas. Examples: "1,2,5,9", "0-4,8-12".

Step values can be used in conjunction with ranges. Following a range with "/<number>" specifies skips of the number's value through the range. For example, "0-23/2" can be used in the 'hours' field to specify command execution for every other hour (the alternative in the V7 standard is "0,2,4,6,8,10,12,14,16,18,20,22"). Step values are also permitted after an asterisk, so if specifying a job to be run every two hours, you can use "*/2".

Names can also be used for the 'month' and 'day of week' fields. Use the first three letters of the particular day or month (case does not matter). Ranges and lists of names are allowed. Examples: "mon,wed,fri", "jan-mar".

If the UID of the owner is 0 (root), the first character of a crontab entry can be "-" character. This will prevent cron from writing a syslog message about the command being executed.

The "sixth" field (the rest of the line) specifies the command to be run. The entire command portion of the line, up to a newline or a "%" character, will be executed by **/bin/sh** or by the shell specified in the SHELL variable of the cronfile. A "%" character in the command, unless escaped with a backslash (\), will be changed into newline characters, and all data after the first % will be sent to the command as standard input.

Note: The day of a command's execution can be specified in the following two fields — 'day of month', and 'day of week'. If both fields are restricted (i.e., do not contain the "*" character), the command will be run when *either* field matches the current time. For example,

"30 4 1,15 * 5" would cause a command to be run at 4:30 am on the 1st and 15th of each month, plus every Friday.

A crontab file syntax can be tested before an install using the -T option. See **ecrontab(1)** for details.

EXAMPLE CRON FILE

```
# use /bin/sh to run commands, no matter what /etc/passwd says
SHELL=/bin/sh
# mail any output to 'paul', no matter whose crontab this is
MAILTO=paul
#
CRON_TZ=Japan
# run five minutes after midnight, every day
5 0 * * * $HOME/bin/daily.job >> $HOME/tmp/out 2>&1
# run at 2:15pm on the first of every month -- output mailed to paul
15 14 1 * * $HOME/bin/monthly
# run at 10 pm on weekdays, annoy Joe
0 22 * * 1-5 mail -s "It's 10pm" joe%Joe,%%Where are your kids?%
23 0-23/2 * * * echo "run 23 minutes after midn, 2am, 4am ..., everyday"
5 4 * * sun echo "run at 5 after 4 every sunday"
```

FILES

edrc/etc/crontab
main system crontab file.

edrc/var/spool/cron/
a directory for storing crontabs defined by users.

edrc/var/spool/cron.d/
a directory for storing system crontabs.

SEE ALSO

edrcintro(1), **crond(3)**, **ecronnext(1)**, **ecrontab(1)**

EXTENSIONS

These special time specification "nicknames" which replace the 5 initial time and date fields, and are prefixed with the '@' character, are supported:

```
@reboot : Run once after reboot.
@yearly : Run once a year, ie. "0 0 1 1 *".
```

@annually : Run once a year, ie. "0 0 1 1 *".
@monthly : Run once a month, ie. "0 0 1 * *".
@weekly : Run once a week, ie. "0 0 * * 0".
@daily : Run once a day, ie. "0 0 * * *".
@hourly : Run once an hour, ie. "0 * * * *".

CAVEATS

crontab files have to be regular files or symlinks to regular files, they must not be executable or writable for anyone else but the owner. This requirement can be overridden by using the **-p** option on the **crond** command line. If inotify support is in use, changes in the symlinked crontabs are not automatically noticed by the cron daemon. The cron daemon must receive a SIGHUP signal to reload the crontabs. This is a limitation of the inotify API.

cron requires that each entry in a crontab end in a newline character. If the last entry in a crontab is missing a newline (i.e. terminated by EOF), cron will consider the crontab (at least partially) broken. A warning will be written to syslog.

NAME

crypt – encode/decode files

SYNOPSIS

[*password*]

DESCRIPTION

reads from the standard input and writes on the standard output. *password* is a key that selects a particular transformation. If no *password* is given, demands a key from the terminal and turns off printing while the key is being typed in. encrypts and decrypts with the same key:

The latter command decrypts the file and prints the clear version.

Files encrypted by are compatible with those treated by the editor in encryption mode (see *ed*(1)).

Security of encrypted files depends on three factors: the fundamental method must be hard to solve; direct search of the key space must be infeasible; “sneak paths” by which keys or clear text can become visible must be minimized.

implements a one-rotor machine designed along the lines of the German Enigma, but with a 256-element rotor. Methods of attack on such machines are widely known; thus crypt provides minimal security.

The transformation of a key into the internal settings of the machine is deliberately designed to be expensive; i.e., to take a substantial fraction of a second to compute. However, if keys are restricted to, for example, three lowercase letters, then encrypted files can be read by expending only a substantial fraction of five minutes of machine time.

Since the key is an argument to the command, it is potentially visible to users executing the or a derivative (see *ps*(1)). The choice of keys and key security are the most vulnerable aspect of

EXAMPLES

The following example demonstrates the use of to edit a file that the user wants to keep strictly confidential:

```
...
...
...
```

Note that the option is the encryption mode of and prompts the user for the same key with which the file was encrypted.

WARNINGS

If output is piped to and the encryption key is given on the command line, can leave terminal modes in a strange state (see *nroff*(1) and *stty*(1)).

If two or more files encrypted with the same key are concatenated and an attempt is made to decrypt the result, only the the first of the original files is decrypted correctly.

FILES

for typed key

DESCRIPTION

filter to process CSV data.

The field separator of the CSV data is a semicolon (;).

If comma (,) separated data needs to be processed, first use **csv c2s**, if tab separated data needs to be processed, first use **csv t2s** and if whitespace separated data needs to be processed, first use the **csv w2s** command to convert the comma separated data to semicolon separated.

OPTIONS

-h usage.

csv command [*options*]
 command with options to use with the CSV data stream. Description of available commands, see below.

csv addcol *COLNAME* ["*column data*"]
 add a column with the name *COLNAME* and the given "*column data*".

csv c2s convert comma separations to semicolon separations.

csv cat clean and join broken CSV lines.

csv cat:authorized_keys
 cat data with '~user/.ssh/authorized_keys' format as CSV.

csv cat:fstab
 cat data with '/etc/fstab' format as CSV.

csv cat:group
 cat data with '/etc/group' format as CSV.

csv cat:known_hosts
 cat data with '~user/.ssh/known_hosts' format as CSV.

csv cat:mtab
 cat data with '/etc/mtab' format as CSV.

csv cat:crontab
 cat data with user '/var/spool/cron/(...)/crontab' format as CSV.

csv cat:syscrontab
 cat data with system wide '/etc/crontab' format as CSV.

csv cat:mailcap
 cat data with '/etc/mailcap' format as CSV.

csv cat:mailcap:nokey
 cat data with '/etc/mailcap' format as CSV without keys in field data.

csv cat:oratab
 cat data with 'oratab' format as CSV.

csv cat:passwd
 cat data with '/etc/passwd' format as CSV.

csv cat:protocols

cat data with **'/etc/protocols'** format as CSV.

csv cat:rpc

cat data with **'/etc/rpc'** format as CSV.

csv cat:services

cat data with **'/etc/services'** format as CSV.

csv cat:shadow

cat data with **'/etc/shadow'** format as CSV.

csv cat:datalist.dat

cat data with **'edrc/var/lots/object/datalist.dat'** format as CSV.

csv cat:edrcinit.cfg

cat data with **'edrc/etc/edrcinit.cfg'** format as CSV.

csv cat:filedist.block

cat data with **'edrc/etc/filedist.block'** format as CSV.

csv cat:fssum.cfg

cat data with **'edrc/etc/fssum.cfg'** format as CSV.

csv cat:hostlist.dat

cat data with **'edrc/etc/hostlist.dat'** format as CSV.

csv cat:lgcheckd.cfg

cat data with **'edrc/etc/lgcheckd.cfg'** format as CSV.

csv cat:logcheckd.cfg

cat data with **'edrc/etc/logcheckd.cfg'** format as CSV.

csv cat:name_index

cat data with **'..name_index'** format as CSV.

csv cat:osid.dat

cat data with **'edrc/etc/osid.dat'** format as CSV.

csv cat:osid.dat.WA2L

cat data with **'edrc/etc/osid.dat.WA2L'** format as CSV.

csv cat:pscount.kp

cat data with **'edrc/var/pscount/*/ <app>.kp'** format as CSV.

csv cat:role_option.cfg

cat data with '**edrc/etc/role_option.cfg**' format as CSV.

csv cat:schedule.dat

cat data with '**edrc/var/lots/object/schedule.dat**' format as CSV.

csv cat:timezone.dat

cat data with '**edrc/etc/timezone.dat**' format as CSV.

csv cat:volume.dat

cat data with '**edrc/var/lots/object/volume.dat**' format as CSV.

csv cat:list cat data with **csv list** command output format as CSV.

csv cat:name

cat data with **name(1)** command output format as CSV.

csv cat:revision

cat data with **revision(1)** command output format as CSV.

csv cat:usage

cat data with **usage(1)** command output format as CSV.

csv cat:avtar

cat data with Avamar **avtar** command output format as CSV.

csv cat:mccli

cat data with Avamar **mccli** command output format as CSV.

csv comm file

compare **stdin** with a *file*, rows common to both (**stdin** and *file*).

The data from **stdin** and the *file*, is sorted by the **csv comm** command prior to comparing it.

csv comm:both file

compare **stdin** with a *file*, rows common to both (**stdin** and *file*).

The data from **stdin** and the *file*, is sorted by the **csv comm:both** command prior to comparing it.

csv comm:stdin file

compare **stdin** with a *file*, rows unique to **stdin**.

The data from **stdin** and the *file*, is sorted by the **csv comm:stdin** command prior to comparing it.

csv comm:file file

compare **stdin** with a *file*, rows unique to *file*.

The data from **stdin** and the *file*, is sorted by the **csv comm:file** command prior to comparing it.

csv concat *file...*

concatenate **stdin** with a space separated list of *files*.

csv count count number of data rows.

csv diff *file*

compare **stdin** with a *file*.

The data from **stdin** and the *file*, is sorted by the **csv diff** command prior to comparing it.

The file indicators <, > and = as known from the **diff**(1) command on normal files, are shown in an additional column with the name **DIFF**.

csv data print CSV data.

csv head *lines*

print *lines* lines from the beginning of CSV data.

csv header

print CSV header.

csv join *file* [*joinfieldnum1* [*joinfieldnum2*]]

join **stdin** with a file.

csv list print data as formatted list.

csv list:nocount

print data as formatted list without output of the count line.

csv list:noemptycols

print data as formatted list but do not list columns that have no data (which are empty).

csv list:noemptycols:nocount

print data as formatted list but do not list columns that have no data (which are empty) without output of the count line.

csv list:noemptyrows

print data as formatted list but do not list rows that have no data (which are empty).

csv list:noemptyrows:nocount

print data as formatted list but do not list rows that have no data (which are empty) without output of the count line.

csv list:noempty

print data as formatted list but do not list rows and columns that have no data (which are empty).

csv list:noempty:nocount

print data as formatted list but do not list rows and columns that have no data (which are empty) without output of the count line.

csv lscol list columns of CSV header as numbered list.

csv md5 [*COLNAME*]

add a md5 checksum column and optionally name the **MD5** column with *COLNAME*.

csv number [*COLNAME*]

number rows and optionally name the **NR** column with *COLNAME*.

csv order "*COLNAME1;COLNAME2; ... ;COLNAME_n*"

change order of columns.

csv outer *file* [*joinfieldnum1* [*joinfieldnum2* [*unpairablesfilenum*]]]

join **stdin** with a file including unpairable lines.

csv record print CSV line as record.

csv record:nocount

print CSV line as record without output of the count line.

csv renamecol "*OLDCOL1;OLDCOL2; ... ;OLDCOL_n*" "*NEWCOL1;NEWCOL2; ... ;NEWCOL_n*"

rename columns.

csv row *linenumber*

print data of record with *linenumber* from the CSV data.

csv sed "*sed script*"

stream editor (**sed**) for csv data.

csv sed:silent "*sed script*"

stream editor (**sed**) for csv data without automatic printing of pattern space (equals to **sed -n** "*sed script*").

csv select "*COLNAME1;COLNAME2; ... ;COLNAME_n*"

select columns.

csv sort [*sort_options*]

sort data.

csv tac print CSV data in reverse.

csv tail *lines*

print *lines* lines from the end of CSV data.

- csv timestamp** [*COLNAME*]
add a timestamp column in the military format *YYYY-MM-DD HH:MM:SS* and optionally name the **TIMESTAMP** column with *COLNAME*.
- csv transpose**
transpose the CSV file.
- csv t2s** convert tabulator separations to semicolon separations.
- csv unselect** "*COLNAME1;COLNAME2; ... ;COLNAME_n*"
de-select columns.
- csv variable** [*prefix*]
print CSV line as initialize-able variables **COLNAME="field"** or *prefix***COLNAME="field"**.
- csv variable:array** [*prefix*]
print CSV line as initialize-able numbered variables **COLNAME[#]="field"** or *prefix***COLNAME[#]="field"**.
- csv variable:number** [*prefix*]
print CSV line as initialize-able variables array **COLNAME_#="field"** or *prefix***COLNAME_#="field"**.
- csv where** "*regex*"
select data with a regular expression.
- csv where:ignorecase** "*regex*"
select data non case sensitive with a regular expression.
- csv wherenot** "*regex*"
inverse data select with a regular expression.
- csv wherenot:ignorecase** "*regex*"
inverse data select non case sensitive with a regular expression.
- csv match** "*wildcard*"
select data with a wildcard expression.
- csv match:ignorecase** "*wildcard*"
select data non case sensitive with a wildcard expression.
- csv matchnot** "*wildcard*"
inverse data select with a wildcard expression.
- csv matchnot:ignorecase** "*wildcard*"
inverse data select non case sensitive with a wildcard expression.

csv w2s convert whitespace separations to semicolon separations.

ENVIRONMENT

\$TMPDIR

temporary base directory (default=**/tmp/**) needed to sort data.

If file space shortages are observed set this variable to a location with sufficient space.

EXIT STATUS

0 no error.

1 error.

4 usage displayed.

NAME

csvcat – clean, join and cat csv file or stream

SYNOPSIS

edrc/lib/csvcat [**-h**]

csvcat *file...*

cat *file...* | **csvcat**

AVAILABILITY

WA2L/edrc

DESCRIPTION

prepare and print a CSV file or stream for further processing.

Comment lines that begin with a hash (#) and empty lines are eliminated.

If the first line is **sep=...** (as seen in some programatically produced **CSV** files) this line is removed.

Lines that are distributed over multiple lines thru a backslash (\) at the end of the line are joined.

White spaces before and after the field separator (;) are eliminated.

OPTIONS

-h usage message.

file... file(s) to be printed.

ENVIRONMENT

NAME

csvq – SQL-like query language for csv

SYNOPSIS

edrc/lib/csvq [**--help**]

csvq [*options*] [*subcommand*] ["*query*" | *argument*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

csvq is a command line tool to operate **CSV** files.

You can read, update, delete **CSV** records with SQL-like query.

You can also execute multiple operations sequentially in managed transactions by passing a procedure or using the interactive shell. In the multiple operations, you can use variables, cursors, temporary tables, and other features.

For the whole documentation see: <https://mithrandie.github.io/csvq/>

OPTIONS

--help print usage message.

csvq_options

NAME

csv2worksheet – load CSV file into Excel Worksheet

SYNOPSIS

edrc/lib/csv2worksheet [**-h**]

csv2worksheet [**-f filename**] [{ **-e** | **-n** } *sheet*] [**-d delimiter**] [**-o** [*col*] , [*row*]] [**-s cols**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

With the **csv2worksheet** command a CSV file (comma separated ASCII file) can be loaded into an existing Microsoft Excel (TM) **.xlsx** spreadsheet.

An Excel spreadsheet, also known as workbook, consists of one or more sheets, also known as worksheets. This worksheets are represented as named tabs in a workbook. With **csv2worksheet** it is possible to load a file that is structured into rows and the rows consist of fields separated by a delimiter into a worksheet. The row field separator defaults to ; but can be specified with the **-d** option.

This is an easy method to automatically create "nice looking" Excel reports based on plain ASCII data without the need to create Excel makros or to develop hard to maintain programs that create the whole Excel sheet on the fly. The idea is to load the data into a separate "data" worksheet and to perform the calculations, graphical data representation, statistics etc. in an other worksheet in the same Excel workbook which is not affected by the data load.

The advantage of this method is, that reports can be generated automatically without manual intervention (except the generation of the initial Excel sheet) even on non Windows systems, such as Unix or Linux.

It is possible to specify the name on an existing worksheet or to create a new worksheet while loading the data, dependent on your requirements.

However, the **csv2worksheet** command cannot overwrite existing data in a worksheet.

The origin of the data load can be specified. This does mean that data does not need to be loaded into a worksheet starting in cell A:1, a different cell can be specified. This enables the user to load multiple CSV data into the same worksheet as long as the data is loaded into ascending areas of an empty worksheet range.

OPTIONS

-h usage message.

-f filename

Excel file where the CSV data should be loaded into. This file has to be writeable by the user invoking **csv2worksheet**. Be aware, that **csv2worksheet** alters the data in the Excel file specified in the **-f** option and does not create a copy of the file. Therefore you should keep your

original template in a safe place. A good practice is to copy the original Excel file first and then to load the data. If you do not specify a file with the **-f filename** option, the file **io.xlsx** is used as a default.

-e existing_worksheet_name

load the CSV data into the existing worksheet with the name specified. If the worksheet does not exist in the workbook, **csv2worksheet** does exit without loading any data. If you neither specify a file with the **-e** nor the **-n** option, **csv2worksheet** tries to load the data into the existing **DATA** worksheet, that is therefore the default.

-n new_worksheet_name

load the CSV data into a worksheet with the name specified. If the worksheet does not exist currently, it is created at the end of the already existing worksheets.

-d delimiter

delimiter that separates the fields of a row. The delimiter is not restricted to a single character, but spaces or tabulators are not allowed. The default delimiter is **;** if this option is not specified.

-o column_number,row_number

column number and row number where to start the load of the CSV data into the worksheet. If this option is not specified, the data is loaded starting at column 1,1, that means the upper left corner of the data loaded is in cell A:1.

The following examples are allowed specifications: **-o 3,8** (start at cell C:8), **-o ,8** (start at cell A:8), **-o 3**, (start at cell C:1), **-o** , (start at cell A:1).

-s column_list

comma separated list of source column numbers that should be loaded explicitly as text. The normal behaviour of **csv2worksheet** is, that whenever a number is recognized in the input, it is loaded as a floating point value while all other data is loaded as text. See also **NOTES** section.

If you specify **-s 0** all columns will be loaded as text.

ENVIRONMENT

CSV2WORKSHEET_JAVA_OPTIONS="*option*"

additional options for the **Java** JVM process.

1) Example: set heap space

```
CSV2WORKSHEET_JAVA_OPTIONS="-Xmx8g"; export CSV2WORKSHEET_JAVA_OPTIONS
```

to set the **Java** heap space to 8 GBytes which might be needed when loading a large **csv** file into a worksheet and receiving the "java.lang.OutOfMemoryError: Java heap space" error.

To query the default JVM heap size use:

```
java -XX:+PrintFlagsFinal -version | grep HeapSize
```

2) Example: relocate temp files

```
CSV2WORKSHEET_JAVA_OPTIONS="-Djava.io.tmpdir=/dat/tmp"
export CSV2WORKSHEET_JAVA_OPTIONS
```

to relocate the temporary files generated by **csv2worksheet** from **/tmp/** to **/dat/tmp/**.

EXIT STATUS

| | |
|----------|--|
| 0 | no error. |
| 1 | the specified worksheet in the workbook could not be opened or created. |
| 2 | Excel file is not writable by the user invoking csv2worksheet or it does not exist. |
| 4 | usage displayed. |
| 5 | version displayed. |
| 6 | cannot load data. Ensure the worksheet range where to load the data is empty. |

FILES

edrc/var/csv2worksheet/io.xlsx

Empty Microsoft Excel workbook. This workbook contains the worksheets **Sheet1**, **Sheet2**, **Sheet3** and **DATA** and can be used as a template to load data into.

EXAMPLES

1) load data into an existing worksheet

Load file **data.csv** into the existing worksheet '*current*' of file **statistics.xlsx**

```
[ /data_dwh1/dat/exports ]
[ root@dwh_dbl_prod ][ksh]: cat data.csv | \
                           csv2worksheet -f statistics.xlsx \
                           -e current
```

csv2worksheet - load a CSV file into an Excel sheet, by Chr. Walther

```
load data ...
  sheet 'statistics.xlsx/current' opened.
  load origin is '1,1'.
  data delimiter is ';'.
  explicit text columns are ''.
  load rows ...
    1 ..... (36)
    2 ..... (36)
```

```

3      ..... (36)
4      ..... (36)
5      ..... (15)
6      ..... (36)
7      ..... (36)
8      ..... (36)
9      ..... (29)
10     ..... (36)
done.
done.

```

2) load data into a new worksheet using input redirection

Load file **data.csv** into the new worksheet '*Month=Sep*' of file **statistics.xlsx** starting in cell C:5 using 'input redirection' instead of a pipe

```

[ /data_dwh1/dat/exports ]
[ root@dwh_db1_prod ][ksh]: csv2worksheet < data.csv \
                           -f statistics.xlsx \
                           -n Month='date +%b' -o 3,5

```

csv2worksheet - load a CSV file into an Excel sheet, by Chr. Walther

```

load data ...
  sheet 'statistics.xlsx/Month=Sep' created.
  load origin is '3,5'.
  data delimitator is ';'.
  explicit text columns are ''.
  load rows ...
5      ..... (36)
6      ..... (36)
7      ..... (36)
8      ..... (36)
9      ..... (15)
10     ..... (36)
11     ..... (36)
12     ..... (36)
13     ..... (29)
14     ..... (36)
done.
done.

```

3) load data into existing worksheet using in here

Load data into the existing worksheet '*DATA*' of file **io.xlsx** using the 'in here' mechanism

```

[ /data_dwh1/dat/exports ]
[ root@dwh_db1_prod ][ksh]: cat <<EOM | csv2worksheet
NAME;MIN;MAX
alpha;100;200
bravo;150;250
charly;155;400
EOM

```

csv2worksheet - load a CSV file into an Excel sheet, by Chr. Walther

```
load data ...
  sheet 'io.xlsx/DATA' opened.
  load origin is '1,1'.
  data delimiter is ';'.
  explicit text columns are ''.
  load rows ...
    1      ... (3)
    2      ... (3)
    3      ... (3)
    4      ... (3)
  done.
done.
```

4) set a single cell of existing worksheet

Set a single cell (E:20) of an existing worksheet 'DATA' of file **io.xlsx**

```
[ /data_dwh1/dat/exports ]
[ root@dwh_db1_prod ][ksh]: echo "Load at: `date`" | \
                           csv2worksheet -o 5,20
```

csv2worksheet - load a CSV file into an Excel sheet, by Chr. Walther

```
load data ...
  sheet 'io.xlsx/DATA' opened.
  load origin is '5,20'.
  data delimiter is ';'.
  explicit text columns are ''.
  load rows ...
    20      . (1)
  done.
done.
```

5) explicitly load certain columns as text

Load data into the existing worksheet 'DATA' of file io.xlsx using the 'in here' mechanism and explicitly load the columns 4 and 5 (of the input) as text into the worksheet.

```
[ /data_dwh1/dat/exports ]
[ root@dwh_db1_prod ][ksh]: cat <<EOM | csv2worksheet -s 4,5
NAME;MIN;MAX;SERIAL;PHONE
alpha;100;200;2009063009250001;080007121941
bravo;150;250;2009063009250002;080006061944
charly;155;400;2009063009250003;080020071969
EOM
```

csv2worksheet - load a CSV file into an Excel sheet, by Chr. Walther

```
load data ...
  sheet 'io.xlsx/DATA' opened.
  load origin is '1,1'.
```

```

data delimiter is ';' .
explicit text columns are '4,5' .
load rows ...
    1      ..... (3)
    2      ..... (3)
    3      ..... (3)
    4      ..... (3)
done .
done .

```

SEE ALSO

edrcintro(1), Microsoft Excel Help

NOTES

If the field in the CSV file is recognized as a number, it is loaded into the worksheet as a "double" floating point value (+/-1.79769313486231570 * 10³⁰⁸). Otherwise it is loaded as a text (string) value.

csv2worksheet uses "**Jakarta POI – Java API To Access Microsoft Format Files**" of the Apache Jakarta project. See <http://jakarta.apache.org/poi/> for more information about the progress of the implementation.

BUGS

Beginning with version 1.1.11 of 2022, the **csv2worksheet** command does no longer support the since 2006 supported old ***.xls** file format. This for the sake of being now able to process very large worksheet files without memory and performance problems.

Therefore if still jobs are present that operate with ***.xls** files, convert this files to ***.xlsx**.

NAME

datalist.dat – datalist definition for lots

SYNOPSIS

edrc/var/lots/objects/datalist.dat
VARDIR/objects/datalist.dat

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the datalist definition for the **lots** command.

In this file sets of files are defined that can be scheduled to be saved in the **schedule.dat** file.

FILEFORMAT

The fileformat is a list of definitions that have the format

DATALIST ; DESCRIPTION ; DIRECTORY ;

Rows starting with a **#** are considered as comments. Empty lines are allowed, too.

It is allowed to have multiple lines in the file having the identical *DATALIST* definition, but different *DIRECTORY* entries to enable to save data from different directories with one schedule. If multiple lines are defined, ensure that all *DESCRIPTION* entries of those lines are identical due to the fact that only the first *DESCRIPTION* definition of a *DATALIST* will be saved in the **lots** job and conserved for the duration of the data retention.

OPTIONS*DATALIST*

name of the data list, the set of directories or files to be saved. To save data defined here in the *DATALIST*, *DIRECTORY* pair, a relating *DATALIST* entry in the **schedule.dat** file must exist.

DESCRIPTION

description of the datalist respectively of the data to be saved.

Be aware that this should be a meaningful description due to the fact that this data is saved for a long time and people having done the definition might have moved on before the data might be needed for restore.

DIRECTORY

definition of the directory or file(s) to be saved in this set. If a directory is specified, all files and subdirectories are saved. If a file is specified only the matching file(s) are saved. It is allowed to use wild-cards, but if you want to save multiple directories that cannot be defined using wild-cards, create multiple *DATALIST* entries.

To resolve the files/directories to be saved, **lots** uses

find DIRECTORY -print

internally. Therefore if you are unsure if your definition is correct, use this command for verification or start a **collect** run using '**lots -a collect -d DATALIST**' to verify the setting.

EXAMPLES

```
#
# var/lots/objects/datalist.dat - data save definition
#
# [00] 30.09.2009 CWa Initial Version
#
#DATALIST      ;DESCRIPTION                                ;DIRECTORY;
DB_CEDPROD     ;Database, PRODUCTION, PReCED              ;/orara/be/
DB_COIPROD     ;Database, PRODUCTION, OpenCO              ;/orara/be/
DB_DMSPROD     ;Database, PRODUCTION, Phoenix DocumentManagementSystem ;/orara/be/

DB_ASYPROD     ;Database, PRODUCTION, AutoSYS Job Scheduler ;/orara/be/

SQL_CHaT       ;MSSQL Database, PRODUCTION, CHaT          ;/dat/sqlra
SQL_plumdb     ;MSSQL Database, PRODUCTION, plumdb        ;/dat/sqlra
```

SEE ALSO

edrcintro(1), **schedule.dat(4)**, **volume.dat(4)**, **lots.cfg(4)**, **lots(1m)**

NOTES

To verify the datalist definitions, use the **lots -a list_datalist** command. Only correct entries will be listed.

BUGS

-

NAME

`daemon_wrapper` – wrap daemons written in Bourne shell

SYNOPSIS

`edrc/bin/daemon_command -> .daemon_wrapper`

AVAILABILITY

WA2L/edrc

DESCRIPTION

start commands that run as daemons out of the **edrc/lib/daemon** directory.

The *daemon_command* is started with the directory first changed to root (*/*) if **PWDPRESERVE=daemon_command** is not set in the *daemon_command*.

The **.daemon_wrapper** command is used for two purposes:

- 1) start a command from the root (*/*) working directory.
- 2) allow multiple versions of the same command to be present in the **lib/daemon/** directory without to pollute the **bin/** directory with all the symbolic links.

Typically commands that need to be present in different versions simultaneously are commands having long run times, daemons or commands for special purposes, where the program might run during a patch update of the package.

Examples for daemon type commands are: **logcheckd(1m)**, **job(1)** and **passwdsyncd(1m)**.

An example for a long running program is: **lots(1m)**.

An example for a special purpose program is: **patchinstall(1m)**.

OPTIONS

-

ENVIRONMENT

-

EXIT STATUS

- 101** Bourne shell not found in any of the directories: **/bin**, **/sbin** or **/usr/local/bin**.
- 102** program **edrc/lib/daemon/daemon_command** does not exist.
- 103** user calling the command has no permission to access/execute the called *daemon_command*.
- 107** direct call of **.daemon_wrapper** not allowed.

FILES

lib/daemon/
location of the commands started as daemons.

EXAMPLES

-

SEE ALSO

edrcintro(1), **cmdlist(1m)**, **patchinstall(1m)**

NOTES

The **.daemon_wrapper** command is one of the main reasons, why commands in the WA2L/edrc package do not have to be stopped during a patch installation.

NAME

days – print days since January 1st of a given date

SYNOPSIS

edrc/lib/days [**-h**]

days [*MM/DD/YYYY* | *YYYY-MM-DD*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

Evaluate days since January 1st of a given date.

If no date is specified the number of days from January 1st until the current date is printed (this equals to **date +%j** on HP-UX systems).

OPTIONS

-h usage message.

MM/DD/YYYY
date in the format "Month/Day/Year".

YYYY-MM-DD
date in the format "Year/Month/Day".

ENVIRONMENT

\$TZ time zone.

EXIT STATUS

0 no error.

4 usage displayed.

FILES

-

EXAMPLES**1) print days since January 1st 1971 for January 28th 1971**

```
[ /home/mzv7t0 ]  
[ mzv7t0@rh7mzv7t001 ][ksh]: days 01/28/1971  
  
028
```

2) print days since January 1st 1980 for March 1st 1980 (this is leap year)

```
[ /home/mzv7t0 ]  
[ mzv7t0@rh7mzv7t001 ][ksh]: days 03/01/1980  
  
061
```

3) print days since January 1st 1981 for March 1st 1980

```
[ /home/mzv7t0 ]  
[ mzv7t0@rh7mzv7t001 ][ksh]: days 03/01/1981  
  
060
```

NAME

dbrep – run reports/queries against an Oracle database

SYNOPSIS

edrc/bin/dbrep [**-h**]

dbrep -l

dbrep [**-i** *oracle_sid*] [**-Y**] [**-n**] [**-r** *report*] [**-o** *option_list*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

execute reports/queries against an Oracle database.

The **dbrep** allows to run prepared SQL scripts with a simple interface against an Oracle database.

OPTIONS

-h usage message.

-l list all reports.

-i *oracle_sid*
Oracle instance (default is **\$ORACLE_SID**).

-n no report header output.

-Y answer "execute alter report" question with yes.

-r *report* report to generate (default is growth).

-o *option_list*
list of report parameters.

ENVIRONMENT

\$ORACLE_SID

Oracle SID to connect ot by default.

EXIT STATUS

| | |
|----------|--|
| 0 | no error. |
| 2 | operating system not supported. |
| 3 | could not resolve an ORACLE_HOME . |
| 4 | usage printed. |
| 5 | command aborted. |
| 6 | configuration file etc/dbrep.cfg not found. |

FILES

edrc/etc/dbrep.cfg
configuration file of **dbrep**.

edrc/etc/oratab
Oracle **oratab** file.

edrc/etc/tnsnames.ora
Oracle **tnsnames.ora** file.

edrc/var/log/dbrep.log
log file of **dbrep**.

edrc/lib/dbrep/reports/<report>.sql
prepared SQL script of the report/query.

edrc/lib/dbrep/reports/<report>.desc
prepared SQL script description- and option definition for the the report/query.

edrc/lib/dbrep/admin/<script>.sql
SQL scripts for admin/setup tasks needed in the Oracle database to be queried.

EXAMPLES

-

SEE ALSO

edrcintro(1), **dbrep.cfg**(4), **oratab**(4), **tnsnames.ora**(4)

NOTES

dbrep uses **sqlplus** from Oracle to perform the reports/queries.

BUGS

dbrep needs the Oracle client to be installed on the system.

AUTHOR

dbrep was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

COPYRIGHT

NAME

dbrep.cfg – configuration file for dbrep

SYNOPSIS

edrc/etc/dbrep.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **dbrep** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**TOOLS_USER**

Database default EDS Tools username and password to connect to the database.

Example: **TOOLS_USER**="tools_eds/groove"

Default: **TOOLS_USER**="tools_eds/groove"

NLS_LANG

NLS settings

Example: **NLS_LANG**=AMERICAN_AMERICA.WE8ISO8859P1

Default: **NLS_DATE_FORMAT**=

NLS_DATE_FORMAT

NLS settings

Example: **NLS_DATE_FORMAT**='MON DD YYYY HH24:MI:SS'

Default: **NLS_DATE_FORMAT**=

ORACLE_HOME_SEARCH

Oracle Home search regex

Example: ORACLE_HOME_SEARCH='/ora/product/9*'

Default: ORACLE_HOME_SEARCH=

NAME

diff – compare files line by line

SYNOPSIS

diff [*OPTION*]... *FILES*

DESCRIPTION

Compare *FILES* line by line.

Mandatory arguments to long options are mandatory for short options too.

--normal

output a normal diff (the default)

-q, --brief

report only when files differ

-s, --report-identical-files

report when two files are the same

-c, -C NUM, --context[=*NUM*]

output *NUM* (default 3) lines of copied context

-u, -U NUM, --unified[=*NUM*]

output *NUM* (default 3) lines of unified context

-e, --ed

output an ed script

-n, --rcs

output an RCS format diff

-y, --side-by-side

output in two columns

-W, --width=*NUM*

output at most *NUM* (default 130) print columns

--left-column

output only the left column of common lines

--suppress-common-lines

do not output common lines

-p, --show-c-function

show which C function each change is in

-F, --show-function-line=*RE*

show the most recent line matching *RE*

--label LABEL

use *LABEL* instead of file name and timestamp (can be repeated)

-t, --expand-tabs

expand tabs to spaces in output

-T, --initial-tab

make tabs line up by prepending a tab

--tabsize=*NUM*

tab stops every *NUM* (default 8) print columns

--suppress-blank-empty

suppress space or tab before empty output lines

-l, --paginate

pass output through 'pr' to paginate it

-r, --recursive
recursively compare any subdirectories found

--no-dereference
don't follow symbolic links

-N, --new-file
treat absent files as empty

--unidirectional-new-file
treat absent first files as empty

--ignore-file-name-case
ignore case when comparing file names

--no-ignore-file-name-case
consider case when comparing file names

-x, --exclude=*PAT*
exclude files that match *PAT*

-X, --exclude-from=*FILE*
exclude files that match any pattern in *FILE*

-S, --starting-file=*FILE*
start with *FILE* when comparing directories

--from-file=*FILE1*
compare *FILE1* to all operands; *FILE1* can be a directory

--to-file=*FILE2*
compare all operands to *FILE2*; *FILE2* can be a directory

-i, --ignore-case
ignore case differences in file contents

-E, --ignore-tab-expansion
ignore changes due to tab expansion

-Z, --ignore-trailing-space
ignore white space at line end

-b, --ignore-space-change
ignore changes in the amount of white space

-w, --ignore-all-space
ignore all white space

-B, --ignore-blank-lines
ignore changes where lines are all blank

-I, --ignore-matching-lines=*RE*
ignore changes where all lines match *RE*

-a, --text
treat all files as text

--strip-trailing-cr
strip trailing carriage return on input

-D, --ifdef=*NAME*
output merged file with '#ifdef *NAME*' diffs

--GTYPE-group-format=*GFMT*
format *GTYPE* input groups with *GFMT*

--line-format=LFMT
format all input lines with LFMT

--LTYPE-line-format=LFMT
format LTYPE input lines with LFMT

These format options provide fine-grained control over the output of diff, generalizing **-D/--ifdef**.

LTYPE is 'old', 'new', or 'unchanged'.
GTYPE is LTYPE or 'changed'.
GFMT (only) may contain:

%< lines from FILE1
%> lines from FILE2
%= lines common to FILE1 and FILE2
%[-][WIDTH][.PREC]){doxX}LETTER
printf-style spec for LETTER
LETTERS are as follows for new group, lower case for old group:

F first line number
L last line number
N number of lines = L-F+1
E F-1
M L+1
%(A=B?T:E)
if A equals B then T else E
LFMT (only) may contain:

%L contents of line
%l contents of line, excluding any trailing newline
%[-][WIDTH][.PREC]){doxX}n
printf-style spec for input line number
Both GFMT and LFMT may contain:

%% %
%c'C' the single character C
%c'\OOO'
the character with octal code OOO
C the character C (other characters represent themselves)

-d, --minimal
try hard to find a smaller set of changes

--horizon-lines=NUM
keep NUM lines of the common prefix and suffix

--speed-large-files
assume large files and many scattered small changes

--color[=WHEN]
colorize the output; WHEN can be 'never', 'always', or 'auto' (the default)

--palette=PALETTE

the colors to use when **--color** is active; PALETTE is a colon-separated list of terminfo capabilities

--help display this help and exit

-v, --version

output version information and exit

FILES are 'FILE1 FILE2' or 'DIR1 DIR2' or 'DIR FILE' or 'FILE DIR'. If **--from-file** or **--to-file** is given, there are no restrictions on FILE(s). If a FILE is '-', read standard input. Exit status is 0 if inputs are the same, 1 if different, 2 if trouble.

NAME

dig – send domain name query packets to name servers

SYNOPSIS

dig [*@server*] *domain* [*<query-type>*] [*<query-class>*] [*+<query-option>*] [*–<dig-option>*] [*%comment*]

DESCRIPTION

Dig (domain information groper) is a flexible command line tool which can be used to gather information from the Domain Name System servers. *Dig* has two modes: simple interactive mode which makes a single query, and batch which executes a query for each in a list of several query lines. All query options are accessible from the command line.

The usual simple use of *dig* will take the form:

```
dig @server domain query-type query-class
```

where:

server may be either a domain name or a dot-notation Internet address. If this optional field is omitted, *dig* will attempt to use the default name server for your machine.

Note: If a domain name is specified, this will be resolved using the domain name system resolver (i.e., BIND). If your system does not support DNS, you may *have* to specify a dot-notation address. Alternatively, if there is a server at your disposal somewhere, all that is required is that */etc/resolv.conf* be present and indicate where the default name servers reside, so that *server* itself can be resolved. See *resolver(5)* for information on */etc/resolv.conf*. (WARNING: Changing */etc/resolv.conf* will affect the standard resolver library and potentially several programs which use it.) As an option, the user may set the environment variable LOCALRES to name a file which is to be used instead of */etc/resolv.conf* (LOCALRES is specific to the *dig* resolver and not referenced by the standard resolver). If the LOCALRES variable is not set or the file is not readable then */etc/resolv.conf* will be used.

domain is the domain name for which you are requesting information. See OPTIONS [-x] for convenient way to specify inverse address query.

query-type

is the type of information (DNS query type) that you are requesting. If omitted, the default is "a" (T_A = address). The following types are recognized:

| | | |
|-------|---------|--|
| a | T_A | network address |
| any | T_ANY | all/any information about specified domain |
| mx | T_MX | mail exchanger for the domain |
| ns | T_NS | name servers |
| soa | T_SOA | zone of authority record |
| hinfo | T_HINFO | host information |
| axfr | T_AXFR | zone transfer (must ask an authoritative server) |
| txt | T_TXT | arbitrary number of strings (not yet supported by BIND) |

(See RFC 1035 for the complete list.)

query-class

is the network class requested in the query. If omitted, the default is "in" (C_IN = Internet). The following classes are recognized:

| | | |
|-----|-------|---------------------------|
| in | C_IN | Internet class domain |
| any | C_ANY | all/any class information |

(See RFC 1035 for the complete list.)

Note: "Any" can be used to specify a class and/or a type of query. *Dig* will parse the first occurrence of "any" to mean query-type = T_ANY. To specify query-class = C_ANY you must either specify "any" twice, or set query-class using "-c" option (see below).

OTHER OPTIONS

%ignored-comment

"%" is used to included an argument that is simply not parsed. This may be useful if running *dig* in batch mode. Instead of resolving every @server-domain-name in a list of queries, you can avoid the overhead of doing so, and still have the domain name on the command line as a reference. Example:

```
dig @128.9.0.32 %venera.isi.edu mx isis.edu
```

—<dig option>

"—" is used to specify an option which effects the operation of *dig*. The following options are currently available (although not guaranteed to be useful):

—x *dot-notation-address*

Convenient form to specify inverse address mapping. Instead of "dig 32.0.9.128.in-addr.arpa" one can simply "dig -x 128.9.0.32".

—f *file* File for *dig* batch mode. The file contains a list of query specifications (*dig* command lines) which are to be executed successively. Lines beginning with ';', '#', or '\n' are ignored. Other options may still appear on command line, and will be in effect for each batch query.

—T *time*

Time in seconds between start of successive queries when running in batch mode. Can be used to keep two or more batch *dig* commands running roughly in sync. Default is zero.

—p *port* Port number. Query a name server listening to a non-standard port number. Default is 53.

—P[*ping-string*]

After query returns, execute a *ping*(8) command for response time comparison. This rather unelegantly makes a call to the shell. The last three lines of statistics is printed for the command:

```
ping -s server_name 56 3
```

If the optional "ping string" is present, it replaces "ping -s" in the shell command.

—t *query-type*

Specify type of query. May specify either an integer value to be included in the type field or use the abbreviated mnemonic as discussed above (i.e., mx = T_MX).

—c *query-class*

Specify class of query. May specify either an integer value to be included in the class field or use the abbreviated mnemonic as discussed above (i.e., in = C_IN).

—envsav

This flag specifies that the *dig* environment (defaults, print options, etc.), after all of the arguments are parsed, should be saved to a file to become the default environment. Useful if you do not like the standard set of defaults and do not desire to include a large number of options each time *dig* is used. The environment consists of resolver state variable flags, timeout, and retries as well as the flags detailing *dig* output (see below). If the shell environment variable LOCALDEF is set to the name of a file, this is where the default *dig* environment is saved. If not, the file "DiG.env" is created in the current working

directory.

Note: LOCALDEF is specific to the *dig* resolver, and will not affect operation of the standard resolver library.

Each time *dig* is executed, it looks for *./DiG.env* or the file specified by the shell environment variable LOCALDEF. If such file exists and is readable, then the environment is restored from this file before any arguments are parsed.

-envset This flag only affects batch query runs. When *"-envset"* is specified on a line in a *dig* batch file, the *dig* environment after the arguments are parsed, becomes the default environment for the duration of the batch file, or until the next line which specifies *"-envset"*.

-[no]stick

This flag only affects batch query runs. It specifies that the *dig* environment (as read initially or set by *"-envset"* switch) is to be restored before each query (line) in a *dig* batch file. The default *"-nostick"* means that the *dig* environment does not stick, hence options specified on a single line in a *dig* batch file will remain in effect for subsequent lines (i.e. they are not restored to the "sticky" default).

+<query option>

"+" is used to specify an option to be changed in the query packet or to change *dig* output specifics. Many of these are the same parameters accepted by *nslookup*(1). If an option requires a parameter, the form is as follows:

+keyword[=value]

Most keywords can be abbreviated. Parsing of the *"+"* options is very simplistic — a value must not be separated from its keyword by white space. The following keywords are currently available:

| Keyword | Abbrev. | Meaning [default] |
|-------------|---------|---|
| [no]debug | (deb) | turn on/off debugging mode [deb] |
| [no]d2 | | turn on/off extra debugging mode [nod2] |
| [no]recurse | (rec) | use/don't use recursive lookup [rec] |
| retry=# | (ret) | set number of retries to # [4] |
| time=# | (ti) | set timeout length to # seconds [4] |
| [no]ko | | keep open option (implies vc) [noko] |
| [no]vc | | use/don't use virtual circuit [novc] |
| [no]defname | (def) | use/don't use default domain name [def] |
| [no]search | (sea) | use/don't use domain search list [sea] |
| domain=NAME | (do) | set default domain name to NAME |
| [no]ignore | (i) | ignore/don't ignore trunc. errors [noi] |
| [no]primary | (pr) | use/don't use primary server [nopr] |
| [no]aaonly | (aa) | authoritative query only flag [noaa] |
| [no]sort | (sor) | sort resource records [nosor] |
| [no]cmd | | echo parsed arguments [cmd] |
| [no]stats | (st) | print query statistics (RTT,etc) [st] |
| [no]Header | (H) | print basic header [H] |
| [no]header | (he) | print header flags [he] |
| [no]ttlid | (tt) | print TTLs [tt] |
| [no]cl | | print class info [nocl] |
| [no]qr | | print outgoing query [noqr] |
| [no]reply | (rep) | print reply [rep] |
| [no]ques | (qu) | print question section [qu] |

| | | |
|------------|------|--|
| [no]answer | (an) | print answer section [an] |
| [no]author | (au) | print authoritative section [au] |
| [no]addit | (ad) | print additional section [ad] |
| pfdef | | set to default print flags |
| pfmin | | set to minimal default print flags |
| pfset=# | | set print flags to # (# can be hex/octal/decimal) |
| pfand=# | | bitwise and print flags with # |
| pfor=# | | bitwise or print flags with # |

The retry and time options affect the retransmission strategy used by resolver library when sending datagram queries. The algorithm is as follows:

```

for i = 0 to retry - 1
  for j = 1 to num_servers
    send_query
    wait((time * (2**i)) / num_servers)
  end
end

```

(Note: *dig* always uses a value of 1 for num_servers.)

Pfset, pfand, and pfor were included to make manipulation of the various print options less tedious. Below are the currently defined meanings for the various print flag bits. They may be combined (ANDed) to achieve various output formats.

| | | |
|-----------|--------|--|
| PRF_STATS | 0x0001 | RTT, query & server host, date, msg size |
| PRF_CLASS | 0x0004 | Resource record class information |
| PRF_CMD | 0x0008 | dig command line echo |
| PRF_QUES | 0x0010 | questions section |
| PRF_ANS | 0x0020 | answers section |
| PRF_AUTH | 0x0040 | authoritative section |
| PRF_ADD | 0x0080 | additional records section |
| PRF_HEAD1 | 0x0100 | RR section headers & counts |
| PRF_HEAD2 | 0x0200 | pkt header flags |
| PRF_TTLID | 0x0400 | Resource record ttl |
| PRF_HEADX | 0x0800 | basic header |
| PRF_QUERY | 0x1000 | outgoing query packet |
| PRF_REPLY | 0x2000 | reply packet |
| PRF_SORT | 0x8000 | sort various response sections |
| PRF_DEF | 0x2ff9 | default dig settings |
| PRF_ZONE | 0x24f9 | default setting for zone transfer |
| PRF_MIN | 0xa930 | minimalistic dig settings for (future) automated server testing |

When setting the print options, if you want to see information other than statistics, you should choose to examine the outgoing (0x1000), incoming (0x2000), or both packets plus the specific sections of the packet you are interested in.

DETAILS

Dig requires a slightly modified version of the BIND *resolver*(3) library to gather count and time statistics. Otherwise, it is straight-forward (albeit not pretty) effort of parsing arguments and setting appropriate parameters. *Dig* uses resolver routines *res_init()*, *res_mkquery()*, *res_send()* as well as accessing *_res* structure. Compiling *dig* with the standard resolver library is possible, but will change the output format, make the print options meaningless, and not gather RTT and packet count stats.

FILES

/etc/resolv.conf initial domain name and name server
 addresses

ENVIRONMENT

LOCALRES file to use in place of /etc/resolv.conf
LOCALDEF default environment file

AUTHOR

Steve Hotz hotz@isi.edu

ACKNOWLEDGMENTS

Dig uses functions from *nslookup*(1) authored by Andrew Cherenon; taken from Berkeley BIND 4.8 distribution. The resolver library is primarily from the Berkeley 4.8 BIND distribution.

BUGS

Dig has a serious case of "creeping featurism" -- the result of considering several potential uses during it's development. It would probably benefit from a rigorous diet. Similarly, the print flags and granularity of the items they specify make evident their rather ad hoc genesis.

Dig does not consistently exit nicely (with appropriate status) when a problem occurs somewhere in the resolver (NOTE: most of the common exit cases are handled). This is particularly annoying when running in batch mode. If it exits abnormally (and is not caught), the entire batch aborts; when such an event is trapped, *dig* simply continues with the next query.

NAME

directories – filter to expand filelist with overlying directories

SYNOPSIS

edrc/lib/directories

AVAILABILITY

WA2L/edrc

DESCRIPTION

expand a file list data stream received via **stdin** with the overlying directories and print the result to **stdout**.

This can be used to ensure when copying data that the directory permissions are set correctly.

Suppose the following command is issued as the root user:

```
find /data/source/myApp -name *.java -print |\  
cpio -pdvum /backup/myApp/20100117
```

This will copy all ***.java** files in all underlying directories from **/data/source/myApp** to the **/backup/myApp/20100117** directory, but all directories will have the ownership of the root user and the permissions will be set accordingly to the umask of the root user. All ***.java** files will have the correct permissions and ownership.

When using the **directories** command as the following example:

```
find /data/source/myApp -name *.java -print | directories |\  
cpio -pdvum /backup/myApp/20100117
```

all permissions and all ownership will be correct.

NAME

dmidecode – DMI table decoder

SYNOPSIS

dmidecode [**OPTIONS**]

DESCRIPTION

dmidecode is a tool for dumping a computer's DMI (some say SMBIOS) table contents in a human-readable format. This table contains a description of the system's hardware components, as well as other useful pieces of information such as serial numbers and BIOS revision. Thanks to this table, you can retrieve this information without having to probe for the actual hardware. While this is a good point in terms of report speed and safeness, this also makes the presented information possibly unreliable.

The DMI table doesn't only describe what the system is currently made of, it also can report the possible evolutions (such as the fastest supported CPU or the maximal amount of memory supported).

SMBIOS stands for System Management BIOS, while DMI stands for Desktop Management Interface. Both standards are tightly related and developed by the DMTF (Desktop Management Task Force).

As you run it, **dmidecode** will try to locate the DMI table. If it succeeds, it will then parse this table and display a list of records like this one:

```
Handle 0x0002, DMI type 2, 8 bytes. Base Board Information
Manufacturer: Intel
Product Name: C440GX+
Version: 727281-001
Serial Number: INCY92700942
```

Each record has:

- A handle. This is a unique identifier, which allows records to reference each other. For example, processor records usually reference cache memory records using their handles.
- A type. The SMBIOS specification defines different types of elements a computer can be made of. In this example, the type is 2, which means that the record contains "Base Board Information".
- A size. Each record has a 4-byte header (2 for the handle, 1 for the type, 1 for the size), the rest is used by the record data. This value doesn't take text strings into account (these are placed at the end of the record), so the actual length of the record may be (and is often) greater than the displayed value.
- Decoded values. The information presented of course depends on the type of record. Here, we learn about the board's manufacturer, model, version and serial number.

OPTIONS

-d, --dev-mem FILE

Read memory from device **FILE** (default: **/dev/mem**)

-q, --quiet

Be less verbose. Unknown, inactive and OEM-specific entries are not displayed. Meta-data and handle references are hidden. Mutually exclusive with **--dump**.

-s, --string KEYWORD

Only display the value of the DMI string identified by **KEYWORD**. **KEYWORD** must be a keyword from the following list: **bios-vendor**, **bios-version**, **bios-release-date**, **system-manufacturer**, **system-product-name**, **system-version**, **system-serial-number**, **system-uuid**, **baseboard-manufacturer**, **baseboard-product-name**, **baseboard-version**, **baseboard-serial-number**, **baseboard-asset-tag**, **chassis-manufacturer**, **chassis-type**, **chassis-version**, **chassis-serial-number**, **chassis-asset-tag**, **processor-family**, **processor-manufacturer**, **processor-version**,

processor-frequency. Each keyword corresponds to a given DMI type and a given offset within this entry type. Not all strings may be meaningful or even defined on all systems. Some keywords may return more than one result on some systems (e.g. **processor-version** on a multi-processor system). If **KEYWORD** is not provided or not valid, a list of all valid keywords is printed and **dmidecode** exits with an error. This option cannot be used more than once, and implies **--quiet**. Mutually exclusive with **--type** and **--dump**.

-t, --type TYPE

Only display the entries of type **TYPE**. **TYPE** can be either a DMI type number, or a comma-separated list of type numbers, or a keyword from the following list: **bios**, **system**, **baseboard**, **chassis**, **processor**, **memory**, **cache**, **connector**, **slot**. Refer to the DMI TYPES section below for details. If this option is used more than once, the set of displayed entries will be the union of all the given types. If **TYPE** is not provided or not valid, a list of all valid keywords is printed and **dmidecode** exits with an error. Mutually exclusive with **--string**.

-u, --dump

Do not decode the entries, dump their contents as hexadecimal instead. Note that this is still a text output, no binary data will be thrown upon you. The strings attached to each entry are displayed as both hexadecimal and ASCII. This option is mainly useful for debugging. Mutually exclusive with **--quiet** and **--string**.

-h, --help

Display usage information and exit

-V, --version

Display the version and exit

DMI TYPES

The SMBIOS specification defines the following DMI types:

| Type | Information |
|------|------------------------------|
| 0 | BIOS |
| 1 | System |
| 2 | Base Board |
| 3 | Chassis |
| 4 | Processor |
| 5 | Memory Controller |
| 6 | Memory Module |
| 7 | Cache |
| 8 | Port Connector |
| 9 | System Slots |
| 10 | On Board Devices |
| 11 | OEM Strings |
| 12 | System Configuration Options |
| 13 | BIOS Language |
| 14 | Group Associations |
| 15 | System Event Log |
| 16 | Physical Memory Array |
| 17 | Memory Device |
| 18 | 32-bit Memory Error |
| 19 | Memory Array Mapped Address |
| 20 | Memory Device Mapped Address |
| 21 | Built-in Pointing Device |
| 22 | Portable Battery |
| 23 | System Reset |

| | |
|----|----------------------------------|
| 24 | Hardware Security |
| 25 | System Power Controls |
| 26 | Voltage Probe |
| 27 | Cooling Device |
| 28 | Temperature Probe |
| 29 | Electrical Current Probe |
| 30 | Out-of-band Remote Access |
| 31 | Boot Integrity Services |
| 32 | System Boot |
| 33 | 64-bit Memory Error |
| 34 | Management Device |
| 35 | Management Device Component |
| 36 | Management Device Threshold Data |
| 37 | Memory Channel |
| 38 | IPMI Device |
| 39 | Power Supply |

Additionally, type 126 is used for disabled entries and type 127 is an end-of-table marker. Types 128 to 255 are for OEM-specific data. **dmidecode** will display these entries by default, but it can only decode them when the vendors have contributed documentation or code for them.

Keywords can be used instead of type numbers with **--type**. Each keyword is equivalent to a list of type numbers:

| Keyword | Types |
|-----------|-------------------|
| bios | 0, 13 |
| system | 1, 12, 15, 23, 32 |
| baseboard | 2, 10 |
| chassis | 3 |
| processor | 4 |
| memory | 5, 6, 16, 17 |
| cache | 7 |
| connector | 8 |
| slot | 9 |

Keywords are matched case-insensitively. The following command lines are equivalent:

- `dmidecode --type 0 --type 13`
- `dmidecode --type 0,13`
- `dmidecode --type bios`
- `dmidecode --type BIOS`

FILES

`/dev/mem`

BUGS

More often than not, information contained in the DMI tables is inaccurate, incomplete or simply wrong.

NAME

dos2ux – convert ASCII file format from DOS to UNIX format

SYNOPSIS

edrc/lib/dos2ux [**-h**]

dos2ux *dosfile* > *unixfile*

cat *dosfile* | **dos2ux** > *unixfile*

AVAILABILITY

WA2L/edrc

DESCRIPTION

dos2ux reads the specified *dosfile* and writes it to **stdout**, converting to UNIX format.

If no input file is given or if a *unixfile* is specified as -, **dos2ux** reads from **stdin**.

OPTIONS

-h print usage message.

unixfile file in UNIX file format.

dosfile file in DOS file format.

ENVIRONMENT

-

EXIT STATUS

0 no error.

1 given file does not exist.

4 usage message printed.

NAME

du_report – create a disk usage summary report

SYNOPSIS

edrc/bin/du_report [-h]

du_report [-c][-s][-l *language*][-f *output_file*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

Create a disk usage summary report based on the directories labeled with "disk usage index" files (see: **du_index**(4)) using the **duvi**(1) command.

du_report searches **..du_index** files to create a report which lists the purpose of all labeled directories and some additional information as the size of the directory in kByte.

du_report only includes "disk usage index" files that have the correct file permissions of '700'.

OPTIONS

-h usage message.

-l *language*
generate the report in the corresponding *language*. The language is resolved from the index file.

-c use index cache file to create the report. The cache file contains all "disk usage index" files of previous runs. When you know, that no additional index files have been created since the last run of **du_report** in the root (/) directory, the report creation is speed up drastically due to the fact that not the whole system has to be searched for index files. All index files in the cache are verified against the current situation ahead of do the reporting. If an index file has been created in a certain sub directory (e.g. /export/dat/development/docs) and **du_report has been called while staying in this directory, it is added** to the index cache file, too.

-s do not summarize the disk usage for the directories.

-f *output_file*
file where to save the report to. If this option is not specified, the report is printed to stdout.

ENVIRONMENT

-

EXIT STATUS

- | | |
|-----------|--|
| 0 | no error. |
| 1 | du_report has been started as another user then 'root'. |
| 1 | the directory where to place the <i>output_file</i> does not exist. |
| 4 | usage printed. |
| 5 | report creation aborted. |
| 11 | temporary directory could not be claimed or created in /tmp . Check the system temporary directory /tmp if you get this error, it is an indicator of system intrusion. |

FILES

..du_index "disk usage" index file.

/var/tmp/du_report.indexfilecache

cache of all "disk usage index" files found during previous runs. If **du_report** is called using the **-c** option, this file is read.

EXAMPLES

NAME

duvi – edit/create the disk usage index file

SYNOPSIS

edrc/bin/duvi [**-h**]

duvi [**-l** *language*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

Create or edit the "disk usage index" file. This file (**..du_index**) contains the purpose (usage) of a certain directory. It is like a label of a directory.

After wards this file is searched by the **du_report** command to create a report which lists the usage of all labeled directories with and some additional information like the size of the directory in kByte.

duvi has to be started as user 'root' and saves the **..du_index** file with the access permissions of '700'. **du_report** will only include files with those credentials into the report.

To label a directory you have to change to the directory and call the **duvi** command. This command loads an existing **..du_index** file into **vi** or provides a template to be filled out. The **..du_index** file can hold the description of the directory in different languages.

The provided languages are:

en for English

de for german

With this mechanism it is very easy to document a system without maintaining extra lists which document the purpose of certain directories.

OPTIONS

-h usage message.

-l *language*
 jump to the corresponding *language* : token in the **..du_index** file.

FILES

..du_index "disk usage" index file.

etc/exrc settings for the **vi** / **vim** editor.

SEE ALSO

edrcintro(1), **du_report(1)**, **du_index(4)**, **vi(1)**, **swvi(1)**

NOTES

To see how to efficiently maintain a software inventory, see **swvi(1)**.

NAME

ecrontab – maintains crontab files for individual users (cron in WA2L/edrc)

SYNOPSIS

edrc/bin/ecrontab [-u *user*] <*file* | ->

ecrontab [-T] <*file* | ->

ecrontab [-u *user*] <-l | -r | -e> [-i] [-s]

ecrontab -V

DESCRIPTION

ecrontab is the program used to install a crontab table *file*, remove or list the existing tables used to serve the **crond**(3) daemon. Each user can have their own crontab, and though these are files in **edrc/var/spool/cron/**, they are not intended to be edited directly.

Prior to editing a crontab table it is automatically saved using **vsav**(1).

Scheduling cron jobs with **ecrontab** can be allowed or disallowed for different users. For this purpose, use the **edrc/etc/cron.allow** and **edrc/etc/cron.deny** files. If the **cron.allow** file exists, a user must be listed in it to be allowed to use **ecrontab**. If the **cron.allow** file does not exist but the **cron.deny** file does exist, then a user must *not* be listed in the **cron.deny** file in order to use **ecrontab**. If neither of these files exist, then only the super user is allowed to use **ecrontab**.

The temporary directory can be set in an environment variable. If it is not set by the user, the **/tmp/** directory is used.

When listing a crontab on a terminal the output will be colorized unless an environment variable **NO_COLOR** is set.

OPTIONS

- u** Specifies the name of the user whose crontab is to be modified. If this option is not used, **ecrontab** examines "your" crontab, i.e., the crontab of the person executing the command. If no crontab exists for a particular user, it is created for them the first time the **ecrontab -u** command is used under their username.
- T** Test the crontab file syntax without installing it. Once an issue is found, the validation is interrupted, so this will not return all the existing issues at the same execution.
- l** Displays the current crontab on standard output.
- r** Removes the current crontab.
- e** Edits the current crontab using the editor specified by the **VISUAL** or **EDITOR** environment variables. After you exit from the editor, the modified crontab will be installed automatically.

Be aware, that the configuration file is saved automatically before editing using the **vsav**(1) command internally. Therefore when a messed-up file was saved, or to check changes, the **vls**(1), **vdiff**(1), **vrestore**(1) etc. commands can be used to verify changes or revert to a previous version.

- i** This option modifies the **-r** option to prompt the user for a 'y/Y' response before actually removing the crontab.

- s** Appends the current SELinux security context string as an **MLS_LEVEL** setting to the crontab file before editing / replacement occurs - see the documentation of **MLS_LEVEL** in **crontab(5)**.
- V** Print version and exit.

CAVEATS

The files **cron.allow** and **cron.deny** cannot be used to restrict the execution of cron jobs; they only restrict the use of **ecrontab**. In particular, restricting access to **ecrontab** has no effect on an existing **crontab** of a user. Its jobs will continue to be executed until the crontab is removed.

The files **cron.allow** and **cron.deny** must be readable by the user invoking **crontab**. If this is not the case, then they are treated as non-existent.

SEE ALSO

edrcintro(1), **crontab(4)**, **crond(3)**, **ecronnext(1)**, **vdiff(1)**, **vls(1)**, **vrestore(1)**, **vsav(1)**

FILES

edrc/etc/cron.allow

List of users to allow **ecrontab** access.

edrc/etc/cron.deny

List of users to deny **ecrontab** access.

STANDARDS

The **ecrontab** command conforms to IEEE Std1003.2-1992 (“POSIX”) with one exception: For replacing the current crontab with data from standard input the **-** has to be specified on the command line if the standard input is a TTY. This new command syntax differs from previous versions of Vixie Cron, as well as from the classic SVR3 syntax.

DIAGNOSTICS

An informative usage message appears if you run a crontab with a faulty command defined in it.

AUTHOR

Paul Vixie <vixie@isc.org>

Colin Dean <colin@colin-dean.org>

NAME

ecronnext – time of next job cron will execute (cron in WA2L/edrc)

SYNOPSIS

edrc/bin/ecronnext

[-i users] [-e users] [-s] [-a] [-t time] [-q time] [-j command] [-l] [-c] [-f] [-h] [-V] [file]...

DESCRIPTION

Determine the time **crond** will execute the next job. Without arguments, it prints that time considering all crontabs, in number of seconds since the Epoch, rounded to the minute. This number can be converted into other formats using **date(1)**, like **date --date @43243254**

The file arguments are optional. If provided, *ecronnext* uses them as crontabs instead of the ones installed in the system.

OPTIONS

-i user,user,user,...

Consider only the crontabs of the specified users. Use ***system*** for the system crontab.

-e user,user,user,...

Do not consider the crontabs of the specified users.

-s

Do not consider the system crontab, usually the **edrc/etc/crontab** file. The system crontab usually contains the hourly, daily, weekly and montly crontabs.

-a

Use the crontabs installed in the system in addition to the ones passed as file arguments. This is implicit if no file is passed.

-t time

Determine the next job from this time, instead of now. The time is expressed in number of seconds since the Epoch, as obtained for example by **date +%s --date "now + 2 hours"**, and is internally rounded to the minute.

-q time

Do not check jobs over this time, expressed in the same way as in option **-t**.

-j command

Only look for jobs that contain *command* as a substring.

-l

Print the whole entries of the jobs that are the next to be executed by **crond(3)**. The default is to only print their next time of execution.

-c

Print every entry in every crontab with the next time it is executed.

-f

Print all jobs that are executed in the given interval. Requires option **-q**.

-h

Print usage output and exit.

-V

Print version and exit.

AUTHOR

Marco Migliori <sgerwk@aol.com>

NAME

edrc – EDRC, Enterprise Disaster Recovery Console

SYNOPSIS

edrc/sbin/edrc [**-h** | **-V**]

edrc [**-c** *cfg*] [**-n** *session_name*] [**-s**] [**-t**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

The **edrc** program is the core part of the WA2L/edrc environment. The EDRC provides an easy to use, easy to customize and easy to enhance framework to recover your environment after a "Disaster Case".

The EDRC simplify the development of recovery scripts and helps to recover your environment in an efficient and reliable way.

The WA2L/edrc package has to be an integral part of a whole disaster recovery plan and process. This process is documented step by step in an "Emergency Handbook".

edrc is an interactive (character oriented) tool that supports the administrator and gives the freedom to change settings and invoked scripts at any point.

OPTIONS

-h usage message.

-V print version and patch level of **edrc**. For an explanation of the release numbering system see **edrcrevision**(1).

-c *configfile*
specify a special configuration file. If you do not use this option the default configuration file **edrc/etc/edrc.cfg** is used.

-n *session_name*
specify the session name on the command line. If you use this option you cannot set and alter the session name with the **name** EDRC command during runtime. Therefore the session name is read only if you use the **-n** option.

This can be used to ensure that only one **edrc** instance of a certain configuration is started per host (e.g.: **-n JOBCTL**).

If a session has to be marked, but it is allowed to start multiple instances of the same configuration, the **@ID@** field should be used in the **-n** option to generate a dynamic read only session name. The **@ID@** field is replaced by the process id of the started **edrc** instance, but if there is already an instance running with the same name it is replaced by a random number (e.g.: **-n JOB_@ID@**).

When session names are passed thru trunks to remote systems the remote session name is set equal to the local session name if possible.

If there is already a session with the same name running and the **@ID@** field is used as part of the session name, the **@ID@** field content will be resolved new and the trunk can be established. If the **@ID@** field is not used the trunk will not be established due to the fact that only one session with the identical name is allowed to be set/started per host.

Hint: when starting **sat(1)** the option **-n SAT_@ID@** is passed internally to **edrc**.

- s** silent startup. startup without showing the EDRC banner.
- t** no terminal initialization. Sometimes the terminal initialization causes unwanted behavior. To skip terminal initialization, invoke **edrc** with this option.

COMMANDS

This section describes all interactive internal commands of **edrc**;

- !<number>** execute the command with the number *<number>* listed in the **edrc** history. To list the history use the **history** command.
- !!** execute the command you invoked the last. This command is evaluated from the **edrc** history. To list the history use the **history** command.
- @** execute the menupoint you invoked the last. This command re-invokes the menupoint which is displayed after the ":" in the EDRC prompt.
- b, back, up** go one menu back. Respectively exit a submenu and go back to the overlying menu.
- banner** display the program startup banner with the copyright and version information.
- busy** print a rotating slash. This command does nothing productive. It might be useful to keep a line open when for instance a firewall cuts the connection if a TCP timeout is reached. To end the rotating press Ctrl+C.
- clear** clear screen.
- date** print the current system date and time.

debug toggle the script debug variable **\$DEBUG** between *False* and *True*. All recovery shells scripts should have the following line included to be able to react to the **debug** command:

```
test "$DEBUG" = True && set -x
```

After startup the **\$DEBUG** variable is set to *False*.

distribute distribute recovery scripts to other hosts. This command allows you to keep all recovery scripts on all your hosts synchronized. It is recommended that you set up your recovery menu tree that way that you can have an identical set of scripts on all your hosts. This has the advantage of a "single point of administration".

See **edrc.cfg(4)** for information about the configuration and the configuration file names.

The **distribute** command will guide you to a couple of steps needed to transfer the scripts to a set of hosts. It is also possible to enter hostgroups (*@HOSTGROUP*), as known from the **hostlist** command.

You will have the opportunity to cancel at several points.

Distribution types:

To speed up distribution and to allow some parallel editing on different hosts you can choose between a *differential* and a *full* distribution. A *full* distribution contains all files in a recovery script tree, a *differential* distribution contains only the files that are newer then the last *full* distribution.

The following guideline helps to decide which distribution type to use in what situation: If things are removed or renamed, use a *full* distribution, in all other cases use a *differential* distribution.

The following steps are performed by the distribute command:

- 1.) create a new distribution file. This file contains scripts in **SCRIPTS_BASEDIR**. If you decide to create a *full* distribution, all files will be packed. If you decide to create a *differential* distribution, only the files will be packed which are newer then the last distribution file created by a *full* distribution.
- 2.) specify a list of hosts to distribute the distribution file to.
- 3.) distribute (copy) the distribution file to each target host in the list.
- 4.) on the target host backup the current scripts. If it is a *full* distribution all scripts are backed up. If it is a *differential* distribution only the files which will be overwritten are backed up.
- 5.) if it is a full distribution remove all scripts in **SCRIPTS_BASEDIR** on the target host.
- 6.) extract the distribution file to the **SCRIPTS_BASEDIR** on the target host.

Hint:

The host where you invoke the **distribute** command is excluded from distribution. Therefore you can keep the local host in the **DIST_HOSTLIST** and the configuration file **edrc.cfg** can be kept identical on all your hosts.

To view the contents of a compressed backup file (without decompressing it) you can use the **lscomp**, **llcomp** and **catcomp** commands in the shell.

edrcdebug this will toggle debugging on the **edrc** command between *False* and *True*. Normally only the author of **edrc** will use this command for debugging of the EDRC itself. To debug your recovery scripts use the **debug** command.

edrcperm list the complete permission set and all functionality that is defined to be denied. The denial of the startup of certain functions can be specified in the **edrc.cfg** file with the **DENY_LIST** setting.

For a disaster recovery configuration, you should **never** deny any functionality from startup, due to the fact that in a disaster recovery maximal flexibility has to be provided under all circumstances.

Therefore the feature to deny certain functions from execution should only be used for system administration configurations, and even there - use it moderately! The user gets the message: "edrc-WARNING: execution of functionality '<option>' not permitted." if a certain command/functionality is not permitted to be executed. See also **edrc.cfg**(4) for more information.

env create, edit, view, remove the environment file. The environment file (**_env**) is used to do common settings for a certain menu (=directory).

So you can set passwords, ORACLE_SID's etc. in this file and you don't have to edit all your recovery scripts in this menu if you change the password (for instance). You could also do some user prompting in this environment file if you have to.

To keep the process and the dependencies simple the environment settings are not inherited to sub-menus.

If you like to share a whole recovery script tree later with other system administrators you can strip out all passwords from **_env** files with the **envpasswdstrip** shell command. This command triggers for patterns like 'export*password=my_secret' and 'export*passwd=my_secret' and substitutes the password with the string 'PASSWORD_STRIPED_OUT'.

How a recovery script is started:

- 1.) If an environment file (**_env**) exists for the current menu (=directory), the **_env** file is sourced and the variables defined in it are set. Your code has to be ksh conform and the variables have to be exported.
- 2.) If the recovery script is executable, invoke it directly. It is also validated, if the command defined in the recovery scripts magic key exists. If the shell in the magic key does not exist a fallback mechanism tries to resolve an alternate shell to be used to start the recovery script.
- 3.) If the recovery script is not executable, start it in using the shell as defined in the magic key. Here the fallback mechanism as described above applies as well.

Hint:

To be sure that your settings will reach the recovery script you should always export your variables.

When you create a new environment file a template is provided.

The environment file has the filepermissions 600.

Example _env file:

```
#
# _env - Environment settings for commands in ....
#
# [00] 29.01.2003 CWa Initial Version
#
#
test "$DEBUG" = True && set -x
export system_password=coolrunnings
export sys_password=helloworld
export scott_passwd=tiger
export app_user=psoft
export oracle_sid=FS75PROD
export oracle_owner=oracle
```

erase set the erase terminal character. Normally the system can determine the erase character by itself. However, in some circumstances it is still wrong. The **erase** command allows you to choose an erase character from a list or to specify the correct character by yourself.

header create, edit, view, remove a menu header. The menu header is intended to display additional information below the menu title, if the menu title information is not sufficient.

help, h, usage, ?
print a short help of all internal and contributed (**contrib.edrc(1m)**) commands.

history, hist
print the history of **edrc**. The history contains all invoked commands. Commands which are entered repetitive are listed only once.

hostname print the hostname of the system you started **edrc** on.

loadrec load a previous saved recovery point in time from disk. This will set the **\$EDRC_RECOVERYTIME** environment variable which is exported to all recovery scripts. To display a recovery point in time, use the **printrec** command, to set a recovery point in time, use the **setrec** command.

log view the last logfile. Every output of a recovery script is saved to a logfile. Therefore your recovery scripts don't have to care about logging information.

man display manual pages.

menu, m, ls

print the menu. In the menu title the name of the current session (if set with the **name** command) is displayed. All menupoints are enclosed by square brackets: [28]. Submenus are marked with a " > " sign. The current location in the script tree is part of the **edrc** prompt. The prompt consists of three parts which might not be present at all times:

edrc@host/Oracle/PSYS:157>

In this example you are in the sub-sub menu "PSYS" and the last menupoint you selected was "157". If you execute a **edrc** command after you selected a menupoint this will not influence the prompt. So it is very easy to see what your last action during the recovery was.

It will make sense that the menupoints correspond to the reference numbers in the "Emergency Handbook" of your environment.

name give the current session a name. This is useful to avoid confusion and to find the right session if you started parallel multiple sessions.

The logfiles contain the session name in square brackets: [example].

If you do not set a session name the current process id or a random value is used as an (ad hoc) session name.

The current session name is printed in the menu head (SESSION:) when the menu is listed using the **menu** command.

During a "Disaster Case" or "Disaster Case Simulation" it is highly recommended to set the session name as advised by the "Emergency Handbook".

If possible a session name is transferred to a remote host when a trunk is established. However, if on the remote system a session with the same name is already running, a new (ad hoc) session name will be set automatically.

newmenu, newdir

create a new menu in the recovery script menu tree. **edrc** will guide you thru the naming of the menu. Finally a menu is a directory with the name:

<menu_point>:<name>

menu_point *and* *name* has to be unique in the current menu.

If the menu title contains a semicolon (;) the menu entry will be broken into two lines at the position of the semicolon when using the **menu** command.

newscript create a new recovery script. **edrc** will guide you thru the naming of the script and will provide a template script which contains some key elements. The name of the script will be:

<menu_point>:<name>

menu_point *and* *name* has to be unique in the current menu.

If the script header contains a semicolon (;) the menu entry will be broken into two lines at the position of the semicolon when using the **menu** command.

PID print the UNIX process id of the **edrc** session.

printrec display the currently set recovery point in time. To set a recovery point in time, use the **setrec** command, to load a saved recovery point in time, use the **loadrec** command.

quit quit **edrc** at any point.

removemenu
remove an existing submenu. Prior to the removal the menu is backuped.

removescript
remove an existing recovery script. Prior to the removal the file is backuped.

renamemenu
rename an existing submenu.

renamescript
rename an existing recovery script. Prior to the rename the file is backuped.

setrec set recovery point in time. This will set the **\$EDRC_RECOVERYTIME** environment variable which is exported to all recovery scripts.

The date format has to be compliant to the **NLS_DATE_FORMAT** configured in **edrc.cfg**.

You can save your recovery point in time to have it available after a newstart of **edrc**. To save the recovery point in time would be a good idea in most cases. If you have to change the recovery point in time only temporarily for a certain recovery action you probably won't save it.

To display a recovery point in time, use the **printrec** command, to load a saved recovery point in time, use the **loadrec** command.

shell start a shell in **edrc**. You should use this command to exit to the operating system rather than to do an other telnet or rlogin to the system.

When you use the **shell** command the current working directory is the location in the menu you are currently in. Furthermore the shell settings are tuned and customized to the WA2L/edrc environment and all **\$EDRC_** environment variables are exported to the shell.

On UNIX the Korn-Shell (ksh), on Linux the Bourne-Again-Shell (bash) will be started. To see all additional commands and aliases you have available in the shell type **usage** within the started shell.

See **shell(1)** for a description of the additional commands available.

term set the terminal emulation (the **\$TERM** environment variable) for the current session. See also: **edrc.cfg(4)**.

title edit, view, remove a menu title created while creating a new submenu. Or create a menutitle for a menu which was not labeled so far.

top browse directly back to the root menu. If it is a trunk, browse to the trunk root.

trunk create, edit, view, remove, activate, deactivate the trunk definition (**_trunk**) for a menu. A trunk is basically the invocation of a menu on a remote system. Therefore, ahead of defining a trunk, a normal menu has to be created. A trunk definition enhances a menu with the behavior to be started on a remote system transparently without the need to first manually log on to the remote system, start **edrc** and then change to the desired submenu.

To establish a trunk to a remote system it must be possible to connect with *OpenSSH* mode (**-m OpenSSH**) to the remote system using the **remote_shell** command and the recovery scripts have to be distributed. See also **remote_shell(3)** and **edrc.cfg(4)** for more information.

When a new trunk is defined using the **trunk** command, a specification template consisting of the following elements is provided:

target::= [*comment* :] *hostname*

The *target* listed in the specifications below can consist of a *comment* (optional) and a *hostname* (not optional) where to connect to. The *comment*, if specified, is displayed at the trunk dialog instead of the *hostname*. The *comment* and the *hostname* has to be separated by a colon (:). Furthermore spaces and tabs are not allowed in a *comment* text and between the *comment*, the : and the *hostname*. If spaces in the *comment* output are needed, they have to be replaced by a % character in the definition.

ACTIVE= *True* | *False*

If **ACTIVE** is set to *True* the trunk specification is active and a remote menu invocation will be established based on the remaining trunk settings. If it is set to *False* the trunk specification exists but is not active. In this case the menu behaves as a normal submenu. When the **trunk** command is invoked, it is possible to toggle this setting using the (a)ctivate and (d)eactivate options prompted when invoking the **trunk** command.

TYPE= *direct* | *prompt* | *prompt:nolocal*

If **TYPE** is set to *direct* the trunk is established immediately without prompting the user. When it is set to *prompt* or *prompt:nolocal* a dialog is displayed and the user is prompted for a selection of a target to establish the trunk to. The dialog for a *prompt* trunk always includes one menu point to stay on the local system and not to establish a trunk to a remote system. A *prompt:nolocal* trunk does not provide the local selection.

DEFAULT= " *target* "

The target definition here takes into effect if the **TYPE** setting is set to *direct* and no *target* is entered in the **TARGETS** definition. If **TYPE** is set to *prompt* the setting made here is printed in the "Default:" section of the user dialog. This setting is interpreted by a shell, therefore it is also possible to do some dynamic stuff here.

TARGETS= " *target* [{ *target* }]"

White space separated list of targets to be listed in the "Targets:" section of the user dialog when **TYPE** is set to *prompt*. If **TYPE** is set to *direct* and no **DEFAULT** target is defined, all elements of this list are probed and the first one that is up is used to establish the trunk to. This setting is interpreted by a shell, therefore it is also possible to do some dynamic stuff here.

TARGET_MENUPATH= " *menupath* "

This is an optional setting that is only used for advanced exceptional trunk specifications. When specifying the *menupath* it is possible to choose a different entry menu at the trunk target.

TARGET_CONFIG= " *configfile* "

This is an optional setting that is only used for advanced exceptional trunk specifications. When specifying the *configfile* it is possible to establish a trunk to a target using a target configuration that differs from the local configuration.

1) Example of a simple trunk specification:

```
#
# _trunk - Trunk specification for menu /HP_11/services
#
# [00] 22.03.2007 CWa Initial Version
#
#
ACTIVE=True
TYPE=prompt
DEFAULT="host-001"
TARGETS="host-001 host-002 host-003 host-004"
```

2) Example of a more enhanced trunk specification:

```
#
# _trunk - Trunk specification for menu /HP_11/services
#
# [00] 22.03.2007 CWa Initial Version
#
#
```

```

ACTIVE=True
TYPE=prompt
DEFAULT="'server_environment':localhost"
TARGETS="
    MAINTENANCE:host-001
    TEST:host-002
    PREPRODUCTION:host-003
    PRODUCTION:host-004
"

```

3) Example defining a dynamic target list

The target list consists of all hosts defined to be member of the group `@ALL` as defined in the `HOSTGRPS` setting in the `edrc/etc/hostlist.cfg` file. Therefore, if a host is added to the `@ALL` group, the trunk target list will be automatically enhanced.

```

#
# _trunk - Trunk specification for menu /HP_11/services
#
# [00] 22.03.2007 CWa Initial Version
#
#
ACTIVE=True
TYPE=prompt
DEFAULT=""
TARGETS="'hostlist -g @ALL'"

```

4) Example of exceptional advanced trunk specification

Suppose `~edrc/bin/sat` is started (`~edrc/sbin/edrc -c edrc.sat.cfg`), you are in the menu `/HP_11` and the submenu `services` is a trunk. This example definition will establish a trunk using the configuration `~edrc/etc/edrc.psup.cfg` on the trunk target. The entry menu on the remote system is `/user_mgmt` instead of `/HP_11/services`. It is not imperative to use both advanced trunk specification options in an advanced trunk definition.

Hint: The advanced trunk definition options (`TARGET_MENUPATH` and `TARGET_CONFIG`) should be used **very** moderately and with a good reason, due to the fact that the chance is high that advanced trunks cannot be established later on (error message: **edrc-FATAL: menu does not exist, aborting**), because the target menu structure could be changed without realizing that a certain (sub)menu is a trunk target. On normal trunks, where the menu and the configuration is identical and the menu tree is distributed, this cannot happen.

```

#
# _trunk - Trunk specification for menu /HP_11/services
#
# [00] 22.03.2007 CWa Initial Version
#
#
ACTIVE=True
TYPE=prompt
DEFAULT="host-001"
TARGETS="host-002 host-003 host-004"
TARGET_MENUPATH="/user_mgmt"

```

```
TARGET_CONFIG="edrc.psup.cfg"
```

trunkbypass

toggle bypassing of active trunks between *True* and *False*. When toggle trunk bypassing to *True* all active trunks are bypassed in the current session and are not followed.

It might be helpful to bypass trunks to efficiently edit many menu points in submenus which are defined as trunks. Doing so you do not have to first deactivate and after editing activate the trunk for each menu separately.

tty print the TTY you are logged on and the **edrc** program is started in.

tz set the time zone (the **\$TZ** environment variable) for the current session. See also: **edrc.cfg**(4) and **timezone**(3).

ENVIRONMENT

The following environment variables are exported to all recovery scripts, contributed commands and the shell. Do not use other variables seen by your scripts which are related to the WA2L/edrc environment because they may disappear in future releases or its content may change without notice.

Use the **edrcenv** command within the **shell** or **edrc** to see the current environment settings.

\$EDRC_NLS_DATE_FORMAT

national language support date format. The recovery point in time has to comply with this format.

\$NLS_DATE_FORMAT

same as **\$EDRC_NLS_DATE_FORMAT**.

\$EDRC_NLS_LANG

national language support language name.

\$NLS_LANG

same as **\$EDRC_NLS_LANG**.

\$DEBUG

used to debug recovery scripts or contributed commands. This variable is set to *False* (no debugging) or *True* (debugging). Your script should contain the following line to allow debugging:

```
test "$DEBUG" = True && set -x
```

\$EDRC_ENTRY_DIR

current directory where your recovery script is located or where you enter the filesystem tree when you invoke the **shell** command.

\$EDRC_TMP_DIR

this variable points to a secure temporary directory that exists during the execution of a recovery script, contributed command or the shell command and is afterwards removed. This variable is therefore exported to recovery scripts, contributed commands and the shell command only.

This variable should be used to securely save temporary data during the execution of a recovery script or a contributed command.

\$EDRC_TMP_DIR_SESSION

this variable points to a secure temporary directory that exists during the execution of an **edrc** session and is afterwards removed. This variable is exported to recovery scripts, contributed commands and the shell command only.

This variable should be used to securely save temporary data from recovery scripts or contributed commands that must be accessed multiple times throughout the **edrc** session.

You should add the name of the recovery script or contributed command as prefix to ensure a unique filename.

Example:

```
date > $EDRC_TMP_DIR_SESSION/$EDRC_SCRIPTNAME.begin
```

If you need to save temporary data during the execution of a recovery script or a contributed command the **\$EDRC_TMP_DIR** variable shall be used.

\$EDRC_OSID

the systems operating system id evaluated by **osid**. See **osid(3)** for more information.

\$EDRC_SCRIPTS_BASEDIR

name of the recovery scripts basedir. This environment variable is set to the value you specified with the **SCRIPTS_BASEDIR** option in the **edrc.cfg** configuration file. See **edrc.cfg(4)** for more information.

\$EDRC_ENV

name of the environment file. See description in section **COMMANDS**, at the **env** command. Therefore do **not** hard-code **_env** in your scripts, use this variable.

\$EDRC_CONFIGFILE

name of the configuration file loaded in the current **edrc** session.

\$EDRC_LOGFILE

logfile of the current script. Normally you will not have to write to this file by your own, **edrc** will redirect all output of your recovery script to this file.

\$EDRC_RECOVERYTIME

point in time to recover to. See description in section **COMMANDS**, at the **setrec** command.

\$EDRC_SCRIPTNAME

name of the recovery script (without the "<menu_point>:" part). If you use the **msg** command for message output this name will appear in front of the "-" sign.

\$EDRC_MENUPPOINT

menu point of the recovery script (without the ":<scriptname>:" part).

\$EDRC_SESSION

name of the **edrc** session. If you use the **log** command (what will normally not be the case in recovery scripts) the session name is written between the square brackets into the logfile (**\$EDRC_LOGFILE**).

\$EDRC_CONTRIB_VARDIR

var directory for contributed commands. This environment variable is only exported to contributed commands. If you have to save persistent information store it to this location.

You should add the name of the contributed command as prefix to ensure a unique filename.

Example:

```
date > $EDRC_CONTRIB_VARDIR/$EDRC_SCRIPTNAME.begin
```

\$EDRC_SEED

session persistent random seed number.

\$EDRC_SHELLHIST

history file for the shell started with the **shell** EDRC command. This environment variable is only exported to the shell started within **edrc**.

\$EDRC_DIST_USER

this variable equals to the **DIST_USER** setting in the **etc/edrc.cfg** file.

\$EDRC_DEBUG

switch all commands in **edrc/bin** and **edrc/lib** into debugging mode. This allows to debug also commands that don't have the debugging option **-x** implemented.

Do not mix up this environment variable with the **\$DEBUG** environment variable. When debugging recovery scripts only the **\$DEBUG** variable is of significance.

\$EDRC_DEBUG_COMMAND

switch a *command* in **edrc/bin** or **edrc/lib** into debugging mode. This allows to debug also commands that don't have the debugging option **-x** implemented.

Do not mix up this environment variable with the **\$DEBUG** environment variable. When debugging recovery scripts only the **\$DEBUG** variable is of significance.

\$TODAY current date in the form YYYYMMDD (example: 20061021).

SIGNALS

The following signals are handled by **edrc**. Do not use other signals as those listed below, as long as you do not really know what you are doing and what the consequences are.

- INT** interrupt from keyboard (Ctrl+C).
If **ABORT_MODE** is set to *hard* **edrc** will abort completely, if **ABORT_MODE** is set to *soft* only the current running command or recovery script will be aborted.
- TERM** kill the process without an argument.
If **ABORT_MODE** is set to *hard* **edrc** will abort completely, if **ABORT_MODE** is set to *soft* only the current running command or recovery script will be aborted.
- USR1** the **edrc** command will perform a "soft" abort, as if **ABORT_MODE** is set to *soft*.
- USR2** the **edrc** command will perform a "hard" abort, as if **ABORT_MODE** is set to *hard*.

EXIT STATUS

- 0** no error.
- 1** you started **edrc** using the wrong operating system user.
- 2** operating system is not supported. See **osid(3)** if you get this error.
- 3** version printed.
- 4** usage listed.
- 5** program aborted (Ctrl+C ...).
- 6** the configuration file does not exist.
- 7** the directory specified in **SCRIPTS_BASEDIR** does not exist.
- 8** **edrc** was started using the **-n session_name** option and another session with the same *session_name* is already running on this host.

- 9 the **edrcrevision.cfg** file is missing or the **VERSION** or **PATCHLEVEL** options within this file are not set properly.
- 10 **edrc** was started in trunk mode from a remote system and the trunk root menu does not exist.
- 11 a temporary directory could not be claimed or created in **/tmp**. Check the system temporary directory **/tmp** if you get this error, it is an indicator of system intrusion.

FILES

The **name(1)** command can be used to list a short description of files and directories.

etc/edrc.cfg

configuration file of **edrc**, see **edrc.cfg(4)** for more information.

etc/edrcrevision.cfg

configuration file which holds the current version and patchlevel of EDRC. See **edrcrevision.cfg(4)** for more information.

etc/exrc

configuration file for the vi-Editor and viewer started within **edrc**. See **svi(1)**, **exrc(4)** and **vi(1)** for additional information.

etc/shell.cfg

generic configuration file for the shell started by the **shell** command. This file is read by the **etc/kshrc** shell startup file. The intention of this configuration file is to be able to configure some shell variables without changing the more complicated **kshrc** file.

etc/kshrc

startup file for the shell started by the **shell** command. Normally you won't have to change this file, changing configurations are handled in the **etc/shell.cfg** file. See **kshrc(4)** for more information.

contrib/edrc/

contributed commands to edrc. Do not change the **edrc** program if you miss a general command. Create the command in this directory and you will be able to invoke it as it is an **edrc** internal command. This will protect you from losing your work after an upgrade of **edrc** and will keep the **edrc** command itself stable.

lib/

commands which are mostly used within scripts. Some of them require some environment settings. This directory is in \$PATH

lib/edrc/

library functions called by the **edrc** command.

scripts/

here are all recovery scripts stored by default. The content of this directory has to be customized to your environment. For a description how to write scripts for EDRC see **edrc-scripts(1M)** or the example configuration included in the WA2L/edrc package.

.sav

backup directory in a recovery script tree. Whenever a file in **edrc** is edited or removed a backup copy is automatically saved into the **.sav** directory of the current menu (=subdir). Therefore, if you like to restore a file to a prior version, invoke the **shell** command in **edrc**,

change to the **.sav** directory and restore the desired file using the normal operating system commands. The **.sav** directory is excluded from distributions when invoking the **distribute** command.

var/backup/

several backups.

var/contrib/edrc/

var directory for contributed commands. The **\$EDRC_CONTRIB_VARDIR** environment variable points to this directory. See section **ENVIRONMENT** for information how to save persistent information in contributed commands.

var/lock/

lockfiles. Do not edit them by hand.

var/log/

all logfiles of the EDRC environment. Here the logfile of **edrc** and the output of all recovery scripts is saved. Therefore customizing scripts don't have to implement an own logging mechanism. All output sent to **stdout** and **stderr** will be saved in a designated logfile.

var/repl/

this directory is used to save scripts replicated with the **distribute** EDRC command.

var/connection/security/<DIST_USER>/<DIST_MODE>/<host_from>|default/<host_to>|default}

this directory holds security information used for example by secure shell connections. See **edrc.cfg(4)** for more information about the currently possible **DIST_MODE** settings and **remote_shell(3)** and **remote_copy(3)** for more information about the **var/connection** directory.

var/connection/cache/<DIST_USER>

this directory holds the cache of successful connections. This is used to speed up the initialization of a connection due to the fact that the first try is to use the **DIST_MODE** first which resulted already in a successful connection.

var/repl/own.<cfg>.full.cpio.gz

full distribution file created on the local host. This archive contains all scripts from **SCRIPTS_BASEDIR** defined in the configuration file *cfg*.

var/repl/rec.<cfg>.full.cpio.gz

full distribution file created on a remote host and distributed to the local host. This archive contains all scripts from **SCRIPTS_BASEDIR** defined in the configuration file *cfg*.

var/repl/own.<cfg>.diff.cpio.gz

differential distribution file created on the local host. This archive contains all scripts from **SCRIPTS_BASEDIR** defined in the configuration file *cfg* which are newer then the most recent full distribution file available on the local host.

var/repl/rec.<cfg>.diff.cpio.gz

differential distribution file created on a remote host and distributed to the local host. This archive contains all scripts from **SCRIPTS_BASEDIR** defined in the configuration file *cfg* which are newer then the most recent full distribution file available on the remote host where the distribution file comes from.

var/settings/

persistent settings.

var/shell/ Here the shell history of each session of the interactive shell built in to **edrc** and the own history of **edrc** is kept.

NAME

edrc.cfg – configuration file for edrc

SYNOPSIS

edrc/etc/edrc.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **edrc** command.

It is important that on all hosts in your disaster recovery environment the configuration files with the same purpose have the same name. Otherwise the **distribute** EDRC command won't function correctly.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**SCRIPTS_BASEDIR**

name of the recovery scripts basedir. In this directory all recovery scripts for your environment are stored in a hierarchical directory tree. This directory is relative to the root of the WA2L/edrc installation.

Example: **SCRIPTS_BASEDIR=scripts/customer**

Default: **SCRIPTS_BASEDIR=scripts**

SCRIPTS_SHELL

path to the shell you will use the most in your recovery scripts located in the **SCRIPTS_BASEDIR**. This setting will be used to build a template script when you invoke the newscript command in **edrc**.

Example: **SCRIPTS_SHELL=/bin/ksh**

Default: **SCRIPTS_SHELL=/bin/sh**

SCRIPTS_SHELLFALLBACKS

fallback shell definitions for magic keys of recovery scripts. This fall-backs come into action, if the shell defined in the magic key of a recovery script does not exist on the system. Be

aware, that only for magic keys without options the fallback shell will be resolved. For scripts having options the script must be edited and the correct shell has to be defined in the script. The entry is a list in the format `<original_shell>:<fallback_shell>`. The fallback resolution is performed in the order of the entries. Before resolving the entries in the **SCRIPTS_SHELL_FALLBACKS** list, the shell as defined in the recovery script is searched in alternate locations on the system. For all shell location resolutions the **\$PATH** is used.

Example: `SCRIPTS_SHELLFALLBACKS="ksh:pfksh ksh:bash sh:ksh sh:pfsh sh:bash"`

Default: `SCRIPTS_SHELLFALLBACKS="ksh:bash sh:ksh sh:bash"`

NLS_DATE_FORMAT

NLS date format. This format is exported to each recovery script. You should set your most used format here. If you have exceptions to this format you can set it for each EDRC menu with the **env** EDRC command.

Example: `NLS_DATE_FORMAT='MON DD YYYY HH24:MI:SS'`

Default: `NLS_DATE_FORMAT='MON DD YYYY HH24:MI:SS'`

NLS_LANG

NLS language name. This name is exported to each recovery script. You should set your most used format here. If you have exceptions to this format you can set it for each EDRC menu with the **env** EDRC command.

Example: `NLS_LANG=american`

Default: `NLS_LANG=american`

TERM

Terminal emulation used. You should set this setting to the terminal you use the most. You can change the **TERM** setting using the **term** EDRC command for an **edrc** session.

Example: `TERM=dtterm`

Default: `TERM=vt220`

LOG

Log output dir of **edrc**. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation.

Example: `LOG=/var/opt/edrc/log`

Default: `LOG=var/log`

LOGCOMPRESS

Compress logfiles of recovery scripts and contributed commands. If this setting is set to *False* the logfiles will not be compressed, if it is set to *True* the logfiles will be compressed after completion of the recovery script or contributed command. Using this setting you can save a significant amount of disk space. To view the logfile you can still use the **log** command or the **logs** contributed command within **edrc** without having to care if a log file is compressed or not. If you go to the **edrc/var/log** directory you can use **zgrep**(1) to grep the compressed logfiles.

Example: `LOGCOMPRESS=True`

Default: LOGCOMPRESS=False

LOGHEAD_OUTPUT

Output of the log header. If this setting is set to *False* the log header will only go to the logfile, if it is set to *True* it will go to the screen and to the logfile.

Example: LOGHEAD_OUTPUT=False

Default: LOGHEAD_OUTPUT=True

START_USER

This is the user **edrc** has to be started with.

Example: START_USER=root

Default: START_USER=root

DIST_HOSTLIST

Space separated list of hosts. To this hosts the files in **SCRIPTS_BASEDIR** will be distributed.

Example: DIST_HOSTLIST="acme045 acme014"

Default: –

DIST_USER

User used to distribute the files in **SCRIPTS_BASEDIR**. The home of this user is considered as the root of the **WA2L/edrc** installation. See **edrcsetup**(1m) for information about user settings needed by **WA2L/edrc**.

Example: DIST_USER=edrc

Default: DIST_USER=edrc

EDRC_OWNER

Owner of the **WA2L/edrc** software. This is the user the EDRC environment is installed with. See **edrcsetup**(1m) for information about user settings needed by **WA2L/edrc**.

Example: EDRC_OWNER=root

Default: EDRC_OWNER=root

DENY_LIST

Space separated list of functions/commands to be denied from invocation in EDRC. Be aware, that certain denials made here could be by-passed dependent of the operating system by the built in functionality of the **more**(1) and **vi**(1) commands used by EDRC internally. Be also aware, that potential sources of by-passing the denials are also the contributed commands, and of course the recovery scripts.

To minimize possible by-passes in contributed commands and in recovery script configurations (used in shared configurations with partly restricted rights) the **is_permitted**(3) command should be used to control command startup.

Currently the following denials are available: *banner, browse, busy, clear, contrib, contrib.*, date, debug, distribute, edit_file, edrcdebug, edrcperm, env, env.edit, env.more, env.new, env.remove, env.view, erase, header, header.edit, header.more, header.new, header.remove, help, history, hostname, loadrec, log, log.grep, log.head, log.more, log.tail, log.view, man, menu, more_file, name, new_file, newmenu, newscript, PID, printrec, recoveryscript.*, remove_file, removemenu, removescript, renamemenu, renamescript, script, script.edit, script.more, script.start, script.view, setrec, shell, term, title, title.edit, title.more, title.new, title.remove, trunk, trunk.change, trunk.edit, trunk.follow, trunk.more, trunk.new, trunk.remove, trunkbypass, tty, tz, view_file.*

Denials represented by a single word deny access to a command as a whole. If a denial consists of two words separated by a point, this will deny access to a sub function of a command. Denials containing an underscore deny access to low level functions that are used by many commands or command functions. Therefore if you like to deny any file editing in **edrc** you should add *edit_file* to the **DENY_LIST** instead of listing all *<command>.edit* denials.

Honestly, I could not imagine why to use many of those denials, but it gives you the maximal flexibility of configuration.

Example: `DENY_LIST="newscript newmenu contrib.omnimon"`

Default: `DENY_LIST=""`

DIST_MODE

Comma separated list of modes used to distribute the files in **SCRIPTS_BASEDIR**. The supported modes are: *rtools* which result in the use of **rcp** and **rsh** or *OpenSSH* which results in the use of **scp** and **ssh** for distribution. If a comma separated list is provided, the connection initiation is made in the sequence specified. A pseudo distribution mode is *default* which results in the use of the **CONNECTION_MODE** specified in the configuration files **remote_shell.cfg** and **remote_copy.cfg**. It is not allowed to specify *default* as part of a comma separated list.

Example: `DIST_MODE=rtools,OpenSSH`

Default: `DIST_MODE=rtools`

DIST_TYPE

Type of distribution. The supported types are: *serial* which results in a host by host distribution or *parallel:max* which results in a parallel distribution to multiple hosts. The *max* option specifies the maximal number of parallel distribution sessions.

Example: `DIST_TYPE=parallel:20`

Default: `DIST_TYPE=serial`

EDRC_OWNER

Owner of the WA2L/edrc software. This is the user the EDRC environment is installed with. See **edrcsetup(1m)** for information about user settings needed by WA2L/edrc.

Example: `EDRC_OWNER=root`

Default: `EDRC_OWNER=root`

EDRC_PROMPT

Prompt to be displayed before the @ symbol in **edrc**.

Example: `EDRC_PROMPT=sysadmin`

Default: `EDRC_PROMPT=edrc`

EDRC_HOSTPROMPT

With this setting it can be chosen, if the host name in the prompt that is displayed after the @ symbol in **edrc** is displayed in full length (*long*), or if only the host name part (*short*) is displayed.

Example: `EDRC_HOSTPROMPT=short`

Default: `EDRC_HOSTPROMPT=long`

BACKUP_DIR

This setting is used by **scriptextract** only. **scriptextract** saves all script files ahead of extracting (installing) the newly distributed scripts to this directory.

Example: `BACKUP_DIR=/var/opt/edrc/backup`

Default: `BACKUP_DIR=var/backup`

BACKUP_GENERATIONS

This setting is used by **scriptextract** only. Here the number of kept script backup versions can be specified. If this setting is set to 0, all versions will be kept and no backup purging will take place.

Based on experiences with systems having WA2L/edrc installed for about five years, the space needed to keep all script backup versions is not huge in average. Therefore this value can be set to a reasonable high value or to 0 without having bad feelings.

Example: `BACKUP_GENERATIONS=200`

Default: `BACKUP_GENERATIONS=0`

TMP_DIR

Specify the location of temporary files generated by **edrc** and **scriptextract**. It is only needed to change this setting from the default value if you experience filesystem fill ups on the default location. An alternate temporary directory has to have the identical permissions as the default location */tmp*.

Example: TMP_DIR=/var/tmp

Default: TMP_DIR=/tmp

CONTRIB_MESSAGE

Normally ahead of executing a contributed command the message "edrc-INFO: starting contributed command 'example'" is printed. To switch this message off, change this setting from *True* to *False*.

Example: CONTRIB_MESSAGE=False

Default: CONTRIB_MESSAGE=True

NOTRECOGNIZED_MESSAGE

If this option is set to *True* the message "edrc-WARNING: 'example' is not recognized as a command or menu point." is printed if the user enters a command which is neither an internal/contributed command nor a menu point in the current recovery script menu. To switch this message off, change this setting from *True* to *False*.

Example: NOTRECOGNIZED_MESSAGE=True

Default: NOTRECOGNIZED_MESSAGE=False

RECOVERYPOINTINTIME_MESSAGE

If this option is set to *True* the message "edrc-WARNING: recovery point in time is *NOT* set!" is printed if the user starts a command and the recovery point in time is not set. It will not make sense to set this option to *False* in a disaster recovery script tree. However, if you use **sat** or an other configuration whose main purpose is not disaster recovery but system administration where you'll never use the "recovery point in time" it might be useful to not to print this message. To switch this message off, change this setting from *True* to *False*.

Example: RECOVERYPOINTINTIME_MESSAGE=False

Default: RECOVERYPOINTINTIME_MESSAGE=True

SETENVIRONMENT_MESSAGE

If this option is set to *True* the message "edrc-INFO: ahead of starting 'a:example' the environment defined in '_env' will be set" is printed if the user starts a command and an environment file exists for the current menu. It will not make sense to set this option to *False* in a disaster recovery script tree. However, if you use **sat** or an other configuration whose main purpose is not disaster recovery but system administration where you don't want to show ahead of each command start the message if an environment will be set it might be useful to not to print this message. To switch this message off, change this setting from *True* to *False*.

Example: SETENVIRONMENT_MESSAGE=False

Default: SETENVIRONMENT_MESSAGE=True

ABORT_MODE

Abort mode. This setting influences the abort behavior of edrc. If edrc receives the INT (Ctrl+C) or TERM (kill) signal the program will abort completely if **ABORT_MODE** = *hard*, **edrc** will only abort the current running script or command if **ABORT_MODE** = *soft*.

Example: ABORT_MODE=soft

Default: ABORT_MODE=hard

HISTORY_LENGTH

edrc saves every command you enter in a history. When you issue the **history** EDRC command a list of your last invoked commands is displayed. The length of this list can be configured with this option.

Example: HISTORY_LENGTH=20

Default: HISTORY_LENGTH=100

HISTORY_SEARCH

Number of history lines to be searched for a numbered command. The history is searched from the end to the beginning.

Example: HISTORY_SEARCH=200

Default: HISTORY_SEARCH=100

HISTORY_BROWSE

Control if the history can be accessed using the cursor keys and **vi** controls (**j**, **k**, **/**).

On systems with **OSID=*Linux*** the **HISTORY_BROWSE** is turned on (**=True**) by default (if the system supports it), on other OSIDs it's turned off.

Example: HISTORY_BROWSE=False

Default: HISTORY_BROWSE=True (for OSID *Linux*)

Default: HISTORY_BROWSE=False (for other OSID)

MAN_PATH

Additional man pages which are not available in the \$MANPATH of the user defined in **START_USER**. This additional manpages will be appended to the current \$MANPATH and are accessible thru the **man** command within EDRC. Do not add the man pages of EDRC to this path, those pages are available by default.

Note: This setting has become of minor importance. If all defined manual pages should be displayed in all **edrc** configurations identically, and also in **man** (**edrcman**), the manual page locations should be listed in the **edrcman.cfg** file.

Example: MAN_PATH=/opt/omni/man:/opt/apl/asystools/man

Default: MAN_PATH=-

NAME

edrcinit – WA2L/edrc services startup/shutdown/restart/status

SYNOPSIS

edrc/bin/edrcinit [**-h**]

edrcinit (**start** | **stop** | **restart** | **refresh** | **status** | **statuslist**) [*name*]

edrcinit list | **guard** | **unguard** | **checknow** | **rcinstall** | **enable** | **disable**

edrcinit (**cfg-activate** | **cfg-unactivate** | **cfg-guard** | **cfg-unguard**) *name*

AVAILABILITY

WA2L/edrc

DESCRIPTION

handle services start/stop/restart, primarily for daemons included in WA2L/edrc, but other services can be handled as well. **edrcinit** supports to monitor and to restart a failed service based on the definitions made in the **edrcinit.cfg** config file.

OPTIONS

start start WA2L/edrc service(s).

stop stop WA2L/edrc service(s).

When a guarded service is stopped using '**edrcinit stop name**' it is not guarded until '**edrcinit start [name]**' is invoked.

restart restart WA2L/edrc service(s). A **restart** is equal to a '**edrcinit stop; edrcinit start**' invocation.

refresh restart a non interruptive service restart. In the **edrcinit_handler** a restart should be implemented that way, that the targeted service receives a command or signal, that causes a non-interruptive restart. This is often implemented by reacting to a received **SIGHUP** signal.

status print status of all activated service(s).

statuslist print status of all service(s) in list form.

name service name. If this option is not specified, all defined and activated service(s) are addressed.

- list** list all defined service(s).
- guard** guard the service(s). With this option it is possible to switch on the guarding of the services, that are defined to be guarded. This option is only used after switching off the service guarding using the '**edrcinit unguard**' command.
- unguard** Switch the guarding of the services globally off. After a newstart of **edrcinit** or the invocation of '**edrcinit guard**' the guarding is switched on again.
- checknow** force an immediate service check.
- rcinstall** install a small rc script to the system related **init** directory (**/etc/init.d/**, **/sbin/init.d/** or **/etc/init/**) and ensure that **edrcinit** is started on system boot.
- enable** globally enable the start of services handled thru **edrcinit** after the startup has been disabled using **edrcinit disable**.
- The prerequisite to ensure the start of **edrcinit** is the installation of the related rc script thru the invocation of **edrcinit rcinstall**.
- disable** globally disable the start of **edrcinit** even if **edrcinit rcinstall** has been invoked, but without the need to disable the service startup system wide.
- Even when the service startup has been disabled using the **edrcinit disable** command, services can still interactively be started, stopped, etc. using the **edrcinit { start | stop | ... }**
- cfg-activate** *name*
set *activated* in the configuration file for the service *name* to **Y**.
- cfg-unactivate** *name*
set *activated* in the configuration file for the service *name* to **N**.
- cfg-guard** *name*
set *guarded* in the configuration file for the service *name* to **Y**.
- cfg-unguard** *name*
set *guarded* in the configuration file for the service *name* to **N**.

ENVIRONMENT

\$PRINT_FIT2WIDTH

If not set to *False*, the output when invoking the **list** option is limited to the current width of the terminal window and rows extending the window width are marked with '>>'. If set to *False* the whole output line is printed and wrapped at the line end if applicable.

EXIT STATUS

- 0** no error.
- 1** error in start/stop/restart/refresh/status of specified service(s) or guard/unguard of services(s).
- 2** operating system not supported.
- 3** configfile does not exist.
- 4** usage listed.
- 5** specified service name (*name*) is not defined or is not activated.
- 8** **edrcinit** cannot write to logfile.
- 11** temporary directory could not be claimed or created in **/tmp**. Check the system temporary directory **/tmp** if you get this error, it is an indicator of system intrusion.

FILES

- etc/edrcinit.cfg**
config file of **edrcinit**.
- lib/edrcinit/**
directory for handlers of the service(s) handled thru **edrcinit**. See **edrcinit.handler(3)** for additional information.
- lib/edrcinit/WA2Ledrc.edrcinit.check**
check script of watchdog to guard the services in **edrcinit**.
- lib/edrcinit/WA2Ledrc.edrcinit.bite**
bite script of watchdog to guard the services in **edrcinit**.
- var/log/edrcinit.log**
log file of **edrcinit**.
- var/edrcinit/settings**
persistent data of **edrcinit**.
- var/edrcinit/stopped**
list of stopped services using the '**edrcinit stop** [*name*]' command.

EXAMPLES

-

SEE ALSO

edrcintro(1), **edrcinit.cfg(4)**, **edrcinit.handler(3)**, **kill(1)**, **signal(7)**, **vsav(1)**, **watchdog(1)**

NOTES

The guarding of the services is handled thru a watchdog with the name **EDRCINIT** which is started thru **edrcinit**. See **watchdog(1)** for more information.

BUGS

edrcinit is tested on Solaris, HPUX, RedHat Linux, SuSE Linux, Fedora Linux and Ubuntu Linux and supports the specific startup methods of the related operating system.

NAME

edrcinit.cfg – configuration file for edrcinit

SYNOPSIS

edrc/etc/edrcinit.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **edrcinit** command.

FILEFORMAT

Rows starting with a **#** are considered as comments.

The fileformat for the '**GENERAL OPTIONS**' is **OPTION=VALUE**

Between the **OPTION**, the **=** and the **VALUE** are no spaces.

You should not comment out any **OPTION**. If you like to use default settings simply do not specify a **VALUE**.

For the '**SERVICE HANDLING OPTIONS**', the fileformat is *field ; field ; field ; field ; field ; field ; field ; .*

OPTIONS**GENERAL OPTIONS****LOG_HANDLEROUTPUT**

Set to True to log the output of the startup handlers to the logfile.

Example: LOG_HANDLEROUTPUT=False

Default: LOG_HANDLEROUTPUT=False

SCREEN_HANDLEROUTPUT

Set to True to print the output of the startup handlers to the screen.

Example: SCREEN_HANDLEROUTPUT=False

Default: SCREEN_HANDLEROUTPUT=False

LOG Log output dir of edrcinit. If you specify a relative path name the path is relative to the root of the EDRC installation.

Example: LOG=/var/opt/ACME/log

Default: LOG=/var/log

CHECK_INTERVAL

Interval of edrcinit checks in seconds.

Example: CHECK_INTERVAL=600,120

Default: CHECK_INTERVAL=600,120

WATCHDOG_NAME

Name of the watchdog that guards the services. This setting has to be changed only if there is a clash with another watchdog using the same name on the system.

Example: WATCHDOG_NAME=EDRCINIT

Default: WATCHDOG_NAME=EDRCINIT

EDRC_USER

User in which HOME WA2L/edrc is installed.

Example: EDRC_USER=edrc

Default: EDRC_USER=edrc

SERVICE HANDLING OPTIONS

The format of the service handling specification is:

sequence ; activated ; guarded ; name ; description ; handler ; handleroptions ;

where the fields have the following content:

sequence startup sequence number.

activated startup activated (**Y**=activated, **N**=not activated).

guarded service monitored and guarded (**Y**=YES, **N**=NO).

name name of the service (should be unique).

description
short service description.

handler service handler

handleroptions
optional service handler options.

EXAMPLE

```
#
# etc/edrcinit.cfg - configuration file for edrcinit
#
# [00] 26.05.2009 CWa    Initial Version
#

NAME

edrcinit.handler – handle start/stop/refresh/status of a service

SYNOPSIS

edrc/lib/edrcinit/PreFix.ApplicationName

AVAILABILITY

WA2L/edrc

DESCRIPTION

handler to start/stop/status/refresh services for an application handled by the **edrcinit**(1m) command.

OPTIONS

- | | |
|----------------|---|
| start | start the service. |
| stop | stop the service. |
| refresh | reload the service configuration (if possible without service interruption). |
| status | return 0 if the service is running (UP), return 1 if the service is not running (DOWN). |

ENVIRONMENT

-

EXIT STATUS

- | | |
|----------|---|
| 0 | handler could execute the related action with success. The status of the service is: UP. |
| 1 | handler executed the related action with failure. The status of the service is: DOWN. |

FILES

edrc/lib/edrcinit/

directory where all **edrcinit**(1m) handlers are saved.

EXAMPLES

See in directory **edrc/lib/edrcinit/** for example handler scripts.

NAME

edrcenv – display the environment variables exported by edrc

SYNOPSIS

edrc/bin/edrcenv

AVAILABILITY

WA2L/edrc

DESCRIPTION

Print all environment variables that are exported to the recovery scripts and the shell by **edrc**. Aside the environment variable names the current values are printed, too.

Do not use other variables seen by your scripts which are related to the WA2L/edrc environment because they may disappear in future releases or its content may change without notice.

The **edrcenv** is intended to be used in the **shell** invoked within **edrc** to quickly display all official **edrc** environment variables.

OPTIONS

-

ENVIRONMENT

For an explanation of all environment variables listed with **edrcenv** see section **ENVIRONMENT** in **edrc(1m)**.

Everyone is permitted to copy and distribute verbatim copies
of this license document, but changing it is not allowed.

Preamble

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public License is intended to guarantee your freedom to share and change free software--to make sure the software is free for all its users. This General Public License applies to most of the Free Software Foundation's software and to any other program whose authors commit to using it. (Some other Free Software Foundation software is covered by the GNU Library General Public License instead.) You can apply it to your programs, too.

When we speak of free software, we are referring to freedom, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish), that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs; and that you know you can do these things.

To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights. These restrictions translate to certain responsibilities for you if you distribute copies of the software, or if you modify it.

For example, if you distribute copies of such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.

We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.

Also, for each author's protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original authors' reputations.

Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the

program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.

The precise terms and conditions for copying, distribution and modification follow.

GNU GENERAL PUBLIC LICENSE
TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The "Program", below, refers to any such program or work, and a "work based on the Program" means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or translated into another language. (Hereinafter, translation is included without limitation in the term "modification".) Each licensee is addressed as "you".

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program). Whether that is true depends on what the Program does.

1. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program.

You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

2. You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:

- a) You must cause the modified files to carry prominent notices stating that you changed the files and the date of any change.
- b) You must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.
- c) If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a

notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this License. (Exception: if the Program itself is interactive but does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Program.

In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

3. You may copy and distribute the Program (or a work based on it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:

- a) Accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,
- b) Accompany it with a written offer, valid for at least three years, to give any third party, for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,
- c) Accompany it with the information you received as to the offer to distribute corresponding source code. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for making modifications to it. For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable. However, as a special exception, the source code distributed need not include

anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.

4. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

5. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Program or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Program (or any work based on the Program), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Program or works based on it.

6. Each time you redistribute the Program (or any work based on the Program), the recipient automatically receives a license from the original licensor to copy, distribute or modify the Program subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties to this License.

7. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Program at all. For example, if a patent license would not permit royalty-free redistribution of the Program by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Program.

If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply and the section as a whole is intended to apply in other circumstances.

It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system, which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and a licensee cannot impose that choice.

This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

8. If the distribution and/or use of the Program is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Program under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.

9. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Program specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Program does not specify a version number of this License, you may choose any version ever published by the Free Software Foundation.

10. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

NO WARRANTY

11. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

12. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

END OF TERMS AND CONDITIONS

How to Apply These Terms to Your New Programs

If you develop a new program, and you want it to be of the greatest possible use to the public, the best way to achieve this is to make it free software which everyone can redistribute and change under these terms.

To do so, attach the following notices to the program. It is safest to attach them to the start of each source file to most effectively convey the exclusion of warranty; and each file should have at least the "copyright" line and a pointer to where the full notice is found.

```
<one line to give the program's name and a brief idea of what it does.>
Copyright (C) <year> <name of author>
```

```
This program is free software; you can redistribute it and/or modify
it under the terms of the GNU General Public License as published by
the Free Software Foundation; either version 2 of the License, or
(at your option) any later version.
```

```
This program is distributed in the hope that it will be useful,
but WITHOUT ANY WARRANTY; without even the implied warranty of
MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the
GNU General Public License for more details.
```

```
You should have received a copy of the GNU General Public License
along with this program; if not, write to the Free Software
Foundation, Inc., 59 Temple Place, Suite 330, Boston, MA 02111-1307 USA
```

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this when it starts in an interactive mode:

```
Gnomovision version 69, Copyright (C) year name of author
Gnomovision comes with ABSOLUTELY NO WARRANTY; for details type `show w'.
This is free software, and you are welcome to redistribute it
under certain conditions; type `show c' for details.
```

The hypothetical commands `show w' and `show c' should show the appropriate parts of the General Public License. Of course, the commands you use may be called something other than `show w' and `show c'; they could even be

mouse-clicks or menu items--whatever suits your program.

You should also get your employer (if you work as a programmer) or your school, if any, to sign a "copyright disclaimer" for the program, if necessary. Here is a sample; alter the names:

Yoyodyne, Inc., hereby disclaims all copyright interest in the program
'Gnomovision' (which makes passes at compilers) written by James Hacker.

<signature of Ty Coon>, 1 April 1989
Ty Coon, President of Vice

This General Public License does not permit incorporating your program into proprietary programs. If your program is a subroutine library, you may consider it more useful to permit linking proprietary applications with the library. If this is what you want to do, use the GNU Library General Public License instead of this License.

NAME

edrcman – display WA2L/edrc manual pages

SYNOPSIS

edrc/bin/edrcman [**-h** | **-w** | **-s** | **-m** | **-l** ([*os*] | *sys*)]

edrcman [*manpage*]

edrcman [*section*] *manpage*
edrcman *manpage* [. *section*]

edrcman [*man_options*] [*section*] *manpage*
edrcman [*man_options*] *manpage* [. *section*]

edrcman -o [*OS*] [*man_options*] [*section*] *manpage*
edrcman -o [*OS*] [*man_options*] *manpage* [. *section*]

edrcman -i [*SYSTEM*] *manpage* [. *section*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

With **edrcman** you can view the manual pages provided with WA2L/edrc without setting the `$MANPATH` environment variable. To display the manpages the operating system's own **man** command is used internally.

OPTIONS

- h** show **edrcman** usage.
- help** show **man**(1) usage.
- w** print `$MANPATH` that is searched by the **man** command.
- s** print `$MANSECT` that defines the manual page sections that are searched by the **man** command.

-m list man page mappings from **edrc/etc/edrcman.map**.

-l ([*os*] | *sys*)
list available bundled *OS* or *SYSTEM* man pages.

-o [*OS*] show/search only the WA2L/edrc bundled native manual pages of the related operating system.

The *OS* (not case sensitive) can be an operating system ID as returned by **osid(3)**, or the operating system name and version (use: **-l** to list the possible *OS* specifications).

If the *OS* is not specified, the **\$MAN_OSID** is used as *OS*.

-i [*SYSTEM*]
show internet based (<https://manned.org/>, <https://man.freebsd.org/>) manual pages of the given operating *SYSTEM* variant.

Available *SYSTEM*s are: **alpine**, **arch**, **centos**, **darwin**, **debian**, **dragonfly**, **fedora**, **freebsd**, **hpux**, **irix**, **linux**, **macos**, **macosx**, **minix**, **netbsd**, **openbsd**, **opendarwin**, **opensuse**, **osf1**, **plan9**, **rocky**, **slackware**, **solaris**, **sunos**, **sunos4**, **sunos5**, **suse**, **true64**, **ubuntu**, **ultrix**, **v7**, **x11**, **xfree86** and to query the general manual pages: **[M]ANNED** or **[F]REEBSD**, whereas the default is derived from the **/etc/os-release** file, if possible.

man_options
all native man options.

manpage manual page to be read. If no *manpage* is specified, the **edrcintro(1)** is displayed.

section manual page section.

ENVIRONMENT

\$MAN_OSID
if this environment variable is not set, the **osid(3)** command. The only reason to set the **\$MAN_OSID** variable is, when it is needed to check manual pages of operating system dependent commands without logging in to a system resolving that operating system to the related OS-id.

\$LANG if **LC_ALL** in **edrcman.cfg** is not set and **\$LANG** is not empty, the contents of **\$LANG** is used as **\$LC_ALL** for the **man** command. Else the *C* locale is used as default.

\$LC_ALL if **LC_ALL** is not defined in **edrcman.cfg** the contents of the environment variable is used for the **man** command

other for other possible environment variable settings see **man(1)**.

EXIT STATUS

- 4** usage displayed.
- 6** config file **edrcman.cfg** not found.
- 16** manual page requested does not exist. If the requested page is a currently missing WA2L/edrc manual page, a message indicating to call **edrcman edrcintro** is printed.
- 17** for the operating system specified in the **-o OS** option no native manual pages are bundled with WA2L/edrc.
- x** the exit status of native **man**, see **man(1)** for more information.

FILES

- edrc/man/** manual pages.
- edrc/man/all**
WA2L/edrc manual pages and manual pages for all operating systems.
- edrc/man/all/man1/EDRC.1**
index man page of WA2L/edrc.
- edrc/man/<OS-id>/**
manpages of operating system dependent WA2L/edrc commands.
- edrc/man/OS/<OS-id>/**
manpages collection of operating system commands. This to provide (closely native) operating system manual pages on systems where the manual pages are not installed or to check command usage of other operating systems (**export MAN_OSID=osid**) when developing commands (see also: **mandir(4)** manpage). To view this manual pages, add

```
'approot'/man/OS/${MAN_OSID}
```

preferably as last entry to the **MAN_PAGE=...** setting in **edrc/etc/edrcman.cfg**.
- edrc/etc/edrcman.cfg**
configuration file of **edrcman**, see **edrcman.cfg(4)** for more information.
- edrc/etc/edrcman.map**
mapfile to map certain manual pages.
- edrc/etc/perl_wrapper.cfg**
configuration file of **perl_wrapper(3)**. The **MODULE_DIR** setting of this file is read to resolve the man page location of perl modules bundled with WA2L/edrc. See **perl_wrapper.cfg(4)** for more information.

edrc/var/cache/edrcman/

resolution cache of the **edrcman** command if the **CACHE** setting in the configuration file **edrc/etc/edrcman.cfg** is not set to *False*.

edrc/var/cache/edrcman/meta

meta data for the resolution cache. This file is used to check if the cache data is still valid.

edrc/var/cache/edrcman/data

this file contains the cache data, the resolved **MANPATH** and **MANSECT** settings for the system where **edrcman** has been executed.

/etc/os-release

Linux operating system release information file.

EXAMPLES

-

SEE ALSO

edrcintro(1), **edrcman.cfg(4)**, **edrcman.map(4)**, **edrc(1m)**, **man(1)**, **mandir(4)**, **manpages(4)**, **osid(3)**, **perl_wrapper.cfg(4)**

NOTES

If you called the shell command within **edrc** the **man** command is an alias to **edrcman**.

NAME

edrcman.cfg – configuration file for edrcman

SYNOPSIS

edrc/etc/edrcman.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **edrcman** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS

CACHE Cache settings resolved by **edrcman** if setting is not set to **False**.

Example: **CACHE=False**

Default: **CACHE=True**

LC_ALL Set **LC_ALL** to ensure proper manpage display (also special characters).

Example: **LC_ALL=C**

Default: **LC_ALL=**

MAN_PATH

space separated list of additional man pages which are not available in the **\$MANPATH** of the user starting **edrcman**. This additional manpages will be appended to the standard **\$MANPATH** and are accessible thru the **edrc 'man'** command. Do not add the man-pages of WA2L/edrc to this path, those pages are available by default.

Example: MAN_PATH= /opt/graphics/common/man /opt/hparray/share/man

Default: MAN_PATH= 'approot'/man/<OSID> 'approot'/man/all

MAN_SYS

Operating system variant name.

Available names are: **alpine**, **arch**, **centos**, **darwin**, **debian**, **dragonfly**, **fedora**, **freebsd**, **hpux**, **irix**, **linux**, **macos**, **macosx**, **minix**, **netbsd**, **openbsd**, **opendarwin**, **opensuse**, **osf1**, **plan9**, **rocky**, **slackware**, **solaris**, **sunos**, **sunos4**, **sunos5**, **suse**, **true64**, **ubuntu**, **ultrix**, **v7**, **x11**, **xfree86** and for general manual pages: **[M]ANNED** or **[F]REEBSD**.

If no **MAN_SYS** is set the name is resolved from the **/etc/os-release** configuration file.

Example: MAN_SYS=ALL

Default: MAN_SYS=

NAME

edrcman.map – manual page mappings

SYNOPSIS

etc/edrcman.map

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the manual page map file for the **edrcman** command.

The mappings defined here take into effect, when the manual page is not found in other locations of the **\$MANPATH**.

FILEFORMAT

Rows starting with a **#** are considered as comments.

ENTERED;*MAPPED*;

Where:

ENTERED manual page one entered on the command line: **man** *manual-page* .
The *ENTERED* field entry is not case sensitive.

MAPPED this entry specified the manual page that is displayed in place of the one entered on the command line.
The *MAPPED* field entry is not case sensitive.

EXAMPLES

```
#
# edrcman.map - map manual pages
#
# [00] 10.02.2019 CWa   Initial Version
#
FROM;TO;
a;edrcintro;
abc;edrcintro;
history;edrcintro;
intro;edrcintro;
ll;ls;
llcomp;edrcintro;
lscomp;edrcintro;
month;edrcintro;
name;edrcintro;
path;edrcintro;
```

```
pathlist;edrcintro;  
pid;ps;  
revision;edrcintro;
```

NAME

edrcpack – pack WA2L/edrc application to a software package

SYNOPSIS

edrc/bin/edrcpack [**-h**]

edrcpack [**-d** *output_dir*] [**-p** *version*] [**-s**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

!! edrcpack IS DEPRECIATED AND THE FUNCTIONALITY HAS BEEN REDUCED, USE pack !!

edrcpack uses the command **pack -a edrc** *edrcpack_options* internally.

But only a very reduced set of options of **pack** is available when using **edrcpack**. Therefore use **pack** to create a software package of WA2L/edrc.

See **pack**(1m) for the description.

OPTIONS

See **pack**(1m) for the detail description of all options.

-h usage message.

-d *output_dir*
 directory where to put the package file.

-p *version* patch package to the specified version.

-s split package also in pieces which fit to a diskette.

ENVIRONMENT

See **pack**(1m).

EXIT STATUS

See **pack**(1m).

FILES

See **pack**(1m).

EXAMPLES

See **pack**(1m).

SEE ALSO

edrcintro(1), **pack**(1m), **pack.cfg**(4)

NOTES

edrcpack is only available for backward compatibility and no longer maintained.

BUGS

See **pack**(1m).

AUTHOR

NAME

edrcports – directory of network ports and protocols used by WA2L/edrc

SYNOPSIS

-

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is a directory of network ports used by default by the WA2L/edrc package.

The following table shows the ports needed for a certain WA2L/edrc command/service to be able to run.

Index:

- x = mandatory, needed for base functionality
- + = mandatory, needed on bidirectional connection (between WA2L/edrc systems)
- . = not mandatory, but needed if tools shall be used on bidirectional connection (between WA2L/edrc systems)
- L = localhost connection only.
- ! = default port (can be changed in configuration file or on command line)

Reasonable User Experience: WA2L/edrc

For a reasonable user experience and most common use where WA2L/edrc is installed on multiple nodes within customer environment(s), at least the following protocols and ports should be enabled for use. This enables the use of the base functionality of WA2L/edrc without using advanced capabilities of the toolset:

| NAME | PROTOCOL | PORT | INBOUND | OUTBOUND | COMMAND / SERVICE | COMMENTS |
|-------|----------|------|---------|----------|--|----------|
| SSH | TCP | 22 | + | + | edrc (and: sat, asup, psup, sys, rsat, lots) | |
| ICMP | IP | - | | | | |
| DNS | TCP/UDP | 53 | | | | |
| HTTPS | TCP | 443 | | x | edrc → edrcupgrade | download |

Details: SSH

| NAME | PROTOCOL | PORT | INBOUND | OUTBOUND | COMMAND / SERVICE | COMMENTS |
|------|----------|------|---------|----------|---|---|
| SSH | TCP | 22 | + | + | edrc → distribute edrc → edrcupgrade edrc → tail edrc → trunk | also for: sat, asup, psup, sys, lots |
| | | | | | filedist is_up passwdsyncd rcmd remote_copy remote_shell rsat | |
| | | | . | x | loggrep lgrep rcat rcomm rdiff rosid rsync rssh shell <i>host</i> ssh-exec sys2html syspoll whoisin | |

Details: ICMP, SMB

| NAME | PROTOCOL | PORT | INBOUND | OUTBOUND | COMMAND / SERVICE | COMMENTS |
|--------------|----------|------------|---------|----------|---|---|
| ICMP ECHO | IP | – | + | + | edrc → distribute edrc → edrcupgrade edrc → tail edrc → trunk is_up | also for: sat, asup, psup, sys, lots |
| | | | | | edrc → ping | |
| | | | . | x | traceroute | |
| SMB | TCP | 135 445 | . | x | syspoll winexe wmic | WMI |

Details: RPC

Most likely in your WA2L/edrc environment RPC is not used and not needed. See **edrcsetup(1m)** step 3.1 for additional information.

| NAME | PROTOCOL | PORT | INBOUND | OUTBOUND | COMMAND / SERVICE | COMMENTS |
|------|----------|------|---------|----------|--|---|
| RPC | TCP/UDP | 111 | + | + | edrc → distribute edrc → edrcupgrade edrc → tail edrc → trunk | also for: sat, asup, psup, sys, lots |
| | | | | | filedist passwdsyncd rcmd remote_copy remote_shell rsat shell <i>host</i> syspoll | |

NAME

edrcperm.no_shell – pseudo shell to deny access to a shell from vi, more, etc.

SYNOPSIS

edrc/lib/edrc/edrcperm.no_shell

AVAILABILITY

WA2L/edrc

DESCRIPTION

The **edrcperm.no_shell** command is used within **edrc** as a pseudo shell to deny access to the real shell via the built in commands of **vi**, **view** and **more** when the *shell* permission is listed in **DENY_LIST** in the **edrc** config file **etc/edrc.cfg**.

Beside the stdout message, a log entry is created.

The following dialog appears, if a user tries to invoke the shell within **vi** :

```
edrc-WARNING execution of functionality 'shell' not permitted.  
Press RETURN to continue
```

OPTIONS

-

ENVIRONMENT

-

EXIT STATUS

0 always.

EXAMPLES

1) How to implement shell access denial

Code cut-out to deny shell access within commands that provide shell access as **vi**, **view** and **more** :

```
:  
save_shell=$SHELL  
export SHELL='aproot `/lib/edrc/edrcperm.no_shell
```

```
vi $file
export SHELL=$save_shell
:
```

NAME

edrcrevision.cfg – configuration file for edrcrevision

SYNOPSIS

edrcrevision/etc/edrcrevision.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file containing the revision of the WA2L/edrc package.

edrc reads the **edrcrevision.cfg** file to resolve the package revision. To display the package revision invoke **edrc -V** or **banner** within **edrc**.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**VERSION**

Version of the WA2L/edrc in the format <major>.<update> . See **edrcrevision(1)** section **RELEASE-NUMBERS** for an explanation of the release numbering system used in WA2L/edrc.

Example: VERSION=1.5

Default: -

PATCHLEVEL

Patchlevel of the WA2L/edrc in the format <patchlevel> . The Patchlevel is a two-digit number. See **edrcrevision(1)** section **RELEASE-NUMBERS** for an explanation of the release numbering system used in WA2L/edrc.

Example: PATCHLEVEL=02

Default: -

SEE ALSO

NAME

edrcroot – print the root of the WA2L/edrc installation

SYNOPSIS

edrc/lib/edrcroot

AVAILABILITY

WA2L/edrc

DESCRIPTION

!! DO NOT USE edrcroot FOR NEW COMMANDS, USE approot !!

With **edrcroot** the root of the WA2L/edrc software installation is printed. This command is used inside the command to evaluate the basedir.

EXIT STATUS

0 always

SEE ALSO

edrcintro(1), **approot(3)**

NOTES

edrcroot will be replaced by **approot** completely as soon as all commands has been migrated to use **approot** instead of **edrcroot**.

BUGS

-

AUTHOR

edrcroot was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

edrcscripts – writing recovery scripts in edrc

SYNOPSIS

edrc/bin/scripts/CUSTOMER-edrc/...

edrc/bin/scripts/CUSTOMER-sat/...

edrc/bin/scripts/CUSTOMER-sat/sup:Support/osup:OperationSupport/...

edrc/bin/scripts/CUSTOMER-sat/sup:Support/psup:ProductionSupport/...

CUSTOMER ::= ‘server_environment -C’

AVAILABILITY

WA2L/edrc

DESCRIPTION**READ ALSO**

It is highly recommended to also read the manual pages listed in the **SEE ALSO** section, especially **edrc(1m)** and **edrcintro(1)** because the WA2L/edrc package provides many commands and concepts that significantly ease up the efficient development of recovery scripts.

CREATE/RENAME/REMOVE RECOVERY SCRIPTS

Recovery scripts are created using the **newscript** command in **edrc (1m)**, are renamed using the **rename-script** command and are removed using **removescript**.

The **newscript** command provides a script file template and ensures that the recovery script name adheres to the supported name convention.

edrc maintains an environment that makes it obsolete to initialize common settings of the operating system in each script and makes a recovery script tree portable.

CENTRAL INITIALIZATION AND COMMAND EXECUTION

If it is needed to centrally initialize variables or execute commands before each script in a menu, the **env** command in **edrc** supports to do this initialization or command start before each script by handling an environment-file that sits in the menu.

Candidates of commands to be executed in an environment-file created with **env** are for example **scripttitle(3)** and **scriptsequence(3)**.

CREATE/RENAME/REMOVE (SUB) MENUS

(Sub)Menus are created, renamed and removed using the **newmenu**, **renamemenu** and **removemenu** commands in **edrc**.

DOCUMENTATION

A recovery script can easily be documented using **doc** tags as understood by the **contrib.doc (1m)** command.

Doing this the description can be easily displayed using the **doc** contributed command, which generates an ah-hoc manual page where the essentials to know about a script, as if a RE-RUN of the script is allowed, the duration of the execution or an example output and more can be documented.

This documentation can be used later to produce a whole documentation, the ScriptDocBook using the **scriptdocbook** command that can be used for offline-reading in a Web-browser without the need to write another documentation.

OPTIONS

recovery scripts do not receive options, all input needs to be queried, best using the **input(3)** and **choice(3)** commands which are tuned to work smooth with **edrc(1m)**.

ENVIRONMENT

See section **ENVIRONMENT** in **edrc(1m)** for a description of all environment variables exported to a recovery script.

Use the **edrcenv(1)** command in the **shell** started from **edrc** or the **edrcenv** contributed command in **edrc** to print the official environment variables that can be used.

EXIT STATUS

a recovery script can exit with any exit status, it will not be resolved.

FILES**\$EDRC_TMP_DIR/**

secure temporary directory that should be used by a recovery script to save temporary data.

The directory with a unique name is created new just before the start of a recovery script and is removed after the script execution.

Therefore a recovery script doesn't need to take care of the temporary directory.

\$EDRC_TMP_DIR_SESSION/

this variable points to a secure temporary directory that exists during the execution of an **edrc** session and is afterwards removed. This variable is exported to recovery scripts, contributed commands and the shell command only.

This variable should be used to securely save temporary data from recovery scripts or contributed commands that must be accessed multiple times throughout the **edrc** session.

You should add the name of the recovery script or contributed command as prefix to ensure a unique filename.

Example:

```
date > $EDRC_TMP_DIR_SESSION/$EDRC_SCRIPTNAME.data
```

If you need to save temporary data during the execution of a recovery script or a contributed command the **\$EDRC_TMP_DIR** variable shall be used.

EXAMPLES

1) Example environment (_env) file:

```
#
# _env - Environment settings for commands in /DR
#
# [00] 07.05.2020 CWa Initial Version
#
#
test "$DEBUG" = True && set -x

scripttitle
scriptsequence -a query || exit

export AVAMAR_ADMIN="admin"
export AVAMAR_SYSADMIN="sysadmin"

export CONNECTION_USER="edrc"
```

2) Example recovery script:

```
#!/bin/bash
#
# 1291:setup_ndmp - setup NDMP accelerator
#
# [00] 06.05.2020 CWa Initial Version
#
#
test "$DEBUG" = True && set -x

# const and defaults
#
user_at_node=root@acme-007.acme.ch
root_password="\pwsafe root@IDPA\""

# query information
#
while [ "$ok" != "y" ]; do
    echo
```

```

        root_password=`input "Root server password" "$root_password" \
                           LOG_STARS,NOT_NULL,NO_TRIM`
        echo
        ok=`choice "input OK? <yn>" yn n`
done
echo

# execute commands
#
ssh-exec -l $CONNECTION_USER -u $user_at_node <<EOM

[COMMANDS]

NAME

edrcsetup – How to install WA2L/edrc (Quick Installation Guide)

AVAILABILITY

WA2L/edrc

DESCRIPTION

The following seven steps explain how to efficiently perform an initial setup of WA2L/edrc in an environment.

The distribution package is a shell archive (example: **edrc-1.4.08-200502150919.sh**). When you execute the shell archive all needed credentials are prompted and the installation is straight forward.

If you received WA2L/edrc as a splitted archive (example: **edrc-1.0.00-200401281209.sh.piece_aa ... ax, edrc-1.0.00-200401281209.sh.piece.sh**) you have to invoke the **edrc-1.0.00-200401281209.sh.piece.sh** command first to concatenate the pieces to the shell archive (see step 0 below).

REQUIREMENTS

The WA2L/edrc package has the following requirements to software installed on the system:

Bourne Shell

the Bourne shell **/bin/sh** has to be installed in **/bin/**.

Korn- or Bourne-Again Shell

The Korn shell **ksh** or the Bourne-Again shell **bash** has to be installed somewhere on the system. See **ksh_wrapper(1)** for additional information.

Perl

The Perl interpreter **perl** has to be installed somewhere on the system. See **perl_wrapper(1)** for additional information.

AWK

The AWK interpreter **awk** and **nawk** (only on Solaris) has to be installed somewhere in the standard **\$PATH** of the related operating system.

Java

The Java runtime environment **java** should be installed somewhere on the system. See **java_wrapper(1)** for additional information. If Java is not installed only a limited non-mandatory set of commands of WA2L/edrc is not available. See **compatibility(1)** and watch out for *JBIN* entries.

INSTALL STEPS

For a productive installation which will profit from the full functionality and is used for disaster recovery (DR) and/or operating system administration WA2L/edrc should be installed as user *root*.

0. Concatenate the splited WA2L/edrc package

If you received the archive splited into pieces, you have to concatenate the pieces first. A splited archive consists of a setup script and the splited archive: **edrc-1.0.00-200401281209.sh.piece.sh** (command to concatenate the pieces) **edrc-1.0.00-200401281209.sh.piece_ab ... ax** (splited archive). The **edrc-1.0.00-200401281209.sh.piece.sh** takes care that you have all needed pieces available and that those pieces are concatenated correctly.

```
host-001# sh ./edrc-1.0.00-200401281209.sh.piece.sh
```

→ goto step 1.

1. Copy the WA2L/edrc package to the first host

Ensure that you transfer the package in ***BINARY*** mode to the target system. Many SCP or SFTP clients on Windows (as FileZilla) will transfer this package in ASCII mode if the transfer mode is not explicitly specified as BINARY.

```
Start FileZilla
-> Connect to server using: SFTP - SSH File Transfer Protocol
-> Set Standard Transfer Type to: Binary
-> Transfer the package file to: host-001:/tmp
```

→ goto step 2.

2. Install the WA2L/edrc software

2.1 Execute the shell archive to install the software

Only install the software on the initial system.

In the subsequent steps the installation is configured and repacked. Then the repacked software is installed on all other hosts in the environment.

```
host-001# sh /tmp/edrc-1.4.08-200502150919.sh
```

The install script will prompt for all credentials and create the *edrc* user/group if selected:

```
***
***
***      SOFTWARE SHELL ARCHIVE
***
***      E D R C - Enterprise Disaster Recovery Console
***      UNIX/Linux version 1.4
```

```

install software package ...
  extract software to installation directory ...
    252519 blocks
  done.
  create group ...
    Groupname .. : edrc
    Group-ID ... : 911
  done.
  create user ...
    Username ... : edrc
    User-ID .... : 911
  done.
  check OSID mapping ...
    osid on this system is 'Linux'
  done.
  post installation steps ...
    1) read manpage: /opt/edrc/bin/edrcman edrcsetup
    2) read manpage: /opt/edrc/bin/edrcman edrc
    3) read manpage: /opt/edrc/bin/edrcman edrcintro
  done.
done.

```

HINTS:

- the "Installation Logfile" (**/tmp/edrc-1.4.08-200502150919.sh.1291.log**) content is appended to the install logfile (**edrc/var/log/install.log**) in the related installation directory when the installation of the WA2L/edrc package was possible.
- the temporary directory **/tmp/** has to have sufficient disk space holding at least the size of the shell archive. If this temporary space is not sufficient, the installation will abort and a message is printed. To

be able to install the WA2L/edrc package on systems with low free space in the **/tmp/** directory, set the **\$TMPDIR** variable to a directory having sufficient free space. Ensure that the directory specified in **\$TMPDIR** exists and that the install user has write permission in it.

- if the installation directory has not sufficient space to install the WA2L/edrc package, the installation will abort and a message is printed.

→ goto step 2.2

2.2 Edit the **osid.dat.WA2L** file to ensure that your operating system is supported.

WA2L/edrc has been developed on HP-UX 11.00 and tested on 11.11 ... 11.31, Solaris 8 ... 10 SPARC and x86, RedHat Linux 7.2, 8.0, Fedora Core 4 ... 17, SuSE Linux 5.3 ... 11.1, Ubuntu 14.04 and has been run on other flavors.

The installation gives the hint in

```
:
check OSID mapping ...
    osid on this system is 'Linux'
done.
:
```

if the operating system id (OSID) could be resolved.

If the OSID cannot be resolved, the **osid** command returns **unknown**:

```
host-001# ~edrc/lib/osid

unknown
```

The installation of the shell archive will give a hint of the OSID definition, as:

```
Linux:3.6.11-5.fc17.x86_64:x86_64:unknown:<Comment>:
```

The *unknown* placeholder must be replaced by a matching OSID, the *<Comment>* placeholder should be replaced by a meaningful human readable operating system description.

The OSID definition line can also be resolved later, invoking the **~edrc/lib/osid -e** command.

If your Operating System is sufficient similar to:

- **HP-UX 11.00, 11.11**, map it to the HP-11 OSID
- **Solaris 8**, map it to the Solaris OSID
- **RedHat Linux 7.2, 8.0**, map it to the Linux OSID
- **non of them**, ask the author about porting plans

See also manpages **osid(3)** and **osid.dat(4)**.

```
host-001# vi ~edrc/etc/osid.dat.WA2L
```

```

1  #
2  # osid.dat.WA2L - operating system map
3  #
4  # [00] ???.???.19?? SFI   Initial Version
5  # [01] 31.01.2003 CWa   Integrated into EDRC
6  #
7  :
8  30 #
9  31 # Fileformat: (see also man osid.dat)
10 32 #
11 33 #   <OS>:<release>:<machine>:<OSID>:<Comment>
12 34 #
13 35 #   <OS>          ::= uname -s
14 36 #   <release>     ::= uname -r
15 37 #   <machine>     ::= uname -m
16 38 #
17  :
18 94 Linux:2.6.18-164.el5:x86_64:Linux:RedHat ELinux Srv 5.4 (Tikanga):
19 95 Linux:2.6.18-164.el5:ia64:Linux-ia:RedHat ELinux Srv 5.4 (Tikanga):
20 96 Linux:2.6.35.[0-9].[0-9]-[0-9].[0-9].fc14.i686:i686:Linux:Fedora Core 14:
21 97 Linux:3.6.11-5.fc17.x86_64:x86_64:Linux:Fedora Core 17:
22 ~
23 ~

```

→ goto step 2.3

2.3 Start the interactive shell

The **shell**(1) command provides a proper environment with all needed **\$PATH** and other environment settings and useful additional commands and functions. Invoke **usage** within the **shell** to get a quick overview.

```

host-001# ~edrc/bin/shell

[ /root ]
[ root@host-001 ][*eshell*/bash]:

```

→ goto step 3.

3. Security setup (rtools and/or secure shell)

If you like to use the **distribute** command of **edrc** (highly recommended), the **~edrc/bin/filedist**, **~edrc/bin/rcmd** commands (very useful) and the **~edrc/bin/passwdsyncd**, edit the corresponding security files. It is possible to run the base functionality of WA2L/edrc in a rtools, secure shell or in a mixed setup.

The newer commands **~edrc/bin/rcat**, **~edrc/bin/rcomm**, **~edrc/bin/rdiff**, **~edrc/bin/rosid**, **~edrc/bin/ssh-exec**, **~edrc/bin/loggrep** and **~edrc/bin/whoisin** need a secure shell setup.

→ goto step 3.2 (for secure shell connection setup)

- goto step 3.1 (for rtools connection setup)
- goto step 3.1 and 3.2 (for a mixed setup)

3.1 Connection using rtools: rsh and rcp (DIST_MODE=rtools)

In nowadays rtools should not be used any more if there is not a really good reason to do so. Instead secure shell as explained in step 3.2. should be used.

- goto step 3.1.1

3.1.1 Edit the `~root/.rhosts` file on all hosts:

```
[ /root ]
[ root@host-001 ][*eshell*/bash]: vi ~root/.rhosts

1 host-001.acme.net edrc
2 host-002.acme.net edrc
:
:
~
~
```

- goto step 3.2 or 4.

3.2 Connection using secure shell: ssh and scp (DIST_MODE=OpenSSH)

Without doubt, this should be the default method to connect to the systems.

- goto step 3.2.1

3.2.1 Create the authentication keys (RSA and DSA)

This are the "local" ssh keys hat are used to connect within one customer environment.

```
[ / ]
[ root@host-001 ][*eshell*/bash]: su edrc

[ / ]
[ root@host-001 ][*eshell*/bash]: id

uid=911(edrc) gid=911(edrc) groups=911(edrc)

[ / ]
[ root@host-001 ][*eshell*/bash]: ssh-keygen -t dsa -C edrc@ACME \
    -f ~edrc/var/connection/security/edrc/OpenSSH/default/default/id_dsa
```

```
[ / ]
[ root@host-001 ][*eshell*/bash]: ssh-keygen -t rsa -C edrc@ACME \
    -f ~edrc/var/connection/security/edrc/OpenSSH/default/default/id_rsa

[ / ]
[ root@host-001 ][*eshell*/bash]: exit
```

See **edrc(1m)**, **remote_copy(3)** and **remote_shell(3)** for more information about the **edrc/var/connection** directory and **ssh-keygen(1)** for more information about authentication key generation.

If you get the error message "open /opt/edrc/.../default/id_dsa failed: Permission denied" can this be related to SELinux (Security-Enhanced-Linux). To fix this issue without to disable SELinux, invoke:

```
[ /opt/edrc/var/connection/security/edrc/OpenSSH/default ]
[ root@host-001 ][*eshell*/bash]: chcon -t ssh_home_t default
```

→ goto step 3.2.2

3.2.2 Add global authentication keys to the ~edrc/etc/ssh-keyadd.pub file

The "global" ssh public keys are those keys that might be used to manage all your customers environments and to connect from your central administration environment.

If you strictly use "local" ssh keys to connect within one customer and the "global" keys to connect from the central admin environment to all your customers and ensure that the private keys ***never*** leave an environment you can create an easy to manage and secure administration situation where you know all your keys.

In this example **ACME** is the customer environment and **Highlander** is the central administration environment (that can consist of a number of Linux/HP-UX/Solaris systems needed to centrally administer all your customers).

```
[ /root ]
[ root@host-001 ][*eshell*/bash]: vi ~edrc/etc/ssh-keyadd.pub

1 #
2 # ssh-keyadd.pub - global SSH public keys
3 #
4 # [00] 19.09.2010 CWa Initial Version

~
~

```

See **ssh-keyadd.pub**(4) for more information about this configuration file.

→ goto step 3.2.3

3.2.3 Add the authentication keys to the `~root/.ssh/authorized_keys` file

The command **ssh-keyadd** allows to efficiently handle the different ssh keys and also to quickly check the applied keys:

```

[ /root ]
[ root@host-001 ][*eshell*/bash]: ssh-keyadd

ssh-keyadd - add SSH public keys to a user, by Chr. Walther

add public keys to user 'root' ...
  list user's public SSH keys ...
    TYPE  KEY  COMMENT

    (4)

```

```

done.
adjust SSH daemon configuration? <yn> [y] :
adjust SSH daemon configuration ...
    edit configfile '/etc/ssh/sshd_config' ... done.
done.
send HUP signal to SSH daemon? <yn> [y] :
send HUP signal to SSH daemon ...
    process '/usr/sbin/sshd' with PID '9268' ... done.
done.
done.

```

See **ssh-keyadd(1m)** for more information about the command.

→ goto step 4.

4. Read at least the following man pages

With **edrcman** you can read the system and WA2L/edrc manpages without the need of adjusting the **\$MANPATH** variable.

If **shell** or **edrc** is started, the **man** command is an alias to **edrcman**.

```

[ /root ]
[ root@host-001 ][*eshell*/bash]: edrcman EDRC

[ /root ]
[ root@host-001 ][*eshell*/bash]: edrcman edrcintro

[ /root ]
[ root@host-001 ][*eshell*/bash]: edrcman edrc

```

→ goto step 5.

5. Configure the WA2L/edrc package

5.1 Edit the server_environment.cfg, hostlist.cfg and hostlist.dat files

Change to the configuration directory of WA2L/edrc.

```

[ /root ]
[ root@host-001 ][*eshell*/bash]: cdetc

```

→ goto step 5.1.1

5.1.1 Edit the server_environment.cfg file

In the **server_environment.cfg** it is defined which customer and environment (e.g. Customer=ACME, Environment=DEVELOPMENT) is related to certain servers.

```
[ /opt/edrc/etc ]
[ root@host-001 ][*eshell*/bash]: vi server_environment.cfg

1  #
2  # server_environment.cfg - config for server_environment
3  #
4  # [00] 24.07.2004 CWa Initial Version
5  #
6
7  # Server environment definition.
8  #
9  # If you log on to a system, the <NAME> field of the
10 # first matching <server_regex> will be returned.
11 #
12 :
13 #
14 #
15 #
16 # Format:
17 # <NAME>:<Description>:<server_regex>:<Customer>:
18 #
19 :
20 #
21 #
22 #
23 #
24 #
25 # ACME
26 #
27 PRODUCTION:Datacenter Bern, PRODUCTION Env:host-3[0-9][0-9]:ACME:
28 PREPRODUCTION:Datacenter Boston, Integration Env:host-2[0-9][0-9]:ACME:
29 TEST:Datacenter Plano, Test Env:host-1[0-9][0-9]:ACME:
30 DEVELOPMENT:Datacenter San Jose, Development Env:host-0[0-9][0-9]:ACME:
31
~
~
```

→ goto step 5.1.2

5.1.2 Edit the hostlist.cfg and hostlist.dat files

The hosts listed in the **hostlist.dat** file are returned when the **hostlist** [*options*] command is used. This enables you to write scripts that dynamically only address the hosts that are located in the same environment (e.g. TEST) as where you are starting the script. In other environments (e.g. PRODUCTION) the identical script can be used without modifications, but it will automatically address the hosts in that environment. With this method your script does not need to know about the actual setup of the environment.

Furthermore, to address a certain set of hosts, hostgroups can be defined.

The **@_DIST** hostgroup is "private" and is used to define the targets where the recovery script tree is distributed when invoking the **distribute** command in **edrc**. The **@_DIST** hostgroup should not be used in scripts.

The **@ALL** hostgroup is to address all hosts that exist in all environments of a customer setup (e.g. DEVELOPMENT + TEST + PREPRODUCTION + PRODUCTION). This hostgroup can be used in scripts.

In the following example the **@APP** hostgroup is used to address all application servers. The **@DB** hostgroup contains all database servers in the environment.

Set the **USE_HOSTLIST_DAT** setting in the **hostlist.cfg** file to *True* as in the given example:

```
[ /opt/edrc/etc ]
[ root@host-001 ][*eshell*/bash]: vi hostlist.cfg

1  #
2  # etc/hostlist.cfg - configuration of hostlist
3  #
4  # [00] 16.02.2004 CWa   Initial Version
5  #
6
7  # Set USE_HOSTLIST_DAT to True, if hosts are listed in
8  # the etc/hostlist.dat file, if hosts are defined directly
9  # in etc/hostlist.cfg, set USE_HOSTLIST_DAT to False.
10 #
11 USE_HOSTLIST_DAT=True
:
```

and add the hosts in the **hostlist.dat** file as in the following example:

```
[ /opt/edrc/etc ]
[ root@host-001 ][*eshell*/bash]: vi hostlist.dat

1  #
2  # etc/hostlist.dat - hostlist csv database file
3  #
4  # [00] 12.08.2008 CWa   Initial Version
5  # [58] 16.03.2013 CWa   chg: to hostlistdat2cfg structure
6  #
7
8  #
9  # Format:
10 #
11 #   <CUSTOMER>;<ENVIRONMENT>;<GROUPS>;<OPTIONS>;<HOSTS>
12 #
13 #   To verify the syntax, use: hostlistdat2cfg -a list_dat
14 #   Only correct entries will be listed.
15 #
16 ACME   ;DEVELOPMENT   ;@APP   ;;host-001 host-002;
17 ACME   ;DEVELOPMENT   ;@DB    ;;host-003;
18 ACME   ;TEST          ;        ;;host-101 host-103;
19 ACME   ;PREPRODUCTION ;        ;;host-201 host-203 host-205;
20 ACME   ;PRODUCTION    ;        ;;host-303 host-308 host-309;
~
~
```

The **@_DIST** and **@ALL** host groups don't have to be defined. The **hostlistdat2cfg** command, that is used to generate the **hostlist** configuration, creates those groups automatically.

If the setting **CMAN_ENVIRONMENT=CUSTOMER.NAME** in **hostlist.cfg** is used, more groups are available automatically when calling the **hostlist** command on a host that is part of the environment that is defined as the central administration environment.

To verify your settings use

```
[ /opt/edrc/etc ]
[ root@host-001 ][*eshell*/bash]: hostlist -p
```

to print all available hostgroups (human readable) and

```
[ /opt/edrc/etc ]
[ root@host-001 ][*eshell*/bash]: server_environment -l
```

to list all defined server environments.

See **server_environment(3)**, **server_environment.cfg(4)**, **hostlist(3)**, **hostlist.cfg(4)**, **hostlistdat2cfg(3)** and **hostlist.dat(4)** for more information. Configuration file samples are available in the **edrc/var/samples/hostlist/** directory.

If you installed WA2L/edrc as user *root* and used the *edrc* user to point to the software, as suggested in step 2.1, the main functions of the WA2L/edrc package are configured now.

→ goto step 5.2

5.2 Edit the .cfg files located in ~edrc/etc on one host

Now all other configuration files of WA2L/edrc can be checked and adjusted.

The general concept of the configurations in WA2L/edrc is, that the configuration files can be kept identical on all hosts across environments and customers.

To achieve this, the **server_environment(3)** and **hostlist(3)** commands are used extensively to set configuration values dynamically whenever possible.

```
[ /root ]
[ root@host-001 ][*eshell*/bash]: cdetc

[ /opt/edrc/etc ]
[ root@host-001 ][*eshell*/bash]: vi *.cfg
```

This step can also be performed later. The files then can be edited on one host and distributed to the others easily using the **filedist(1)** command.

→ goto step 5.3

5.3 Optional on low disk space in install directory

If disk space consumption is of concern the *contents* of the directories **edrc/src/** and **edrc/man/OS/** can be removed without impact to the running WA2L/edrc installation.

```
[ /opt/edrc ]
[ root@host-001 ][*eshell*/bash]: rm -rf man/OS/*

[ /opt/edrc ]
[ root@host-001 ][*eshell*/bash]: rm -rf src/*
```

→ goto step 6

6. Installation of WA2L/edrc on all hosts in the Customer Environment

6.1 Create an installable package of the configured software

Now, when the configuration is done, the software is repacked. This will supersede the configuration effort on the other systems within the customer environments.

```
[ /opt/edrc ]
[ root@host-001 ][*eshell*/bash]: pack

pack - create application package, by Chr. Walther

create package of application in '/opt/edrc' ...
  application information ...
    APPLICATION ..... : default
    APPLICATION_PREFIX ... : edrc_ACME
    APPLICATION_NAME ..... : WA2L/edrc
    APPLICATION_RELEASE .. : 1.4.08
    DESCRIPTION ..... : WA2L/edrc complete
  done.
  package information ...
    format ..... : shar
    type ..... : RELEASE
    file ..... : host-001:/tmp/edrc_ACME-1.4.08-20050401231
  done.
  write sadm file ...(/opt/edrc/var/pack/sadm/edrc_ACME-1.4.08-200504012315
  evaluate files to be packed ...(15137 files)... done.
  evaluate properties of files to be packed ... done.
  pack files to package file ...(258374 kB)... done.
done.
```

→ goto step 6.2

6.2 Copy software package to other hosts

Copy the created package to all environments of one customer.

```
[ /opt/edrc ]
[ root@host-001 ][*eshell*/bash]: scp \
```

```

/tmp/edrc_ACME-1.4.08-200504012315.sh root@host-002:/tmp

[ /opt/edrc ]
[ root@host-001 ][*eshell*/bash]: scp \
    /tmp/edrc_ACME-1.4.08-200504012315.sh root@host-003:/tmp

:
:

→ goto step 6.3

```

6.3 Install newly created package on all hosts and apply ssh keys

Initially this is a manual task.

Later the **filedist(1)** and **rcmd(1)** commands can be used to roll-out files and to execute commands easily on many systems.

For common software handling tasks, as patching, package generation etc. a special "recovery" script tree provided thru the **sys(1m)** short start, can be used.

```

host-002# sh /tmp/edrc_ACME-1.4.08-200504012315.sh
host-002# ~edrc/bin/ssh-keyadd -y

host-003# sh /tmp/edrc_ACME-1.4.08-200504012315.sh
host-003# ~edrc/bin/ssh-keyadd -y

:
:

→ goto step 7

```

7. Use EDRC - Enterprise Disaster Recovery Console

The "EDRC - Enterprise Disaster Recovery Console" startup command is **~edrc/sbin/edrc**. The short starts **~edrc/bin/sat**, **~edrc/bin/asup**, **~edrc/bin/psup** and **~edrc/bin/osup** give access to special purpose "recovery" script trees, as system- or application administration tasks.

From now on you can also use the **filedist(1)** command to easily distribute files and **rcmd(1)** to execute command(s) on all hosts in the environment.

To distribute recovery script trees in **edrc(1m)**, **sat(1m)** etc., the **distribute** command in **edrc** can be used.

Patches of the application can be downloaded from <http://sourceforge.net/projects/wa2l-edrc/> or your repository server and installed using the **edrcupgrade** command in **edrc**.

Currently the following pre-configured "recovery" script trees are distributed with WA2L/edrc:

- **~edrc/sbin/edrc** (= **~edrc/sbin/edrc -c edrc.cfg**)

Disaster recovery script tree.

- **~edrc/bin/sys** (= ~edrc/sbin/edrc -c edrc.sys.cfg)

System configuration handling and some automated EDRC tasks as WA2L/edrc roll-out and WA2L/edrc patch installation.

This menu tree is considered to be part of the WA2L/edrc package and is patched, too. Therefore you should not add/remove/change files in this "recovery" script tree, due to the fact that your changes might be lost after an WA2L/edrc update.

- **~edrc/bin/lotsetl** (= ~edrc/sbin/edrc -c edrc.lotsetl.cfg)

Menu tree to efficiently handle **lots**(1m), (long term data save).

This menu is also considered to be part of the WA2L/edrc package and is patched, too. The config files **lotsetl.cfg**(4), **edrc.lotsetl.cfg** and the topmost **_env** file in the menu tree will not be overwritten by patches and are allowed to be changed.

If adjusting the mentioned configuration files is not sufficient for your needs and you like to adjust the menu tree provided thru **lotsetl**, consider to create a copy of it using **edrc/scripts/lotsetl** as template when invoking the **newscripttree** contributed **edrc** command and adjusting the **SCRIPTS_BASEDIR** setting in **edrc/etc/edrc.lotsetl.cfg** to point to the created copy.

- **~edrc/bin/sat** (= ~edrc/sbin/edrc -c edrc.sat.cfg)

System Administration menus to automate common tasks in the environment.

- **~edrc/bin/asup** (= ~edrc/sbin/edrc -c edrc.asup.cfg)

System Administration menu for application support tasks in the environment. Please pay attention to the special configuration for this menu tree, which is part of the **~edrc/bin/sat** tree, but editing and distribution is denied because the idea is to start it by non-root users via **sudo**.

- **~edrc/bin/psup** (= ~edrc/sbin/edrc -c edrc.psup.cfg)

System Administration menu for production support tasks in the environment. Please pay attention to the special configuration for this menu tree, which is part of the **~edrc/bin/sat** tree, but editing and distribution is denied because the idea is to start it by non-root users via **sudo**.

- **~edrc/bin/osup** (= ~edrc/sbin/edrc -c edrc.osup.cfg)

System Administration menus for operation support tasks in the environment. Please pay attention to the special configuration for this menu tree, which is part of the **~edrc/bin/sat** tree, but editing and distribution is denied.

EDRC(1), **edrc**(1m), **edrcintro**(1), **edrcports**(4), **binprobe**(1m), **compatibility**(1), **filedist**(1), **hostlist**(3), **hostlistdat2cfg**(3), **java_wrapper**(1), **ksh_wrapper**(1), **loggrep**(1), **osid**(3), **osid.dat**(4), **pack**(1m), **patchinstall**(1m), **pf_wrapper**(1), **perl_wrapper**(1), **rcat**(1), **rcmd**(1), **rcomm**(1), **rdiff**(1), **rosid**(3), **ssh-exec**(1), **sudo**(8), **sudoers**(5), **sys**(1)

NOTES

See **pack(1m)** for instructions how to create an installable shell archive of an already installed WA2L/edrc package.

To start some commands thru **sudo**, the following lines could be added to the **/etc/sudoers** file, using the **visudo** command. To ensure, that the user has to supply the own password to execute the privileged commands, the settings in line 55 and 56 should be commented out or removed from the file.

In the example below the **PASSWD:** setting results in asking for the password of the calling (unprivileged) user prior to command execution as an additional security measurement.

```
[ /etc ]
[ root@host-001 ][*eshell*/bash]: sav sudoers; visudo

1  #
2  # /etc/sudoers - sudo access definition file
3  #
4  # [01] 25.02.2012 CWa  +*_EDRC_* definitions
5  #
6  ##
7  ## Sudoers allows particular users to run various commands
8  ## as the root user, without needing the root password.
9  ##
10 :
11 ## User Aliases
12 User_Alias    ROLE_EDRC_ADM = john, fred
13 User_Alias    ROLE_EDRC_OPS = barney
14 User_Alias    ROLE_EDRC_USR = wilma, betty
15
16 # WA2L/edrc definitions
17 #
18 ROLE_EDRC_ADM ALL = PASSWD: CMD_EDRC_USR, CMD_EDRC_OPS, CMD_EDRC_ADM
19 ROLE_EDRC_OPS ALL = PASSWD: CMD_EDRC_USR, CMD_EDRC_OPS
20 ROLE_EDRC_USR ALL = PASSWD: CMD_EDRC_USR
21 Cmnd_Alias    CMD_EDRC_ADM = /opt/edrc/bin/shell, /opt/edrc/bin/sat,\
22                                     /opt/edrc/sbin/edrc, /opt/edrc/bin/sys
23 Cmnd_Alias    CMD_EDRC_OPS = /opt/edrc/bin/osup, /opt/edrc/bin/lotsctl
24 Cmnd_Alias    CMD_EDRC_USR = /opt/edrc/bin/asup, /opt/edrc/bin/psup
25 :
26 # In the default (unconfigured) configuration, sudo asks for the root
27 # password. This allows use of an ordinary user account for
28 # administration of a fresh installed system. When configuring sudo,
29 # delete the two following lines:
30 #Defaults     targetpw      # specify passwd of target user i.e root
31 #ALL          ALL=(ALL) ALL # only together with 'Defaults targetpw'
32 :
33 ~
34 ~
35 ~
```

See also **pf_wrapper(1)** for a more detailed description of the **sudoers** example above.

As soon as the **sudoers** entries are defined as given above, the commands **asup**, **edrc**, **lotsctl**, **osup**, **psup**, **sat**, **shell** and **sys** can be started by the user being member of the related role with **root** permissions simply

by adding the directory **~edrc/pbin** to the **\$PATH** environment variable (**export PATH=~edrc/pbin:\$PATH**) in the related personal shell startup rc-file. This also works, if **RBAC** for controlling elevated permissions is used.

Therefore when using the **pbin** directory, a user having elevated permissions on those commands does not need to know, if it is needed to use **sudo sat** or **pfexec sat** on a certain system, it is sufficient to call **sat**.

See section **FILES** in **edrcintro(1)** for a description of the **pbin** directory and **pf_wrapper(1)**.

NAME

env – environment configuration file for ini

SYNOPSIS

edrc/etc/env

\$HOME/.myenv

\$BASEDIR/etc/env

\$BASEDIR/etc/env. domainname

\$BASEDIR/etc/env. hostname

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the environment configuration definition for the **ini** command.

FILEFORMAT

The fileformat is a list of definitions that have the format

KEY:VARIABLE=setting

Rows starting with a **#** are considered as comments. Empty lines are allowed, too.

OPTIONS

KEY application name.

VARIABLE
environment variable.

setting value settings of the *VARIABLE*.

EXAMPLES

```

#
# etc/env - central environment settings for ini
#
# [00] 07.02.2000 CWa   Initial Version
# [01] 06.02.2000 CWa   integrated into edrc
#

NAME

envpasswdstrip – strip out passwords from `_env` files

SYNOPSIS

`edrc/bin/envpasswdstrip [-h]`

`envpasswdstrip -print | -execute`

AVAILABILITY

WA2L/edrc

DESCRIPTION

strip passwords from all `_env` files below the current directory. Files in the `.sav` directory are not changed.

The purpose of **envpasswdstrip** is to avoid a hand out of the passwords saved in `_env` files of recovery script trees that will be shared with other administrators.

envpasswdstrip replaces the *VALUES* setting in the definition of the format "**export passwd=VALUE**" or "**export password=VALUE**" with *PASSWORD_STRIPED_OUT*.

OPTIONS

- h** usage message.
- print** do not actually change the `_env` files found starting in the current directory, print only the original and the changed entries of the file.
- execute** change the files `_env` files below the current directory.

ENVIRONMENT

-

EXIT STATUS

- 0** no error.
- 2** operating system not supported yet. See **osid(3)** if you get this error.
- 4** usage printed.

- 11** temporary directory could not be claimed in **/tmp/**. Check the system if you get this error it is an indicator of system intrusion.

NAME

epub2pdf – convert an ePUB eBook to PDF

SYNOPSIS

edrc/bin/epub2pdf [*file.epub*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

epub2pdf is a command-line tool that quickly generates PDF files from EPUB ebooks. It allows the user to specify page size, fonts, margins, and default paragraph alignment. See also <http://epub2pdf.com/>

OPTIONS

usage message.

file.epub ePUB eBook file to be converted to *file.pdf*

ENVIRONMENT

-

EXIT STATUS

0 always.

NAME

eshell – start the interactive shell in user context

SYNOPSIS

edrc/pbin/eshell [**-h**]

eshell [*host*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

The **eshell** command starts **shell**.

This command is located in the **edrc/pbin/** directory to enable the user to conveniently start the **shell** command in his own user context.

See **pf_wrapper**(1) for a description of the benefits of the use of the **edrc/pbin/** directory.

OPTIONS

See: **shell**(1).

ENVIRONMENT

See: **shell**(1).

NAME

eterm – start **edrc**, **asup**, **psup**, **shell**, **eshell** etc. in a separate X-terminal window

SYNOPSIS

edrc/(**pbin**|**bin**)/**eterm** [**-h** | **-l** | **-t**]

eterm [*app*]

eterm [**-i** | **-u**] [*app*]

app ::= **edrc** | **asup** | **osup** | **psup** | **sys** | **lotsctl** | **eshell** | **shell** | ...

AVAILABILITY

WA2L/**edrc**

DESCRIPTION

start application **edrc**, **asup**, **osup**, **psup**, **sys**, **lotsctl**, **eshell**, or **shell** (basically any application available in the **pbin/** directory) in a separate X-terminal window.

The **eterm** command also supports to create **Desktop** icons in the **Gnome** desktop environment.

If **eterm** is started when not logged into a X-session, the given *application* is started in the current shell.

This command is (also) located in the **pbin/** directory to enable the user to conveniently start it.

See **pf_wrapper**(1) for a description of the benefits of the use of the **edrc/pbin/** directory.

OPTIONS

-h usage.

-i install/define an application icon in the **Gnome** desktop environment for the given *app*.

-u uninstall/remove an application icon in the **Gnome** desktop environment for the given *app*.

-l list all defined **Desktop** icons.

-t list x-terminal search list.

app application to start in a separate X-terminal.

The applications available are those available in the **edrc/pbin/** directory: **edrc**, **asup**, **osup**, **psup**, **sys**, **lotsctl**, **eshell**, and **shell**, whereas **edrc** is the default.

ENVIRONMENT

\$ETERM_TERMINALS

space separated list of x-terminals to search (and start). The setting in **\$ETERM_TERMINALS** is prepended to the default search list.

Default on Linux: **gnome-terminal xterm uxterm lxterminal xfce4-terminal tilix mate-terminal konsole sakura urxvt dtterm**.

Default on HP-UX and Solaris: **dtterm xterm**.

\$DISPLAY

X display. If this variable is not set, the current terminal is not started in a X-session.

EXIT STATUS

- | | |
|----------|---|
| 0 | no error. |
| 1 | no terminal application found. |
| 2 | the Desktop directory was not found. |
| 4 | usage displayed. |
| 5 | command aborted. |

FILES

\$HOME/.local/share/application/eterm-app.desktop

icon definition file for the **G**nome desktop environment.

lib/icons/eterm.png

the application icon.

EXAMPLES

NAME

expect – programmed dialogue with interactive programs, Version 5

SYNOPSIS

expect [**-dDinN**] [**-c** *cmds*] [[**-[f]b**]] *cmdfile*] [*args*]

INTRODUCTION

Expect is a program that "talks" to other interactive programs according to a script. Following the script, **Expect** knows what can be expected from a program and what the correct response should be. An interpreted language provides branching and high-level control structures to direct the dialogue. In addition, the user can take control and interact directly when desired, afterward returning control to the script.

Expectk is a mixture of **Expect** and **Tk**. It behaves just like **Expect** and **Tk**'s **wish**. **Expect** can also be used directly in C or C++ (that is, without Tcl). See libexpect(3).

The name "Expect" comes from the idea of *send/expect* sequences popularized by uucp, kermi and other modem control programs. However unlike uucp, **Expect** is generalized so that it can be run as a user-level command with any program and task in mind. **Expect** can actually talk to several programs at the same time.

For example, here are some things **Expect** can do:

- Cause your computer to dial you back, so that you can login without paying for the call.
- Start a game (e.g., rogue) and if the optimal configuration doesn't appear, restart it (again and again) until it does, then hand over control to you.
- Run fsck, and in response to its questions, answer "yes", "no" or give control back to you, based on predetermined criteria.
- Connect to another network or BBS (e.g., MCI Mail, CompuServe) and automatically retrieve your mail so that it appears as if it was originally sent to your local system.
- Carry environment variables, current directory, or any kind of information across rlogin, telnet, tip, su, chgrp, etc.

There are a variety of reasons why the shell cannot perform these tasks. (Try, you'll see.) All are possible with **Expect**.

In general, **Expect** is useful for running any program which requires interaction between the program and the user. All that is necessary is that the interaction can be characterized programmatically. **Expect** can also give the user back control (without halting the program being controlled) if desired. Similarly, the user can return control to the script at any time.

USAGE

Expect reads *cmdfile* for a list of commands to execute. **Expect** may also be invoked implicitly on systems which support the #! notation by marking the script executable, and making the first line in your script:

```
#!/usr/bin/expect -f
```

Of course, the path must accurately describe where **Expect** lives. /usr/bin is just an example.

The **-c** flag prefaces a command to be executed before any in the script. The command should be quoted to prevent being broken up by the shell. This option may be used multiple times. Multiple commands may be executed with a single **-c** by separating them with semicolons. Commands are executed in the order they appear. (When using Expectk, this option is specified as **-command**.)

The **-d** flag enables some diagnostic output, which primarily reports internal activity of commands such as **expect** and **interact**. This flag has the same effect as "exp_internal 1" at the beginning of an Expect script, plus the version of **Expect** is printed. (The **strace** command is useful for tracing statements, and the **trace** command is useful for tracing variable assignments.) (When using Expectk, this option is specified as **-diag**.)

The **-D** flag enables an interactive debugger. An integer value should follow. The debugger will take control before the next Tcl procedure if the value is non-zero or if a ^C is pressed (or a breakpoint is hit, or other appropriate debugger command appears in the script). See the README file or SEE ALSO (below) for more information on the debugger. (When using Expectk, this option is specified as **-Debug**.)

The **-f** flag prefaces a file from which to read commands from. The flag itself is optional as it is only useful when using the **#!** notation (see above), so that other arguments may be supplied on the command line. (When using Expectk, this option is specified as **-file**.)

By default, the command file is read into memory and executed in its entirety. It is occasionally desirable to read files one line at a time. For example, stdin is read this way. In order to force arbitrary files to be handled this way, use the **-b** flag. (When using Expectk, this option is specified as **-buffer**.) Note that stdio-buffering may still take place however this shouldn't cause problems when reading from a fifo or stdin.

If the string "-" is supplied as a filename, standard input is read instead. (Use "-." to read from a file actually named "-".)

The **-i** flag causes **Expect** to interactively prompt for commands instead of reading them from a file. Prompting is terminated via the **exit** command or upon EOF. See **interpreter** (below) for more information. **-i** is assumed if neither a command file nor **-c** is used. (When using Expectk, this option is specified as **-interactive**.)

-- may be used to delimit the end of the options. This is useful if you want to pass an option-like argument to your script without it being interpreted by **Expect**. This can usefully be placed in the **#!** line to prevent any flag-like interpretation by Expect. For example, the following will leave the original arguments (including the script name) in the variable *argv*.

```
#!/usr/bin/expect --
```

Note that the usual getopt(3) and execve(2) conventions must be observed when adding arguments to the **#!** line.

The file `$exp_library/expect.rc` is sourced automatically if present, unless the **-N** flag is used. (When using Expectk, this option is specified as **-NORC**.) Immediately after this, the file `~/expect.rc` is sourced automatically, unless the **-n** flag is used. If the environment variable DOTDIR is defined, it is treated as a directory and `.expect.rc` is read from there. (When using Expectk, this option is specified as **-norc**.) This sourcing occurs only after executing any **-c** flags.

-v causes Expect to print its version number and exit. (The corresponding flag in Expectk, which uses long flag names, is **-version**.)

Optional *args* are constructed into a list and stored in the variable named *argv*. *argc* is initialized to the length of *argv*.

argv0 is defined to be the name of the script (or binary if no script is used). For example, the following prints out the name of the script and the first three arguments:

```
send_user "$argv0 [lrange $argv 0 2]\n"
```

COMMANDS

Expect uses *Tcl* (Tool Command Language). Tcl provides control flow (e.g., if, for, break), expression evaluation and several other features such as recursion, procedure definition, etc. Commands used here but not defined (e.g., **set**, **if**, **exec**) are Tcl commands (see tcl(3)). **Expect** supports additional commands, described below. Unless otherwise specified, commands return the empty string.

Commands are listed alphabetically so that they can be quickly located. However, new users may find it easier to start by reading the descriptions of **spawn**, **send**, **expect**, and **interact**, in that order.

Note that the best introduction to the language (both Expect and Tcl) is provided in the book "Exploring

Expect" (see SEE ALSO below). Examples are included in this man page but they are very limited since this man page is meant primarily as reference material.

Note that in the text of this man page, "Expect" with an uppercase "E" refers to the **Expect** program while "expect" with a lower-case "e" refers to the **expect** command within the **Expect** program.)

close [*-slave*] [*-onexec 0|1*] [*-i spawn_id*]

closes the connection to the current process. Most interactive programs will detect EOF on their stdin and exit; thus **close** usually suffices to kill the process as well. The **-i** flag declares the process to close corresponding to the named *spawn_id*.

Both **expect** and **interact** will detect when the current process exits and implicitly do a **close**. But if you kill the process by, say, "exec kill \$pid", you will need to explicitly call **close**.

The **-onexec** flag determines whether the spawn id will be closed in any new spawned processes or if the process is overlayed. To leave a spawn id open, use the value 0. A non-zero integer value will force the spawn closed (the default) in any new processes.

The **-slave** flag closes the slave associated with the spawn id. (See "spawn -pty".) When the connection is closed, the slave is automatically closed as well if still open.

No matter whether the connection is closed implicitly or explicitly, you should call **wait** to clear up the corresponding kernel process slot. **close** does not call **wait** since there is no guarantee that closing a process connection will cause it to exit. See **wait** below for more info.

debug [*-now*] *0|1*

controls a Tcl debugger allowing you to step through statements, set breakpoints, etc.

With no arguments, a 1 is returned if the debugger is not running, otherwise a 0 is returned.

With a 1 argument, the debugger is started. With a 0 argument, the debugger is stopped. If a 1 argument is preceded by the **-now** flag, the debugger is started immediately (i.e., in the middle of the **debug** command itself). Otherwise, the debugger is started with the next Tcl statement.

The **debug** command does not change any traps. Compare this to starting Expect with the **-D** flag (see above).

See the README file or SEE ALSO (below) for more information on the debugger.

disconnect

disconnects a forked process from the terminal. It continues running in the background. The process is given its own process group (if possible). Standard I/O is redirected to /dev/null.

The following fragment uses **disconnect** to continue running the script in the background.

```
if {[fork]! = 0} exit
disconnect
...
```

The following script reads a password, and then runs a program every hour that demands a password each time it is run. The script supplies the password so that you only have to type it once. (See the **stty** command which demonstrates how to turn off password echoing.)

```
send_user "password?\n"
expect_user -re "(.*)\n"
for {} 1 {} {
    if {[fork]! = 0} {sleep 3600;continue}
```

```

    disconnect
    spawn priv_prog
    expect Password:
    send "$expect_out(1,string)\r"
    ...
    exit
}

```

An advantage to using **disconnect** over the shell asynchronous process feature (&) is that **Expect** can save the terminal parameters prior to disconnection, and then later apply them to new ptys. With &, **Expect** does not have a chance to read the terminal's parameters since the terminal is already disconnected by the time **Expect** receives control.

exit [*-opts*] [*status*]

causes **Expect** to exit or otherwise prepare to do so.

The **-onexit** flag causes the next argument to be used as an exit handler. Without an argument, the current exit handler is returned.

The **-noexit** flag causes **Expect** to prepare to exit but stop short of actually returning control to the operating system. The user-defined exit handler is run as well as **Expect**'s own internal handlers. No further **Expect** commands should be executed. This is useful if you are running **Expect** with other Tcl extensions. The current interpreter (and main window if in the Tk environment) remain so that other Tcl extensions can clean up. If **Expect**'s **exit** is called again (however this might occur), the handlers are not rerun.

Upon exiting, all connections to spawned processes are closed. Closure will be detected as an EOF by spawned processes. **exit** takes no other actions beyond what the normal `_exit(2)` procedure does. Thus, spawned processes that do not check for EOF may continue to run. (A variety of conditions are important to determining, for example, what signals a spawned process will be sent, but these are system-dependent, typically documented under `exit(3)`.) Spawned processes that continue to run will be inherited by `init`.

status (or 0 if not specified) is returned as the exit status of **Expect**. **exit** is implicitly executed if the end of the script is reached.

exp_continue [*-continue_timer*]

The command **exp_continue** allows **expect** itself to continue executing rather than returning as it normally would. By default **exp_continue** resets the timeout timer. The **-continue_timer** flag prevents timer from being restarted. (See **expect** for more information.)

exp_internal [*-f file*] *value*

causes further commands to send diagnostic information internal to **Expect** to `stderr` if *value* is non-zero. This output is disabled if *value* is 0. The diagnostic information includes every character received, and every attempt made to match the current output against the patterns.

If the optional *file* is supplied, all normal and debugging output is written to that file (regardless of the value of *value*). Any previous diagnostic output file is closed.

The **-info** flag causes **exp_internal** to return a description of the most recent non-info arguments given.

exp_open [*args*] [*-i spawn_id*]

returns a Tcl file identifier that corresponds to the original spawn id. The file identifier can then be used as if it were opened by Tcl's **open** command. (The spawn id should no longer be used. A **wait** should not be executed.

The **-leaveopen** flag leaves the spawn id open for access through Expect commands. A **wait** must be executed on the spawn id.

exp_pid [*-i spawn_id*]

returns the process id corresponding to the currently spawned process. If the **-i** flag is used, the pid returned corresponds to that of the given spawn id.

exp_send

is an alias for **send**.

exp_send_error

is an alias for **send_error**.

exp_send_log

is an alias for **send_log**.

exp_send_tty

is an alias for **send_tty**.

exp_send_user

is an alias for **send_user**.

exp_version [*[-exit] version*]

is useful for assuring that the script is compatible with the current version of Expect.

With no arguments, the current version of **Expect** is returned. This version may then be encoded in your script. If you actually know that you are not using features of recent versions, you can specify an earlier version.

Versions consist of three numbers separated by dots. First is the major number. Scripts written for versions of **Expect** with a different major number will almost certainly not work. **exp_version** returns an error if the major numbers do not match.

Second is the minor number. Scripts written for a version with a greater minor number than the current version may depend upon some new feature and might not run. **exp_version** returns an error if the major numbers match, but the script minor number is greater than that of the running **Expect**.

Third is a number that plays no part in the version comparison. However, it is incremented when the **Expect** software distribution is changed in any way, such as by additional documentation or optimization. It is reset to 0 upon each new minor version.

With the **-exit** flag, **Expect** prints an error and exits if the version is out of date.

expect [*[-opts] pat1 body1*] ... [*[-opts] patn [bodyn]*]

waits until one of the patterns matches the output of a spawned process, a specified time period has passed, or an end-of-file is seen. If the final body is empty, it may be omitted.

Patterns from the most recent **expect_before** command are implicitly used before any other patterns. Patterns from the most recent **expect_after** command are implicitly used after any other patterns.

If the arguments to the entire **expect** statement require more than one line, all the arguments may be "braced" into one so as to avoid terminating each line with a backslash. In this one case, the usual Tcl substitutions will occur despite the braces.

If a pattern is the keyword **eof**, the corresponding body is executed upon end-of-file. If a pattern is the keyword **timeout**, the corresponding body is executed upon timeout. If no timeout keyword is used, an implicit null action is executed upon timeout. The default timeout period is 10 seconds but may be set, for example to 30, by the command "set timeout 30". An infinite timeout may be designated by the value **-1**. If a pattern is the keyword **default**, the corresponding body is executed upon either timeout or end-of-file.

If a pattern matches, then the corresponding body is executed. **expect** returns the result of the body (or the empty string if no pattern matched). In the event that multiple patterns match, the one appearing first is used to select a body.

Each time new output arrives, it is compared to each pattern in the order they are listed. Thus, you may test for absence of a match by making the last pattern something guaranteed to appear, such as a prompt. In situations where there is no prompt, you must use **timeout** (just like you would if you were interacting manually).

Patterns are specified in three ways. By default, patterns are specified as with Tcl's **string match** command. (Such patterns are also similar to C-shell regular expressions usually referred to as "glob" patterns). The **-gl** flag may be used to protect patterns that might otherwise match **expect** flags from doing so. Any pattern beginning with a "-" should be protected this way. (All strings starting with "-" are reserved for future options.)

For example, the following fragment looks for a successful login. (Note that **abort** is presumed to be a procedure defined elsewhere in the script.)

```
expect {
    busy      {puts busy\n ; exp_continue}
    failed    abort
    "invalid password" abort
    timeout   abort
    connected
}
```

Quotes are necessary on the fourth pattern since it contains a space, which would otherwise separate the pattern from the action. Patterns with the same action (such as the 3rd and 4th) require listing the actions again. This can be avoided by using regexp-style patterns (see below). More information on forming glob-style patterns can be found in the Tcl manual.

Regexp-style patterns follow the syntax defined by Tcl's **regexp** (short for "regular expression") command. regexp patterns are introduced with the flag **-re**. The previous example can be rewritten using a regexp as:

```
expect {
    busy      {puts busy\n ; exp_continue}
    -re "failed|invalid password" abort
    timeout   abort
    connected
}
```

Both types of patterns are "unanchored". This means that patterns do not have to match the entire string, but can begin and end the match anywhere in the string (as long as everything else matches). Use **^** to match the beginning of a string, and **\$** to match the end. Note that if you do not wait for the end of a string, your responses can easily end up in the middle of the string as they are echoed from the spawned process. While still producing correct results, the output can look unnatural. Thus, use of **\$** is encouraged if you can exactly describe the characters at the end of a string.

Note that in many editors, the **^** and **\$** match the beginning and end of lines respectively. However, because expect is not line oriented, these characters match the beginning and end of the data (as opposed to lines) currently in the expect matching buffer. (Also, see the note below on "system indigestion.")

The **-ex** flag causes the pattern to be matched as an "exact" string. No interpretation of *****, **^**, etc is made (although the usual Tcl conventions must still be observed). Exact patterns are always unanchored.

The **-nocase** flag causes uppercase characters of the output to compare as if they were lowercase characters. The pattern is not affected.

While reading output, more than 2000 bytes can force earlier bytes to be "forgotten". This may be changed with the function **match_max**. (Note that excessively large values can slow down the pattern matcher.) If *patlist* is **full_buffer**, the corresponding body is executed if *match_max* bytes have been received and no other patterns have matched. Whether or not the **full_buffer** keyword is used, the forgotten characters are written to `expect_out(buffer)`.

If *patlist* is the keyword **null**, and nulls are allowed (via the **remove_nulls** command), the corresponding body is executed if a single ASCII 0 is matched. It is not possible to match 0 bytes via glob or regexp patterns.

Upon matching a pattern (or eof or full_buffer), any matching and previously unmatched output is saved in the variable `expect_out(buffer)`. Up to 9 regexp substring matches are saved in the variables `expect_out(1,string)` through `expect_out(9,string)`. If the **-indices** flag is used before a pattern, the starting and ending indices (in a form suitable for **lrange**) of the 10 strings are stored in the variables `expect_out(X,start)` and `expect_out(X,end)` where X is a digit, corresponds to the substring position in the buffer. 0 refers to strings which matched the entire pattern and is generated for glob patterns as well as regexp patterns. For example, if a process has produced output of "abcdefgh\n", the result of:

```
expect "cd"
```

is as if the following statements had executed:

```
set expect_out(0,string) cd
set expect_out(buffer) abcd
```

and "efgh\n" is left in the output buffer. If a process produced the output "abbbcabkkkka\n", the result of:

```
expect -indices -re "b(b*).*(k+)"
```

is as if the following statements had executed:

```
set expect_out(0,start) 1
set expect_out(0,end) 10
set expect_out(0,string) bbbcabkkkk
set expect_out(1,start) 2
set expect_out(1,end) 3
set expect_out(1,string) bb
set expect_out(2,start) 10
set expect_out(2,end) 10
set expect_out(2,string) k
set expect_out(buffer) abbbcabkkkk
```

and "a\n" is left in the output buffer. The pattern "*" (and **-re ".*"**) will flush the output buffer without reading any more output from the process.

Normally, the matched output is discarded from Expect's internal buffers. This may be prevented by prefixing a pattern with the **-notransfer** flag. This flag is especially useful in experimenting (and can be abbreviated to **-not** for convenience while experimenting).

The spawn id associated with the matching output (or eof or full_buffer) is stored in `expect_out(spawn_id)`.

The **-timeout** flag causes the current expect command to use the following value as a timeout instead of using the value of the timeout variable.

By default, patterns are matched against output from the current process, however the **-i** flag declares the output from the named spawn_id list be matched against any following patterns (up to the next **-i**). The spawn_id list should either be a whitespace separated list of spawn_ids or a variable referring to such a list of spawn_ids.

For example, the following example waits for "connected" from the current process, or "busy", "failed" or "invalid password" from the spawn_id named by \$proc2.

```
expect {
    -i $proc2 busy {puts busy\n ; exp_continue}
    -re "failed|invalid password" abort
    timeout abort
    connected
}
```

The value of the global variable *any_spawn_id* may be used to match patterns to any spawn_ids that are named with all other **-i** flags in the current **expect** command. The spawn_id from a **-i** flag with no associated pattern (i.e., followed immediately by another **-i**) is made available to any other patterns in the same **expect** command associated with *any_spawn_id*.

The **-i** flag may also name a global variable in which case the variable is read for a list of spawn ids. The variable is reread whenever it changes. This provides a way of changing the I/O source while the command is in execution. Spawn ids provided this way are called "indirect" spawn ids.

Actions such as **break** and **continue** cause control structures (i.e., **for**, **proc**) to behave in the usual way. The command **exp_continue** allows **expect** itself to continue executing rather than returning as it normally would.

This is useful for avoiding explicit loops or repeated expect statements. The following example is part of a fragment to automate rlogin. The **exp_continue** avoids having to write a second **expect** statement (to look for the prompt again) if the rlogin prompts for a password.

```
expect {
    Password: {
        stty -echo
        send_user "password (for $user) on $host: "
        expect_user -re "(.*)\n"
        send_user "\n"
        send "$expect_out(1,string)\r"
        stty echo
        exp_continue
    } incorrect {
        send_user "invalid password or account\n"
        exit
    } timeout {
        send_user "connection to $host timed out\n"
        exit
    } eof {
        send_user \
            "connection to host failed: $expect_out(buffer)"
        exit
    } -re $prompt
```

```
}
```

For example, the following fragment might help a user guide an interaction that is already totally automated. In this case, the terminal is put into raw mode. If the user presses "+", a variable is incremented. If "p" is pressed, several returns are sent to the process, perhaps to poke it in some way, and "i" lets the user interact with the process, effectively stealing away control from the script. In each case, the **exp_continue** allows the current **expect** to continue pattern matching after executing the current action.

```
stty raw -echo
expect_after {
    -i $user_spawn_id
    "p" {send "\r\r\r"; exp_continue}
    "+" {incr foo; exp_continue}
    "i" {interact; exp_continue}
    "quit" exit
}
```

By default, **exp_continue** resets the timeout timer. The timer is not restarted, if **exp_continue** is called with the **-continue_timer** flag.

expect_after [*expect_args*]

works identically to the **expect_before** except that if patterns from both **expect** and **expect_after** can match, the **expect** pattern is used. See the **expect_before** command for more information.

expect_background [*expect_args*]

takes the same arguments as **expect**, however it returns immediately. Patterns are tested whenever new input arrives. The pattern **timeout** and **default** are meaningless to **expect_background** and are silently discarded. Otherwise, the **expect_background** command uses **expect_before** and **expect_after** patterns just like **expect** does.

When **expect_background** actions are being evaluated, background processing for the same spawn id is blocked. Background processing is unblocked when the action completes. While background processing is blocked, it is possible to do a (foreground) **expect** on the same spawn id.

It is not possible to execute an **expect** while an **expect_background** is unblocked. **expect_background** for a particular spawn id is deleted by declaring a new **expect_background** with the same spawn id. Declaring **expect_background** with no pattern removes the given spawn id from the ability to match patterns in the background.

expect_before [*expect_args*]

takes the same arguments as **expect**, however it returns immediately. Pattern-action pairs from the most recent **expect_before** with the same spawn id are implicitly added to any following **expect** commands. If a pattern matches, it is treated as if it had been specified in the **expect** command itself, and the associated body is executed in the context of the **expect** command. If patterns from both **expect_before** and **expect** can match, the **expect_before** pattern is used.

If no pattern is specified, the spawn id is not checked for any patterns.

Unless overridden by a **-i** flag, **expect_before** patterns match against the spawn id defined at the time that the **expect_before** command was executed (not when its pattern is matched).

The **-info** flag causes **expect_before** to return the current specifications of what patterns it will match. By default, it reports on the current spawn id. An optional spawn id specification may be given for information on that spawn id. For example

```
expect_before -info -i $proc
```

At most one spawn id specification may be given. The flag `-indirect` suppresses direct spawn ids that come only from indirect specifications.

Instead of a spawn id specification, the flag `"-all"` will cause `"-info"` to report on all spawn ids.

The output of the `-info` flag can be reused as the argument to `expect_before`.

expect_tty [*expect_args*]

is like **expect** but it reads characters from `/dev/tty` (i.e. keystrokes from the user). By default, reading is performed in cooked mode. Thus, lines must end with a return in order for **expect** to see them. This may be changed via **stty** (see the **stty** command below).

expect_user [*expect_args*]

is like **expect** but it reads characters from `stdin` (i.e. keystrokes from the user). By default, reading is performed in cooked mode. Thus, lines must end with a return in order for **expect** to see them. This may be changed via **stty** (see the **stty** command below).

fork creates a new process. The new process is an exact copy of the current **Expect** process. On success, **fork** returns 0 to the new (child) process and returns the process ID of the child process to the parent process. On failure (invariably due to lack of resources, e.g., swap space, memory), **fork** returns -1 to the parent process, and no child process is created.

Forked processes exit via the **exit** command, just like the original process. Forked processes are allowed to write to the log files. If you do not disable debugging or logging in most of the processes, the result can be confusing.

Some pty implementations may be confused by multiple readers and writers, even momentarily. Thus, it is safest to **fork** before spawning processes.

interact [*string1 body1*] ... [*stringn bodyn*]

gives control of the current process to the user, so that keystrokes are sent to the current process, and the `stdout` and `stderr` of the current process are returned.

String-body pairs may be specified as arguments, in which case the body is executed when the corresponding string is entered. (By default, the string is not sent to the current process.) The **interpreter** command is assumed, if the final body is missing.

If the arguments to the entire **interact** statement require more than one line, all the arguments may be "braced" into one so as to avoid terminating each line with a backslash. In this one case, the usual Tcl substitutions will occur despite the braces.

For example, the following command runs **interact** with the following string-body pairs defined: When `^Z` is pressed, **Expect** is suspended. (The `-reset` flag restores the terminal modes.) When `^A` is pressed, the user sees "you typed a control-A" and the process is sent a `^A`. When `$` is pressed, the user sees the date. When `^C` is pressed, **Expect** exits. If "foo" is entered, the user sees "bar". When `~` is pressed, the **Expect** interpreter runs interactively.

```
set CTRLZ \032
interact {
    -reset $CTRLZ {exec kill -STOP [pid]}
    \001 {send_user "you typed a control-A\n";
        send "\001"
    }
    $ {send_user "The date is [clock format [clock seconds]]."}
    \003 exit
    foo {send_user "bar"}
    ~
}
```

In string-body pairs, strings are matched in the order they are listed as arguments. Strings that partially match are not sent to the current process in anticipation of the remainder coming. If characters are then entered such that there can no longer possibly be a match, only the part of the string will be sent to the process that cannot possibly begin another match. Thus, strings that are substrings of partial matches can match later, if the original strings that was attempting to be match ultimately fails.

By default, string matching is exact with no wild cards. (In contrast, the **expect** command uses glob-style patterns by default.) The **-ex** flag may be used to protect patterns that might otherwise match **interact** flags from doing so. Any pattern beginning with a "-" should be protected this way. (All strings starting with "-" are reserved for future options.)

The **-re** flag forces the string to be interpreted as a regexp-style pattern. In this case, matching substrings are stored in the variable *interact_out* similarly to the way **expect** stores its output in the variable **expect_out**. The **-indices** flag is similarly supported.

The pattern **eof** introduces an action that is executed upon end-of-file. A separate **eof** pattern may also follow the **-output** flag in which case it is matched if an eof is detected while writing output. The default **eof** action is "return", so that **interact** simply returns upon any EOF.

The pattern **timeout** introduces a timeout (in seconds) and action that is executed after no characters have been read for a given time. The **timeout** pattern applies to the most recently specified process. There is no default timeout. The special variable "timeout" (used by the **expect** command) has no affect on this timeout.

For example, the following statement could be used to autologout users who have not typed anything for an hour but who still get frequent system messages:

```
interact -input $user_spawn_id timeout 3600 return -output \
    $spawn_id
```

If the pattern is the keyword **null**, and nulls are allowed (via the **remove_nulls** command), the corresponding body is executed if a single ASCII 0 is matched. It is not possible to match 0 bytes via glob or regexp patterns.

Prefacing a pattern with the flag **-iwrite** causes the variable *interact_out(spawn_id)* to be set to the *spawn_id* which matched the pattern (or eof).

Actions such as **break** and **continue** cause control structures (i.e., **for**, **proc**) to behave in the usual way. However **return** causes **interact** to return to its caller, while **inter_return** causes **interact** to cause a return in its caller. For example, if "proc foo" called **interact** which then executed the action **inter_return**, **proc foo** would return. (This means that if **interact** calls **interpreter** interactively typing **return** will cause the **interact** to continue, while **inter_return** will cause the **interact** to return to its caller.)

During **interact**, raw mode is used so that all characters may be passed to the current process. If the current process does not catch job control signals, it will stop if sent a stop signal (by default ^Z). To restart it, send a continue signal (such as by "kill -CONT <pid>"). If you really want to send a SIGSTOP to such a process (by ^Z), consider spawning **cs** first and then running your program. On the other hand, if you want to send a SIGSTOP to **Expect** itself, first call **interpreter** (perhaps by using an escape character), and then press ^Z.

String-body pairs can be used as a shorthand for avoiding having to enter the interpreter and execute commands interactively. The previous terminal mode is used while the body of a string-body pair is being executed.

For speed, actions execute in raw mode by default. The **-reset** flag resets the terminal to the mode it had before **interact** was executed (invariably, cooked mode). Note that characters entered when the mode is being switched may be lost (an unfortunate feature of the terminal driver on some systems). The only reason to use **-reset** is if your action depends on running in cooked mode.

The **-echo** flag sends characters that match the following pattern back to the process that generated them as each character is read. This may be useful when the user needs to see feedback from partially typed patterns.

If a pattern is being echoed but eventually fails to match, the characters are sent to the spawned process. If the spawned process then echoes them, the user will see the characters twice. **-echo** is probably only appropriate in situations where the user is unlikely to not complete the pattern. For example, the following excerpt is from `rftp`, the recursive-ftp script, where the user is prompted to enter `~g`, `~p`, or `~l`, to get, put, or list the current directory recursively. These are so far away from the normal ftp commands, that the user is unlikely to type `~` followed by anything else, except mistakenly, in which case, they'll probably just ignore the result anyway.

```
interact {
    -echo ~g {getcurdirectory 1}
    -echo ~l {getcurdirectory 0}
    -echo ~p {putcurdirectory}
}
```

The **-nobuffer** flag sends characters that match the following pattern on to the output process as characters are read.

This is useful when you wish to let a program echo back the pattern. For example, the following might be used to monitor where a person is dialing (a Hayes-style modem). Each time "atd" is seen the script logs the rest of the line.

```
proc lognumber { } {
    interact -nobuffer -re "(.*)\r" return
    puts $log "[clock format [clock seconds]]: dialed $interact_out(1,string)"
}

interact -nobuffer "atd" lognumber
```

During **interact**, previous use of **log_user** is ignored. In particular, **interact** will force its output to be logged (sent to the standard output) since it is presumed the user doesn't wish to interact blindly.

The **-o** flag causes any following key-body pairs to be applied to the output of the current process. This can be useful, for example, when dealing with hosts that send unwanted characters during a telnet session.

By default, **interact** expects the user to be writing stdin and reading stdout of the **Expect** process itself. The **-u** flag (for "user") makes **interact** look for the user as the process named by its argument (which must be a spawned id).

This allows two unrelated processes to be joined together without using an explicit loop. To aid in debugging, Expect diagnostics always go to stderr (or stdout for certain logging and debugging information). For the same reason, the **interpreter** command will read interactively from stdin.

For example, the following fragment creates a login process. Then it dials the user (not shown), and finally connects the two together. Of course, any process may be substituted for login. A shell, for example, would allow the user to work without supplying an account and password.

```
spawn login
set login $spawn_id
```

```
spawn tip modem
# dial back out to user
# connect user to login
interact -u $login
```

To send output to multiple processes, list each spawn id list prefaced by a **-output** flag. Input for a group of output spawn ids may be determined by a spawn id list prefaced by a **-input** flag. (Both **-input** and **-output** may take lists in the same form as the **-i** flag in the **expect** command, except that any_spawn_id is not meaningful in **interact**.) All following flags and strings (or patterns) apply to this input until another **-input** flag appears. If no **-input** appears, **-output** implies "-input \$user_spawn_id -output". (Similarly, with patterns that do not have **-input**.) If one **-input** is specified, it overrides \$user_spawn_id. If a second **-input** is specified, it overrides \$spawn_id. Additional **-input** flags may be specified.

The two implied input processes default to having their outputs specified as \$spawn_id and \$user_spawn_id (in reverse). If a **-input** flag appears with no **-output** flag, characters from that process are discarded.

The **-i** flag introduces a replacement for the current spawn_id when no other **-input** or **-output** flags are used. A **-i** flag implies a **-o** flag.

It is possible to change the processes that are being interacted with by using indirect spawn ids. (Indirect spawn ids are described in the section on the **expect** command.) Indirect spawn ids may be specified with the **-i**, **-u**, **-input**, or **-output** flags.

interpreter [args]

causes the user to be interactively prompted for **Expect** and Tcl commands. The result of each command is printed.

Actions such as **break** and **continue** cause control structures (i.e., **for**, **proc**) to behave in the usual way. However **return** causes interpreter to return to its caller, while **inter_return** causes **interpreter** to cause a return in its caller. For example, if "proc foo" called **interpreter** which then executed the action **inter_return**, **proc foo** would return. Any other command causes **interpreter** to continue prompting for new commands.

By default, the prompt contains two integers. The first integer describes the depth of the evaluation stack (i.e., how many times Tcl_Eval has been called). The second integer is the Tcl history identifier. The prompt can be set by defining a procedure called "prompt1" whose return value becomes the next prompt. If a statement has open quotes, parens, braces, or brackets, a secondary prompt (by default "+> ") is issued upon newline. The secondary prompt may be set by defining a procedure called "prompt2".

During **interpreter**, cooked mode is used, even if the its caller was using raw mode.

If stdin is closed, **interpreter** will return unless the **-eof** flag is used, in which case the subsequent argument is invoked.

log_file [args] [[-a] file]

If a filename is provided, **log_file** will record a transcript of the session (beginning at that point) in the file. **log_file** will stop recording if no argument is given. Any previous log file is closed.

Instead of a filename, a Tcl file identifier may be provided by using the **-open** or **-leaveopen** flags. This is similar to the **spawn** command. (See **spawn** for more info.)

The **-a** flag forces output to be logged that was suppressed by the **log_user** command.

By default, the **log_file** command *appends* to old files rather than truncating them, for the convenience of being able to turn logging off and on multiple times in one session. To truncate files, use

the **-noappend** flag.

The **-info** flag causes `log_file` to return a description of the most recent non-info arguments given.

log_user *-info|0|1*

By default, the send/expect dialogue is logged to stdout (and a logfile if open). The logging to stdout is disabled by the command "log_user 0" and reenabled by "log_user 1". Logging to the logfile is unchanged.

The **-info** flag causes `log_user` to return a description of the most recent non-info arguments given.

match_max *[-d] [-i spawn_id] [size]*

defines the size of the buffer (in bytes) used internally by **expect**. With no *size* argument, the current size is returned.

With the **-d** flag, the default size is set. (The initial default is 2000.) With the **-i** flag, the size is set for the named spawn id, otherwise it is set for the current process.

overlay *[-# spawn_id] [-# spawn_id] [...] program [args]*

executes *program args* in place of the current **Expect** program, which terminates. A bare hyphen argument forces a hyphen in front of the command name as if it was a login shell. All spawn_ids are closed except for those named as arguments. These are mapped onto the named file identifiers.

Spawn_ids are mapped to file identifiers for the new program to inherit. For example, the following line runs chess and allows it to be controlled by the current process – say, a chess master.

```
overlay -0 $spawn_id -1 $spawn_id -2 $spawn_id chess
```

This is more efficient than "interact -u", however, it sacrifices the ability to do programmed interaction since the **Expect** process is no longer in control.

Note that no controlling terminal is provided. Thus, if you disconnect or remap standard input, programs that do job control (shells, login, etc) will not function properly.

parity *[-d] [-i spawn_id] [value]*

defines whether parity should be retained or stripped from the output of spawned processes. If *value* is zero, parity is stripped, otherwise it is not stripped. With no *value* argument, the current value is returned.

With the **-d** flag, the default parity value is set. (The initial default is 1, i.e., parity is not stripped.) With the **-i** flag, the parity value is set for the named spawn id, otherwise it is set for the current process.

remove_nulls *[-d] [-i spawn_id] [value]*

defines whether nulls are retained or removed from the output of spawned processes before pattern matching or storing in the variable *expect_out* or *interact_out*. If *value* is 1, nulls are removed. If *value* is 0, nulls are not removed. With no *value* argument, the current value is returned.

With the **-d** flag, the default value is set. (The initial default is 1, i.e., nulls are removed.) With the **-i** flag, the value is set for the named spawn id, otherwise it is set for the current process.

Whether or not nulls are removed, **Expect** will record null bytes to the log and stdout.

send *[-flags] string*

Sends *string* to the current process. For example, the command

```
send "hello world\r"
```

sends the characters, h e l l o <blank> w o r l d <return> to the current process. (Tcl includes a printf-like command (called **format**) which can build arbitrarily complex strings.)

Characters are sent immediately although programs with line-buffered input will not read the characters until a return character is sent. A return character is denoted "\r".

The **--** flag forces the next argument to be interpreted as a string rather than a flag. Any string can be preceded by "--" whether or not it actually looks like a flag. This provides a reliable mechanism to specify variable strings without being tripped up by those that accidentally look like flags. (All strings starting with "-" are reserved for future options.)

The **-i** flag declares that the string be sent to the named `spawn_id`. If the `spawn_id` is `user_spawn_id`, and the terminal is in raw mode, newlines in the string are translated to return-newline sequences so that they appear as if the terminal was in cooked mode. The **-raw** flag disables this translation.

The **-null** flag sends null characters (0 bytes). By default, one null is sent. An integer may follow the **-null** to indicate how many nulls to send.

The **-break** flag generates a break condition. This only makes sense if the spawn id refers to a tty device opened via "spawn -open". If you have spawned a process such as `tip`, you should use `tip's` convention for generating a break.

The **-s** flag forces output to be sent "slowly", thus avoid the common situation where a computer outtypes an input buffer that was designed for a human who would never outtype the same buffer. This output is controlled by the value of the variable "send_slow" which takes a two element list. The first element is an integer that describes the number of bytes to send atomically. The second element is a real number that describes the number of seconds by which the atomic sends must be separated. For example, "set send_slow {10 .001}" would force "send -s" to send strings with 1 millisecond in between each 10 characters sent.

The **-h** flag forces output to be sent (somewhat) like a human actually typing. Human-like delays appear between the characters. (The algorithm is based upon a Weibull distribution, with modifications to suit this particular application.) This output is controlled by the value of the variable "send_human" which takes a five element list. The first two elements are average interarrival time of characters in seconds. The first is used by default. The second is used at word endings, to simulate the subtle pauses that occasionally occur at such transitions. The third parameter is a measure of variability where .1 is quite variable, 1 is reasonably variable, and 10 is quite invariable. The extremes are 0 to infinity. The last two parameters are, respectively, a minimum and maximum interarrival time. The minimum and maximum are used last and "clip" the final time. The ultimate average can be quite different from the given average if the minimum and maximum clip enough values.

As an example, the following command emulates a fast and consistent typist:

```
set send_human {.1 .3 1 .05 2}
send -h "I'm hungry. Let's do lunch."
```

while the following might be more suitable after a hangover:

```
set send_human {.4 .4 .2 .5 100}
send -h "Goodd party lash night!"
```

Note that errors are not simulated, although you can set up error correction situations yourself by embedding mistakes and corrections in a send argument.

The flags for sending null characters, for sending breaks, for forcing slow output and for human-

style output are mutually exclusive. Only the one specified last will be used. Furthermore, no *string* argument can be specified with the flags for sending null characters or breaks.

It is a good idea to precede the first **send** to a process by an **expect**. **expect** will wait for the process to start, while **send** cannot. In particular, if the first **send** completes before the process starts running, you run the risk of having your data ignored. In situations where interactive programs offer no initial prompt, you can precede **send** by a delay as in:

```
# To avoid giving hackers hints on how to break in,
# this system does not prompt for an external password.
# Wait for 5 seconds for exec to complete
spawn telnet very.secure.gov
sleep 5
send password\r
```

exp_send is an alias for **send**. If you are using Expecttk or some other variant of Expect in the Tk environment, **send** is defined by Tk for an entirely different purpose. **exp_send** is provided for compatibility between environments. Similar aliases are provided for other Expect's other send commands.

send_error [*-flags*] *string*

is like **send**, except that the output is sent to stderr rather than the current process.

send_log [*--*] *string*

is like **send**, except that the string is only sent to the log file (see **log_file**.) The arguments are ignored if no log file is open.

send_tty [*-flags*] *string*

is like **send**, except that the output is sent to /dev/tty rather than the current process.

send_user [*-flags*] *string*

is like **send**, except that the output is sent to stdout rather than the current process.

sleep *seconds*

causes the script to sleep for the given number of seconds. Seconds may be a decimal number. Interrupts (and Tk events if you are using Expecttk) are processed while Expect sleeps.

spawn [*args*] *program* [*args*]

creates a new process running *program args*. Its stdin, stdout and stderr are connected to Expect, so that they may be read and written by other **Expect** commands. The connection is broken by **close** or if the process itself closes any of the file identifiers.

When a process is started by **spawn**, the variable *spawn_id* is set to a descriptor referring to that process. The process described by *spawn_id* is considered the *current process*. *spawn_id* may be read or written, in effect providing job control.

user_spawn_id is a global variable containing a descriptor which refers to the user. For example, when *spawn_id* is set to this value, **expect** behaves like **expect_user**.

error_spawn_id is a global variable containing a descriptor which refers to the standard error. For example, when *spawn_id* is set to this value, **send** behaves like **send_error**.

tty_spawn_id is a global variable containing a descriptor which refers to /dev/tty. If /dev/tty does not exist (such as in a cron, at, or batch script), then *tty_spawn_id* is not defined. This may be tested as:

```
if {[info vars tty_spawn_id]} {
    # /dev/tty exists
} else {
    # /dev/tty doesn't exist
```

```

    # probably in cron, batch, or at script
}

```

spawn returns the UNIX process id. If no process is spawned, 0 is returned. The variable *spawn_out(slave,name)* is set to the name of the pty slave device.

By default, **spawn** echoes the command name and arguments. The **-noecho** flag stops **spawn** from doing this.

The **-console** flag causes console output to be redirected to the spawned process. This is not supported on all systems.

Internally, **spawn** uses a pty, initialized the same way as the user's tty. This is further initialized so that all settings are "sane" (according to `stty(1)`). If the variable *stty_init* is defined, it is interpreted in the style of `stty` arguments as further configuration. For example, "set *stty_init* raw" will cause further spawned processes's terminals to start in raw mode. **-notttycopy** skips the initialization based on the user's tty. **-nottyinit** skips the "sane" initialization.

Normally, **spawn** takes little time to execute. If you notice **spawn** taking a significant amount of time, it is probably encountering ptys that are wedged. A number of tests are run on ptys to avoid entanglements with errant processes. (These take 10 seconds per wedged pty.) Running Expect with the **-d** option will show if **Expect** is encountering many ptys in odd states. If you cannot kill the processes to which these ptys are attached, your only recourse may be to reboot.

If *program* cannot be spawned successfully because `exec(2)` fails (e.g. when *program* doesn't exist), an error message will be returned by the next **interact** or **expect** command as if *program* had run and produced the error message as output. This behavior is a natural consequence of the implementation of **spawn**. Internally, **spawn** forks, after which the spawned process has no way to communicate with the original **Expect** process except by communication via the *spawn_id*.

The **-open** flag causes the next argument to be interpreted as a Tcl file identifier (i.e., returned by **open**.) The *spawn_id* can then be used as if it were a spawned process. (The file identifier should no longer be used.) This lets you treat raw devices, files, and pipelines as spawned processes without using a pty. 0 is returned to indicate there is no associated process. When the connection to the spawned process is closed, so is the Tcl file identifier. The **-leaveopen** flag is similar to **-open** except that **-leaveopen** causes the file identifier to be left open even after the *spawn_id* is closed.

The **-pty** flag causes a pty to be opened but no process spawned. 0 is returned to indicate there is no associated process. *Spawn_id* is set as usual.

The variable *spawn_out(slave,fd)* is set to a file identifier corresponding to the pty slave. It can be closed using "close -slave".

The **-ignore** flag names a signal to be ignored in the spawned process. Otherwise, signals get the default behavior. Signals are named as in the **trap** command, except that each signal requires a separate flag.

strace *level*

causes following statements to be printed before being executed. (Tcl's `trace` command traces variables.) *level* indicates how far down in the call stack to trace. For example, the following command runs **Expect** while tracing the first 4 levels of calls, but none below that.

```
expect -c "strace 4" script.exp
```

The **-info** flag causes **strace** to return a description of the most recent non-info arguments given.

stty *args*

changes terminal modes similarly to the external stty command.

By default, the controlling terminal is accessed. Other terminals can be accessed by appending "</dev/tty..." to the command. (Note that the arguments should not be grouped into a single argument.)

Requests for status return it as the result of the command. If no status is requested and the controlling terminal is accessed, the previous status of the raw and echo attributes are returned in a form which can later be used by the command.

For example, the arguments **raw** or **-cooked** put the terminal into raw mode. The arguments **-raw** or **cooked** put the terminal into cooked mode. The arguments **echo** and **-echo** put the terminal into echo and noecho mode respectively.

The following example illustrates how to temporarily disable echoing. This could be used in otherwise-automatic scripts to avoid embedding passwords in them. (See more discussion on this under EXPECT HINTS below.)

```
stty -echo
send_user "Password: "
expect_user -re "(.*)\n"
set password $expect_out(1,string)
stty echo
```

system *args*

gives *args* to sh(1) as input, just as if it had been typed as a command from a terminal. **Expect** waits until the shell terminates. The return status from sh is handled the same way that **exec** handles its return status.

In contrast to **exec** which redirects stdin and stdout to the script, **system** performs no redirection (other than that indicated by the string itself). Thus, it is possible to use programs which must talk directly to /dev/tty. For the same reason, the results of **system** are not recorded in the log.

timestamp [*args*]

returns a timestamp. With no arguments, the number of seconds since the epoch is returned.

The **-format** flag introduces a string which is returned but with substitutions made according to the POSIX rules for strftime. For example %a is replaced by an abbreviated weekday name (i.e., Sat). Others are:

| | |
|----|---|
| %a | abbreviated weekday name |
| %A | full weekday name |
| %b | abbreviated month name |
| %B | full month name |
| %c | date-time as in: Wed Oct 6 11:45:56 1993 |
| %d | day of the month (01-31) |
| %H | hour (00-23) |
| %I | hour (01-12) |
| %j | day (001-366) |
| %m | month (01-12) |
| %M | minute (00-59) |
| %p | am or pm |
| %S | second (00-61) |
| %u | day (1-7, Monday is first day of week) |
| %U | week (00-53, first Sunday is first day of week one) |
| %V | week (01-53, ISO 8601 style) |

| | |
|----|---|
| %w | day (0-6) |
| %W | week (00-53, first Monday is first day of week one) |
| %x | date-time as in: Wed Oct 6 1993 |
| %X | time as in: 23:59:59 |
| %y | year (00-99) |
| %Y | year as in: 1993 |
| %Z | timezone (or nothing if not determinable) |
| %% | a bare percent sign |

Other % specifications are undefined. Other characters will be passed through untouched. Only the C locale is supported.

The **–seconds** flag introduces a number of seconds since the epoch to be used as a source from which to format. Otherwise, the current time is used.

The **–gmt** flag forces timestamp output to use the GMT timezone. With no flag, the local timezone is used.

trap *[[command] signals]*

causes the given *command* to be executed upon future receipt of any of the given signals. The command is executed in the global scope. If *command* is absent, the signal action is returned. If *command* is the string SIG_IGN, the signals are ignored. If *command* is the string SIG_DFL, the signals are reset to the system default. *signals* is either a single signal or a list of signals. Signals may be specified numerically or symbolically as per signal(3). The "SIG" prefix may be omitted.

With no arguments (or the argument **–number**), **trap** returns the signal number of the trap command currently being executed.

The **–code** flag uses the return code of the command in place of whatever code Tcl was about to return when the command originally started running.

The **–interp** flag causes the command to be evaluated using the interpreter active at the time the command started running rather than when the trap was declared.

The **–name** flag causes the **trap** command to return the signal name of the trap command currently being executed.

The **–max** flag causes the **trap** command to return the largest signal number that can be set.

For example, the command "trap {send_user "Ouch!"} SIGINT" will print "Ouch!" each time the user presses ^C.

By default, SIGINT (which can usually be generated by pressing ^C) and SIGTERM cause Expect to exit. This is due to the following trap, created by default when Expect starts.

```
trap exit {SIGINT SIGTERM}
```

If you use the **–D** flag to start the debugger, SIGINT is redefined to start the interactive debugger. This is due to the following trap:

```
trap {exp_debug 1} SIGINT
```

The debugger trap can be changed by setting the environment variable EXPECT_DEBUG_INIT to a new trap command.

You can, of course, override both of these just by adding trap commands to your script. In particular, if you have your own "trap exit SIGINT", this will override the debugger trap. This is useful if you want to prevent users from getting to the debugger at all.

If you want to define your own trap on SIGINT but still trap to the debugger when it is running, use:

```
if { ![exp_debug] } { trap mystuff SIGINT }
```

Alternatively, you can trap to the debugger using some other signal.

trap will not let you override the action for SIGALRM as this is used internally to **Expect**. The disconnect command sets SIGALRM to SIG_IGN (ignore). You can reenable this as long as you disable it during subsequent spawn commands.

See signal(3) for more info.

wait [*args*]

delays until a spawned process (or the current process if none is named) terminates.

wait normally returns a list of four integers. The first integer is the pid of the process that was waited upon. The second integer is the corresponding spawn id. The third integer is -1 if an operating system error occurred, or 0 otherwise. If the third integer was 0, the fourth integer is the status returned by the spawned process. If the third integer was -1, the fourth integer is the value of errno set by the operating system. The global variable errorCode is also set.

Additional elements may appear at the end of the return value from **wait**. An optional fifth element identifies a class of information. Currently, the only possible value for this element is CHILD-KILLED in which case the next two values are the C-style signal name and a short textual description.

The **-i** flag declares the process to wait corresponding to the named spawn_id (NOT the process id). Inside a SIGCHLD handler, it is possible to wait for any spawned process by using the spawn id -1.

The **-nowait** flag causes the wait to return immediately with the indication of a successful wait. When the process exits (later), it will automatically disappear without the need for an explicit wait.

The **wait** command may also be used wait for a forked process using the arguments "-i -1". Unlike its use with spawned processes, this command can be executed at any time. There is no control over which process is reaped. However, the return value can be checked for the process id.

LIBRARIES

Expect automatically knows about two built-in libraries for Expect scripts. These are defined by the directories named in the variables exp_library and exp_exec_library. Both are meant to contain utility files that can be used by other scripts.

exp_library contains architecture-independent files. exp_exec_library contains architecture-dependent files. Depending on your system, both directories may be totally empty. The existence of the file \$exp_exec_library/cat-buffers describes whether your /bin/cat buffers by default.

PRETTY-PRINTING

A vgrind definition is available for pretty-printing **Expect** scripts. Assuming the vgrind definition supplied with the **Expect** distribution is correctly installed, you can use it as:

```
vgrind -lexpect file
```

EXAMPLES

It may not be apparent how to put everything together that the man page describes. I encourage you to read and try out the examples in the example directory of the **Expect** distribution. Some of them are real programs. Others are simply illustrative of certain techniques, and of course, a couple are just quick hacks. The `INSTALL` file has a quick overview of these programs.

The **Expect** papers (see `SEE ALSO`) are also useful. While some papers use syntax corresponding to earlier versions of Expect, the accompanying rationales are still valid and go into a lot more detail than this man page.

CAVEATS

Extensions may collide with Expect's command names. For example, **send** is defined by Tk for an entirely different purpose. For this reason, most of the **Expect** commands are also available as `"exp_XXXX"`. Commands and variables beginning with `"exp"`, `"inter"`, `"spawn"`, and `"timeout"` do not have aliases. Use the extended command names if you need this compatibility between environments.

Expect takes a rather liberal view of scoping. In particular, variables read by commands specific to the **Expect** program will be sought first from the local scope, and if not found, in the global scope. For example, this obviates the need to place `"global timeout"` in every procedure you write that uses **expect**. On the other hand, variables written are always in the local scope (unless a `"global"` command has been issued). The most common problem this causes is when `spawn` is executed in a procedure. Outside the procedure, `spawn_id` no longer exists, so the spawned process is no longer accessible simply because of scoping. Add a `"global spawn_id"` to such a procedure.

If you cannot enable the multispawning capability (i.e., your system supports neither `select` (BSD `*.*`), `poll` (SVR<2>), nor something equivalent), **Expect** will only be able to control a single process at a time. In this case, do not attempt to set `spawn_id`, nor should you execute processes via `exec` while a spawned process is running. Furthermore, you will not be able to **expect** from multiple processes (including the user as one) at the same time.

Terminal parameters can have a big effect on scripts. For example, if a script is written to look for echoing, it will misbehave if echoing is turned off. For this reason, Expect forces sane terminal parameters by default. Unfortunately, this can make things unpleasant for other programs. As an example, the emacs shell wants to change the "usual" mappings: newlines get mapped to newlines instead of carriage-return newlines, and echoing is disabled. This allows one to use emacs to edit the input line. Unfortunately, Expect cannot possibly guess this.

You can request that Expect not override its default setting of terminal parameters, but you must then be very careful when writing scripts for such environments. In the case of emacs, avoid depending upon things like echoing and end-of-line mappings.

The commands that accepted arguments braced into a single list (the **expect** variants and **interact**) use a heuristic to decide if the list is actually one argument or many. The heuristic can fail only in the case when the list actually does represent a single argument which has multiple embedded `\n`'s with non-whitespace characters between them. This seems sufficiently improbable, however the argument `"-nobrace"` can be used to force a single argument to be handled as a single argument. This could conceivably be used with machine-generated Expect code. Similarly, `-brace` forces a single argument to be handled as multiple patterns/actions.

BUGS

It was really tempting to name the program `"sex"` (for either `"Smart EXec"` or `"Send-EXpect"`), but good sense (or perhaps just Puritanism) prevailed.

On some systems, when a shell is spawned, it complains about not being able to access the `tty` but runs anyway. This means your system has a mechanism for gaining the controlling `tty` that **Expect** doesn't know

about. Please find out what it is, and send this information back to me.

Ultrix 4.1 (at least the latest versions around here) considers timeouts of above 1000000 to be equivalent to 0.

Digital UNIX 4.0A (and probably other versions) refuses to allocate ptys if you define a SIGCHLD handler. See grantpt page for more info.

IRIX 6.0 does not handle pty permissions correctly so that if Expect attempts to allocate a pty previously used by someone else, it fails. Upgrade to IRIX 6.1.

Telnet (verified only under SunOS 4.1.2) hangs if TERM is not set. This is a problem under cron, at and in cgi scripts, which do not define TERM. Thus, you must set it explicitly - to what type is usually irrelevant. It just has to be set to something! The following probably suffices for most cases.

```
set env(TERM) vt100
```

Tip (verified only under BSDI BSD/OS 3.1 i386) hangs if SHELL and HOME are not set. This is a problem under cron, at and in cgi scripts, which do not define these environment variables. Thus, you must set them explicitly - to what type is usually irrelevant. It just has to be set to something! The following probably suffices for most cases.

```
set env(SHELL) /bin/sh
set env(HOME) /usr/bin
```

Some implementations of ptys are designed so that the kernel throws away any unread output after 10 to 15 seconds (actual number is implementation-dependent) after the process has closed the file descriptor. Thus **Expect** programs such as

```
spawn date
sleep 20
expect
```

will fail. To avoid this, invoke non-interactive programs with **exec** rather than **spawn**. While such situations are conceivable, in practice I have never encountered a situation in which the final output of a truly interactive program would be lost due to this behavior.

On the other hand, Cray UNICOS ptys throw away any unread output immediately after the process has closed the file descriptor. I have reported this to Cray and they are working on a fix.

Sometimes a delay is required between a prompt and a response, such as when a tty interface is changing UART settings or matching baud rates by looking for start/stop bits. Usually, all this is require is to sleep for a second or two. A more robust technique is to retry until the hardware is ready to receive input. The following example uses both strategies:

```
send "speed 9600\r";
sleep 1
expect {
    timeout {send "\r"; exp_continue}
    $prompt
}
```

trap -code will not work with any command that sits in Tcl's event loop, such as sleep. The problem is that in the event loop, Tcl discards the return codes from async event handlers. A workaround is to set a flag in the trap code. Then check the flag immediately after the command (i.e., sleep).

The expect_background command ignores -timeout arguments and has no concept of timeouts in general.

EXPECT HINTS

There are a couple of things about **Expect** that may be non-intuitive. This section attempts to address some of these things with a couple of suggestions.

A common expect problem is how to recognize shell prompts. Since these are customized differently by differently people and different shells, portably automating rlogin can be difficult without knowing the prompt. A reasonable convention is to have users store a regular expression describing their prompt (in particular, the end of it) in the environment variable EXPECT_PROMPT. Code like the following can be used. If EXPECT_PROMPT doesn't exist, the code still has a good chance of functioning correctly.

```
set prompt "(%|#|\\$) $"      ;# default prompt
catch {set prompt $env(EXPECT_PROMPT)}
```

```
expect -re $prompt
```

I encourage you to write **expect** patterns that include the end of whatever you expect to see. This avoids the possibility of answering a question before seeing the entire thing. In addition, while you may well be able to answer questions before seeing them entirely, if you answer early, your answer may appear echoed back in the middle of the question. In other words, the resulting dialogue will be correct but look scrambled.

Most prompts include a space character at the end. For example, the prompt from ftp is 'f', 't', 'p', '>' and <blank>. To match this prompt, you must account for each of these characters. It is a common mistake not to include the blank. Put the blank in explicitly.

If you use a pattern of the form X*, the * will match all the output received from the end of X to the last thing received. This sounds intuitive but can be somewhat confusing because the phrase "last thing received" can vary depending upon the speed of the computer and the processing of I/O both by the kernel and the device driver.

In particular, humans tend to see program output arriving in huge chunks (atomically) when in reality most programs produce output one line at a time. Assuming this is the case, the * in the pattern of the previous paragraph may only match the end of the current line even though there seems to be more, because at the time of the match that was all the output that had been received.

expect has no way of knowing that further output is coming unless your pattern specifically accounts for it.

Even depending on line-oriented buffering is unwise. Not only do programs rarely make promises about the type of buffering they do, but system indigestion can break output lines up so that lines break at seemingly random places. Thus, if you can express the last few characters of a prompt when writing patterns, it is wise to do so.

If you are waiting for a pattern in the last output of a program and the program emits something else instead, you will not be able to detect that with the **timeout** keyword. The reason is that **expect** will not timeout – instead it will get an **eof** indication. Use that instead. Even better, use both. That way if that line is ever moved around, you won't have to edit the line itself.

Newlines are usually converted to carriage return, linefeed sequences when output by the terminal driver. Thus, if you want a pattern that explicitly matches the two lines, from, say, printf("foo\nbar"), you should use the pattern "foo\r\nbar".

A similar translation occurs when reading from the user, via **expect_user**. In this case, when you press return, it will be translated to a newline. If **Expect** then passes that to a program which sets its terminal to raw mode (like telnet), there is going to be a problem, as the program expects a true return. (Some programs are actually forgiving in that they will automatically translate newlines to returns, but most don't.) Unfortunately, there is no way to find out that a program put its terminal into raw mode.

Rather than manually replacing newlines with returns, the solution is to use the command "stty raw", which will stop the translation. Note, however, that this means that you will no longer get the cooked line-editing features.

interact implicitly sets your terminal to raw mode so this problem will not arise then.

It is often useful to store passwords (or other private information) in **Expect** scripts. This is not recommended since anything that is stored on a computer is susceptible to being accessed by anyone. Thus, interactively prompting for passwords from a script is a smarter idea than embedding them literally. Nonetheless, sometimes such embedding is the only possibility.

Unfortunately, the UNIX file system has no direct way of creating scripts which are executable but unreadable. Systems which support setgid shell scripts may indirectly simulate this as follows:

Create the **Expect** script (that contains the secret data) as usual. Make its permissions be 750 (-rwxr-x---) and owned by a trusted group, i.e., a group which is allowed to read it. If necessary, create a new group for this purpose. Next, create a /bin/sh script with permissions 2751 (-rwxr-s---x) owned by the same group as before.

The result is a script which may be executed (and read) by anyone. When invoked, it runs the **Expect** script.

ACKNOWLEDGMENTS

Thanks to John Ousterhout for Tcl, and Scott Paisley for inspiration. Thanks to Rob Savoye for Expect's autoconfiguration code.

The HISTORY file documents much of the evolution of **expect**. It makes interesting reading and might give you further insight to this software. Thanks to the people mentioned in it who sent me bug fixes and gave other assistance.

Design and implementation of **Expect** was paid for in part by the U.S. government and is therefore in the

public domain. However the author and NIST would like credit if this program and documentation or portions of them are used.

NAME

exiftool – Read and write meta information in files

SYNOPSIS**Reading**

exiftool [*OPTIONS*] [*-TAG...*] [*--TAG...*] *FILE...*

Writing

exiftool [*OPTIONS*] *-TAG[+-<]=[VALUE]...* *FILE...*

Copying

exiftool [*OPTIONS*] **-tagsFromFile** *SRCFILE* [*-SRCTAG[>DSTTAG]...*] *FILE...*

Other

exiftool [**-ver** | **-list**[*w|f|r|wf|g[*NUM*]|d|x*]]

For specific examples, see the **EXAMPLES** sections below.

This documentation is displayed if exiftool is run without an input *FILE* when one is expected.

DESCRIPTION

A command-line interface to Image::ExifTool, used for reading and writing meta information in a variety of file types. *FILE* is one or more source file names, directory names, or – for the standard input. Metadata is read from source files and printed in readable form to the console (or written to output text files with **-w**).

To write or delete metadata, tag values are assigned using *-TAG=[VALUE]*, and/or the **-geotag**, **-csv=** or **-json=** options. To copy or move metadata, the **-tagsFromFile** feature is used. By default the original files are preserved with *_original* appended to their names — be sure to verify that the new files are OK before erasing the originals. Once in write mode, exiftool will ignore any read-specific options.

Note: If *FILE* is a directory name then only supported file types in the directory are processed (in write mode only writable types are processed). However, files may be specified by name, or the **-ext** option may be used to force processing of files with any extension. Hidden files in the directory are also processed. Adding the **-r** option causes subdirectories to be processed recursively, but subdirectories with names beginning with “.” are skipped unless **-r** is used.

Below is a list of file types and meta information formats currently supported by ExifTool (r = read, w = write, c = create):

File Types

OPTIONS

Case is not significant for any command-line option (including tag and group names), except for single-character options when the corresponding upper-case option exists. Many single-character options have equivalent long-name versions (shown in brackets), and some options have inverses which are invoked with a leading double-dash. Unrecognized options are interpreted as tag names (for this reason, multiple single-character options may NOT be combined into one argument). Contrary to standard practice, options may appear after source file names on the exiftool command line.

Option Overview

Tag operations

| | |
|-----------------------|---------------------------------------|
| -TAG or --TAG | Extract or exclude specified tag |
| -TAG[+-^]=[VALUE] | Write new value for tag |
| -TAG[+-]<=DATFILE | Write tag value from contents of file |
| -TAG[+-]<SRCTAG | Copy tag value (see -tagsFromFile) |
| -tagsFromFile SRCFILE | Copy tag values from file |

| | | |
|-------------------------------------|-----------------------|---|
| -x TAG | (-exclude) | Exclude specified tag |
| Input-output text formatting | | |
| -args | (-argFormat) | Format metadata as exiftool arguments |
| -b | (-binary) | Output metadata in binary format |
| -c FMT | (-coordFormat) | Set format for GPS coordinates |
| -charset [[TYPE=]CHARSET] | | Specify encoding for special characters |
| -csv[[+]=CSVFILE] | | Export/import tags in CSV format |
| -d FMT | (-dateFormat) | Set format for date/time values |
| -D | (-decimal) | Show tag ID numbers in decimal |
| -E,-ex,-ec | (-escape(HTML XML C)) | Escape tag values for HTML, XML or C |
| -f | (-forcePrint) | Force printing of all specified tags |
| -g[NUM...] | (-groupHeadings) | Organize output by tag group |
| -G[NUM...] | (-groupNames) | Print group name for each tag |
| -h | (-htmlFormat) | Use HTML formatting for output |
| -H | (-hex) | Show tag ID numbers in hexadecimal |
| -htmlDump[OFFSET] | | Generate HTML-format binary dump |
| -j[[+]=JSONFILE] (-json) | | Export/import tags in JSON format |
| -l | (-long) | Use long 2-line output format |
| -L | (-latin) | Use Windows Latin1 encoding |
| -lang [LANG] | | Set current language |
| -listItem INDEX | | Extract specific item from a list |
| -n | (--printConv) | No print conversion |
| -p FMTFILE | (-printFormat) | Print output in specified format |
| -php | | Export tags as a PHP Array |
| -s[NUM] | (-short) | Short output format |
| -S | (-veryShort) | Very short output format |
| -sep STR | (-separator) | Set separator string for list items |
| -sort | | Sort output alphabetically |
| -struct | | Enable output of structured information |
| -t | (-tab) | Output in tab-delimited list format |
| -T | (-table) | Output in tabular format |
| -v[NUM] | (-verbose) | Print verbose messages |
| -w[+ !] EXT | (-textOut) | Write (or overwrite!) output text files |
| -W[+ !] FMT | (-tagOut) | Write output text file for each tag |
| -Wext EXT | (-tagOutExt) | Write only specified file types with -W |
| -X | (-xmlFormat) | Use RDF/XML output format |
| Processing control | | |
| -a | (-duplicates) | Allow duplicate tags to be extracted |
| -e | (--composite) | Do not generate composite tags |
| -ee | (-extractEmbedded) | Extract information from embedded files |
| -ext[+] EXT | (-extension) | Process files with specified extension |
| -F[OFFSET] | (-fixBase) | Fix the base for maker notes offsets |
| -fast[NUM] | | Increase speed when extracting metadata |
| -fileOrder[NUM] [-]TAG | | Set file processing order |
| -i DIR | (-ignore) | Ignore specified directory name |
| -if[NUM] EXPR | | Conditionally process files |
| -m | (-ignoreMinorErrors) | Ignore minor errors and warnings |
| -o OUTFILE | (-out) | Set output file or directory name |
| -overwrite_original | | Overwrite original by renaming tmp file |
| -overwrite_original_in_place | | Overwrite original by copying tmp file |
| -P | (-preserve) | Preserve file modification date/time |
| -password PASSWD | | Password for processing protected files |
| -progress[:[TITLE]] | | Show file progress count |

| | | |
|--------------------------|---------------------------|------------------------------------|
| <code>-q</code> | <code>(-quiet)</code> | Quiet processing |
| <code>-r[.]</code> | <code>(-recurse)</code> | Recursively process subdirectories |
| <code>-scanForXMP</code> | | Brute force XMP scan |
| <code>-u</code> | <code>(-unknown)</code> | Extract unknown tags |
| <code>-U</code> | <code>(-unknown2)</code> | Extract unknown binary tags too |
| <code>-wm MODE</code> | <code>(-writeMode)</code> | Set mode for writing/creating tags |
| <code>-z</code> | <code>(-zip)</code> | Read/write compressed information |

Other options

| | | |
|---|-----------------------|---------------------------------------|
| <code>-@ ARGFILE</code> | | Read command-line arguments from file |
| <code>-k</code> | <code>(-pause)</code> | Pause before terminating |
| <code>-list [w f wf g[<i>NUM</i>] d x]</code> | | List various exiftool capabilities |
| <code>-ver</code> | | Print exiftool version number |
| <code>--</code> | | End of options |

Special features

| | | |
|-------------------------------------|--|--------------------------------------|
| <code>-geotag TRKFILE</code> | | Geotag images from specified GPS log |
| <code>-globalTimeShift SHIFT</code> | | Shift all formatted date/time values |
| <code>-use MODULE</code> | | Add features from plug-in module |

Utilities

| | | |
|----------------------------------|--|----------------------------------|
| <code>-delete_original[!]</code> | | Delete "_original" backups |
| <code>-restore_original</code> | | Restore from "_original" backups |

Advanced options

| | | |
|---|--|--|
| <code>-api OPT[[^]=[VAL]]</code> | | Set ExifTool API option |
| <code>-common_args</code> | | Define common arguments |
| <code>-config CFGFILE</code> | | Specify configuration file name |
| <code>-echo[<i>NUM</i>] TEXT</code> | | Echo text to stdout or stderr |
| <code>-efile[<i>NUM</i>] [!] ERRFILE</code> | | Save names of files with errors |
| <code>-execute[<i>NUM</i>]</code> | | Execute multiple commands on one line |
| <code>-srcfile FMT</code> | | Process a different source file |
| <code>-stay_open FLAG</code> | | Keep reading -@ argfile even after EOF |
| <code>-userParam PARAM[[^]=[VAL]]</code> | | Set user parameter (API UserParam opt) |

Option Details

Tag operations

`-TAG`

Extract information for the specified tag (eg. `-CreateDate`). Multiple tags may be specified in a single command. A tag name is the handle by which a piece of information is referenced. See `Image::ExifTool::TagNames` for documentation on available tag names. A tag name may include leading group names separated by colons (eg. `-EXIF:CreateDate`, or `-Doc1:XMP:Creator`), and each group name may be prefixed by a digit to specify family number (eg. `-1IPTC:City`). Use the **-listg** option to list available group names by family.

A special tag name of `All` may be used to indicate all meta information (ie. **-All**). This is particularly useful when a group name is specified to extract all information in a group (but beware that unless the **-a** option is also used, some tags in the group may be suppressed by same-named tags in other groups). The wildcard characters `?` and `*` may be used in a tag name to match any single character and zero or more characters respectively. These may not be used in a group name, with the exception that a group name of `*` (or `All`) may be used to extract all instances of a tag (as if **-a** was used). Note that arguments containing wildcards must be quoted on the command line of most systems to prevent shell globbing.

A `#` may be appended to the tag name to disable the print conversion on a per-tag basis (see the **-n** option). This may also be used when writing or copying tags.

If no tags are specified, all available information is extracted (as if `-All` had been specified).

Note: Descriptions, not tag names, are shown by default when extracting information. Use the `-s` option to see the tag names instead.

`--TAG`

Exclude specified tag from extracted information. Same as the `-x` option. Group names and wildcards are permitted as described above for `-TAG`. Once excluded from the output, a tag may not be re-included by a subsequent option. May also be used following a `-tagsFromFile` option to exclude tags from being copied (when redirecting to another tag, it is the source tag that should be excluded), or to exclude groups from being deleted when deleting all information (eg. `-all=--exif:all` deletes all but EXIF information). But note that this will not exclude individual tags from a group delete (unless a family 2 group is specified, see note 4 below). Instead, individual tags may be recovered using the `-tagsFromFile` option (eg. `-all= -tagsfromfile @ -artist`).

`-TAG[+-^]=[VALUE]`

Write a new value for the specified tag (eg. `-comment=wow`), or delete the tag if no *VALUE* is given (eg. `-comment=`). `+=` and `-=` are used to add or remove existing entries from a list, or to shift date/time values (see `Image::ExifTool::Shift.pl` and note 6 below for more details). `+=` may also be used to increment numerical values (or decrement if *VALUE* is negative), and `-=` may be used to conditionally delete or replace a tag (see “WRITING EXAMPLES” for examples). `^=` is used to write an empty string instead of deleting the tag when no *VALUE* is given, but otherwise it is equivalent to `=`.

TAG may contain one or more leading family 0, 1 or 2 group names, prefixed by optional family numbers, and separated colons. If no group name is specified, the tag is created in the preferred group, and updated in any other location where a same-named tag already exists. The preferred group is the first group in the following list where *TAG* is valid: 1) EXIF, 2) IPTC, 3) XMP.

The wildcards `*` and `?` may be used in tag names to assign the same value to multiple tags. When specified with wildcards, “unsafe” tags are not written. A tag name of `All` is equivalent to `*` (except that it doesn’t require quoting, while arguments with wildcards do on systems with shell globbing), and is often used when deleting all metadata (ie. `-All=`) or an entire group (eg. `-XMP-dc:All=`, see note 4 below). Note that not all groups are deletable, and that the JPEG APP14 “Adobe” group is not removed by default with `-All=` because it may affect the appearance of the image. However, color space information is removed, so the colors may be affected (but this may be avoided by copying back the tags defined by the `ColorSpaceTags` shortcut). Use the `-listd` option for a complete list of deletable groups, and see note 5 below regarding the “APP” groups. Also, within an image some groups may be contained within others, and these groups are removed if the containing group is deleted:

JPEG Image:

- Deleting EXIF or IFD0 also deletes ExifIFD, GlobParamIFD, GPS, IFD1, InteropIFD, MakerNotes, PrintIM and SubIFD.
- Deleting ExifIFD also deletes InteropIFD and MakerNotes.
- Deleting Photoshop also deletes IPTC.

TIFF Image:

- Deleting EXIF only removes ExifIFD which also deletes InteropIFD and MakerNotes.

Notes:

1) **Many tag values may be assigned in a single command.** If two assignments affect the same tag, the latter takes precedence (except for list-type tags, for which both values are written).

2) In general, MakerNotes tags are considered “Permanent”, and may be edited but not created or deleted individually. This avoids many potential problems, including the inevitable compatibility problems with OEM software which may be very inflexible about the information it expects to find in

the maker notes.

3) Changes to PDF files by ExifTool are reversible (by deleting the update with `-PDF-update:all=`) because the original information is never actually deleted from the file. So ExifTool alone may not be used to securely edit metadata in PDF files.

4) Specifying `-GROUP:all=` deletes the entire group as a block only if a single family 0 or 1 group is specified. Otherwise all deletable tags in the specified group(s) are removed individually, and in this case it is possible to exclude individual tags from a mass delete. For example, `-time:all --Exif:Time:All` removes all deletable Time tags except those in the EXIF. This difference also applies if family 2 is specified when deleting all groups. For example, `-2all:all=` deletes tags individually, while `-all:all=` deletes entire blocks.

5) The “APP” group names (“APP0” through “APP15”) are used to delete JPEG application segments which are not associated with another deletable group. For example, specifying `-APP14:All=` will NOT delete the APP14 “Adobe” segment because this is accomplished with `-Adobe:All`.

6) When shifting a value, the shift is applied to the original value of the tag, overriding any other values previously assigned to the tag on the same command line. To shift a date/time value and copy it to another tag in the same operation, use the `-globalTimeShift` option.

Special feature: Integer values may be specified in hexadecimal with a leading 0x, and simple rational values may be specified as fractions.

`-TAG<=DATFILE` or `-TAG<=FMT`

Set the value of a tag from the contents of file *DATFILE*. The file name may also be given by a *FMT* string where %d, %f and %e represent the directory, file name and extension of the original *FILE* (see the `-w` option for more details). Note that quotes are required around this argument to prevent shell redirection since it contains a < symbol. If *DATFILE/FMT* is not provided, the effect is the same as `-TAG=`, and the tag is simply deleted. `+<=` or `-<=` may also be used to add or delete specific list entries, or to shift date/time values.

`-tagsFromFile SRCFILE` or *FMT*

Copy tag values from *SRCFILE* to *FILE*. Tag names on the command line after this option specify the tags to be copied, or excluded from the copy. Wildcards are permitted in these tag names. If no tags are specified, then all possible tags (see note 1 below) from the source file are copied to same-named tags in the preferred location of the output file (the same as specifying `-all`). More than one `-tagsFromFile` option may be used to copy tags from multiple files.

By default, this option will update any existing and writable same-named tags in the output *FILE*, but will create new tags only in their preferred groups. This allows some information to be automatically transferred to the appropriate group when copying between images of different formats. However, if a group name is specified for a tag then the information is written only to this group (unless redirected to another group, see below). If *All* is used as a group name, then the specified tag(s) are written to the same family 1 group they had in the source file (ie. the same specific location, like ExifIFD or XMP-dc). For example, the common operation of copying all writable tags to the same specific locations in the output *FILE* is achieved by adding `-all:all`. A different family may be specified by adding a leading family number to the group name (eg. `-0all:all` preserves the same general location, like EXIF or XMP).

SRCFILE may be the same as *FILE* to move information around within a single file. In this case, @ may be used to represent the source file (ie. `-tagsFromFile @`), permitting this feature to be used for batch processing multiple files. Specified tags are then copied from each file in turn as it is rewritten. For advanced batch use, the source file name may also be specified using a *FMT* string in which %d, %f and %e represent the directory, file name and extension of *FILE*. (eg. the current *FILE* would be represented by %d%f.%e, with the same effect as @). See the `-w` option for *FMT* string examples.

A powerful redirection feature allows a destination tag to be specified for each copied tag. With this feature, information may be written to a tag with a different name or group. This is done using

""-DSTTAG<SRCTAG"" or ""-SRCTAG>DSTTAG"" on the command line after **-tagsFromFile**, and causes the value of *SRCTAG* to be copied from *SRCFILE* and written to *DSTTAG* in *FILE*. Has no effect unless *SRCTAG* exists in *SRCFILE*. Note that this argument must be quoted to prevent shell redirection, and there is no = sign as when assigning new values. Source and/or destination tags may be prefixed by a group name and/or suffixed by #. Wildcards are allowed in both the source and destination tag names. A destination group and/or tag name of All or * writes to the same family 1 group and/or tag name as the source. If no destination group is specified, the information is written to the preferred group. Whitespace around the > or < is ignored. As a convenience, **-tagsFromFile @** is assumed for any redirected tags which are specified without a prior **-tagsFromFile** option. Copied tags may also be added or deleted from a list with arguments of the form ""-SRCTAG+<DSTTAG"" or ""-SRCTAG-<DSTTAG"" (but see Note 5 below).

An extension of the redirection feature allows strings involving tag names to be used on the right hand side of the < symbol with the syntax ""-DSTTAG<STR"", where tag names in *STR* are prefixed with a \$ symbol. See the **-p** option and the "Advanced formatting feature" section for more details about this syntax. Strings starting with a = sign must insert a single space after the < to avoid confusion with the <= operator which sets the tag value from the contents of a file. A single space at the start of the string is removed if it exists, but all other whitespace in the string is preserved. See note 8 below about using the redirection feature with list-type tags, shortcuts or when using wildcards in tag names.

See "COPYING EXAMPLES" for examples using **-tagsFromFile**.

Notes:

- 1) Some tags (generally tags which may affect the appearance of the image) are considered "unsafe" to write, and are only copied if specified explicitly (ie. no wildcards). See the tag name documentation for more details about "unsafe" tags.
- 2) Be aware of the difference between excluding a tag from being copied (**--TAG**), and deleting a tag (**-TAG=**). Excluding a tag prevents it from being copied to the destination image, but deleting will remove a pre-existing tag from the image.
- 3) The maker note information is copied as a block, so it isn't affected like other information by subsequent tag assignments on the command line, and individual makernote tags may not be excluded from a block copy. Also, since the PreviewImage referenced from the maker notes may be rather large, it is not copied, and must be transferred separately if desired.
- 4) The order of operations is to copy all specified tags at the point of the **-tagsFromFile** option in the command line. Any tag assignment to the right of the **-tagsFromFile** option is made after all tags are copied. For example, new tag values are set in the order One, Two, Three then Four with this command:

```
exiftool -One=1 -tagsFromFile s.jpg -Two -Four=4 -Three d.jpg
```

This is significant in the case where an overlap exists between the copied and assigned tags because later operations may override earlier ones.

- 5) The normal behaviour of copied tags differs from that of assigned tags for list-type tags and conditional replacements because each copy operation on a tag overrides any previous operations. While this avoids duplicate list items when copying groups of tags from a file containing redundant information, it also prevents values of different tags from being copied into the same list when this is the intent. So a **-addTagsFromFile** option is provided which allows copying of multiple tags into the same list. eg)

```
exiftool -addtagsfromfile @ '-subject<make' '-subject<model' ...
```

Similarly, **-addTagsFromFile** must be used when conditionally replacing a tag to prevent overriding earlier conditions.

Other than these differences, the **-tagsFromFile** and **-addTagsFromFile** options are equivalent.

6) The **-a** option (allow duplicate tags) is always in effect when copying tags from *SRCFILE*, but the highest priority tag is always copied last so it takes precedence.

7) Structured tags are copied by default when copying tags. See the **-struct** option for details.

8) With the redirection feature, copying a tag directly (ie. `"-DSTTAG<SRCTAG"`) is not the same as interpolating its value inside a string (ie. `"-DSTTAG<$SRCTAG"`) for list-type tags, shortcut tags, tag names containing wildcards, or UserParam variables. When copying directly, the values of each matching source tag are copied individually to the destination tag (as if they were separate assignments). However, when interpolated inside a string, list items and the values of shortcut tags are concatenated (with a separator set by the **-sep** option), and wildcards are not allowed. Also, UserParam variables are available only when interpolated in a string. Another difference is that a minor warning is generated if a tag doesn't exist when interpolating its value in a string (with `$`), but isn't when copying the tag directly.

Finally, the behaviour is different when a destination tag or group of All is used. When copying directly, a destination group and/or tag name of All writes to the same family 1 group and/or tag name as the source. But when interpolated in a string, the identity of the source tags are lost and the value is written to all possible groups/tags. For example, the string form must be used in the following command since the intent is to set the value of all existing date/time tags from `CreateDate`:

```
exiftool "-time:all<$createdate" -wm w FILE
```

-x TAG (-exclude)

Exclude the specified tag. There may be multiple **-x** options. This has the same effect as `---TAG` on the command line. See the `---TAG` documentation above for a complete description.

Input-output text formatting

Note that trailing spaces are removed from extracted values for most output text formats. The exceptions are **-b**, **-csv**, **-j** and **-X**.

-args (-argFormat)

Output information in the form of exiftool arguments, suitable for use with the **-@** option when writing. May be combined with the **-G** option to include group names. This feature may be used to effectively copy tags between images, but allows the metadata to be altered by editing the intermediate file (`out.args` in this example):

```
exiftool -args -G1 --filename --directory src.jpg > out.args
exiftool -@ out.args -sep ", " dst.jpg
```

Note: Be careful when copying information with this technique since it is easy to write tags which are normally considered "unsafe". For instance, the `FileName` and `Directory` tags are excluded in the example above to avoid renaming and moving the destination file. Also note that the second command above will produce warning messages for any tags which are not writable.

As well, the **-sep** option should be used as in the second command above to maintain separate list items when writing metadata back to image files, and the **-struct** option may be used when extracting to preserve structured XMP information.

-b (-binary)

Output requested metadata in binary format without tag names or descriptions. This option is mainly used for extracting embedded images or other binary data, but it may also be useful for some text strings since control characters (such as newlines) are not replaced by `'.'` as they are in the default output. By default, list items are separated by a newline when extracted with the **-b** option, but this may be changed (see the **-sep** option for details). May be combined with **-j**, **-php** or **-X** to extract binary data in JSON, PHP or XML format, but note that "unsafe" tags must be specified explicitly to be extracted as binary in these formats.

-c *FMT* (-coordFormat)

Set the print format for GPS coordinates. *FMT* uses the same syntax as a `printf` format string. The specifiers correspond to degrees, minutes and seconds in that order, but minutes and seconds are optional. For example, the following table gives the output for the same coordinate using various formats:

| FMT | Output |
|---------------------|---|
| ----- | ----- |
| "%d deg %d' %.2f\"" | 54 deg 59' 22.80" (default for reading) |
| "%d %d %.8f" | 54 59 22.80000000 (default for copying) |
| "%d deg %.4f min" | 54 deg 59.3800 min |
| "%.6f degrees" | 54.989667 degrees |

Notes:

- 1) To avoid loss of precision, the default coordinate format is different when copying tags using the **-tagsFromFile** option.
- 2) If the hemisphere is known, a reference direction (N, S, E or W) is appended to each printed coordinate, but adding a + to the format specifier (eg. `%+.6f`) prints a signed coordinate instead.
- 3) This print formatting may be disabled with the **-n** option to extract coordinates as signed decimal degrees.

-charset [*TYPE*=]*CHARSET*

If *TYPE* is `ExifTool` or not specified, this option sets the ExifTool character encoding for output tag values when reading and input values when writing, with a default of UTF8. If no *CHARSET* is given, a list of available character sets is returned. Valid *CHARSET* values are:

| CHARSET | Alias(es) | Description |
|-------------|-----------------|-----------------------------------|
| ----- | ----- | ----- |
| UTF8 | cp65001, UTF-8 | UTF-8 characters (default) |
| Latin | cp1252, Latin1 | Windows Latin1 (West European) |
| Latin2 | cp1250 | Windows Latin2 (Central European) |
| Cyrillic | cp1251, Russian | Windows Cyrillic |
| Greek | cp1253 | Windows Greek |
| Turkish | cp1254 | Windows Turkish |
| Hebrew | cp1255 | Windows Hebrew |
| Arabic | cp1256 | Windows Arabic |
| Baltic | cp1257 | Windows Baltic |
| Vietnam | cp1258 | Windows Vietnamese |
| Thai | cp874 | Windows Thai |
| DOSLatinUS | cp437 | DOS Latin US |
| DOSLatin1 | cp850 | DOS Latin1 |
| DOSCyrillic | cp866 | DOS Cyrillic |
| MacRoman | cp10000, Roman | Macintosh Roman |
| MacLatin2 | cp10029 | Macintosh Latin2 (Central Europe) |
| MacCyrillic | cp10007 | Macintosh Cyrillic |
| MacGreek | cp10006 | Macintosh Greek |
| MacTurkish | cp10081 | Macintosh Turkish |
| MacRomanian | cp10010 | Macintosh Romanian |
| MacIceland | cp10079 | Macintosh Icelandic |
| MacCroatian | cp10082 | Macintosh Croatian |

TYPE may be `FileName` to specify the encoding of file names on the command line (ie. *FILE* arguments). In Windows, this triggers use of wide-character i/o routines, thus providing support for Unicode file names. See the "WINDOWS UNICODE FILE NAMES" section below for details.

Other values of *TYPE* listed below are used to specify the internal encoding of various meta

information formats.

| TYPE | Description | Default |
|-----------|--|----------|
| ----- | ----- | ----- |
| EXIF | Internal encoding of EXIF "ASCII" strings | (none) |
| ID3 | Internal encoding of ID3v1 information | Latin |
| IPTC | Internal IPTC encoding to assume when IPTC:CodedCharacterSet is not defined | Latin |
| Photoshop | Internal encoding of Photoshop IRB strings | Latin |
| QuickTime | Internal encoding of QuickTime strings | MacRoman |
| RIFF | Internal encoding of RIFF strings | 0 |

See <<https://exiftool.org/faq.html#Q10>> for more information about coded character sets, and the Image::ExifTool Options for more details about the **-charset** settings.

-csv[**[+]=CSVFILE**]

Export information in CSV format, or import information if *CSVFILE* is specified. When importing, the CSV file must be in exactly the same format as the exported file. The first row of the *CSVFILE* must be the ExifTool tag names (with optional group names) for each column of the file, and values must be separated by commas. A special "SourceFile" column specifies the files associated with each row of information (and a SourceFile of "*" may be used to define default tags to be imported for all files which are combined with any tags specified for the specific SourceFile processed). The following examples demonstrate basic use of this option:

```
# generate CSV file with common tags from all images in a directory
exiftool -common -csv dir > out.csv

# update metadata for all images in a directory from CSV file
exiftool -csv=a.csv dir
```

Empty values are ignored when importing (unless the **-f** option is used and the API MissingTagValue is set to an empty string, in which case the tag is deleted). Also, FileName and Directory columns are ignored if they exist (ie. ExifTool will not attempt to write these tags with a CSV import). To force a tag to be deleted, use the **-f** option and set the value to "-" in the CSV file (or to the MissingTagValue if this API option was used). Multiple databases may be imported in a single command.

When exporting a CSV file, the **-g** or **-G** option adds group names to the tag headings. If the **-a** option is used to allow duplicate tag names, the duplicate tags are only included in the CSV output if the column headings are unique. Adding the **-G4** option ensures a unique column heading for each tag. The **-b** option may be added to output binary data, encoded in base64 if necessary (indicated by ASCII "base64:" as the first 7 bytes of the value). Values may also be encoded in base64 if the **-charset** option is used and the value contains invalid characters.

When exporting specific tags, the CSV columns are arranged in the same order as the specified tags provided the column headings exactly match the specified tag names, otherwise the columns are sorted in alphabetical order.

When importing from a CSV file, only files specified on the command line are processed. Any extra entries in the CSV file are ignored.

List-type tags are stored as simple strings in a CSV file, but the **-sep** option may be used to split them back into separate items when importing.

Special feature: **-csv+=CSVFILE** may be used to add items to existing lists. This affects only list-type tags. Also applies to the **-j** option.

Note that this option is fundamentally different than all other output format options because it requires information from all input files to be buffered in memory before the output is written. This may result in excessive memory usage when processing a very large number of files with a single

command. Also, it makes this option incompatible with the **-w** option. When processing a large number of files, it is recommended to either use the JSON (**-j**) or XML (**-X**) output format, or use **-p** to generate a fixed-column CSV file instead of using the **-csv** option.

-d FMT (**-dateFormat**)

Set the format for date/time tag values. The *FMT* string may contain formatting codes beginning with a percent character (%) to represent the various components of a date/time value. The specifics of the *FMT* syntax are system dependent — consult the `strftime` man page on your system for details. The default format is equivalent to “%Y:%m:%d %H:%M:%S”. This option has no effect on date-only or time-only tags and ignores timezone information if present. Only one **-d** option may be used per command. Requires POSIX::strftime or Time::Piece for the inversion conversion when writing.

-D (**-decimal**)

Show tag ID number in decimal when extracting information.

-E, -ex, -ec (**-escapeHTML, -escapeXML, -escapeC**)

Escape characters in output tag values for HTML (**-E**), XML (**-ex**) or C (**-ec**). For HTML, all characters with Unicode code points above U+007F are escaped as well as the following 5 characters: & (') " (") > (>) and < (<). For XML, only these 5 characters are escaped. The **-E** option is implied with **-h**, and **-ex** is implied with **-X**. For C, all control characters and the backslash are escaped. The inverse conversion is applied when writing tags.

-f (**-forcePrint**)

Force printing of tags even if their values are not found. This option only applies when specific tags are requested on the command line (ie. not with wildcards or by **-all**). With this option, a dash (-) is printed for the value of any missing tag, but the dash may be changed via the `API MissingTagValue` option. May also be used to add a 'flags' attribute to the **-listx** output, or to allow tags to be deleted when writing with the **-csv=CSVFILE** feature.

-g[*NUM*][:*NUM*...] (**-groupHeadings**)

Organize output by tag group. *NUM* specifies a group family number, and may be 0 (general location), 1 (specific location), 2 (category), 3 (document number), 4 (instance number), 5 (metadata path) or 6 (EXIF/TIFF format). **-g0** is assumed if a family number is not specified, and family numbers may be added wherever **-g** is mentioned in the documentation. Multiple families may be specified by separating them with colons. By default the resulting group name is simplified by removing any leading `Main:` and collapsing adjacent identical group names, but this can be avoided by placing a colon before the first family number (eg. **-g:3:1**). Use the **-listg** option to list group names for a specified family. The `SavePath` and `SaveFormat` API options are automatically enabled if the respective family 5 or 6 group names are requested. See the `API GetGroup` documentation for more information.

-G[*NUM*][:*NUM*...] (**-groupNames**)

Same as **-g** but print group name for each tag. **-G0** is assumed if *NUM* is not specified. May be combined with a number of other options to add group names to the output. Note that *NUM* may be added wherever **-G** is mentioned in the documentation. See the **-g** option above for details.

-h (**-htmlFormat**)

Use HTML table formatting for output. Implies the **-E** option. The formatting options **-D**, **-H**, **-g**, **-G**, **-I** and **-s** may be used in combination with **-h** to influence the HTML format.

-H (**-hex**)

Show tag ID number in hexadecimal when extracting information.

-htmlDump[*OFFSET*]

Generate a dynamic web page containing a hex dump of the EXIF information. This can be a very powerful tool for low-level analysis of EXIF information. The **-htmlDump** option is also invoked if the **-v** and **-h** options are used together. The verbose level controls the maximum length of the blocks dumped. An *OFFSET* may be given to specify the base for displayed offsets. If not provided, the EXIF/TIFF base offset is used. Use **-htmlDump0** for absolute offsets. Currently only EXIF/TIFF and JPEG information is dumped, but the **-u** option can be used to give a raw hex dump of other file

formats.

-j[+=JSONFILE] (-json)

Use JSON (JavaScript Object Notation) formatting for console output, or import JSON file if *JSONFILE* is specified. This option may be combined with **-g** to organize the output into objects by group, or **-G** to add group names to each tag. List-type tags with multiple items are output as JSON arrays unless **-sep** is used. By default XMP structures are flattened into individual tags in the JSON output, but the original structure may be preserved with the **-struct** option (this also causes all list-type XMP tags to be output as JSON arrays, otherwise single-item lists would be output as simple strings). The **-a** option is implied if the **-g** or **-G** options are used, otherwise it is ignored and tags with identical JSON names are suppressed. (**-g4** may be used to ensure that all tags have unique JSON names.) Adding the **-D** or **-H** option changes tag values to JSON objects with “val” and “id” fields, and adding **-I** adds a “desc” field, and a “num” field if the numerical value is different from the converted “val”. The **-b** option may be added to output binary data, encoded in base64 if necessary (indicated by ASCII “base64:” as the first 7 bytes of the value), and **-t** may be added to include tag table information (see **-t** for details). The JSON output is UTF-8 regardless of any **-L** or **-charset** option setting, but the UTF-8 validation is disabled if a character set other than UTF-8 is specified.

If *JSONFILE* is specified, the file is imported and the tag definitions from the file are used to set tag values on a per-file basis. The special “SourceFile” entry in each JSON object associates the information with a specific target file. An object with a missing SourceFile or a SourceFile of “*” defines default tags for all target files which are combined with any tags specified for the specific SourceFile processed. The imported JSON file must have the same format as the exported JSON files with the exception that the **-g** option is not compatible with the import file format (use **-G** instead). Additionally, tag names in the input JSON file may be suffixed with a # to disable print conversion.

Unlike CSV import, empty values are not ignored, and will cause an empty value to be written if supported by the specific metadata type. Tags are deleted by using the **-f** option and setting the tag value to “-” (or to the MissingTagValue setting if this API option was used). Importing with **-j+=JSONFILE** causes new values to be added to existing lists.

-l (-long)

Use long 2-line Canon-style output format. Adds a description and unconverted value (if it is different from the converted value) to the XML, JSON or PHP output when **-X**, **-j** or **-php** is used. May also be combined with **-listf**, **-listr** or **-listwf** to add descriptions of the file types.

-L (-latin)

Use Windows Latin1 encoding (cp1252) for output tag values instead of the default UTF-8. When writing, **-L** specifies that input text values are Latin1 instead of UTF-8. Equivalent to **-charset latin**.

-lang [LANG]

Set current language for tag descriptions and converted values. *LANG* is *de*, *fr*, *ja*, etc. Use **-lang** with no other arguments to get a list of available languages. The default language is *en* if **-lang** is not specified. Note that tag/group names are always English, independent of the **-lang** setting, and translation of warning/error messages has not yet been implemented. May also be combined with **-listx** to output descriptions in one language only.

By default, ExifTool uses UTF-8 encoding for special characters, but the **-L** or **-charset** option may be used to invoke other encodings. Note that ExifTool uses Unicode::LineBreak if available to help preserve the column alignment of the plain text output for languages with a variable-width character set.

Currently, the language support is not complete, but users are welcome to help improve this by submitting their own translations. To submit a translation, follow these steps (you must have Perl installed for this):

1. Download and unpack the latest Image-ExifTool full distribution.
2. 'cd' into the Image-ExifTool directory.

3. Run this command to make an XML file of the desired tags (eg. EXIF):

```
./exiftool -listx -exif:all > out.xml
```

4. Copy this text into a file called 'import.pl' in the exiftool directory:

```
push @INC, 'lib';
require Image::ExifTool::TagInfoXML;
my $file = shift or die "Expected XML file name\n";
$Image::ExifTool::TagInfoXML::makeMissing = shift;
Image::ExifTool::TagInfoXML::BuildLangModules($file,8);
```

5. Run the 'import.pl' script to Import the XML file, generating the 'MISSING' entries for your language (eg. Russian):

```
perl import.pl out.xml ru
```

6. Edit the generated language module lib/Image/ExifTool/Lang/ru.pm, and search and replace all 'MISSING' strings in the file with your translations.

7. Email the module ('ru.pm' in this example) to philharvey66 at gmail.com

8. Thank you!!

-listItem INDEX

For list-type tags, this causes only the item with the specified index to be extracted. *INDEX* is 0 for the first item in the list. Negative indices may also be used to reference items from the end of the list. Has no effect on single-valued tags. Also applies to tag values when copying from a tag, and in **-if** conditions.

-n (--printConv)

Disable print conversion for all tags. By default, extracted values are converted to a more human-readable format, but the **-n** option disables this conversion, revealing the machine-readable values. For example:

```
> exiftool -Orientation -S a.jpg
Orientation: Rotate 90 CW
> exiftool -Orientation -S -n a.jpg
Orientation: 6
```

The print conversion may also be disabled on a per-tag basis by suffixing the tag name with a # character:

```
> exiftool -Orientation# -Orientation -S a.jpg
Orientation: 6
Orientation: Rotate 90 CW
```

These techniques may also be used to disable the inverse print conversion when writing. For example, the following commands all have the same effect:

```
> exiftool -Orientation='Rotate 90 CW' a.jpg
> exiftool -Orientation=6 -n a.jpg
> exiftool -Orientation#=6 a.jpg
```

-p FMFILE or STR (-printFormat)

Print output in the format specified by the given file or string. The argument is interpreted as a string unless a file of that name exists, in which case the string is loaded from the contents of the file. Tag names in the format file or string begin with a \$ symbol and may contain leading group names and/or a trailing # (to disable print conversion). Case is not significant. Braces { } may be used around the tag name to separate it from subsequent text. Use \$\$ to represent a \$ symbol, and \$/ for a newline.

Multiple **-p** options may be used, each contributing a line (or more) of text to the output. Lines beginning with # [HEAD] and # [TAIL] are output before the first processed file and after the last

processed file respectively. Lines beginning with `#[SECT]` and `#[ENDS]` are output before and after each section of files. A section is defined as a group of consecutive files with the same section header (eg. files are grouped by directory if `#[SECT]` contains `$directory`). Lines beginning with `#[BODY]` and lines not beginning with `#` are output for each processed file. Lines beginning with `#[IF]` are not output, but all BODY lines are skipped if any tag on an IF line doesn't exist. Other lines beginning with `#` are ignored. For example, this format file:

```
# this is a comment line
#[HEAD]-- Generated by ExifTool $exifToolVersion --
File: $FileName - $DateTimeOriginal
(f/$Aperture, ${ShutterSpeed}s, ISO $EXIF:ISO)
#[TAIL]-- end --
```

with this command:

```
exiftool -p test.fmt a.jpg b.jpg
```

produces output like this:

```
-- Generated by ExifTool 12.00 --
File: a.jpg - 2003:10:31 15:44:19
(f/5.6, 1/60s, ISO 100)
File: b.jpg - 2006:05:23 11:57:38
(f/8.0, 1/13s, ISO 100)
-- end --
```

The values of List-type tags with multiple items and Shortcut tags representing multiple tags are joined according to the `-sep` option setting when interpolated in the string.

When `-ee` (`-extractEmbedded`) is combined with `-p`, embedded documents are effectively processed as separate input files.

If a specified tag does not exist, a minor warning is issued and the line with the missing tag is not printed. However, the `-f` option may be used to set the value of missing tags to `'-'` (but this may be configured via the `MissingTagValue` API option), or the `-m` option may be used to ignore minor warnings and leave the missing values empty. Alternatively, `-q -q` may be used to simply suppress the warning messages.

The “Advanced formatting feature” may be used to modify the values of individual tags with the `-p` option.

-php

Format output as a PHP Array. The `-g`, `-G`, `-D`, `-H`, `-I`, `-sep` and `-struct` options combine with `-php`, and duplicate tags are handled in the same way as with the `-json` option. As well, the `-b` option may be added to output binary data, and `-t` may be added to include tag table information (see `-t` for details). Here is a simple example showing how this could be used in a PHP script:

```
<?php
eval('$array=' . `exiftool -php -q image.jpg`);
print_r($array);
?>
```

-s[*NUM*] (-short)

Short output format. Prints tag names instead of descriptions. Add *NUM* or up to 3 `-s` options for even shorter formats:

```
-s1 or -s          - print tag names instead of descriptions
-s2 or -s -s       - no extra spaces to column-align values
-s3 or -s -s -s    - print values only (no tag names)
```

Also effective when combined with `-t`, `-h`, `-X` or `-listx` options.

-S (-veryShort)

Very short format. The same as **-s2** or two **-s** options. Tag names are printed instead of descriptions, and no extra spaces are added to column-align values.

-sep STR (-separator)

Specify separator string for items in list-type tags. When reading, the default is to join list items with “, ”. When writing, this option causes values assigned to list-type tags to be split into individual items at each substring matching *STR* (otherwise they are not split by default). Space characters in *STR* match zero or more whitespace characters in the value.

Note that an empty separator ("") is allowed, and will join items with no separator when reading, or split the value into individual characters when writing.

For pure binary output (**-b** used without **-j**, **-php** or **-X**), the first **-sep** option specifies a list-item separator, and a second **-sep** option specifies a terminator for the end of the list (or after each value if not a list). In these strings, `\n`, `\r` and `\t` may be used to represent a newline, carriage return and tab respectively. By default, binary list items are separated by a newline, and no terminator is added.

-sort, --sort

Sort output by tag description, or by tag name if the **-s** option is used. When sorting by description, the sort order will depend on the **-lang** option setting. Without the **-sort** option, tags appear in the order they were specified on the command line, or if not specified, the order they were extracted from the file. By default, tags are organized by groups when combined with the **-g** or **-G** option, but this grouping may be disabled with **--sort**.

-struct, --struct

Output structured XMP information instead of flattening to individual tags. This option works well when combined with the XML (**-X**) and JSON (**-j**) output formats. For other output formats, XMP structures and lists are serialized into the same format as when writing structured information (see <https://exiftool.org/struct.html> for details). When copying, structured tags are copied by default unless **--struct** is used to disable this feature (although flattened tags may still be copied by specifying them individually unless **-struct** is used). These options have no effect when assigning new values since both flattened and structured tags may always be used when writing.

-t (-tab)

Output a tab-delimited list of description/values (useful for database import). May be combined with **-s** to print tag names instead of descriptions, or **-S** to print tag values only, tab-delimited on a single line. The **-t** option may be combined with **-j**, **-php** or **-X** to add tag table information (`table`, `tag id`, and `index` for cases where multiple conditional tags exist with the same ID).

-T (-table)

Output tag values in table form. Equivalent to **-t -S -q -f**.

-v[*NUM*] (-verbose)

Print verbose messages. *NUM* specifies the level of verbosity in the range 0–5, with higher numbers being more verbose. If *NUM* is not given, then each **-v** option increases the level of verbosity by 1. With any level greater than 0, most other options are ignored and normal console output is suppressed unless specific tags are extracted. Using **-v0** causes the console output buffer to be flushed after each line (which may be useful to avoid delays when piping exiftool output), and prints the name of each processed file when writing. Also see the **-progress** option.

-w[+!]*EXT* or *FMT* (-textOut)

Write console output to files with names ending in *EXT*, one for each source file. The output file name is obtained by replacing the source file extension (including the ‘.’) with the specified extension (and a ‘.’ is added to the start of *EXT* if it doesn’t already contain one). Alternatively, a *FMT* string may be used to give more control over the output file name and directory. In the format string, `%d`, `%f` and `%e` represent the directory, filename and extension of the source file, and `%c` represents a copy number which is automatically incremented if the file already exists. `%d` includes the trailing ‘/’ if necessary, but `%e` does not include the leading ‘.’. For example:

```

-w %d%f.txt      # same effect as "-w txt"
-w dir/%f_%e.out # write files to "dir" as "FILE_EXT.out"
-w dir2/%d%f.txt # write to "dir2", keeping dir structure
-w a%c.txt       # write to "a.txt" or "a1.txt" or "a2.txt"...
```

Existing files will not be changed unless an exclamation point is added to the option name (ie. **-w!** or **-textOut!**) to overwrite the file, or a plus sign (ie. **-w+** or **-textOut+**) to append to the existing file. Both may be used (ie. **-w+!** or **-textOut+!**) to overwrite output files that didn't exist before the command was run, and append the output from multiple source files. For example, to write one output file for all source files in each directory:

```
exiftool -filename -createdate -T -w+! %d/out.txt -r DIR
```

Capitalized format codes %D, %F, %E and %C provide slightly different alternatives to the lower case versions. %D does not include the trailing '/', %F is the full filename including extension, %E includes the leading '.', and %C increments the count for each processed file (see below).

Notes:

1) In a Windows BAT file the % character is represented by %, so an argument like %d%f.txt is written as %%d%%f.txt.

2) If the argument for **-w** does not contain a valid format code (eg. %f), then it is interpreted as a file extension. It is not possible to specify a simple filename as an argument — creating a single output file from multiple source files is typically done by shell redirection, ie)

```
exiftool FILE1 FILE2 ... > out.txt
```

But if necessary, an empty format code may be used to force the argument to be interpreted as a format string, and the same result may be obtained without the use of shell redirection:

```
exiftool -w+! %0fout.txt FILE1 FILE2 ...
```

Advanced features:

A substring of the original file name, directory or extension may be taken by specifying a field width immediately following the '%' character. If the width is negative, the substring is taken from the end. The substring position (characters to ignore at the start or end of the string) may be given by a second optional value after a decimal point. For example:

| Input File Name | Format Specifier | Output File Name |
|------------------|------------------|------------------|
| ----- | ----- | ----- |
| Picture-123.jpg | %7f.txt | Picture.txt |
| Picture-123.jpg | %-.4f.out | Picture.out |
| Picture-123.jpg | %7f.%-3f | Picture.123 |
| Picture-123a.jpg | Meta%-3.1f.txt | Meta123.txt |

(Note that special characters may have a width of greater than one.)

For %d and %D, the field width/position specifiers may be applied to the directory levels instead of substring position by using a colon instead of a decimal point in the format specifier. For example:

| Source Dir | Format | Result | Notes |
|--------------|--------|------------|--------------------------|
| ----- | ----- | ----- | ----- |
| pics/2012/02 | %2:d | pics/2012/ | take top 2 levels |
| pics/2012/02 | %-:1d | pics/2012/ | up one directory level |
| pics/2012/02 | %:1d | 2012/02/ | ignore top level |
| pics/2012/02 | %1:1d | 2012/ | take 1 level after top |
| pics/2012/02 | %-1:D | 02 | bottom level folder name |
| /Users/phil | %:2d | phil/ | ignore top 2 levels |

(Note that the root directory counts as one level when an absolute path is used as in the last example)

above.)

For %c, these modifiers have a different effects. If a field width is given, the copy number is padded with zeros to the specified width. A leading '-' adds a dash before the copy number, and a '+' adds an underline. By default, the copy number is omitted from the first file of a given name, but this can be changed by adding a decimal point to the modifier. For example:

```
-w A%-cZ.txt      # AZ.txt, A-1Z.txt, A-2Z.txt ...
-w B%5c.txt       # B.txt, B00001.txt, B00002.txt ...
-w C%.c.txt       # C0.txt, C1.txt, C2.txt ...
-w D%-c.txt       # D-0.txt, D-1.txt, D-2.txt ...
-w E%-4c.txt      # E-0000.txt, E-0001.txt, E-0002.txt ...
-w F%-4nc.txt     # F-0001.txt, F-0002.txt, F-0003.txt ...
-w G%+c.txt       # G.txt, G_1.txt, G_2.txt ...
-w H%-lc.txt      # H.txt, H-b.txt, H-c.txt ...
-w I.%.3uc.txt    # I.AAA.txt, I.AAB.txt, I.AAC.txt ...
```

A special feature allows the copy number to be incremented for each processed file by using %C (upper case) instead of %c. This allows a sequential number to be added to output file names, even if the names are different. For %C, a copy number of zero is not omitted as it is with %c. A leading '-' causes the number to be reset at the start of each new directory, and '+' has no effect. The number before the decimal place gives the starting index, the number after the decimal place gives the field width. The following examples show the output filenames when used with the command `exiftool`

```
-w %C%f.txt       # 0rose.txt, 1star.txt, 2jet.txt
-w %f-%10C.txt    # rose-10.txt, star-11.txt, jet-12.txt
-w %.3C-%f.txt    # 000-rose.txt, 001-star.txt, 002-jet.txt
-w %57.4C%f.txt   # 0057rose.txt, 0058star.txt, 0059jet.txt
```

All format codes may be modified by 'l' or 'u' to specify lower or upper case respectively (ie. %le for a lower case file extension). When used to modify %c or %C, the numbers are changed to an alphabetical base (see example H above). Also, %c and %C may be modified by 'n' to count using natural numbers starting from 1, instead of 0 (see example F above).

This same *FMT* syntax is used with the `-o` and `-tagsFromFile` options, although %c and %C are only valid for output file names.

-W[+!] *FMT* (-tagOut)

This enhanced version of the `-w` option allows a separate output file to be created for each extracted tag. See the `-w` option documentation above for details of the basic functionality. Listed here are the differences between `-W` and `-w`:

- 1) With `-W`, a new output file is created for each extracted tag.
- 2) `-W` supports three additional format codes: %t, %g and %s represent the tag name, group name, and suggested extension for the output file (based on the format of the data). The %g code may be followed by a single digit to specify the group family number (eg. %g1), otherwise family 0 is assumed. The substring width/position/case specifiers may be used with these format codes in exactly the same way as with %f and %e.
- 3) The argument for `-W` is interpreted as a file name if it contains no format codes. (For `-w`, this would be a file extension.) This change allows a simple file name to be specified, which, when combined with the append feature, provides a method to write metadata from multiple source files to a single output file without the need for shell redirection. For example, the following pairs of commands give the same result:

```
# overwriting existing text file
exiftool test.jpg > out.txt      # shell redirection
exiftool test.jpg -W+! out.txt  # equivalent -W option

# append to existing text file
exiftool test.jpg >> out.txt     # shell redirection
exiftool test.jpg -W+ out.txt    # equivalent -W option
```

4) Adding the **-v** option to **-W** sends a list of the tags and output file names to the console instead of giving a verbose dump of the entire file. (Unless appending all output to one file for each source file by using **-W+** with an output file *FMT* that does not contain %t, %g or %s.)

5) Individual list items are stored in separate files when **-W** is combined with **-b**, but note that for separate files to be created %c or %C must be used in *FMT* to give the files unique names.

-Wext EXT, --Wext EXT (-tagOutExt)

This option is used to specify the type of output file(s) written by the **-W** option. An output file is written only if the suggested extension matches *EXT*. Multiple **-Wext** options may be used to write more than one type of file. Use **--Wext** to write all but the specified type(s).

-X (-xmlFormat)

Use ExifTool-specific RDF/XML formatting for console output. Implies the **-a** option, so duplicate tags are extracted. The formatting options **-b**, **-D**, **-H**, **-I**, **-s**, **-sep**, **-struct** and **-t** may be used in combination with **-X** to affect the output, but note that the tag ID (**-D**, **-H** and **-t**), binary data (**-b**) and structured output (**-struct**) options are not effective for the short output (**-s**). Another restriction of **-s** is that only one tag with a given group and name may appear in the output. Note that the tag ID options (**-D**, **-H** and **-t**) will produce non-standard RDF/XML unless the **-I** option is also used.

By default, **-X** outputs flattened tags, so **-struct** should be added if required to preserve XMP structures. List-type tags with multiple values are formatted as an RDF Bag, but they are combined into a single string when **-s** or **-sep** is used. Using **-L** changes the XML encoding from “UTF-8” to “windows-1252”. Other **-charset** settings change the encoding only if there is a corresponding standard XML character set. The **-b** option causes binary data values to be written, encoded in base64 if necessary. The **-t** option adds tag table information to the output (see **-t** for details).

Note: This output is NOT the same as XMP because it uses dynamically-generated property names corresponding to the ExifTool tag names, and not the standard XMP properties. To write XMP instead, use the **-o** option with an XMP extension for the output file.

Processing control

-a, --a (-duplicates, --duplicates)

Allow (**-a**) or suppress (**--a**) duplicate tag names to be extracted. By default, duplicate tags are suppressed when reading unless the **-ee** or **-X** options are used or the Duplicates option is enabled in the configuration file. This option has an affect when writing only to allow duplicate Warning messages to be shown. Duplicate tags are always extracted when copying.

-e (--composite)

Extract existing tags only — don't generate composite tags.

-ee (-extractEmbedded)

Extract information from embedded documents in EPS files, embedded EPS information and JPEG and Jpeg2000 images in PDF files, embedded MPF images in JPEG and MPO files, streaming metadata in AVCHD videos, and the resource fork of Mac OS files. Implies the **-a** option. Use **-g3** or **-G3** to identify the originating document for extracted information. Embedded documents containing sub-documents are indicated with dashes in the family 3 group name. (eg. Doc2-3 is the 3rd sub-document of the 2nd embedded document.) Note that this option may increase processing time substantially, especially for PDF files with many embedded images or videos with streaming metadata.

When used with **-ee**, the **-p** option is evaluated for each embedded document as if it were a separate

input file. This allows, for example, generation of GPS track logs from timed metadata in videos. See <<https://exiftool.org/geotag.html#Inverse>> for examples.

-ext[+] EXT, --ext EXT (-extension)

Process only files with (**-ext**) or without (**--ext**) a specified extension. There may be multiple **-ext** and **--ext** options. A plus sign may be added (ie. **-ext+**) to add the specified extension to the normally processed files. EXT may begin with a leading '.', which is ignored. Case is not significant. "*" may be used to process files with any extension (or none at all), as in the last three examples:

```
exiftool -ext JPG DIR           # process only JPG files
exiftool --ext cr2 --ext dng DIR # supported files but CR2/DNG
exiftool -ext+ txt DIR          # supported files plus TXT
exiftool -ext "*" DIR           # process all files
exiftool -ext "*" --ext xml DIR  # process all but XML files
exiftool -ext "*" --ext . DIR    # all but those with no ext
```

Using this option has two main advantages over specifying ***.EXT** on the command line: 1) It applies to files in subdirectories when combined with the **-r** option. 2) The **-ext** option is case-insensitive, which is useful when processing files on case-sensitive filesystems.

Note that all files specified on the command line will be processed regardless of extension unless the **-ext** option is used.

-F[OFFSET] (-fixBase)

Fix the base for maker notes offsets. A common problem with some image editors is that offsets in the maker notes are not adjusted properly when the file is modified. This may cause the wrong values to be extracted for some maker note entries when reading the edited file. This option allows an integer *OFFSET* to be specified for adjusting the maker notes base offset. If no *OFFSET* is given, ExifTool takes its best guess at the correct base. Note that exiftool will automatically fix the offsets for images which store original offset information (eg. newer Canon models). Offsets are fixed permanently if **-F** is used when writing EXIF to an image. eg)

```
exiftool -F -exif:resolutionunit=inches image.jpg
```

-fast[*NUM*]

Increase speed of extracting information. With **-fast** (or **-fast1**), ExifTool will not scan to the end of a JPEG image to check for an AFCP or PreviewImage trailer, or past the first comment in GIF images or the audio/video data in WAV/AVI files to search for additional metadata. These speed benefits are small when reading images directly from disk, but can be substantial if piping images through a network connection. For more substantial speed benefits, **-fast2** also causes exiftool to avoid extracting any EXIF MakerNote information. **-fast3** avoids extracting metadata from the file, and returns only pseudo System tags, but still reads the file header to obtain an educated guess at FileType. **-fast4** doesn't even read the file header, and returns only System tags and a FileType based on the file extension. Has no effect when writing.

Note that a separate **-fast** setting may be used for evaluation of a **-if** condition, or when ordering files with the **-fileOrder** option. See the **-if** and **-fileOrder** options for details.

-fileOrder[*NUM*] [-]TAG

Set file processing order according to the sorted value of the specified TAG. For example, to process files in order of date:

```
exiftool -fileOrder DateTimeOriginal DIR
```

Additional **-fileOrder** options may be added for secondary sort keys. Numbers are sorted numerically, and all other values are sorted alphabetically. Files missing the specified tag are sorted last. The sort order may be reversed by prefixing the tag name with a - (eg. **-fileOrder -createdate**). Print conversion of the sorted values is disabled with the **-n** option, or a # appended to the tag name. Other formatting options (eg. **-d**) have no effect on the sorted values. Note that the **-fileOrder** option can have a large performance impact since it involves an additional

processing pass of each file, but this impact may be reduced by specifying a *NUM* for the **-fast** level used during the metadata-extraction phase. For example, **-fileOrder4** may be used if *TAG* is a pseudo System tag. If multiple **-fileOrder** options are used, the extraction is done at the lowest **-fast** level.

-i DIR (-ignore)

Ignore specified directory name. *DIR* may be either an individual folder name, or a full path. If a full path is specified, it must match the Directory tag exactly to be ignored. Use multiple **-i** options to ignore more than one directory name. A special *DIR* value of SYMLINKS (case sensitive) may be specified to ignore symbolic links when the **-r** option is used.

-if[*NUM*] *EXPR*

Specify a condition to be evaluated before processing each *FILE*. *EXPR* is a Perl-like logic expression containing tag names prefixed by \$ symbols. It is evaluated with the tags from each *FILE* in turn, and the file is processed only if the expression returns true. Unlike Perl variable names, tag names are not case sensitive and may contain a hyphen. As well, tag names may have a leading group names separated by colons, and/or a trailing # character to disable print conversion. The expression \$GROUP:all evaluates to 1 if any tag exists in the specified GROUP, or 0 otherwise (see note 2 below). When multiple **-if** options are used, all conditions must be satisfied to process the file. Returns an exit status of 2 if all files fail the condition. Below are a few examples:

```
# extract shutterspeed from all Canon images in a directory
exiftool -shutterspeed -if '$make eq "Canon"' dir

# add one hour to all images created on or after Apr. 2, 2006
exiftool -alldates+=1 -if '$CreateDate ge "2006:04:02"' dir

# set EXIF ISO value if possible, unless it is set already
exiftool '-exif:iso<iso' -if 'not $exif:iso' dir

# find images containing a specific keyword (case insensitive)
exiftool -if '$keywords =~ /harvey/i' -filename dir
```

Adding *NUM* to the **-if** option causes a separate processing pass to be executed for evaluating *EXPR* at a **-fast** level given by *NUM* (see the **-fast** option documentation for details). Without *NUM*, only one processing pass is done at the level specified by the **-fast** option. For example, using **-if4** is possible if *EXPR* uses only pseudo System tags, and may significantly speed processing if enough files fail the condition.

The expression has access to the current ExifTool object through \$self, and the following special functions are available to allow short-circuiting of the file processing. Both functions have a return value of 1. Case is significant for function names.

```
End()      - end processing after this file
EndDir()   - end processing of files in this directory
```

Notes:

- 1) The **-n** and **-b** options also apply to tags used in *EXPR*.
- 2) Some binary data blocks are not extracted unless specified explicitly. These tags are not available for use in the **-if** condition unless they are also specified on the command line. The alternative is to use the \$GROUP:all syntax. (eg. Use \$exif:all instead of \$exif in *EXPR* to test for the existence of EXIF tags.)
- 3) Tags in the string are interpolated the same way as with **-p** before the expression is evaluated. In this interpolation, \$/ is converted to a newline and \$\$ represents a single \$ symbol (so Perl variables, if used, require a double \$).
- 4) The condition may only test tags from the file being processed. To process one file based on tags

from another, two steps are required. For example, to process XMP sidecar files in directory *DIR* based on tags from the associated NEF:

```
exiftool -if EXPR -p '$directory/$filename' -ext nef DIR > nef.txt
exiftool -@ nef.txt -srcfile %d%f.xmp ...
```

5) The **-a** option has no effect on the evaluation of the expression, and the values of duplicate tags are accessible only by specifying a group name (such as a family 4 instance number, eg. *\$Copy1:TAG*, *\$Copy2:TAG*, etc).

6) A special “OK” UserParam is available to test the success of the previous command when **-execute** was used, and may be used like any other tag in the condition (ie. “\$OK”).

-m (-ignoreMinorErrors)

Ignore minor errors and warnings. This enables writing to files with minor errors and disables some validation checks which could result in minor warnings. Generally, minor errors/warnings indicate a problem which usually won’t result in loss of metadata if ignored. However, there are exceptions, so ExifTool leaves it up to you to make the final decision. Minor errors and warnings are indicated by “[minor]” at the start of the message. Warnings which affect processing when ignored are indicated by “[Minor]” (with a capital “M”). Note that this causes missing values in **-tagsFromFile**, **-p** and **-if** strings to be set to an empty string rather than an undefined value.

-o OUTFILE or FMT (-out)

Set the output file or directory name when writing information. Without this option, when any “real” tags are written the original file is renamed to *FILE_original* and output is written to *FILE*. When writing only FileName and/or Directory “pseudo” tags, **-o** causes the file to be copied instead of moved, but directories specified for either of these tags take precedence over that specified by the **-o** option.

OUTFILE may be **-** to write to stdout. The output file name may also be specified using a *FMT* string in which *%d*, *%f* and *%e* represent the directory, file name and extension of *FILE*. Also, *%c* may be used to add a copy number. See the **-w** option for *FMT* string examples.

The output file is taken to be a directory name if it already exists as a directory or if the name ends with *’/’*. Output directories are created if necessary. Existing files will not be overwritten. Combining the **-overwrite_original** option with **-o** causes the original source file to be erased after the output file is successfully written.

A special feature of this option allows the creation of certain types of files from scratch, or with the metadata from another type of file. The following file types may be created using this technique:

```
XMP, EXIF, EXV, MIE, ICC/ICM, VRD, DR4
```

The output file type is determined by the extension of *OUTFILE* (specified as **- .EXT** when writing to stdout). The output file is then created from a combination of information in *FILE* (as if the **-tagsFromFile** option was used), and tag values assigned on the command line. If no *FILE* is specified, the output file may be created from scratch using only tags assigned on the command line.

-overwrite_original

Overwrite the original *FILE* (instead of preserving it by adding *_original* to the file name) when writing information to an image. Caution: This option should only be used if you already have separate backup copies of your image files. The overwrite is implemented by renaming a temporary file to replace the original. This deletes the original file and replaces it with the edited version in a single operation. When combined with **-o**, this option causes the original file to be deleted if the output file was successfully written (ie. the file is moved instead of copied).

-overwrite_original_in_place

Similar to **-overwrite_original** except that an extra step is added to allow the original file attributes to be preserved. For example, on a Mac this causes the original file creation date, type, creator, label color, icon, Finder tags, other extended attributes and hard links to the file to be preserved (but note that the Mac OS resource fork is always preserved unless specifically deleted with **-rsrc:all=**).

This is implemented by opening the original file in update mode and replacing its data with a copy of a temporary file before deleting the temporary. The extra step results in slower performance, so the **-overwrite_original** option should be used instead unless necessary.

Note that this option reverts to the behaviour of the **-overwrite_original** option when also writing the FileName and/or Directory tags.

-P (-preserve)

Preserve the filesystem modification date/time (FileModifyDate) of the original file when writing. Note that some filesystems store a creation date (ie. FileCreateDate on Windows and Mac systems) which is not affected by this option. This creation date is preserved on Windows systems where Win32API::File and Win32::API are available regardless of this setting. For other systems, the **-overwrite_original_in_place** option may be used if necessary to preserve the creation date. The **-P** option is superseded by any value written to the FileModifyDate tag.

-password *PASSWD*

Specify password to allow processing of password-protected PDF documents. If a password is required but not given, a warning is issued and the document is not processed. This option is ignored if a password is not required.

-progress[:*[TITLE]*]

Show the progress when processing files. Without a colon, the **-progress** option adds a progress count in brackets after the name of each processed file, giving the current file number and the total number of files to be processed. Implies the **-v0** option, causing the names of processed files to also be printed when writing. When combined with the **-if** option, the total count includes all files before the condition is applied, but files that fail the condition will not have their names printed.

If followed by a colon (ie. **-progress:**), the console window title is set according to the specified *TITLE* string. If no *TITLE* is given, a default *TITLE* string of "ExifTool %p%%" is assumed. In the string, %f represents the file name, %p is the progress as a percent, %r is the progress as a ratio, %##b is a progress bar of width "##" (20 characters if "##" is omitted), and %% is a % character. May be combined with the normal **-progress** option to also show the progress count in console messages. (Note: For this feature to function correctly on Mac/Linux, stderr must go to the console.)

-q (-quiet)

Quiet processing. One **-q** suppresses normal informational messages, and a second **-q** suppresses warnings as well. Error messages can not be suppressed, although minor errors may be downgraded to warnings with the **-m** option, which may then be suppressed with **-q -q**.

-r[.] (-recurse)

Recursively process files in subdirectories. Only meaningful if *FILE* is a directory name. Subdirectories with names beginning with "." are not processed unless "." is added to the option name (ie. **-r.** or **-recurse.**). By default, exiftool will also follow symbolic links to directories if supported by the system, but this may be disabled with **-i SYMLINKS** (see the **-i** option for details). Combine this with **-ext** options to control the types of files processed.

-scanForXMP

Scan all files (even unsupported formats) for XMP information unless found already. When combined with the **-fast** option, only unsupported file types are scanned. Warning: It can be time consuming to scan large files.

-u (-unknown)

Extract values of unknown tags. Add another **-u** to also extract unknown information from binary data blocks. This option applies to tags with numerical tag ID's, and causes tag names like "Exif_0xc5d9" to be generated for unknown information. It has no effect on information types which have human-readable tag ID's (such as XMP), since unknown tags are extracted automatically from these formats.

-U (-unknown2)

Extract values of unknown tags as well as unknown information from some binary data blocks. This is the same as two **-u** options.

-wm *MODE* (-writeMode)

Set mode for writing/creating tags. *MODE* is a string of one or more characters from the list below. The default write mode is *wcg*.

```
w - Write existing tags
c - Create new tags
g - create new Groups as necessary
```

For example, use **-wm cg** to only create new tags (and avoid editing existing ones).

The level of the group is the SubDirectory level in the metadata structure. For XMP or IPTC this is the full XMP/IPTC block (the family 0 group), but for EXIF this is the individual IFD (the family 1 group).

-z (-zip)

When reading, causes information to be extracted from .gz and .bz2 compressed images (only one image per archive; requires gzip and bzip2 to be available). When writing, causes compressed information to be written if supported by the metadata format (eg. compressed textual metadata in PNG), disables the recommended padding in embedded XMP (saving 2424 bytes when writing XMP in a file), and writes XMP in shorthand format — the equivalent of setting the API Compress=1 and Compact="NoPadding,Shorthand".

*Other options***-@ *ARGFILE***

Read command-line arguments from the specified file. The file contains one argument per line (NOT one option per line — some options require additional arguments, and all arguments must be placed on separate lines). Blank lines and lines beginning with # are ignored (unless they start with # [CSTR], in which case the rest of the line is treated as a C string, allowing standard C escape sequences such as "\n" for a newline). White space at the start of a line is removed. Normal shell processing of arguments is not performed, which among other things means that arguments should not be quoted and spaces are treated as any other character. *ARGFILE* may exist relative to either the current directory or the exiftool directory unless an absolute pathname is given.

For example, the following *ARGFILE* will set the value of Copyright to "Copyright YYYY, Phil Harvey", where "YYYY" is the year of CreateDate:

```
-d
%Y
-copyright<Copyright $createdate, Phil Harvey
```

Arguments in *ARGFILE* behave exactly the same as if they were entered at the location of the **-@** option on the command line, with the exception that the **-config** and **-common_args** options may not be used in an *ARGFILE*.

-k (-pause)

Pause with the message `-- press any key --` or `-- press RETURN --` (depending on your system) before terminating. This option is used to prevent the command window from closing when run as a Windows drag and drop application.

-list, -listw, -listf, -listr, -listwf, -listg[*NUM*], -listd, -listx

Print a list of all valid tag names (**-list**), all writable tag names (**-listw**), all supported file extensions (**-listf**), all recognized file extensions (**-listr**), all writable file extensions (**-listwf**), all tag groups [in a specified family] (**-listg[*NUM*]**), all deletable tag groups (**-listd**), or an XML database of tag details including language translations (**-listx**). The **-list**, **-listw** and **-listx** options may be followed by an additional argument of the form **-GROUP:All** to list only tags in a specific group, where *GROUP* is one or more family 0–2 group names (excepting EXIF IFD groups) separated by colons. With **-listg**,

NUM may be given to specify the group family, otherwise family 0 is assumed. The **-l** option may be combined with **-listf**, **-listr** or **-listwf** to add file descriptions to the list. The **-lang** option may be combined with **-listx** to output descriptions in a single language. Here are some examples:

```
-list          # list all tag names
-list -EXIF:All # list all EXIF tags
-list -xmp:time:all # list all XMP tags relating to time
-listw -XMP-dc:All # list all writable XMP-dc tags
-listf        # list all supported file extensions
-listr        # list all recognized file extensions
-listwf       # list all writable file extensions
-listg1       # list all groups in family 1
-listd        # list all deletable groups
-listx -EXIF:All # list database of EXIF tags in XML format
-listx -XMP:All -s # list short XML database of XMP tags
```

When combined with **-listx**, the **-s** option shortens the output by omitting the descriptions and values (as in the last example above), and **-f** adds a 'flags' attribute if applicable. The flags are formatted as a comma-separated list of the following possible values: Avoid, Binary, List, Mandatory, Permanent, Protected, Unknown and Unsafe (see the Tag Name documentation). For XMP List tags, the list type (Alt, Bag or Seq) is added to the flags, and flattened structure tags are indicated by a Flattened flag.

Note that none of the **-list** options require an input *FILE*.

- ver** Print exiftool version number. The **-v** option may be added to print addition system information (see the README file of the full distribution for more details about optional libraries), or **-v2** to also list the Perl include directories.
- Indicates the end of options. Any remaining arguments are treated as file names, even if they begin with a dash (-).

Special features

-geotag *TRKFILE*

Geotag images from the specified GPS track log file. Using the **-geotag** option is equivalent to writing a value to the Geotag tag. The GPS position is interpolated from the track at a time specified by the value written to the Geotime tag. If Geotime is not specified, the value is copied from DateTimeOriginal# (the # is added to copy the unformatted value, avoiding potential conflicts with the **-d** option). For example, the following two commands are equivalent:

```
exiftool -geotag trk.log image.jpg
exiftool -geotag trk.log "-Geotime<DateTimeOriginal#" image.jpg
```

When the `Geotime` value is converted to UTC, the local system timezone is assumed unless the date/time value contains a timezone. Writing `Geotime` causes the following tags to be written (provided they can be calculated from the track log, and they are supported by the destination metadata format): `GPSPLatitude`, `GPSPLatitudeRef`, `GPSPLongitude`, `GPSPLongitudeRef`, `GPSPAltitude`, `GPSPAltitudeRef`, `GPSPDateStamp`, `GPSPTimeStamp`, `GPSPDateTime`, `GPSPTrack`, `GPSPTrackRef`, `GPSSpeed`, `GPSSpeedRef`, `GPSPImgDirection`, `GPSPImgDirectionRef`, `GPSPitch`, `GPSPRoll`, `AmbientTemperature` and `CameraElevationAngle`. By default, tags are created in EXIF, and updated in XMP only if they already exist. However, `EXIF:Geotime` or `XMP:Geotime` may be specified to write only EXIF or XMP tags respectively. Note that `GPSPitch` and `GPSPRoll` are non-standard, and require user-defined tags in order to be written.

The `Geosync` tag may be used to specify a time correction which is applied to each `Geotime` value for synchronization with GPS time. For example, the following command compensates for image times which are 1 minute and 20 seconds behind GPS:

```
exiftool -geosync=+1:20 -geotag a.log DIR
```

Advanced Geosync features allow a linear time drift correction and synchronization from previously geotagged images. See “geotag.html” in the full ExifTool distribution for more information.

Multiple **-geotag** options may be used to concatenate GPS track log data. Also, a single **-geotag** option may be used to load multiple track log files by using wildcards in the *TRKFILE* name, but note that in this case *TRKFILE* must be quoted on most systems (with the notable exception of Windows) to prevent filename expansion. For example:

```
exiftool -geotag "TRACKDIR/*.log" IMAGEDIR
```

Currently supported track file formats are GPX, NMEA RMC/GGA/GLL, KML, IGC, Garmin XML and TCX, Magellan PMGNTRK, Honeywell PTNTHPR, Bramor gEO, Winplus Beacon TXT, and GPS/IMU CSV files. See “GEOTAGGING EXAMPLES” for examples. Also see “geotag.html” in the full ExifTool distribution and the Image::ExifTool Options for more details and for information about geotag configuration options.

-globalTimeShift *SHIFT*

Shift all formatted date/time values by the specified amount when reading. Does not apply to unformatted (**-n**) output. *SHIFT* takes the same form as the date/time shift when writing (see Image::ExifTool::Shift.pl for details), with a negative shift being indicated with a minus sign (-) at the start of the *SHIFT* string. For example:

```
# return all date/times, shifted back by 1 hour
exiftool -globalTimeShift -1 -time:all a.jpg

# set the file name from the shifted CreateDate (-1 day) for
# all images in a directory
exiftool "-filename<createdate" -globaltimeshift "-0:0:1 0:0:0" \
-d %Y%m%d-%H%M%S.%e dir
```

-use *MODULE*

Add features from specified plug-in *MODULE*. Currently, the MWG module is the only plug-in module distributed with exiftool. This module adds read/write support for tags as recommended by the Metadata Working Group. As a convenience, **-use MWG** is assumed if the MWG group is specified for any tag on the command line. See the MWG Tags documentation for more details. Note that this option is not reversible, and remains in effect until the application terminates, even across the **-execute** option.

Utilities

-restore_original

-delete_original [**!**]

These utility options automate the maintenance of the *_original* files created by exiftool. They have no effect on files without an *_original* copy. The **-restore_original** option restores the specified files from their original copies by renaming the *_original* files to replace the edited versions. For example, the following command restores the originals of all JPG images in directory DIR:

```
exiftool -restore_original -ext jpg DIR
```

The **-delete_original** option deletes the *_original* copies of all files specified on the command line. Without a trailing **!** this option prompts for confirmation before continuing. For example, the following command deletes *a.jpg_original* if it exists, after asking “Are you sure?”:

```
exiftool -delete_original a.jpg
```

These options may not be used with other options to read or write tag values in the same command, but may be combined with options such **-ext**, **-if**, **-r**, **-q** and **-v**.

Advanced options

Among other things, the advanced options allow complex processing to be performed from a single command without the need for additional scripting. This may be particularly useful for implementations such as Windows drag-and-drop applications. These options may also be used to improve performance in multi-pass processing by reducing the overhead required to load exiftool for each invocation.

-api *OPT*[*^[^]=[VAL]*]

Set ExifTool API option. *OPT* is an API option name. The option value is set to 1 if *VAL* is omitted. If *VAL* is omitted, the option value is set to undef if = is used, or an empty string with ^=. See Image::ExifTool Options for a list of available API options. This overrides API options set via the config file.

-common_args

Specifies that all arguments following this option are common to all executed commands when **-execute** is used. This and the **-config** option are the only options that may not be used inside a **-@ARGFILE**. Note that by definition this option and its arguments **MUST** come after all other options on the command line.

-config *CFGFILE*

Load specified configuration file instead of the default ".ExifTool_config". If used, this option must come before all other arguments on the command line and applies to all **-execute**'d commands. The *CFGFILE* must exist relative to the current working directory or the exiftool application directory unless an absolute path is specified. Loading of the default config file may be disabled by setting *CFGFILE* to an empty string (ie. ""). See <<https://exiftool.org/config.html>> and config_files/example.config in the full ExifTool distribution for details about the configuration file syntax.

-echo[*NUM*] *TEXT*

Echo *TEXT* to stdout (**-echo** or **-echo1**) or stderr (**-echo2**). Text is output as the command line is parsed, before the processing of any input files. *NUM* may also be 3 or 4 to output text (to stdout or stderr respectively) after processing is complete.

-efile[*NUM*][!] *ERRFILE*

Save the names of files giving errors (*NUM* missing or 1), files that were unchanged (*NUM* is 2), files that fail the **-if** condition (*NUM* is 4), or any combination thereof (by summing *NUM*, eg. **-efile3** is the same as having both **-efile** and **-efile2** options with the same *ERRFILE*). By default, file names are appended to any existing *ERRFILE*, but *ERRFILE* is overwritten if an exclamation point is added to the option (eg. **-efile!**). Saves the name of the file specified by the **-srcfile** option if applicable.

-execute[*NUM*]

Execute command for all arguments up to this point on the command line (plus any arguments specified by **-common_args**). The result is as if the commands were executed as separate command lines (with the exception of the **-config** and **-use** options which remain in effect for subsequent commands). Allows multiple commands to be executed from a single command line. *NUM* is an optional number that is echoed in the "{ready}" message when using the **-stay_open** feature.

-srcfile *FMT*

Specify a different source file to be processed based on the name of the original *FILE*. This may be useful in some special situations for processing related preview images or sidecar files. See the **-w** option for a description of the *FMT* syntax. Note that file name *FMT* strings for all options are based on the original *FILE* specified from the command line, not the name of the source file specified by **-srcfile**.

For example, to copy metadata from NEF files to the corresponding JPG previews in a directory where other JPG images may exist:

```
exiftool -ext nef -tagsfromfile @ -srcfile %d%f.jpg dir
```

If more than one **-srcfile** option is specified, the files are tested in order and the first existing source file is processed. If none of the source files already exist, then exiftool uses the first **-srcfile**

specified.

A *FMT* of @ may be used to represent the original *FILE*, which may be useful when specifying multiple **-srcfile** options (eg. to fall back to processing the original *FILE* if no sidecar exists).

When this option is used, two special UserParam tags (OriginalFileName and OriginalDirectory) are generated to allow access to the original *FILE* name and directory.

-stay_open *FLAG*

If *FLAG* is 1 or True, causes exiftool keep reading from the **-@** *ARGFILE* even after reaching the end of file. This feature allows calling applications to pre-load exiftool, thus avoiding the overhead of loading exiftool for each command. The procedure is as follows:

- 1) Execute `exiftool -stay_open True -@ ARGFILE`, where *ARGFILE* is the name of an existing (possibly empty) argument file or - to pipe arguments from the standard input.
- 2) Write exiftool command-line arguments to *ARGFILE*, one argument per line (see the **-@** option for details).
- 3) Write `-execute\n` to *ARGFILE*, where \n represents a newline sequence. (Note: You may need to flush your write buffers here if using buffered output.) Exiftool will then execute the command with the arguments received up to this point, send a "{ready}" message to stdout when done (unless the **-q** or **-T** option is used), and continue trying to read arguments for the next command from *ARGFILE*. To aid in command/response synchronization, any number appended to the `-execute` option is echoed in the "{ready}" message. For example, `-execute613` results in "{ready613}".
- 4) Repeat steps 2 and 3 for each command.
- 5) Write `-stay_open\nFalse\n` to *ARGFILE* when done. This will cause exiftool to process any remaining command-line arguments then exit normally.

The input *ARGFILE* may be changed at any time before step 5 above by writing the following lines to the currently open *ARGFILE*:

```
-stay_open
True
-@
NEWARGFILE
```

This causes *ARGFILE* to be closed, and *NEWARGFILE* to be kept open. (Without the **-stay_open** here, exiftool would have returned to reading arguments from *ARGFILE* after reaching the end of *NEWARGFILE*.)

Note: When writing arguments to a disk file there is a delay of up to 0.01 seconds after writing `-execute\n` before exiftool starts processing the command. This delay may be avoided by sending a CONT signal to the exiftool process immediately after writing `-execute\n`. (There is no associated delay when writing arguments via a pipe with **-@** -, so the signal is not necessary when using this technique.)

-userParam *PARAM*[[^]=[*VAL*]]

Set user parameter. *PARAM* is an arbitrary user parameter name. This is an interface to the API UserParam option (see the Image::ExifTool Options documentation), and provides a method to access user-defined parameters in arguments to the **-if** and **-p** options as if they were any other tag. Appending a hash tag (#) to *PARAM* also causes the parameter to be extracted as a normal tag (in the UserParam group). Similar to the **-api** option, the parameter value is set to 1 if *=VAL* is omitted, undef if just *VAL* is omitted with =, or an empty string if *VAL* is omitted with ^=.

```
exiftool -p '$test from $filename' -userparam test=Hello FILE
```

Advanced formatting feature

An advanced formatting feature allows modification of the value of any tag interpolated within a **-if** or **-p** option argument, or a **-tagsFromFile** redirection string. Tag names within these strings are prefixed by a \$

symbol, and an arbitrary Perl expression may be applied to the tag value by placing braces around the tag name and inserting the expression after the name, separated by a semicolon (ie. `${TAG;EXPR}`). The expression acts on the value of the tag through the default input variable (`$_`), and has access to the full ExifTool API through the current ExifTool object (`$self`) and the tag key (`$tag`). It may contain any valid Perl code, including translation (`tr///`) and substitution (`s///`) operations, but note that braces within the expression must be balanced. The example below prints the camera Make with spaces translated to underlines, and multiple consecutive underlines replaced by a single underline:

```
exiftool -p '${make;tr/ /_/;s/___+/_/g}' image.jpg
```

An `@` may be added after the tag name to make the expression act on individual list items for list-type tags, simplifying list processing. Set `$_` to `undef` to remove an item from the list. As an example, the following command returns all subjects not containing the string "xxx":

```
exiftool -p '${subject@;$_=undef if /xxx/}' image.jpg
```

A default expression of `tr(/\\?*:|"<>\0)()d` is assumed if the expression is empty (ie. `${TAG;}`). This removes the characters `/\?*:|<>` and null from the printed value. (These characters are illegal in Windows file names, so this feature is useful if tag values are used in file names.)

Helper functions

DateFmt

Simplifies reformatting of individual date/time values. This function acts on a standard EXIF-formatted date/time value in `$_` and formats it according to the specified format string (see the `-d` option). To avoid trying to reformat an already-formatted date/time value, a `#` must be added to the tag name (as in the example below) if the `-d` option is also used. For example:

```
exiftool -p '${createdate#;DateFmt("%Y-%m-%d_%H%M%S")}' a.jpg
```

ShiftTime

Shifts EXIF-formatted date/time string by a specified amount. Start with a leading minus sign to shift backwards in time. See `Image::ExifTool::Shift.pl` for details about shift syntax. For example, to shift a date/time value back by one year:

```
exiftool -p '${createdate;ShiftTime("-1:0:0 0")}' a.jpg
```

NoDups

Removes duplicate items from a list with a separator specified by the `-sep` option. This function is most useful when copying list-type tags. For example, the following command may be used to remove duplicate Keywords:

```
exiftool -sep '##' '-keywords<${keywords;NoDups}' a.jpg
```

The `-sep` option is necessary to split the string back into individual list items when writing to a list-type tag.

An optional flag argument may be set to 1 to cause `NoDups` to return `undef` if no duplicates existed, thus preventing the file from being rewritten unnecessarily:

```
exiftool -sep '##' '-keywords<${keywords;NoDups(1)}' a.jpg
```

Note that function names are case sensitive.

WINDOWS UNICODE FILE NAMES

In Windows, command-line arguments are specified using the current code page and are recoded automatically to the system code page. This recoding is not done for arguments in ExifTool arg files, so by default filenames in arg files use the system code page. Unfortunately, these code pages are not complete character sets, so not all file names may be represented.

ExifTool 9.79 and later allow the file name encoding to be specified with `-charset filename=CHARSET`, where `CHARSET` is the name of a valid ExifTool character set, preferably UTF8 (see the `-charset` option for a complete list). Setting this triggers the use of Windows wide-character i/o

routines, thus providing support for most Unicode file names (see note 4). But note that it is not trivial to pass properly encoded file names on the Windows command line (see <<https://exiftool.org/faq.html#Q18>> for details), so placing them in a UTF-8 encoded `-@ argfile` and using `-charset filename=utf8` is recommended if possible.

A warning is issued if a specified filename contains special characters and the filename character set was not provided. However, the warning may be disabled by setting `-charset filename=""`, and ExifTool may still function correctly if the system code page matches the character set used for the file names.

When a directory name is provided, the file name encoding need not be specified (unless the directory name contains special characters), and ExifTool will automatically use wide-character routines to scan the directory.

The filename character set applies to the *FILE* arguments as well as filename arguments of `-@`, `-geotag`, `-o`, `-p`, `-srcfile`, `-tagsFromFile`, `-csv=`, `-j=` and `-TAG<=`. However, it does not apply to the `-config filename`, which always uses the system character set. The `-charset filename=` option must come before the `-@` option to be effective, but the order doesn't matter with respect to other options.

Notes:

- 1) FileName and Directory tag values still use the same encoding as other tag values, and are converted to/from the filename character set when writing/reading if specified.
- 2) Unicode support is not yet implemented for other Windows-based systems like Cygwin.
- 3) See "WRITING READ-ONLY FILES" below for a note about editing read-only files with Unicode names.
- 4) Unicode file names with surrogate pairs (code points over U+FFFF) still cause problems.

WRITING READ-ONLY FILES

In general, ExifTool may be used to write metadata to read-only files provided that the user has write permission in the directory. However, there are three cases where file write permission is also required:

- 1) When using the `-overwrite_original_in_place` option.
- 2) When writing only pseudo System tags (eg. FileModifyDate).
- 3) On Windows if the file has Unicode characters in its name, and a) the `-overwrite_original` option is used, or b) the `_original` backup already exists.

Hidden files in Windows behave as read-only files when attempting to write any real tags to the file — an error is generated when using the `-overwrite_original_in_place`, otherwise writing should be successful and the hidden attribute will be removed. But the `-if` option may be used to avoid processing hidden files (provided Win32API::File is available):

```
exiftool -if "$fileattributes !~ /Hidden/" ...
```

READING EXAMPLES

Note: Beware when cutting and pasting these examples into your terminal! Some characters such as single and double quotes and hyphens may have been changed into similar-looking yet functionally-different characters by the text formatter used to display this documentation. Also note that Windows users must use double quotes instead of single quotes as below around arguments containing special characters.

```
exiftool -a -u -g1 a.jpg
```

Print all meta information in an image, including duplicate and unknown tags, sorted by group (for family 1). For performance reasons, this command may not extract all available metadata. (Metadata in embedded documents, metadata extracted by external utilities, and metadata requiring excessive processing time may not be extracted). Add `-ee` and `-api RequestAll=3` to the command to extract absolutely everything available.

```
exiftool -common dir
```

Print common meta information for all images in `dir`. `-common` is a shortcut tag representing common EXIF meta information.

```

exiftool -T -createdate -aperture -shutterspeed -iso dir > out.txt
    List specified meta information in tab-delimited column form for all images in dir to an output text
    file named "out.txt".

exiftool -s -ImageSize -ExposureTime b.jpg
    Print ImageSize and ExposureTime tag names and values.

exiftool -l -canon c.jpg d.jpg
    Print standard Canon information from two image files.

exiftool -r -w .txt -common pictures
    Recursively extract common meta information from files in pictures directory, writing text output
    to .txt files with the same names.

exiftool -b -ThumbnailImage image.jpg > thumbnail.jpg
    Save thumbnail image from image.jpg to a file called thumbnail.jpg.

exiftool -b -JpgFromRaw -w _JFR.JPG -ext NEF -r .
    Recursively extract JPG image from all Nikon NEF files in the current directory, adding _JFR.JPG
    for the name of the output JPG files.

exiftool -a -b -W %d%f_%t%-c.%s -preview:all dir
    Extract all types of preview images (ThumbnailImage, PreviewImage, JpgFromRaw, etc.) from files
    in directory "dir", adding the tag name to the output preview image file names.

exiftool -d '%r %a, %B %e, %Y' -DateTimeOriginal -S -s -ext jpg .
    Print formatted date/time for all JPG files in the current directory.

exiftool -IFD1:XResolution -IFD1:YResolution image.jpg
    Extract image resolution from EXIF IFD1 information (thumbnail image IFD).

exiftool '*resolution*' image.jpg
    Extract all tags with names containing the word "Resolution" from an image.

exiftool -xmp:author:all -a image.jpg
    Extract all author-related XMP information from an image.

exiftool -xmp -b a.jpg > out.xmp
    Extract complete XMP data record intact from a.jpg and write it to out.xmp using the special
    XMP tag (see the Extra tags in Image::ExifTool::TagNames).

exiftool -p '$filename has date $dateTimeOriginal' -q -f dir
    Print one line of output containing the file name and DateTimeOriginal for each image in directory
    dir.

exiftool -ee -p '$gpslatitude, $gpslongitude, $gpstimestamp' a.m2ts
    Extract all GPS positions from an AVCHD video.

exiftool -icc_profile -b -w icc image.jpg
    Save complete ICC_Profile from an image to an output file with the same name and an extension of
    .icc.

exiftool -htmldump -w tmp/%f_%e.html t/images
    Generate HTML pages from a hex dump of EXIF information in all images from the t/images
    directory. The output HTML files are written to the tmp directory (which is created if it didn't exist),
    with names of the form 'FILENAME_EXT.html'.

exiftool -a -b -ee -embeddedimage -W Image_%.3g3.%s file.pdf
    Extract embedded JPG and JP2 images from a PDF file. The output images will have file names like
    "Image_#.jpg" or "Image_#.jp2", where "#" is the ExifTool family 3 embedded document number
    for the image.

```

WRITING EXAMPLES

Note that quotes are necessary around arguments which contain certain special characters such as `>`, `<` or any white space. These quoting techniques are shell dependent, but the examples below will work for most

Unix shells. With the Windows cmd shell however, double quotes should be used (eg. `-Comment="This is a new comment"`).

`exiftool -Comment='This is a new comment' dst.jpg`

Write new comment to a JPG image (replaces any existing comment).

`exiftool -comment= -o newdir -ext jpg .`

Remove comment from all JPG images in the current directory, writing the modified images to a new directory.

`exiftool -keywords=EXIF -keywords=editor dst.jpg`

Replace existing keyword list with two new keywords (EXIF and editor).

`exiftool -Keywords+=word -o newfile.jpg src.jpg`

Copy a source image to a new file, and add a keyword (word) to the current list of keywords.

`exiftool -exposurecompensation+=-0.5 a.jpg`

Decrement the value of ExposureCompensation by 0.5 EV. Note that += with a negative value is used for decrementing because the -= operator is used for conditional deletion (see next example).

`exiftool -credit==xxx dir`

Delete Credit information from all files in a directory where the Credit value was xxx.

`exiftool -xmp:description-de='kühl' -E dst.jpg`

Write alternate language for XMP:Description, using HTML character escaping to input special characters.

`exiftool -all= dst.jpg`

Delete all meta information from an image. Note: You should NOT do this to RAW images (except DNG) since proprietary RAW image formats often contain information in the makernotes that is necessary for converting the image.

`exiftool -all= -comment='lonely' dst.jpg`

Delete all meta information from an image and add a comment back in. (Note that the order is important: `-comment='lonely' -all=` would also delete the new comment.)

`exiftool -all= --jif:all dst.jpg`

Delete all meta information except JFIF group from an image.

`exiftool -Photoshop:All= dst.jpg`

Delete Photoshop meta information from an image (note that the Photoshop information also includes IPTC).

`exiftool -r -XMP-crss:all= DIR`

Recursively delete all XMP-crss information from images in a directory.

`exiftool '-ThumbnailImage<=thumb.jpg' dst.jpg`

Set the thumbnail image from specified file (Note: The quotes are necessary to prevent shell redirection).

`exiftool '-JpgFromRaw<=%d%f_JFR.JPG' -ext NEF -r .`

Recursively write JPEG images with filenames ending in `_JFR.JPG` to the JpgFromRaw tag of like-named files with extension `.NEF` in the current directory. (This is the inverse of the `-JpgFromRaw` command of the "READING EXAMPLES" section above.)

`exiftool -DateTimeOriginal==0:0:0 1:30:0' dir`

Adjust original date/time of all images in directory `dir` by subtracting one hour and 30 minutes. (This is equivalent to `-DateTimeOriginal=-1.5`. See `Image::ExifTool::Shift.pl` for details.)

`exiftool -createdate+=3 -modifydate+=3 a.jpg b.jpg`

Add 3 hours to the CreateDate and ModifyDate timestamps of two images.

`exiftool -AllDates+=1:30 -if '$make eq "Canon"' dir`

Shift the values of DateTimeOriginal, CreateDate and ModifyDate forward by 1 hour and 30 minutes for all Canon images in a directory. (The AllDates tag is provided as a shortcut for these three tags,

allowing them to be accessed via a single tag.)

```
exiftool -xmp:city=Kingston image1.jpg image2.nef
```

Write a tag to the XMP group of two images. (Without the `xmp:` this tag would get written to the IPTC group since `City` exists in both, and IPTC is preferred by default.)

```
exiftool -LightSource==Unknown (0) dst.tiff
```

Delete `LightSource` tag only if it is unknown with a value of 0.

```
exiftool -whitebalance==auto -WhiteBalance=tung dst.jpg
```

Set `WhiteBalance` to `Tungsten` only if it was previously `Auto`.

```
exiftool -comment== -comment='new comment' a.jpg
```

Write a new comment only if the image doesn't have one already.

```
exiftool -o %d%f.xmp dir
```

Create XMP meta information data files for all images in `dir`.

```
exiftool -o test.xmp -owner=Phil -title='XMP File'
```

Create an XMP data file only from tags defined on the command line.

```
exiftool '-ICC_Profile<=%d%f.icc' image.jpg
```

Write `ICC_Profile` to an image from a `.icc` file of the same name.

```
exiftool -hierarchicalkeywords='{keyword=one,children={keyword=B}}'
```

Write structured XMP information. See <<https://exiftool.org/struct.html>> for more details.

```
exiftool -trailer:all= image.jpg
```

Delete any trailer found after the end of image (EOI) in a JPEG file. A number of digital cameras store a large `PreviewImage` after the JPEG EOI, and the file size may be reduced significantly by deleting this trailer. See the JPEG Tags documentation for a list of recognized JPEG trailers.

COPYING EXAMPLES

These examples demonstrate the ability to copy tag values between files.

```
exiftool -tagsFromFile src.cr2 dst.jpg
```

Copy the values of all writable tags from `src.cr2` to `dst.jpg`, writing the information to same-named tags in the preferred groups.

```
exiftool -TagsFromFile src.jpg -all:all dst.jpg
```

Copy the values of all writable tags from `src.jpg` to `dst.jpg`, preserving the original tag groups.

```
exiftool -all= -tagsfromfile src.jpg -exif:all dst.jpg
```

Erase all meta information from `dst.jpg` image, then copy EXIF tags from `src.jpg`.

```
exiftool -exif:all= -tagsfromfile @ -all:all -unsafe bad.jpg
```

Rebuild all EXIF meta information from scratch in an image. This technique can be used in JPEG images to repair corrupted EXIF information which otherwise could not be written due to errors. The `Unsafe` tag is a shortcut for unsafe EXIF tags in JPEG images which are not normally copied. See the tag name documentation for more details about unsafe tags.

```
exiftool -Tagsfromfile a.jpg out.xmp
```

Copy meta information from `a.jpg` to an XMP data file. If the XMP data file `out.xmp` already exists, it will be updated with the new information. Otherwise the XMP data file will be created. Only metadata-only files may be created like this (files containing images may be edited but not created). See "WRITING EXAMPLES" above for another technique to generate XMP files.

```
exiftool -tagsFromFile a.jpg -XMP:All= -ThumbnailImage= -m b.jpg
```

Copy all meta information from `a.jpg` to `b.jpg`, deleting all XMP information and the thumbnail image from the destination.

```
exiftool -TagsFromFile src.jpg -title -author=Phil dst.jpg
```

Copy title from one image to another and set a new author name.

`exiftool -TagsFromFile a.jpg -ISO -TagsFromFile b.jpg -comment dst.jpg`
 Copy ISO from one image and Comment from another image to a destination image.

`exiftool -tagsfromfile src.jpg -exif:all --subifd:all dst.jpg`
 Copy only the EXIF information from one image to another, excluding SubIFD tags.

`exiftool '-FileModifyDate<DateTimeOriginal' dir`
 Use the original date from the meta information to set the same file's filesystem modification date for all images in a directory. (Note that `-TagsFromFile @` is assumed if no other `-TagsFromFile` is specified when redirecting information as in this example.)

`exiftool -TagsFromFile src.jpg '-xmp:all<all' dst.jpg`
 Copy all possible information from `src.jpg` and write in XMP format to `dst.jpg`.

`exiftool '-Description<${FileName;s\.[^\.]*$//}' dir`
 Set the image Description from the file name after removing the extension. This example uses the "Advanced formatting feature" to perform a substitution operation to remove the last dot and subsequent characters from the file name.

`exiftool -@ iptc2xmp.args -iptc:all= a.jpg`
 Translate IPTC information to XMP with appropriate tag name conversions, and delete the original IPTC information from an image. This example uses `iptc2xmp.args`, which is a file included with the ExifTool distribution that contains the required arguments to convert IPTC information to XMP format. Also included with the distribution are `xmp2iptc.args` (which performs the inverse conversion) and a few more `.args` files for other conversions between EXIF, IPTC and XMP.

`exiftool -tagsfromfile %d%f.CR2 -r -ext JPG dir`
 Recursively rewrite all JPG images in `dir` with information copied from the corresponding CR2 images in the same directories.

`exiftool '-keywords+<make' image.jpg`
 Add camera make to list of keywords.

`exiftool '-comment<ISO=$exif:iso Exposure=${shutterspeed}' dir`
 Set the Comment tag of all images in `dir` from the values of the EXIF:ISO and ShutterSpeed tags. The resulting comment will be in the form "ISO=100 Exposure=1/60".

`exiftool -TagsFromFile src.jpg -icc_profile dst.jpg`
 Copy ICC_Profile from one image to another.

`exiftool -TagsFromFile src.jpg -all:all dst.mie`
 Copy all meta information in its original form from a JPEG image to a MIE file. The MIE file will be created if it doesn't exist. This technique can be used to store the metadata of an image so it can be inserted back into the image (with the inverse command) later in a workflow.

`exiftool -o dst.mie -all:all src.jpg`
 This command performs exactly the same task as the command above, except that the `-o` option will not write to an output file that already exists.

`exiftool -b -jpgfromraw -w %d%f_%ue.jpg -execute -b -previewimage -w %d%f_%ue.jpg -execute -tagsfromfile @ -srcfile %d%f_%ue.jpg -overwrite_original -common_args --ext jpg DIR`
 [Advanced] Extract JpgFromRaw or PreviewImage from all but JPG files in DIR, saving them with file names like `image_EXT.jpg`, then add all meta information from the original files to the extracted images. Here, the command line is broken into three sections (separated by `-execute` options), and each is executed as if it were a separate command. The `-common_args` option causes the `--ext jpg DIR` arguments to be applied to all three commands, and the `-srcfile` option allows the extracted JPG image to be the source file for the third command (whereas the RAW files are the source files for the other two commands).

RENAMING EXAMPLES

By writing the `FileName` and `Directory` tags, files are renamed and/or moved to new directories. This can be particularly useful and powerful for organizing files by date when combined with the `-d` option.

New directories are created as necessary, but existing files will not be overwritten. The format codes %d, %f and %e may be used in the new file name to represent the directory, name and extension of the original file, and %c may be used to add a copy number if the file already exists (see the `-w` option for details). Note that if used within a date format string, an extra '%' must be added to pass these codes through the date/time parser. (And further note that in a Windows batch file, all '%' characters must also be escaped, so in this extreme case '%%%%%' is necessary to pass a simple '%f' through the two levels of parsing.) See <<https://exiftool.org/filename.html>> for additional documentation and examples.

```
exiftool -filename=new.jpg dir/old.jpg
```

Rename old.jpg to new.jpg in directory dir.

```
exiftool -directory=%e dir
```

Move all files from directory dir into directories named by the original file extensions.

```
exiftool '-Directory<DateTimeOriginal' -d %Y/%m/%d dir
```

Move all files in dir into a directory hierarchy based on year, month and day of DateTimeOriginal. eg) This command would move the file dir/image.jpg with a DateTimeOriginal of 2005:10:12 16:05:56 to 2005/10/12/image.jpg.

```
exiftool -o . '-Directory<DateTimeOriginal' -d %Y/%m/%d dir
```

Same effect as above except files are copied instead of moved.

```
exiftool '-filename<%f_{$model;}.%e' dir
```

Rename all files in dir by adding the camera model name to the file name. The semicolon after the tag name inside the braces causes characters which are invalid in Windows file names to be deleted from the tag value (see the "Advanced formatting feature" for an explanation).

```
exiftool '-FileName<CreateDate' -d %Y%m%d_%H%M%S%-c.%e dir
```

Rename all images in dir according to the CreateDate date and time, adding a copy number with leading '-' if the file already exists (%-c), and preserving the original file extension (%e). Note the extra '%' necessary to escape the filename codes (%c and %e) in the date format string.

```
exiftool -r '-FileName<CreateDate' -d %Y-%m-%d/%H%M_%.%f.%e dir
```

Both the directory and the filename may be changed together via the FileName tag if the new FileName contains a '/'. The example above recursively renames all images in a directory by adding a CreateDate timestamp to the start of the filename, then moves them into new directories named by date.

```
exiftool '-FileName<${CreateDate}_$filename.jpg' -d %Y%m%d -ext jpg .
```

Set the filename of all JPG images in the current directory from the CreateDate and FileNumber tags, in the form "20060507_118-1861.jpg".

GEOTAGGING EXAMPLES

ExifTool implements geotagging via 3 special tags: Geotag (which for convenience is also implemented as an exiftool option), Geosync and Geotime. The examples below highlight some geotagging features. See <<https://exiftool.org/geotag.html>> for additional documentation.

```
exiftool -geotag track.log a.jpg
```

Geotag an image (a.jpg) from position information in a GPS track log (track.log). Since the Geotime tag is not specified, the value of DateTimeOriginal is used for geotagging. Local system time is assumed unless DateTimeOriginal contains a timezone.

```
exiftool -geotag t.log -geotime='2009:04:02 13:41:12-05:00' a.jpg
```

Geotag an image with the GPS position for a specific time.

```
exiftool -geotag log.gpx '-xmp:geotime<createdate' dir
```

Geotag all images in directory dir with XMP tags instead of EXIF tags, based on the image CreateDate.

```
exiftool -geotag a.log -geosync=-20 dir
```

Geotag images in directory dir, accounting for image timestamps which were 20 seconds ahead of GPS.

```
exiftool -geotag a.log -geosync=1.jpg -geosync=2.jpg dir
    Geotag images using time synchronization from two previously geotagged images (1.jpg and 2.jpg),
    synchronizing the image and GPS times using a linear time drift correction.
```

```
exiftool -geotag a.log '-geotime<${createdate}+01:00' dir
    Geotag images in dir using CreateDate with the specified timezone. If CreateDate already
    contained a timezone, then the timezone specified on the command line is ignored.
```

```
exiftool -geotag= a.jpg
    Delete GPS tags which may have been added by the geotag feature. Note that this does not remove
    all GPS tags — to do this instead use -gps:all=.
```

```
exiftool -xmp:geotag= a.jpg
    Delete XMP GPS tags which were added by the geotag feature.
```

```
exiftool -xmp:geotag=track.log a.jpg
    Geotag an image with XMP tags, using the time from DateTimeOriginal.
```

```
exiftool -geotag a.log -geotag b.log -r dir
    Combine multiple track logs and geotag an entire directory tree of images.
```

```
exiftool -geotag 'tracks/*.log' -r dir
    Read all track logs from the tracks directory.
```

```
exiftool -p gpx.fmt -d %Y-%m-%dT%H:%M:%SZ dir > out.gpx
    Generate a GPX track log from all images in directory dir. This example uses the gpx.fmt file
    included in the full ExifTool distribution package and assumes that the images in dir have all been
    previously geotagged.
```

PIPING EXAMPLES

```
cat a.jpg | exiftool -
    Extract information from stdin.
```

```
exiftool image.jpg -thumbnailimage -b | exiftool -
    Extract information from an embedded thumbnail image.
```

```
cat a.jpg | exiftool -iptc:keywords+=fantastic - > b.jpg
    Add an IPTC keyword in a pipeline, saving output to a new file.
```

```
curl -s http://a.domain.com/bigfile.jpg | exiftool -fast -
    Extract information from an image over the internet using the cURL utility. The -fast option
    prevents exiftool from scanning for trailer information, so only the meta information header is
    transferred.
```

```
exiftool a.jpg -thumbnailimage -b | exiftool -comment=wow - | exiftool a.jpg -thumbnailimage'<==-'
    Add a comment to an embedded thumbnail image. (Why anyone would want to do this I don't know,
    but I've included this as an example to illustrate the flexibility of ExifTool.)
```

EXIT STATUS

The `exiftool` application exits with a status of 0 on success, or 1 if an error occurred, or 2 if all files failed the `-if` condition (for any of the commands if `-execute` was used).

NAME

exrc – vi/vim initialization file

SYNOPSIS

edrc/etc/exrc

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **vi**(1) and **vim**(1) command.

FILEFORMAT

The fileformat is a plain **ASCII** file without the capability of defining comments.

OPTIONS

-

EXAMPLES

```
set autoindent autoprint nomesg noslowopen noterse shiftwidth=4
set report=2 tabstop=4 wrapmargin=0 nu showmatch showmode
set noerrorbells
set cmdheight=2
map ; :
map g :%
map Q :q!
cmap mono set t_Co=0
cmap color set t_Co=8
```

NAME

fcreate – create a file if it does not exist

SYNOPSIS

edrc/lib/fcreate *file* [*text*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

create a file if it does not exist. Optionally text can be written to the file created.

The intention of this command is to use it to create lock files within shell scripts. Or to atomically create a file if it does not exist.

The created *file* has the file permissions 0600.

OPTIONS

file name of the file to be created.

text text to be written to the file specified in the **file** option.

EXIT STATUS

0 specified file did not exist before and could be created.

1 specified file already exists.

2 error occurred during file creation.

NAME

fields2swvi – filter to format data stream with named swvi fields to swvi sequence

SYNOPSIS

edrc/bin/fields2swvi [**-h**]

stream | fields2swvi

fields2swvi < *file*

AVAILABILITY

WA2L/edrc

DESCRIPTION

The **fields2swvi** command is a filter that brings an unordered software inventory 'FIELD = VALUE' data stream into the correct sequence as understood by **swvi**(1).

This command is internally used by **apply2sw_inventory**(1).

OPTIONS

-h usage message.

ENVIRONMENT

-

EXIT STATUS

0 no error.

4 usage displayed.

5 the command has been aborted pressing *Ctrl+C*.

FILES

-

EXAMPLES**1) Example input/output:**

The input sequence is not important, but only known *FIELDS* are printed, unknown *FIELDS* are ignored.

Input:

```
cat <<EOM | fields2swvi
VERSION      = 1.5.02
SOFTWARE     = EDRC - Enterprise Disaster Recovery Console
INST_USER    = root
INST_GROUP   = root
RUN_USER     =
RUN_GROUP    =
CFG_DIR      = etc
VAR_DIR      = var
LICENSE      = GNU GPL
LIC_MGMT     =
WEB          =
DOC          = ~edrc/doc/edrc_manpages-1.5.02.pdf
INST_SRC     = $Pkgfile
PRODUCT      = System
INSTANCE     =
COMMENT      = disaster recovery and system administration
EOM
```

Output:

```
EDRC - Enterprise Disaster Recovery Console
1.5.02
root
root

etc
var
GNU GPL

~edrc/doc/edrc_manpages-1.5.02.pdf
$Pkgfile
System

disaster recovery and system administration
y
y
```

NAME

filedist – distribute file(s) to a list of remote systems

SYNOPSIS

edrc/bin/filedist [**-h**]

filedist [**-f**] [**-t** *host_1,host_2,host_n*] *file* ...

AVAILABILITY

WA2L/edrc

DESCRIPTION

Distribute given file(s) to an interactively queried list of hosts.

The file(s) are distributed to the identical path as they are located on the source system.

The interactive query of hosts suggests as default the hosts as defined in the **DIST_HOSTLIST** setting in the **rcmd.cfg** file. Furthermore it is possible to enter hostgroups (*@HOSTGROUP*), as known from the **hostlist** command. It is possible to specify multiple hostgroups or to mix hostgroups with hostnames. When using hostgroups the input default is expanded and the target prompt is repeated to give the user the opportunity to verify the target list and to correct it if needed.

The host where logged on is excluded from distribution even if it is on the target list.

It is possible to block files from being distributed from or to certain hosts. The blocking rules are specified in the **etc/filedist.block** file. The intention of blocking files is to avoid miss-configurations etc. by distributing files to/from certain hosts by error.

OPTIONS

-h usage message.

-f force distribution of files blocked as defined in **etc/filedist.block**.

-t *hostlist* A comma separated list of target hosts. If the hostlist is not specified, an interactive query asks for it.

See also **resolve_targetlist(3)** to see how to efficiently create a hostlist in scripts.

file ... space separated list of files to be distributed to one or more target systems. The file(s) are distributed to the identical path as it resides on the source system. Directories and symbolic links are not accepted as source in the *file* option. When the file intended to be distributed is a directory or symbolic link on the target system it will not be distributed to that system and a error message is displayed. Also if a *file* is located in a directory on the source system but the directory does not exist on the target system, it is not distributed and an error message will inform

about this.

ENVIRONMENT

-

EXIT STATUS

- 0** no error.
- 2** operating system is not supported, yet. See **osid**(3) if you get this error.
- 4** usage printed.
- 5** the distribution has been aborted using *Ctrl+C*.
- 6** the configuration file **filedist.cfg** does not exist.
- 7** the blockfile **filedist.block** does not exist.
- 11** temporary directory could not be claimed or created in **/tmp**. Check the system temporary directory **/tmp** if you get this error, it is an indicator of system intrusion.

FILES

etc/filedist.cfg

configuration file of **filedist**, see **filedist.cfg**(4) for more information.

etc/filedist.block

configuration file of **filedist** to prevent (block) files from being distributed from/to certain targets, see **filedist.block**(4) for more information.

var/log/filedist.log

default logfile of **filedist**.

EXAMPLES

1) normal target list

Distribute files to a list of targets. In this example the file **/etc/protocol** does not exist on the source node. The file **/etc/init.d** is a directory. On the system dcdbsi63 the file **/etc/telnetd** is a symbolic link, therefore the file is not distributed from the source node to this host.

```
[ /etc ]
[ root@dcdbsi74 ][-sh]: filedist hosts services protocol telnetd init.d
filedist - copy files to other systems, by Chr. Walther
```

```
Target hosts: [ dcdbsi63 dcdbsi64 dcdbsi73 dcdbsi74 ]:
```

```
distribute files ...
  host dcdbsi63 ...
    file /etc/hosts ... done
    file /etc/services ... done
    file protocol ...(not found)... skip
    file /etc/telnetd ...(link)... skip
    file init.d ...(not found)... skip
  done
  host dcdbsi64 ...
    file /etc/hosts ... done
    file /etc/services ... done
    file protocol ...(not found)... skip
    file /etc/telnetd ...(link)... skip
    file init.d ...(not found)... skip
  done
  host dcdbsi73 ...
    file /etc/hosts ... done
    file /etc/services ...(target is link)... fail
    file protocol ...(not found)... skip
    file /etc/telnetd ...(link)... skip
    file init.d ...(not found)... skip
  done
  host dcdbsi74 ...(localhost)... skip
done
```

2) target list using hostgroups

Distribute files to a list of targets using hostgroups. In this example the file **/etc/hosts** is blocked to be distributed to the host dcdbsi50. The host dcdbsi99 is not up.

```
[ / ]
[ root@dcdbsi70 ][-sh]: filedist /hosts/hosts
filedist - copy files to other systems, by Chr. Walther
```

```
Target hosts: [ dcdbsi60 dcdbsi70 ]: @ALL dcdbsi50 dcdbsi99
Target hosts: [ dcdbsi05 dcdbsi10 dcdbsi20 ... dcdbsi73 dcdbsi74 dcdbsi99
```

```
distribute files ...
  host dcdbsi05 ...
    file /etc/hosts ... done
  done
  host dcdbsi10 ...
    file /etc/hosts ... done
  done
  :
  :
  host dcdbsi33 ...
    file /etc/hosts ... done
  done
  host dcdbsi50 ...
    file /etc/hosts ...(blocked)... skip
  done
```

```

host dcdbsi51 ...
    file /etc/hosts ... done
done
:
:
host dcdbsi64 ...
    file /etc/hosts ... done
done
host dcdbsi70 ...(localhost)... skip
host dcdbsi71 ...
    file /etc/hosts ... done
done
:
:
host dcdbsi74 ...
    file /etc/hosts ... done
done
host dcdbsi99 ...(not up)... skip
done

```

3) use filedist in scripts (host only targetlist)

```

echo "host-001 host-002 \n" | \
filedist /etc/hosts

```

4) use filedist in scripts (hostgroups in targetlist)

```

echo "`resolve_targetlist -t host-001 host-002 @BE` \n" | \
filedist /etc/hosts

```

or:

```

echo "host-001 host-002 @BE \n\n" | \
filedist /etc/hosts

```

SEE ALSO

edrcintro(1), **edrcsetup(1m)**, **hostaliases(3)**, **remote_shell(3)**, **remote_copy(3)**, **filedist.cfg(4)**, **filedist.block(4)**, **resolve_targetlist(3)**, **hostlist(3)**

NOTES

When distributing files as user root from the source system, the user as defined in **DIST_USER** in the configuration file **etc/filedist.cfg** is used to connect to the target systems. On the target systems this user has to be allowed to switch to root in the related security files, see **edrcsetup(1m)** for an explanation of the required security settings.

If **filedist** is used as another user as root, the own user is used for the distribution.

NAME

filedist.cfg – configuration file for filedist

SYNOPSIS

edrc/etc/filedist.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **filedist** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS

LOG Log output dir of **filedist**. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation.

Example: LOG=/var/opt/edrc/log

Default: LOG=var/log

DIST_HOSTLIST

Space separated list of hosts. To this hosts the files specified on the command line will be distributed.

Example: DIST_HOSTLIST="acme045 acme014"

Default: –

DIST_USER

User used to distribute the files if the user invoking **filedist** is root. Other users use the own user for the distribution.

Example: DIST_USER=edrc

Default: DIST_USER=edrc

DIST_MODE

Comma separated list of modes used to distribute the files in **SCRIPTS_BASEDIR**. The supported modes are: *rtools* which result in the use of **rcp** and **rsh** or *OpenSSH* which results in the use of **scp** and **ssh** for distribution. If a comma separated list is provided, the connection initiation is made in the sequence specified. A pseudo distribution mode is *default* which results in the use of the **CONNECTION_MODE** specified in the configuration files **remote_shell.cfg** and **remote_copy.cfg**. It is not allowed to specify *default* as part of a comma separated list.

Example: DIST_MODE=rtools,OpenSSH

Default: DIST_MODE=rtools

REMOTE_CMD_PATH

Path on the remote systems to the **cpio** and **gzip** commands.

Example: REMOTE_CMD_PATH=/usr/contrib/bin:/usr/local/bin:/opt/edrc/bin

Default: REMOTE_CMD_PATH=

SUMMARY

If set to *True* at the end of the file distribution execution a state summary is printed. If set to *False* the summary is not printed.

Example: SUMMARY=True

Default: SUMMARY=False

NAME

filedist.block – configuration file for filedist

SYNOPSIS

edrc/etc/filedist.block

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file to block files from distribution using the **filedist** command.

FILEFORMAT

The fileformat is a list of rules that have the format

mode:source_host:destination_host:file

The mode field specifies if a rule is to **allow** or **block** a file being distributed from a source- to a destination host.

The fields *source_host*, *destination_host* and *file* are regular expressions.

The rules are processed in the sequence listed. If a rule matches, the remaining rules are not processed any more.

The last rule that is processed by **filedist** is always

```
block:.*:.*:.*
```

if no previous rule matched. Therefore if you like to allow all distributions except the defined blocked files, the rule

```
allow:.*:.*:.*
```

has to be added as the very last rule in the **etc/filedist.block** file.

Regular expression hints:

```
.*
```

Everything. This can be used to specify all hosts or all files.

dcdbsi5[1-3]

Range. This example defines the hosts dcdbsi51, dcdbsi52 and dcdbsi53.

See also **EXAMPLES** section.

OPTIONS

- mode** mode to define the rules what files can be distributed:
- allow** if the rule definition of *source_host*, *destination_host* and *file* matches, the file is allowed to be distributed.
 - block** if the rule definition of *source_host*, *destination_host* and *file* matches, the file is blocked from distribution.
- source_host* Regular expression of the source host. The source host to be dealt with is as it is resolved by the **hostname(1)** command.
- destination_host* Regular expression of the source host. The destination host to be dealt with is as it is specified in the interactive "Target hosts:" query of the **filedist** command. When specifying the *destination_host* take also into account, that the user could specify aliases for distribution targets or use a full qualified name. In most cases it wouldn't be needed to specify all aliases due to the provided default targets that should lead the user into the right direction.
- file* Regular expression of the file to be distributed.

EXAMPLES

1) block rule example

This definition helps, that only files in the directories **/opt/edrc**, the installation directory of WA2L/edrc, and **/tmp** are allowed to be distributed from and to dcdbsi50.

This example has the background, that the host dcdbsi50 is a Sun Solaris system and all other hosts are HP-UX systems. To avoid miss-configuration of the systems by distributing operating system files that might have a different format on either one of the two operating systems, only a very reduced set of files is allowed to be distributed.

The last rule in this example ensures, that between all other systems all files are allowed to be distributed.

```
#
# filedist.block - filedist configuration file to block
#                  (prevent) files from distribution
#
# [00] 11.08.2003 CWa   Initial Version
#
#
# Fileformat:
#
```

```

# <mode>:<source_host>:<destination_host>:<file>
#
# Fields:
#     <mode>          = allow or block
#     <source_host>, <destination_host> and <file>
#                     are regular expressions
#
# Hints:
#     all hosts      = .*
#     all files      = .*
#     range          = dcdbsi5[1-2]
#
#
# RULES:
#
# The rules are processed in the sequence listed.
# If a rule matches, the remaining rules are not
# processed any more.
#
#
# allow only /opt/edrc/* and /tmp/* files to be
# distributed from and to dcdbsi50.
#
allow:.*:.*:/opt/edrc/.*
allow:.*:.*:/tmp/.*
block:.*:dcdbsi50:.*
block:dcdbsi50:.*:.*
#
# last rule, allow all distributions, when no
# previous rule matched.
#
allow:.*:.*:.*

```

SEE ALSO

edrcintro(1), **filedist(1)**, **hostlist(3)**, **regexintro(4)**

NOTES

The *destination_host* regular expression is checked against the interactive user input. If the user specifies a host alias, the *destination_host* regular expression might not match and the file is distributed even if it was intended to be blocked.

NAME

filegrep – grep underlying recovery scripts for a pattern

SYNOPSIS

edrc/bin/filegrep *pattern*

AVAILABILITY

WA2L/edrc

DESCRIPTION

grep for a pattern in all underlying ASCII files. Files located in a **.sav** directory or files saved with the **sav(1)** command are excluded from the search.

OPTIONS

pattern regular expression pattern to be searched for in underlying file. See **regexintro(4)** for more information about regular expressions.

ENVIRONMENT

-

EXIT STATUS

4 no pattern defined, usage displayed.
X exit code of **grep(1)**.

NAME**SYNOPSIS**

edrc/bin/filelink [**-h**]

filelink -m mode -d directory_1 -d directory_2

AVAILABILITY

WA2L/edrc

DESCRIPTION

create hardlinks between identical files in two directory trees.

The hardlinks are created between files having the identical name and content in the two directories specified.

The main intention of the command is to simplify configuration file management when using **sysconfig(1m)** and having different configurations having some identical files.

OPTIONS

-h usage message.

-m mode mode of the program execution:

print

print expected changes in *directory_2*

execute

execute changes in *directory_2*

-d directory_1
source directory.

-d directory_2
directory where the links are created.

ENVIRONMENT

-

EXIT STATUS

| | |
|----------|--------------------------------------|
| 0 | no error. |
| 2 | operating system not supported. |
| 3 | cannot write to <i>directory_1</i> . |
| 4 | usage message displayed. |
| 5 | command aborted. |

NAME

filesize – print size of a file

SYNOPSIS

edrc/lib/filesize [**-h**]

filesize [**-b** | **-k** | **-m** | **-g**] **-f** *file*

AVAILABILITY

WA2L/edrc

DESCRIPTION

return the size of a given file.

The file size is returned as an integer number of the selected unit option. If the file size is not integer the returned file size is rounded up by one. Therefore if the real file size is 123.01 kBytes, 124 would be returned.

If a more precise file size is needed for units other than Bytes (**-b**) the size has to be queried in Bytes first and then the related calculation has to be done separately:

```
filesize -f /data/example.dmp | \
awk '{printf("%3.2f\n", $1/1024)}'
```

OPTIONS

- h** print usage message.
- b** return the file size in Bytes, this is also the default if no unit option is specified.
- k** return the file size in kilo bytes (1 kByte = 1024 Byte).
- m** return the file size in mega bytes (1 MByte = 1024 kByte).
- g** return the file size in giga bytes (1 GByte = 1024 MByte).
- f** *file* path of the file from which the size should be returned.

ENVIRONMENT

-

EXIT STATUS

- | | |
|----------|---|
| 0 | no error. |
| 1 | given file does not exist. |
| 2 | operating system does not exist. See osid (3) if you get this error. |
| 4 | usage message printed. |

NAME

filewatch – print file size progress of a command

SYNOPSIS

edrc/lib/filewatch [**-h**]

filewatch *file* (*command* | *PID*)

AVAILABILITY

WA2L/edrc

DESCRIPTION

watch the file size progress of a given running command.

OPTIONS

-h print usage message.

file file to watch the file size growth.

command command that produces the *file*.

PID process ID of the command that produces the *file*.

ENVIRONMENT

-

EXIT STATUS

0 no error.

1 given file does not exist.

2 operating system does not exist. See **osid(3)** if you get this error.

4 usage message printed.

5 **filewatch** aborted.

NAME

fit2width – fit a stream to a with

SYNOPSIS

edrc/lib/fit2width [**-h** | **-m**] [*width*]

edrc/lib/fit [**-h** | **-m**] [*width*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

fit a data stream to a specified width.

This command can be used together with **tty_columns(3)** to fit a stream to the current width of a terminal (tty).

OPTIONS

-h print usage message.

-m mark lines that are longer as the specified *width* with '>>' at the end of the line.
If this option is not specified, the lines are shortened to the given *width* without marking it.

width number of characters to be printed. If this option is not set, the default width is resolved by **tty_columns(3)** if it is a tty. If it is not a tty the contents of the **\$COLUMNS** environment variable is used as a default.

ENVIRONMENT

-

EXIT STATUS

0 no error.

4 usage message printed.

FILES

-

EXAMPLES**1) fit the /etc/services file to the screen width using tty_columns**

```
[ / ]
[ root@acme007 ][-sh]: cat /etc/services | \
                        fit2width -m `tty_columns`

#
# /etc/services: - Network services, Internet Style
#
# Each line describes one service, and is of the for >>
#
# service-name  port/protocol  [aliases ...]  [# co >>

tcpmux          1/tcp                # TC >>
tcpmux          1/udp                # TC >>
rje             5/tcp                # Re >>
:
:
```

2) fit the /etc/services file to the screen width using default width

```
[ / ]
[ root@acme007 ][-sh]: cat /etc/services | \
                        fit2width -m

#
# /etc/services: - Network services, Internet Style
#
# Each line describes one service, and is of the for >>
#
# service-name  port/protocol  [aliases ...]  [# co >>

tcpmux          1/tcp                # TC >>
tcpmux          1/udp                # TC >>
rje             5/tcp                # Re >>
:
:
```

3) fit the /etc/services file to a width of 55 characters

```
[ / ]
[ root@acme007 ][-sh]: cat /etc/services | \
                        fit2width -m 55

#
# /etc/services: - Network services, Internet Style
#
```

```
# Each line describes one service, and is of the form >>
#
# service-name port/protocol [aliases ...] [# comment >>

tcpmux          1/tcp          # TC >>
tcpmux          1/udp          # TC >>
rje             5/tcp          # Re >>
:
:
```

NAME

fnmatch – wildcard pattern match of a stream

SYNOPSIS

edrc/lib/fnmatch [-h | -V]

fnmatch [-n] [-m *num*] [-i] [-v] [-e] *pattern* < *file*

cat *file* | fnmatch [-n] [-m *num*] [-i] [-v] [-e] *pattern*

AVAILABILITY

WA2L/edrc

DESCRIPTION

match a stream by a wildcard pattern expression.

Wildcard expressions are different to regular expressions and are known for example from the **ls**(1) command.

However, in some applications wildcard patterns are more intuitive to use then regular expressions.

OPTIONS

-h usage message.

-V print command version.

-n prefix each line of output with the 1-based line number within its input file.

-m *num* stop reading a file after *num* matching lines.

-i case insensitive match.

-e extended expression as known in **ksh**:

The extended format is as follows, with *pattern-list* being a `'|'` separated list of *patterns*.

`'?(pattern-list)'`

The *pattern* matches if zero or one occurrences of any of the *patterns* in the *pattern-list* match the input stream.

`'*(pattern-list)'`

The *pattern* matches if zero or more occurrences of any of the *patterns* in the *pattern-list* match the input stream.

'+(*pattern-list*)'

The *pattern* matches if one or more occurrences of any of the *patterns* in the *pattern-list* match the input stream.

'@(*pattern-list*)'

The *pattern* matches if exactly one occurrence of any of the *patterns* in the *pattern-list* match the input stream.

'!(*pattern-list*)'

The *pattern* matches if the input stream cannot be matched

-v invert the sense of matching, to select non-matching lines.

pattern wildcard expression to match the stream:

***** Matches any string, including the null string.

? Matches any single character.

[?] Matches the question mark (?) character.

[...] Matches any one of the characters enclosed. A pair of characters separated by - matches any character lexically between the pair.

[!...] Matches any character except the enclosed ones.

NAME

fmatch – return values for a given key from a data file

SYNOPSIS

edrc/lib/fmatch [**-h**]

fmatch -k "*key_regex*" [**-f** *data_file*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

prints the values of the given *key_regex* from the file csv database specified on command line using the **-f** option or in the **\$FMATCH_DATA_FILE** environment variable.

The structure of the *data_file* is:

key;values_list;

where empty lines and lines starting with a **#** are considered as comments. The backslash can be used to define rows spanning multiple lines in the *data_file*.

The **values_list** is a white space separated list of values for a certain key and are returned as a uniquely sorted list to **stdout**.

OPTIONS

-h usage message.

-k "*key_regex*"
key as regular expression as known from the **egrep**(1) command for selecting the related values in the *data_file*.

-f *data_file*
file to select the values from. If the environment variable **\$FMATCH_DATA_FILE** is set this option is optional. The *data_file* must have the following format:

key;values;

Empty lines and lines starting with a **#** are considered as comments. The backslash can be used to define rows spanning multiple lines in the *data_file*.

Example *data_file* :

#

```
# etc/hostlist.dat - hostlist csv database file
#
# [00] 12.08.2008 CWa    Initial Version
#
#
# Format:
#
#   key ::= <Customer>--<SERVER_ENVIRONMENT>
#
#   <key>;<value_list>;
#
ACME--INFRASTRUCTURE;    acme001 acme002;

LooneyTunes--TEST;      ltunes001 ltunes005 ltunes008;
LooneyTunes--PRODUCTION;ltunes002 ltunes003 ltunes004 \
                        ltunes006 ltunes007;

BOULDER--DEVELOPMENT;   boulder000 boulder001 boulder002;
BOULDER--TEST;          boulder100 boulder101 boulder102;
BOULDER--PRODUCTION;    boulder201 boulder201 boulder202 \
                        boulder203;
```

ENVIRONMENT**\$FMATCH_DATA_FILE**

data_file as specified in the **-f** option. When this environment variable is set, the **-f** option is optional.

EXIT STATUS

| | |
|----------|-----------------------|
| 0 | no error. |
| 4 | usage message listed. |

NAME

freespace – print freespace of a directory

SYNOPSIS

edrc/lib/freespace [**-h**]

freespace [**-b** | **-k** | **-m** | **-g**] **-d** *directory*

AVAILABILITY

WA2L/edrc

DESCRIPTION

return the available free space of the filesystem where the given directory resides on.

The free space is returned as an integer number of the selected unit option.

If a more precise free space size is needed for units other than Bytes (**-b**) the size has to be queried in Bytes first and then the related calculation has to be done separately:

```
freespace -d /data | \
awk '{printf("%3.2f\n", $1/1024)}'
```

OPTIONS

- h** print usage message.
- b** return the free space in Bytes, this is also the default if no unit option is specified.
- k** return the free space in kilo bytes (1 kByte = 1024 Byte).
- m** return the free space in mega bytes (1 MByte = 1024 kByte).
- g** return the free space in giga bytes (1 GByte = 1024 MByte).
- d** *directory*
path of the directory from where the free space should be returned.

ENVIRONMENT

-

EXIT STATUS

- | | |
|----------|---|
| 0 | no error. |
| 1 | given directory does not exist. |
| 2 | operating system does not exist. See osid (3) if you get this error. |
| 4 | usage message printed. |

NAME

fssum – summarize and group filesystems by product

SYNOPSIS

edrc/bin/fssum [**-h**]

fssum [**-c** *cfg_file*] [**-d** [**-v**]]

fssum [**-c** *cfg_file*] [**-t** [**-v**]]

AVAILABILITY

WA2L/edrc

DESCRIPTION

summarize filesystems based on definitions in a configuration file.

This command is used to create a filesystem summary grouped by product.

OPTIONS

-h usage message.

-c *config_file*

configuration file containing the grouping description, purpose and selection regular expressions. The default config file is **edrc/etc/fssum.cfg** when this option is not used.

-d CSV output to be used for further processing. If this option is not specified a structured ASCII report is printed.

-t print the CSV header as the first row of the CSV output.

-v "verbose" output in the CSV report, that prints the row number of the config file that matched for a certain file system.

ENVIRONMENT

-

EXIT STATUS

0 no error.

- 3** configuration file does not exist.
- 4** usage listed.
- 5** command aborted, e.g. by pressing <Ctrl+C>.

FILES

edrc/etc/fssum.cfg
configuration file for **fssum**.

NAME

fssum.cfg – configuration file for fssum

SYNOPSIS

edrc/etc/fssum.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration for the **fssum** command.

FILEFORMAT

The fileformat is a list of definitions that have the format

type : system : group : title : purpose : storage : selection_regex :

Rows starting with a **#** are considered as comments.

For each file system all definitions are processed in the sequence as listed in the configuration file. A special case is when the *group* is set to '**EXCLUDE**' (see *group* description below).

OPTIONS

type system type:

h hostname

p cluster package name

system system- or cluster package name. This setting can be a regular expression.

If *localhost* is specified here, the *selection_regex* will be resolved on all hosts (system type = **h**), but in the output the real hostname as resolved by the **hostname(1)** command appears instead of *localhost*.

group general grouping selector. This selector can be used to group for example applications that are distributed over multiple nodes in the **fssum** report.

If the special group '**EXCLUDE**' is set, the file system as selected by the *selection_regex* regular expression is excluded completely from the report. To have the desired effect, the '**EXCLUDE**' entry has to be placed before the other definitions in the **fssum.cfg** file.

title description title of the file system selection. The ASCII report is grouped by the combination *system, title*. Therefore a normal **fssum.cfg** file will have multiple identical *title* definitions normally.

purpose purpose description text of a certain file system.

storage storage description, where a certain file system resides.

selection_regex
file system or mount point selection regular expressions.

The input string on which the **selection_regex** takes effect is the "Filesystem" and "Mounted" columns of the **xbdf** output. The two columns are separated by four spaces.

Example:

```
/dev/vg00/lvol0    /
/dev/vg00/lvol1    /var
/dev/sda1          /boot
tmpfs              /dev/shm
```

NAME

ftps – secure FTP to connect to the server using SSL

SYNOPSIS

edrc/bin/ftps [**-h**]

ftps [**-script** *script-file* | *host* [*port*]]

AVAILABILITY

WA2L/edrc

DESCRIPTION

Secure FTP is an FTP program that allows for a secure connection to be made to an FTP server via a Secure Sockets Layer (SSL). This version of Secure FTP supports both implicit and explicit SSL connections.

With no port specified, an implicit SSL connection is attempted on port 990 (the default for implicit SSL connections). If a connection cannot be made implicitly, an explicit SSL connection is attempted on port 21 (the default for explicit SSL connections). These default ports can be changed by defining the properties:

```
default.port.ssl.implicit and default.port.ssl.explicit.
```

For example, you would set the default implicit port to 12345 by saying:

```
java -jar -Ddefault.port.ssl.implicit=12345 secureftp2.jar
```

Scripting Secure FTP:

Secure FTP supports simple scripting. A script is nothing more than a line-by-line representation of what would be entered at the command line. A sample script might look like:

```
# Sample Secure FTP script
open ftp.glub.com
user demo <pass>
lcd /tmp
mkdir test
lcd test
cd /pub
mget *
quit
```

To call this script, from the shell command line you would pass in the arguments:

```
-script <path to script>/<file>
```

Additional Help:

To get additional help, from within the program you can type `help` to get a listing of all available commands.

OPTIONS

-h usage message.

-script *script-file*
 start a ftp script.

host host name to connect to.

port port to connect with.

ENVIRONMENT

-

EXIT STATUS

-

FILES

etc/ftps.cfg
 configuration file of **ftps**.

NAME

gawk – pattern scanning and processing language

SYNOPSIS

gawk [POSIX or GNU style options] **-f** *program-file* [**--**] file ...

gawk [POSIX or GNU style options] [**--**] *program-text* file ...

pgawk [POSIX or GNU style options] **-f** *program-file* [**--**] file ...

pgawk [POSIX or GNU style options] [**--**] *program-text* file ...

DESCRIPTION

Gawk is the GNU Project's implementation of the AWK programming language. It conforms to the definition of the language in the POSIX 1003.1 Standard. This version in turn is based on the description in *The AWK Programming Language*, by Aho, Kernighan, and Weinberger, with the additional features found in the System V Release 4 version of UNIX *awk*. *Gawk* also provides more recent Bell Laboratories *awk* extensions, and a number of GNU-specific extensions.

Pgawk is the profiling version of *gawk*. It is identical in every way to *gawk*, except that programs run more slowly, and it automatically produces an execution profile in the file **awkprof.out** when done. See the **--profile** option, below.

The command line consists of options to *gawk* itself, the AWK program text (if not supplied via the **-f** or **--file** options), and values to be made available in the **ARGC** and **ARGV** pre-defined AWK variables.

OPTION FORMAT

Gawk options may be either traditional POSIX one letter options, or GNU-style long options. POSIX options start with a single “-”, while long options start with “--”. Long options are provided for both GNU-specific features and for POSIX-mandated features.

Following the POSIX standard, *gawk*-specific options are supplied via arguments to the **-W** option. Multiple **-W** options may be supplied. Each **-W** option has a corresponding long option, as detailed below. Arguments to long options are either joined with the option by an = sign, with no intervening spaces, or they may be provided in the next command line argument. Long options may be abbreviated, as long as the abbreviation remains unique.

OPTIONS

Gawk accepts the following options, listed by frequency.

-F *fs*

--field-separator *fs*

Use *fs* for the input field separator (the value of the **FS** predefined variable).

-v *var=val*

--assign *var=val*

Assign the value *val* to the variable *var*, before execution of the program begins. Such variable values are available to the **BEGIN** block of an AWK program.

-f *program-file*

--file *program-file*

Read the AWK program source from the file *program-file*, instead of from the first command line argument. Multiple **-f** (or **--file**) options may be used.

-mf *NNN*

-mr *NNN*

Set various memory limits to the value *NNN*. The **f** flag sets the maximum number of fields, and the **r** flag sets the maximum record size. These two flags and the **-m** option are from an earlier version of the Bell Laboratories research version of UNIX *awk*. They are ignored by *gawk*, since *gawk* has no pre-defined limits.

-W **compat**

-W traditional

--compat

--traditional

Run in *compatibility* mode. In compatibility mode, *gawk* behaves identically to UNIX *awk*; none of the GNU-specific extensions are recognized. The use of **--traditional** is preferred over the other forms of this option. See **GNU EXTENSIONS**, below, for more information.

-W copyleft

-W copyright

--copyleft

--copyright

Print the short version of the GNU copyright information message on the standard output and exit successfully.

-W dump-variables[=file]

--dump-variables[=file]

Print a sorted list of global variables, their types and final values to *file*. If no *file* is provided, *gawk* uses a file named **awkvars.out** in the current directory.

Having a list of all the global variables is a good way to look for typographical errors in your programs. You would also use this option if you have a large program with a lot of functions, and you want to be sure that your functions don't inadvertently use global variables that you meant to be local. (This is a particularly easy mistake to make with simple variable names like *i*, *j*, and so on.)

-W exec file

--exec file

Similar to **-f**, however, this option is the last one processed. This should be used with **#!** scripts, particularly for CGI applications, to avoid passing in options or source code (!) on the command line from a URL. This option disables command-line variable assignments.

-W gen-po

--gen-po

Scan and parse the AWK program, and generate a GNU **.po** format file on standard output with entries for all localizable strings in the program. The program itself is not executed. See the GNU *gettext* distribution for more information on **.po** files.

-W help

-W usage

--help

--usage

Print a relatively short summary of the available options on the standard output. (Per the *GNU Coding Standards*, these options cause an immediate, successful exit.)

-W lint[=value]

--lint[=value]

Provide warnings about constructs that are dubious or non-portable to other AWK implementations. With an optional argument of **fatal**, lint warnings become fatal errors. This may be drastic, but its use will certainly encourage the development of cleaner AWK programs. With an optional argument of **invalid**, only warnings about things that are actually invalid are issued. (This is not fully implemented yet.)

-W lint-old

--lint-old

Provide warnings about constructs that are not portable to the original version of Unix *awk*.

-W non-decimal-data

--non-decimal-data

Recognize octal and hexadecimal values in input data. *Use this option with great caution!*

-W posix**--posix**

This turns on *compatibility* mode, with the following additional restrictions:

- `\x` escape sequences are not recognized.
- Only space and tab act as field separators when **FS** is set to a single space, newline does not.
- You cannot continue lines after `?` and `:`.
- The synonym **func** for the keyword **function** is not recognized.
- The operators `**` and `**=` cannot be used in place of `^` and `^=`.
- The **fflush()** function is not available.

-W profile[=prof_file]**--profile[=prof_file]**

Send profiling data to *prof_file*. The default is **awkprof.out**. When run with *gawk*, the profile is just a “pretty printed” version of the program. When run with *pgawk*, the profile contains execution counts of each statement in the program in the left margin and function call counts for each user-defined function.

-W re-interval**--re-interval**

Enable the use of *interval expressions* in regular expression matching (see **Regular Expressions**, below). Interval expressions were not traditionally available in the AWK language. The POSIX standard added them, to make *awk* and *egrep* consistent with each other. However, their use is likely to break old AWK programs, so *gawk* only provides them if they are requested with this option, or when **--posix** is specified.

-W source program-text**--source program-text**

Use *program-text* as AWK program source code. This option allows the easy intermixing of library functions (used via the **-f** and **--file** options) with source code entered on the command line. It is intended primarily for medium to large AWK programs used in shell scripts.

-W use-lc-numeric**--use-lc-numeric**

This forces *gawk* to use the locale’s decimal point character when parsing input data. Although the POSIX standard requires this behavior, and *gawk* does so when **--posix** is in effect, the default is to follow traditional behavior and use a period as the decimal point, even in locales where the period is not the decimal point character. This option overrides the default behavior, without the full draconian strictness of the **--posix** option.

-W version**--version**

Print version information for this particular copy of *gawk* on the standard output. This is useful mainly for knowing if the current copy of *gawk* on your system is up to date with respect to whatever the Free Software Foundation is distributing. This is also useful when reporting bugs. (Per the *GNU Coding Standards*, these options cause an immediate, successful exit.)

--

Signal the end of options. This is useful to allow further arguments to the AWK program itself to start with a “-”. This provides consistency with the argument parsing convention used by most other POSIX programs.

In compatibility mode, any other options are flagged as invalid, but are otherwise ignored. In normal operation, as long as program text has been supplied, unknown options are passed on to the AWK program in the **ARGV** array for processing. This is particularly useful for running AWK programs via the “#!” executable interpreter mechanism.

AWK PROGRAM EXECUTION

An AWK program consists of a sequence of pattern-action statements and optional function definitions.

```
pattern { action statements }
```

```
function name(parameter list) { statements }
```

Gawk first reads the program source from the *program-file*(s) if specified, from arguments to **--source**, or from the first non-option argument on the command line. The **-f** and **--source** options may be used multiple times on the command line. *Gawk* reads the program text as if all the *program-files* and command line source texts had been concatenated together. This is useful for building libraries of AWK functions, without having to include them in each new AWK program that uses them. It also provides the ability to mix library functions with command line programs.

The environment variable **AWKPATH** specifies a search path to use when finding source files named with the **-f** option. If this variable does not exist, the default path is **"/usr/local/share/awk"**. (The actual directory may vary, depending upon how *gawk* was built and installed.) If a file name given to the **-f** option contains a **"/"** character, no path search is performed.

Gawk executes AWK programs in the following order. First, all variable assignments specified via the **-v** option are performed. Next, *gawk* compiles the program into an internal form. Then, *gawk* executes the code in the **BEGIN** block(s) (if any), and then proceeds to read each file named in the **ARGV** array. If there are no files named on the command line, *gawk* reads the standard input.

If a filename on the command line has the form *var=val* it is treated as a variable assignment. The variable *var* will be assigned the value *val*. (This happens after any **BEGIN** block(s) have been run.) Command line variable assignment is most useful for dynamically assigning values to the variables AWK uses to control how input is broken into fields and records. It is also useful for controlling state if multiple passes are needed over a single data file.

If the value of a particular element of **ARGV** is empty (**""**), *gawk* skips over it.

For each record in the input, *gawk* tests to see if it matches any *pattern* in the AWK program. For each pattern that the record matches, the associated *action* is executed. The patterns are tested in the order they occur in the program.

Finally, after all the input is exhausted, *gawk* executes the code in the **END** block(s) (if any).

VARIABLES, RECORDS AND FIELDS

AWK variables are dynamic; they come into existence when they are first used. Their values are either floating-point numbers or strings, or both, depending upon how they are used. AWK also has one dimensional arrays; arrays with multiple dimensions may be simulated. Several pre-defined variables are set as a program runs; these are described as needed and summarized below.

Records

Normally, records are separated by newline characters. You can control how records are separated by assigning values to the built-in variable **RS**. If **RS** is any single character, that character separates records. Otherwise, **RS** is a regular expression. Text in the input that matches this regular expression separates the record. However, in compatibility mode, only the first character of its string value is used for separating records. If **RS** is set to the null string, then records are separated by blank lines. When **RS** is set to the null string, the newline character always acts as a field separator, in addition to whatever value **FS** may have.

Fields

As each input record is read, *gawk* splits the record into *fields*, using the value of the **FS** variable as the field separator. If **FS** is a single character, fields are separated by that character. If **FS** is the null string, then each individual character becomes a separate field. Otherwise, **FS** is expected to be a full regular expression. In the special case that **FS** is a single space, fields are separated by runs of spaces and/or tabs and/or newlines. (But see the section **POSIX COMPATIBILITY**, below). **NOTE:** The value of **IGNORECASE** (see below) also affects how fields are split when **FS** is a regular expression, and how records are separated when **RS** is a regular expression.

If the **FIELDWIDTHS** variable is set to a space separated list of numbers, each field is expected to have fixed width, and *gawk* splits up the record using the specified widths. The value of **FS** is ignored. Assigning a new value to **FS** overrides the use of **FIELDWIDTHS**, and restores the default behavior.

Each field in the input record may be referenced by its position, **\$1**, **\$2**, and so on. **\$0** is the whole record. Fields need not be referenced by constants:

```
n = 5
print $n
```

prints the fifth field in the input record.

The variable **NF** is set to the total number of fields in the input record.

References to non-existent fields (i.e. fields after **\$NF**) produce the null-string. However, assigning to a non-existent field (e.g., **\$(NF+2) = 5**) increases the value of **NF**, creates any intervening fields with the null string as their value, and causes the value of **\$0** to be recomputed, with the fields being separated by the value of **OFS**. References to negative numbered fields cause a fatal error. Decrementing **NF** causes the values of fields past the new value to be lost, and the value of **\$0** to be recomputed, with the fields being separated by the value of **OFS**.

Assigning a value to an existing field causes the whole record to be rebuilt when **\$0** is referenced. Similarly, assigning a value to **\$0** causes the record to be resplit, creating new values for the fields.

Built-in Variables

Gawk's built-in variables are:

| | |
|--------------------|--|
| ARGC | The number of command line arguments (does not include options to <i>gawk</i> , or the program source). |
| ARGIND | The index in ARGV of the current file being processed. |
| ARGV | Array of command line arguments. The array is indexed from 0 to ARGC - 1. Dynamically changing the contents of ARGV can control the files used for data. |
| BINMODE | On non-POSIX systems, specifies use of "binary" mode for all file I/O. Numeric values of 1, 2, or 3, specify that input files, output files, or all files, respectively, should use binary I/O. String values of "r", or "w" specify that input files, or output files, respectively, should use binary I/O. String values of "rw" or "wr" specify that all files should use binary I/O. Any other string value is treated as "rw", but generates a warning message. |
| CONVFMT | The conversion format for numbers, "%.6g", by default. |
| ENVIRON | An array containing the values of the current environment. The array is indexed by the environment variables, each element being the value of that variable (e.g., ENVIRON["HOME"] might be /home/arnold). Changing this array does not affect the environment seen by programs which <i>gawk</i> spawns via redirection or the system() function. |
| ERRNO | If a system error occurs either doing a redirection for getline , during a read for getline , or during a close() , then ERRNO will contain a string describing the error. The value is subject to translation in non-English locales. |
| FIELDWIDTHS | A white-space separated list of fieldwidths. When set, <i>gawk</i> parses the input into fields of fixed width, instead of using the value of the FS variable as the field separator. |
| FILENAME | The name of the current input file. If no files are specified on the command line, the value of FILENAME is "-". However, FILENAME is undefined inside the BEGIN block (unless set by getline). |
| FNR | The input record number in the current input file. |
| FS | The input field separator, a space by default. See Fields , above. |
| IGNORECASE | Controls the case-sensitivity of all regular expression and string operations. If IGNORECASE has a non-zero value, then string comparisons and pattern matching in rules, field splitting with FS , record separating with RS , regular expression matching with ~ and !~ , and the gensub() , gsub() , index() , match() , split() , and sub() built-in functions all ignore case when doing regular expression operations. NOTE : Array subscripting is <i>not</i> affected. However, the asort() and asorti() functions are affected. Thus, if IGNORECASE is not equal to zero, /aB/ matches all of the strings "ab", "aB", "Ab", and "AB". As with all AWK variables, the initial value of IGNORECASE is zero, so all regular expression and string operations are normally case-sensitive. Under Unix, the full ISO 8859-1 Latin-1 character set is used when ignoring case. As of <i>gawk</i> 3.1.4, the case equivalencies are fully locale-aware, based on the C <ctype.h> facilities such as isalpha() , and toupper() . |
| LINT | Provides dynamic control of the --lint option from within an AWK program. When true, <i>gawk</i> prints lint warnings. When false, it does not. When assigned the string value "fatal", lint warnings become fatal errors, exactly like --lint=fatal . Any other true value just prints warnings. |

| | |
|----------------------------|--|
| NF | The number of fields in the current input record. |
| NR | The total number of input records seen so far. |
| OFMT | The output format for numbers, "%.6g" , by default. |
| OFS | The output field separator, a space by default. |
| ORS | The output record separator, by default a newline. |
| PROCINFO | The elements of this array provide access to information about the running AWK program. On some systems, there may be elements in the array, "group1" through "groupn" for some <i>n</i> , which is the number of supplementary groups that the process has. Use the in operator to test for these elements. The following elements are guaranteed to be available: |
| PROCINFO["egid"] | the value of the <i>getegid</i> (2) system call. |
| PROCINFO["euid"] | the value of the <i>geteuid</i> (2) system call. |
| PROCINFO["FS"] | "FS" if field splitting with FS is in effect, or "FIELDWIDTHS" if field splitting with FIELDWIDTHS is in effect. |
| PROCINFO["gid"] | the value of the <i>getgid</i> (2) system call. |
| PROCINFO["pgrp"] | the process group ID of the current process. |
| PROCINFO["pid"] | the process ID of the current process. |
| PROCINFO["ppid"] | the parent process ID of the current process. |
| PROCINFO["uid"] | the value of the <i>getuid</i> (2) system call. |
| PROCINFO["version"] | The version of <i>gawk</i> . This is available from version 3.1.4 and later. |
| RS | The input record separator, by default a newline. |
| RT | The record terminator. <i>Gawk</i> sets RT to the input text that matched the character or regular expression specified by RS . |
| RSTART | The index of the first character matched by match() ; 0 if no match. (This implies that character indices start at one.) |
| RLENGTH | The length of the string matched by match() ; -1 if no match. |
| SUBSEP | The character used to separate multiple subscripts in array elements, by default "\034" . |
| TEXTDOMAIN | The text domain of the AWK program; used to find the localized translations for the program's strings. |

Arrays

Arrays are subscripted with an expression between square brackets ([and]). If the expression is an expression list (*expr*, *expr* ...) then the array subscript is a string consisting of the concatenation of the (string) value of each expression, separated by the value of the **SUBSEP** variable. This facility is used to simulate multiply dimensioned arrays. For example:

```
i = "A"; j = "B"; k = "C"
x[i, j, k] = "hello, world\n"
```

assigns the string **"hello, world\n"** to the element of the array **x** which is indexed by the string **"A\034B\034C"**. All arrays in AWK are associative, i.e. indexed by string values.

The special operator **in** may be used to test if an array has an index consisting of a particular value.

```
if (val in array)
    print array[val]
```

If the array has multiple subscripts, use **(i, j) in array**.

The **in** construct may also be used in a **for** loop to iterate over all the elements of an array.

An element may be deleted from an array using the **delete** statement. The **delete** statement may also be used to delete the entire contents of an array, just by specifying the array name without a subscript.

Variable Typing And Conversion

Variables and fields may be (floating point) numbers, or strings, or both. How the value of a variable is interpreted depends upon its context. If used in a numeric expression, it will be treated as a number; if used as a string it will be treated as a string.

To force a variable to be treated as a number, add 0 to it; to force it to be treated as a string, concatenate it with the null string.

When a string must be converted to a number, the conversion is accomplished using *strtod*(3). A number is converted to a string by using the value of **CONVFMT** as a format string for *sprintf*(3), with the numeric value of the variable as the argument. However, even though all numbers in AWK are floating-point, integral values are *always* converted as integers. Thus, given

```
CONVFMT = "%2.2f"
```

```
a = 12
```

```
b = a ""
```

the variable **b** has a string value of **"12"** and not **"12.00"**.

When operating in POSIX mode (such as with the **--posix** command line option), beware that locale settings may interfere with the way decimal numbers are treated: the decimal separator of the numbers you are feeding to *gawk* must conform to what your locale would expect, be it a comma (,) or a period (.).

Gawk performs comparisons as follows: If two variables are numeric, they are compared numerically. If one value is numeric and the other has a string value that is a “numeric string,” then comparisons are also done numerically. Otherwise, the numeric value is converted to a string and a string comparison is performed. Two strings are compared, of course, as strings.

Note that string constants, such as **"57"**, are *not* numeric strings, they are string constants. The idea of “numeric string” only applies to fields, **getline** input, **FILENAME**, **ARGV** elements, **ENVIRON** elements and the elements of an array created by **split()** that are numeric strings. The basic idea is that *user input*, and only user input, that looks numeric, should be treated that way.

Uninitialized variables have the numeric value 0 and the string value "" (the null, or empty, string).

Octal and Hexadecimal Constants

Starting with version 3.1 of *gawk*, you may use C-style octal and hexadecimal constants in your AWK program source code. For example, the octal value **011** is equal to decimal **9**, and the hexadecimal value **0x11** is equal to decimal 17.

String Constants

String constants in AWK are sequences of characters enclosed between double quotes ("). Within strings, certain *escape sequences* are recognized, as in C. These are:

**** A literal backslash.

\a The “alert” character; usually the ASCII BEL character.

\b backspace.

\f form-feed.

\n newline.

\r carriage return.

\t horizontal tab.

\v vertical tab.

\xhex digits

The character represented by the string of hexadecimal digits following the **\x**. As in ANSI C, all following hexadecimal digits are considered part of the escape sequence. (This feature should tell us something about language design by committee.) E.g., **"\x1B"** is the ASCII ESC (escape) character.

\ddd The character represented by the 1-, 2-, or 3-digit sequence of octal digits. E.g., **"\033"** is the ASCII ESC (escape) character.

\c The literal character *c*.

The escape sequences may also be used inside constant regular expressions (e.g., **/[\t\n\r\v]/** matches whitespace characters).

In compatibility mode, the characters represented by octal and hexadecimal escape sequences are treated literally when used in regular expression constants. Thus, **/a\52b/** is equivalent to **/a*b/**.

PATTERNS AND ACTIONS

AWK is a line-oriented language. The pattern comes first, and then the action. Action statements are enclosed in { and }. Either the pattern may be missing, or the action may be missing, but, of course, not both. If the pattern is missing, the action is executed for every single record of input. A missing action is equivalent to

```
{ print }
```

which prints the entire record.

Comments begin with the “#” character, and continue until the end of the line. Blank lines may be used to

separate statements. Normally, a statement ends with a newline, however, this is not the case for lines ending in a “;”, {, ?, :, &&, or ||. Lines ending in **do** or **else** also have their statements automatically continued on the following line. In other cases, a line can be continued by ending it with a “\”, in which case the new-line will be ignored.

Multiple statements may be put on one line by separating them with a “;”. This applies to both the statements within the action part of a pattern-action pair (the usual case), and to the pattern-action statements themselves.

Patterns

AWK patterns may be one of the following:

```
BEGIN
END
/regular expression/
relational expression
pattern && pattern
pattern || pattern
pattern ? pattern : pattern
(pattern)
!pattern
pattern1, pattern2
```

BEGIN and **END** are two special kinds of patterns which are not tested against the input. The action parts of all **BEGIN** patterns are merged as if all the statements had been written in a single **BEGIN** block. They are executed before any of the input is read. Similarly, all the **END** blocks are merged, and executed when all the input is exhausted (or when an **exit** statement is executed). **BEGIN** and **END** patterns cannot be combined with other patterns in pattern expressions. **BEGIN** and **END** patterns cannot have missing action parts.

For */regular expression/* patterns, the associated statement is executed for each input record that matches the regular expression. Regular expressions are the same as those in *egrep*(1), and are summarized below.

A *relational expression* may use any of the operators defined below in the section on actions. These generally test whether certain fields match certain regular expressions.

The **&&**, **||**, and **!** operators are logical AND, logical OR, and logical NOT, respectively, as in C. They do short-circuit evaluation, also as in C, and are used for combining more primitive pattern expressions. As in most languages, parentheses may be used to change the order of evaluation.

The **?:** operator is like the same operator in C. If the first pattern is true then the pattern used for testing is the second pattern, otherwise it is the third. Only one of the second and third patterns is evaluated.

The *pattern1, pattern2* form of an expression is called a *range pattern*. It matches all input records starting with a record that matches *pattern1*, and continuing until a record that matches *pattern2*, inclusive. It does not combine with any other sort of pattern expression.

Regular Expressions

Regular expressions are the extended kind found in *egrep*. They are composed of characters as follows:

| | |
|------------------|--|
| <i>c</i> | matches the non-metacharacter <i>c</i> . |
| <i>\c</i> | matches the literal character <i>c</i> . |
| <i>.</i> | matches any character <i>including</i> newline. |
| <i>^</i> | matches the beginning of a string. |
| <i>\$</i> | matches the end of a string. |
| <i>[abc...]</i> | character list, matches any of the characters <i>abc...</i> |
| <i>[^abc...]</i> | negated character list, matches any character except <i>abc...</i> |
| <i>r1 r2</i> | alternation: matches either <i>r1</i> or <i>r2</i> . |
| <i>r1r2</i> | concatenation: matches <i>r1</i> , and then <i>r2</i> . |
| <i>r+</i> | matches one or more <i>r</i> 's. |
| <i>r*</i> | matches zero or more <i>r</i> 's. |
| <i>r?</i> | matches zero or one <i>r</i> 's. |
| <i>(r)</i> | grouping: matches <i>r</i> . |
| <i>r{n}</i> | |

| | |
|--------------------|---|
| $r\{n,\}$ | |
| $r\{n,m\}$ | One or two numbers inside braces denote an <i>interval expression</i> . If there is one number in the braces, the preceding regular expression r is repeated n times. If there are two numbers separated by a comma, r is repeated n to m times. If there is one number followed by a comma, then r is repeated at least n times. |
| | Interval expressions are only available if either --posix or --re-interval is specified on the command line. |
| <code>\y</code> | matches the empty string at either the beginning or the end of a word. |
| <code>\B</code> | matches the empty string within a word. |
| <code>\<</code> | matches the empty string at the beginning of a word. |
| <code>\></code> | matches the empty string at the end of a word. |
| <code>\w</code> | matches any word-constituent character (letter, digit, or underscore). |
| <code>\W</code> | matches any character that is not word-constituent. |
| <code>\‘</code> | matches the empty string at the beginning of a buffer (string). |
| <code>\’</code> | matches the empty string at the end of a buffer. |

The escape sequences that are valid in string constants (see below) are also valid in regular expressions.

Character classes are a feature introduced in the POSIX standard. A character class is a special notation for describing lists of characters that have a specific attribute, but where the actual characters themselves can vary from country to country and/or from character set to character set. For example, the notion of what is an alphabetic character differs in the USA and in France.

A character class is only valid in a regular expression *inside* the brackets of a character list. Character classes consist of `[:`, a keyword denoting the class, and `:]`. The character classes defined by the POSIX standard are:

| | |
|--------------------------------|---|
| <code>[:alnum:]</code> | Alphanumeric characters. |
| <code>[:alpha:]</code> | Alphabetic characters. |
| <code>[:blank:]</code> | Space or tab characters. |
| <code>[:cntrl:]</code> | Control characters. |
| <code>[:digit:]</code> | Numeric characters. |
| <code>[:graph:]</code> | Characters that are both printable and visible. (A space is printable, but not visible, while an a is both.) |
| <code>[:lower:]</code> | Lower-case alphabetic characters. |
| <code>[:print:]</code> | Printable characters (characters that are not control characters.) |
| <code>[:punct:]</code> | Punctuation characters (characters that are not letter, digits, control characters, or space characters). |
| <code>[:space:]</code> | Space characters (such as space, tab, and formfeed, to name a few). |
| <code>[:upper:]</code> | Upper-case alphabetic characters. |
| <code>[:xdigit:]</code> | Characters that are hexadecimal digits. |

For example, before the POSIX standard, to match alphanumeric characters, you would have had to write `/[A-Za-z0-9]/`. If your character set had other alphabetic characters in it, this would not match them, and if your character set collated differently from ASCII, this might not even match the ASCII alphanumeric characters. With the POSIX character classes, you can write `/[[:alnum:]]/`, and this matches the alphabetic and numeric characters in your character set, no matter what it is.

Two additional special sequences can appear in character lists. These apply to non-ASCII character sets, which can have single symbols (called *collating elements*) that are represented with more than one

character, as well as several characters that are equivalent for *collating*, or sorting, purposes. (E.g., in French, a plain “e” and a grave-accented “è” are equivalent.)

Collating Symbols

A collating symbol is a multi-character collating element enclosed in [. and .]. For example, if **ch** is a collating element, then **[[.ch.]]** is a regular expression that matches this collating element, while **[ch]** is a regular expression that matches either **c** or **h**.

Equivalence Classes

An equivalence class is a locale-specific name for a list of characters that are equivalent. The name is enclosed in [= and =]. For example, the name **e** might be used to represent all of “e,” “é,” and “è.” In this case, **[[=e=]]** is a regular expression that matches any of **e**, **é**, or **è**.

These features are very valuable in non-English speaking locales. The library functions that *gawk* uses for regular expression matching currently only recognize POSIX character classes; they do not recognize collating symbols or equivalence classes.

The **\y**, **\B**, **\<**, **\>**, **\w**, **\W**, **\'**, and **\'** operators are specific to *gawk*; they are extensions based on facilities in the GNU regular expression libraries.

The various command line options control how *gawk* interprets characters in regular expressions.

No options

In the default case, *gawk* provide all the facilities of POSIX regular expressions and the GNU regular expression operators described above. However, interval expressions are not supported.

--posix

Only POSIX regular expressions are supported, the GNU operators are not special. (E.g., **\w** matches a literal **w**). Interval expressions are allowed.

--traditional

Traditional Unix *awk* regular expressions are matched. The GNU operators are not special, interval expressions are not available, and neither are the POSIX character classes (**[[:alnum:]]** and so on). Characters described by octal and hexadecimal escape sequences are treated literally, even if they represent regular expression metacharacters.

--re-interval

Allow interval expressions in regular expressions, even if **--traditional** has been provided.

Actions

Action statements are enclosed in braces, { and }. Action statements consist of the usual assignment, conditional, and looping statements found in most languages. The operators, control statements, and input/output statements available are patterned after those in C.

Operators

The operators in AWK, in order of decreasing precedence, are

| | |
|-------|--|
| (...) | Grouping |
| \$ | Field reference. |
| ++ -- | Increment and decrement, both prefix and postfix. |
| ^ | Exponentiation (** may also be used, and **= for the assignment operator). |
| + - ! | Unary plus, unary minus, and logical negation. |
| * / % | Multiplication, division, and modulus. |
| + - | Addition and subtraction. |
| space | String concatenation. |
| & | Piped I/O for getline , print , and printf . |
| < > | |

| | |
|--------------------------|---|
| <code><= >=</code> | |
| <code>!= ==</code> | The regular relational operators. |
| <code>~ !~</code> | Regular expression match, negated match. NOTE: Do not use a constant regular expression (<code>/foo/</code>) on the left-hand side of a <code>~</code> or <code>!~</code> . Only use one on the right-hand side. The expression <code>/foo/ ~ exp</code> has the same meaning as <code>((<code>\$0</code> ~ /foo/) ~ exp)</code> . This is usually <i>not</i> what was intended. |
| <code>in</code> | Array membership. |
| <code>&&</code> | Logical AND. |
| <code> </code> | Logical OR. |
| <code>?:</code> | The C conditional expression. This has the form <code>expr1 ? expr2 : expr3</code> . If <code>expr1</code> is true, the value of the expression is <code>expr2</code> , otherwise it is <code>expr3</code> . Only one of <code>expr2</code> and <code>expr3</code> is evaluated. |
| <code>= += -=</code> | |
| <code>*= /= %= ^=</code> | Assignment. Both absolute assignment (<code>var = value</code>) and operator-assignment (the other forms) are supported. |

Control Statements

The control statements are as follows:

```

if (condition) statement [ else statement ]
while (condition) statement
do statement while (condition)
for (expr1; expr2; expr3) statement
for (var in array) statement
break
continue
delete array[index]
delete array
exit [ expression ]
{ statements }

```

I/O Statements

The input/output statements are as follows:

| | |
|---|---|
| close (<i>file</i> [, <i>how</i>]) | Close file, pipe or co-process. The optional <i>how</i> should only be used when closing one end of a two-way pipe to a co-process. It must be a string value, either "to" or "from" . |
| getline | Set \$0 from next input record; set NF , NR , FNR . |
| getline < <i>file</i> | Set \$0 from next record of <i>file</i> ; set NF . |
| getline <i>var</i> | Set <i>var</i> from next input record; set NR , FNR . |
| getline <i>var</i> < <i>file</i> | Set <i>var</i> from next record of <i>file</i> . |
| command getline [<i>var</i>] | Run <i>command</i> piping the output either into \$0 or <i>var</i> , as above. |
| command & getline [<i>var</i>] | Run <i>command</i> as a co-process piping the output either into \$0 or <i>var</i> , as above. Co-processes are a <i>gawk</i> extension. (<i>command</i> can also be a socket. See the subsection Special File Names , below.) |
| next | Stop processing the current input record. The next input record is read and processing starts over with the first pattern in the AWK program. If the end of the input data is reached, the END block(s), if any, are executed. |

| | |
|---|---|
| nextfile | Stop processing the current input file. The next input record read comes from the next input file. FILENAME and ARGIND are updated, FNR is reset to 1, and processing starts over with the first pattern in the AWK program. If the end of the input data is reached, the END block(s), if any, are executed. |
| print | Prints the current record. The output record is terminated with the value of the ORS variable. |
| print <i>expr-list</i> | Prints expressions. Each expression is separated by the value of the OFS variable. The output record is terminated with the value of the ORS variable. |
| print <i>expr-list</i> > <i>file</i> | Prints expressions on <i>file</i> . Each expression is separated by the value of the OFS variable. The output record is terminated with the value of the ORS variable. |
| printf <i>fmt</i> , <i>expr-list</i> | Format and print. |
| printf <i>fmt</i> , <i>expr-list</i> > <i>file</i> | Format and print on <i>file</i> . |
| system (<i>cmd-line</i>) | Execute the command <i>cmd-line</i> , and return the exit status. (This may not be available on non-POSIX systems.) |
| fflush ([<i>file</i>]) | Flush any buffers associated with the open output file or pipe <i>file</i> . If <i>file</i> is missing, then standard output is flushed. If <i>file</i> is the null string, then all open output files and pipes have their buffers flushed. |

Additional output redirections are allowed for **print** and **printf**.

print ... >> *file*
Appends output to the *file*.

print ... | *command*
Writes on a pipe.

print ... |& *command*
Sends data to a co-process or socket. (See also the subsection **Special File Names**, below.)

The **getline** command returns 0 on end of file and -1 on an error. Upon an error, **ERRNO** contains a string describing the problem.

NOTE: If using a pipe, co-process, or socket to **getline**, or from **print** or **printf** within a loop, you *must* use **close()** to create new instances of the command or socket. AWK does not automatically close pipes, sockets, or co-processes when they return EOF.

The **printf** Statement

The AWK versions of the **printf** statement and **sprintf()** function (see below) accept the following conversion specification formats:

| | |
|-----------------------|--|
| %c | An ASCII character. If the argument used for %c is numeric, it is treated as a character and printed. Otherwise, the argument is assumed to be a string, and the only first character of that string is printed. |
| %d , %i | A decimal number (the integer part). |
| %e , %E | A floating point number of the form [-]d.dddde[+-]dd . The %E format uses E instead of e . |
| %f , %F | A floating point number of the form [-]ddd.ddd . If the system library supports it, %F is available as well. This is like %f , but uses capital letters for special “not a number” and “infinity” values. If %F is not available, <i>gawk</i> uses %f . |
| %g , %G | Use %e or %f conversion, whichever is shorter, with nonsignificant zeros suppressed. The %G format uses %E instead of %e . |

- %o** An unsigned octal number (also an integer).
- %u** An unsigned decimal number (again, an integer).
- %s** A character string.
- %x, %X** An unsigned hexadecimal number (an integer). The **%X** format uses **ABCDEF** instead of **abcdef**.
- %%** A single **%** character; no argument is converted.

NOTE: When using the integer format-control letters for values that are outside the range of a C **long** integer, *gawk* switches to the **%0f** format specifier. If **--lint** is provided on the command line *gawk* warns about this. Other versions of *awk* may print invalid values or do something else entirely.

Optional, additional parameters may lie between the **%** and the control letter:

- count\$** Use the *count*'th argument at this point in the formatting. This is called a *positional specifier* and is intended primarily for use in translated versions of format strings, not in the original text of an AWK program. It is a *gawk* extension.
- The expression should be left-justified within its field.
- space** For numeric conversions, prefix positive values with a space, and negative values with a minus sign.
- +** The plus sign, used before the width modifier (see below), says to always supply a sign for numeric conversions, even if the data to be formatted is positive. The **+** overrides the space modifier.
- #** Use an "alternate form" for certain control letters. For **%o**, supply a leading zero. For **%x**, and **%X**, supply a leading **0x** or **0X** for a nonzero result. For **%e**, **%E**, **%f** and **%F**, the result always contains a decimal point. For **%g**, and **%G**, trailing zeros are not removed from the result.
- 0** A leading **0** (zero) acts as a flag, that indicates output should be padded with zeroes instead of spaces. This applies even to non-numeric output formats. This flag only has an effect when the field width is wider than the value to be printed.
- width** The field should be padded to this width. The field is normally padded with spaces. If the **0** flag has been used, it is padded with zeroes.
- .prec** A number that specifies the precision to use when printing. For the **%e**, **%E**, **%f** and **%F**, formats, this specifies the number of digits you want printed to the right of the decimal point. For the **%g**, and **%G** formats, it specifies the maximum number of significant digits. For the **%d**, **%o**, **%i**, **%u**, **%x**, and **%X** formats, it specifies the minimum number of digits to print. For **%s**, it specifies the maximum number of characters from the string that should be printed.

The dynamic *width* and *prec* capabilities of the ANSI C **printf()** routines are supported. A ***** in place of either the **width** or **prec** specifications causes their values to be taken from the argument list to **printf** or **sprintf()**. To use a positional specifier with a dynamic width or precision, supply the *count\$* after the ***** in the format string. For example, **"%3\$*2\$.*1\$s"**.

Special File Names

When doing I/O redirection from either **print** or **printf** into a file, or via **getline** from a file, *gawk* recognizes certain special filenames internally. These filenames allow access to open file descriptors inherited from *gawk*'s parent process (usually the shell). These file names may also be used on the command line to name data files. The filenames are:

- /dev/stdin** The standard input.
- /dev/stdout** The standard output.
- /dev/stderr** The standard error output.
- /dev/fd/*n*** The file associated with the open file descriptor *n*.

These are particularly useful for error messages. For example:

```
print "You blew it!" > "/dev/stderr"
```

whereas you would otherwise have to use

```
print "You blew it!" | "cat 1>&2"
```

The following special filenames may be used with the `|&` co-process operator for creating TCP/IP network connections.

/inet/tcp/lport/rhost/rport File for TCP/IP connection on local port *lport* to remote host *rhost* on remote port *rport*. Use a port of **0** to have the system pick a port.

/inet/udp/lport/rhost/rport Similar, but use UDP/IP instead of TCP/IP.

/inet/raw/lport/rhost/rport Reserved for future use.

Other special filenames provide access to information about the running *gawk* process. **These filenames are now obsolete.** Use the **PROCINFO** array to obtain the information they provide. The filenames are:

/dev/pid Reading this file returns the process ID of the current process, in decimal, terminated with a newline.

/dev/ppid Reading this file returns the parent process ID of the current process, in decimal, terminated with a newline.

/dev/pgrp Reading this file returns the process group ID of the current process, in decimal, terminated with a newline.

/dev/user Reading this file returns a single record terminated with a newline. The fields are separated with spaces. **\$1** is the value of the *getuid(2)* system call, **\$2** is the value of the *geteuid(2)* system call, **\$3** is the value of the *getgid(2)* system call, and **\$4** is the value of the *getegid(2)* system call. If there are any additional fields, they are the group IDs returned by *getgroups(2)*. Multiple groups may not be supported on all systems.

Numeric Functions

AWK has the following built-in arithmetic functions:

atan2(y, x) Returns the arctangent of *y/x* in radians.

cos(expr) Returns the cosine of *expr*, which is in radians.

exp(expr) The exponential function.

int(expr) Truncates to integer.

log(expr) The natural logarithm function.

rand() Returns a random number *N*, between 0 and 1, such that $0 \leq N < 1$.

sin(expr) Returns the sine of *expr*, which is in radians.

sqr(expr) The square root function.

srand([expr]) Uses *expr* as a new seed for the random number generator. If no *expr* is provided, the time of day is used. The return value is the previous seed for the random number generator.

String Functions

Gawk has the following built-in string functions:

asort(s [, d]) Returns the number of elements in the source array *s*. The contents of *s* are sorted using *gawk*'s normal rules for comparing values, and the indices of the sorted values of *s* are replaced with sequential integers starting with 1. If the optional destination array *d* is specified, then *s* is first duplicated into *d*, and then *d* is sorted, leaving the indices of the source array *s* unchanged.

asorti(s [, d]) Returns the number of elements in the source array *s*. The behavior is the same as that of **asort()**, except that the array *indices* are used for sorting, not the array values. When done, the array is indexed numerically, and the values are those of the

original indices. The original values are lost; thus provide a second array if you wish to preserve the original.

| | |
|---|--|
| gensub (<i>r</i> , <i>s</i> , <i>h</i> [, <i>t</i>]) | Search the target string <i>t</i> for matches of the regular expression <i>r</i> . If <i>h</i> is a string beginning with g or G , then replace all matches of <i>r</i> with <i>s</i> . Otherwise, <i>h</i> is a number indicating which match of <i>r</i> to replace. If <i>t</i> is not supplied, \$0 is used instead. Within the replacement text <i>s</i> , the sequence \n , where <i>n</i> is a digit from 1 to 9, may be used to indicate just the text that matched the <i>n</i> 'th parenthesized subexpression. The sequence \0 represents the entire matched text, as does the character & . Unlike sub() and gsub() , the modified string is returned as the result of the function, and the original target string is <i>not</i> changed. |
| gsub (<i>r</i> , <i>s</i> [, <i>t</i>]) | For each substring matching the regular expression <i>r</i> in the string <i>t</i> , substitute the string <i>s</i> , and return the number of substitutions. If <i>t</i> is not supplied, use \$0 . An & in the replacement text is replaced with the text that was actually matched. Use \& to get a literal & . (This must be typed as "\&" ; see <i>GAWK: Effective AWK Programming</i> for a fuller discussion of the rules for & 's and backslashes in the replacement text of sub() , gsub() , and gensub() .) |
| index (<i>s</i> , <i>t</i>) | Returns the index of the string <i>t</i> in the string <i>s</i> , or 0 if <i>t</i> is not present. (This implies that character indices start at one.) |
| length ([<i>s</i>]) | Returns the length of the string <i>s</i> , or the length of \$0 if <i>s</i> is not supplied. Starting with version 3.1.5, as a non-standard extension, with an array argument, length() returns the number of elements in the array. |
| match (<i>s</i> , <i>r</i> [, <i>a</i>]) | Returns the position in <i>s</i> where the regular expression <i>r</i> occurs, or 0 if <i>r</i> is not present, and sets the values of RSTART and RLENGTH . Note that the argument order is the same as for the ~ operator: <i>str ~ re</i> . If array <i>a</i> is provided, <i>a</i> is cleared and then elements 1 through <i>n</i> are filled with the portions of <i>s</i> that match the corresponding parenthesized subexpression in <i>r</i> . The 0'th element of <i>a</i> contains the portion of <i>s</i> matched by the entire regular expression <i>r</i> . Subscripts a[n, "start"] , and a[n, "length"] provide the starting index in the string and length respectively, of each matching substring. |
| split (<i>s</i> , <i>a</i> [, <i>r</i>]) | Splits the string <i>s</i> into the array <i>a</i> on the regular expression <i>r</i> , and returns the number of fields. If <i>r</i> is omitted, FS is used instead. The array <i>a</i> is cleared first. Splitting behaves identically to field splitting, described above. |
| sprintf (<i>fnt</i> , <i>expr-list</i>) | Prints <i>expr-list</i> according to <i>fnt</i> , and returns the resulting string. |
| strtonum (<i>str</i>) | Examines <i>str</i> , and returns its numeric value. If <i>str</i> begins with a leading 0 , strtonum() assumes that <i>str</i> is an octal number. If <i>str</i> begins with a leading 0x or 0X , strtonum() assumes that <i>str</i> is a hexadecimal number. |
| sub (<i>r</i> , <i>s</i> [, <i>t</i>]) | Just like gsub() , but only the first matching substring is replaced. |
| substr (<i>s</i> , <i>i</i> [, <i>n</i>]) | Returns the at most <i>n</i> -character substring of <i>s</i> starting at <i>i</i> . If <i>n</i> is omitted, the rest of <i>s</i> is used. |
| tolower (<i>str</i>) | Returns a copy of the string <i>str</i> , with all the upper-case characters in <i>str</i> translated to their corresponding lower-case counterparts. Non-alphabetic characters are left unchanged. |
| toupper (<i>str</i>) | Returns a copy of the string <i>str</i> , with all the lower-case characters in <i>str</i> translated to their corresponding upper-case counterparts. Non-alphabetic characters are left unchanged. |

As of version 3.1.5, *gawk* is multibyte aware. This means that **index()**, **length()**, **substr()** and **match()** all work in terms of characters, not bytes.

Time Functions

Since one of the primary uses of AWK programs is processing log files that contain time stamp information, *gawk* provides the following functions for obtaining time stamps and formatting them.

mktime(*datespec*)

Turns *datespec* into a time stamp of the same form as returned by **sysptime()**. The *datespec* is a string of the form *YYYY MM DD HH MM SS[DST]*. The contents of the string are six or seven numbers representing respectively the full year including century, the month from 1 to 12, the day of the month from 1 to 31, the hour of the day from 0 to 23, the minute from 0 to 59, and the second from 0 to 60, and an optional daylight saving flag. The values of these numbers need not be within the ranges specified; for example, an hour of -1 means 1 hour before midnight. The origin-zero Gregorian calendar is assumed, with year 0 preceding year 1 and year -1 preceding year 0. The time is assumed to be in the local timezone. If the daylight saving flag is positive, the time is assumed to be daylight saving time; if zero, the time is assumed to be standard time; and if negative (the default), **mktime()** attempts to determine whether daylight saving time is in effect for the specified time. If *datespec* does not contain enough elements or if the resulting time is out of range, **mktime()** returns -1.

strftime([*format* [, *timestamp* [, *utc-flag*]])

Formats *timestamp* according to the specification in *format*. If *utc-flag* is present and is non-zero or non-null, the result is in UTC, otherwise the result is in local time. The *timestamp* should be of the same form as returned by **sysptime()**. If *timestamp* is missing, the current time of day is used. If *format* is missing, a default format equivalent to the output of *date*(1) is used. See the specification for the **strftime()** function in ANSI C for the format conversions that are guaranteed to be available.

sysptime() Returns the current time of day as the number of seconds since the Epoch (1970-01-01 00:00:00 UTC on POSIX systems).

Bit Manipulations Functions

Starting with version 3.1 of *gawk*, the following bit manipulation functions are available. They work by converting double-precision floating point values to **uintmax_t** integers, doing the operation, and then converting the result back to floating point. The functions are:

- and(*v1*, *v2*)** Return the bitwise AND of the values provided by *v1* and *v2*.
- compl(*val*)** Return the bitwise complement of *val*.
- lshift(*val*, *count*)** Return the value of *val*, shifted left by *count* bits.
- or(*v1*, *v2*)** Return the bitwise OR of the values provided by *v1* and *v2*.
- rshift(*val*, *count*)** Return the value of *val*, shifted right by *count* bits.
- xor(*v1*, *v2*)** Return the bitwise XOR of the values provided by *v1* and *v2*.

Internationalization Functions

Starting with version 3.1 of *gawk*, the following functions may be used from within your AWK program for translating strings at run-time. For full details, see *GAWK: Effective AWK Programming*.

bindtextdomain(*directory* [, *domain*])

Specifies the directory where *gawk* looks for the **.mo** files, in case they will not or cannot be placed in the “standard” locations (e.g., during testing). It returns the directory where *domain* is “bound.”

The default *domain* is the value of **TEXTDOMAIN**. If *directory* is the null string (“”), then **bindtextdomain()** returns the current binding for the given *domain*.

dcgettext(*string* [, *domain* [, *category*]])

Returns the translation of *string* in text domain *domain* for locale category *category*. The default value for *domain* is the current value of **TEXTDOMAIN**. The default value for *category* is **“LC_MESSAGES”**.

If you supply a value for *category*, it must be a string equal to one of the known locale categories described in *GAWK: Effective AWK Programming*. You must also supply a text domain. Use **TEXTDOMAIN** if you want to use the current domain.

dcgettext(*string1* , *string2* , *number* [, *domain* [, *category*]])

Returns the plural form used for *number* of the translation of *string1* and *string2* in text domain *domain* for locale category *category*. The default value for *domain* is the current value of **TEXTDOMAIN**. The default value for *category* is "LC_MESSAGES".

If you supply a value for *category*, it must be a string equal to one of the known locale categories described in *GAWK: Effective AWK Programming*. You must also supply a text domain. Use **TEXTDOMAIN** if you want to use the current domain.

USER-DEFINED FUNCTIONS

Functions in AWK are defined as follows:

```
function name(parameter list) { statements }
```

Functions are executed when they are called from within expressions in either patterns or actions. Actual parameters supplied in the function call are used to instantiate the formal parameters declared in the function. Arrays are passed by reference, other variables are passed by value.

Since functions were not originally part of the AWK language, the provision for local variables is rather clumsy: They are declared as extra parameters in the parameter list. The convention is to separate local variables from real parameters by extra spaces in the parameter list. For example:

```
function f(p, q,  a, b)  # a and b are local
{
    ...
}

/abc/  { ... ; f(1, 2) ; ... }
```

The left parenthesis in a function call is required to immediately follow the function name, without any intervening white space. This avoids a syntactic ambiguity with the concatenation operator. This restriction does not apply to the built-in functions listed above.

Functions may call each other and may be recursive. Function parameters used as local variables are initialized to the null string and the number zero upon function invocation.

Use **return** *expr* to return a value from a function. The return value is undefined if no value is provided, or if the function returns by “falling off” the end.

If **--lint** has been provided, *gawk* warns about calls to undefined functions at parse time, instead of at run time. Calling an undefined function at run time is a fatal error.

The word **func** may be used in place of **function**.

DYNAMICALLY LOADING NEW FUNCTIONS

Beginning with version 3.1 of *gawk*, you can dynamically add new built-in functions to the running *gawk* interpreter. The full details are beyond the scope of this manual page; see *GAWK: Effective AWK Programming* for the details.

extension(*object*, *function*)

Dynamically link the shared object file named by *object*, and invoke *function* in that object, to perform initialization. These should both be provided as strings. Returns the value returned by *function*.

This function is provided and documented in *GAWK: Effective AWK Programming*, but everything about this feature is likely to change eventually. We STRONGLY recommend that you do not use this feature for anything that you aren’t willing to redo.

SIGNALS

pgawk accepts two signals. **SIGUSR1** causes it to dump a profile and function call stack to the profile file, which is either **awkprof.out**, or whatever file was named with the **--profile** option. It then continues to run. **SIGHUP** causes *pgawk* to dump the profile and function call stack and then exit.

EXAMPLES

Print and sort the login names of all users:

```
BEGIN { FS = ":" }
      { print $1 | "sort" }
```

Count lines in a file:

```
      { nlines++ }
END   { print nlines }
```

Precede each line by its number in the file:

```
      { print FNR, $0 }
```

Concatenate and line number (a variation on a theme):

```
      { print NR, $0 }
```

Run an external command for particular lines of data:

```
tail -f access_log |
awk 'myhome.html/ { system("nmap " $1 ">> logdir/myhome.html") }'
```

INTERNATIONALIZATION

String constants are sequences of characters enclosed in double quotes. In non-English speaking environments, it is possible to mark strings in the AWK program as requiring translation to the native natural language. Such strings are marked in the AWK program with a leading underscore (“_”). For example,

```
gawk 'BEGIN { print "hello, world" }'
```

always prints **hello, world**. But,

```
gawk 'BEGIN { print _"hello, world" }'
```

might print **bonjour, monde** in France.

There are several steps involved in producing and running a localizable AWK program.

1. Add a **BEGIN** action to assign a value to the **TEXTDOMAIN** variable to set the text domain to a name associated with your program.

```
BEGIN { TEXTDOMAIN = "myprog" }
```

This allows *gawk* to find the **.mo** file associated with your program. Without this step, *gawk* uses the **messages** text domain, which likely does not contain translations for your program.

2. Mark all strings that should be translated with leading underscores.
3. If necessary, use the **dcgettext()** and/or **bindtextdomain()** functions in your program, as appropriate.
4. Run **gawk --gen-po -f myprog.awk > myprog.po** to generate a **.po** file for your program.
5. Provide appropriate translations, and build and install the corresponding **.mo** files.

The internationalization features are described in full detail in *GAWK: Effective AWK Programming*.

POSIX COMPATIBILITY

A primary goal for *gawk* is compatibility with the POSIX standard, as well as with the latest version of UNIX *awk*. To this end, *gawk* incorporates the following user visible features which are not described in the AWK book, but are part of the Bell Laboratories version of *awk*, and are in the POSIX standard.

The book indicates that command line variable assignment happens when *awk* would otherwise open the argument as a file, which is after the **BEGIN** block is executed. However, in earlier implementations, when such an assignment appeared before any file names, the assignment would happen *before* the **BEGIN** block was run. Applications came to depend on this “feature.” When *awk* was changed to match its documentation, the **-v** option for assigning variables before program execution was added to accommodate applications that depended upon the old behavior. (This feature was agreed upon by both the Bell Laboratories and the GNU developers.)

The **-W** option for implementation specific features is from the POSIX standard.

When processing arguments, *gawk* uses the special option “--” to signal the end of arguments. In compatibility mode, it warns about but otherwise ignores undefined options. In normal operation, such arguments are passed on to the AWK program for it to process.

The AWK book does not define the return value of **srand()**. The POSIX standard has it return the seed it was using, to allow keeping track of random number sequences. Therefore **srand()** in *gawk* also returns its current seed.

Other new features are: The use of multiple **-f** options (from MKS *awk*); the **ENVIRON** array; the **\a**, and **\v** escape sequences (done originally in *gawk* and fed back into the Bell Laboratories version); the **tolower()** and **toupper()** built-in functions (from the Bell Laboratories version); and the ANSI C conversion specifications in **printf** (done first in the Bell Laboratories version).

HISTORICAL FEATURES

There are two features of historical AWK implementations that *gawk* supports. First, it is possible to call the **length()** built-in function not only with no argument, but even without parentheses! Thus,

```
a = length      # Holy Algol 60, Batman!
```

is the same as either of

```
a = length()
a = length($0)
```

This feature is marked as “deprecated” in the POSIX standard, and *gawk* issues a warning about its use if **--lint** is specified on the command line.

The other feature is the use of either the **continue** or the **break** statements outside the body of a **while**, **for**, or **do** loop. Traditional AWK implementations have treated such usage as equivalent to the **next** statement. *Gawk* supports this usage if **--traditional** has been specified.

GNU EXTENSIONS

Gawk has a number of extensions to POSIX *awk*. They are described in this section. All the extensions described here can be disabled by invoking *gawk* with the **--traditional** or **--posix** options.

The following features of *gawk* are not available in POSIX *awk*.

- No path search is performed for files named via the **-f** option. Therefore the **AWKPATH** environment variable is not special.
- The **\x** escape sequence. (Disabled with **--posix**.)
- The **fflush()** function. (Disabled with **--posix**.)
- The ability to continue lines after **?** and **:**. (Disabled with **--posix**.)
- Octal and hexadecimal constants in AWK programs.
- The **ARGIND**, **BINMODE**, **ERRNO**, **LINT**, **RT** and **TEXTDOMAIN** variables are not special.

- The **IGNORECASE** variable and its side-effects are not available.
- The **FIELDWIDTHS** variable and fixed-width field splitting.
- The **PROCINFO** array is not available.
- The use of **RS** as a regular expression.
- The special file names available for I/O redirection are not recognized.
- The **|&** operator for creating co-processes.
- The ability to split out individual characters using the null string as the value of **FS**, and as the third argument to **split()**.
- The optional second argument to the **close()** function.
- The optional third argument to the **match()** function.
- The ability to use positional specifiers with **printf** and **sprintf()**.
- The use of **delete array** to delete the entire contents of an array.
- The use of **nextfile** to abandon processing of the current input file.
- The **and()**, **asort()**, **asorti()**, **bindtextdomain()**, **compl()**, **dcgettext()**, **dcngettext()**, **gensub()**, **lshift()**, **mktime()**, **or()**, **rshift()**, **strftime()**, **strtonum()**, **systime()** and **xor()** functions.
- Localizable strings.
- Adding new built-in functions dynamically with the **extension()** function.

The AWK book does not define the return value of the **close()** function. *Gawk*'s **close()** returns the value from *fclose(3)*, or *pclose(3)*, when closing an output file or pipe, respectively. It returns the process's exit status when closing an input pipe. The return value is -1 if the named file, pipe or co-process was not opened with a redirection.

When *gawk* is invoked with the **--traditional** option, if the *fs* argument to the **-F** option is "t", then **FS** is set to the tab character. Note that typing **gawk -Ft ...** simply causes the shell to quote the "t," and does not pass "t" to the **-F** option. Since this is a rather ugly special case, it is not the default behavior. This behavior also does not occur if **--posix** has been specified. To really get a tab character as the field separator, it is best to use single quotes: **gawk -F't' ...**

If *gawk* is *configured* with the **--enable-switch** option to the *configure* command, then it accepts an additional control-flow statement:

```
switch (expression) {
  case value|regex : statement
  ...
  [ default: statement ]
}
```

If *gawk* is *configured* with the **--disable-directories-fatal** option, then it will silently skip directories named on the command line. Otherwise, it will do so only if invoked with the **--traditional** option.

ENVIRONMENT VARIABLES

The **AWKPATH** environment variable can be used to provide a list of directories that *gawk* searches when looking for files named via the **-f** and **--file** options.

If **POSIXLY_CORRECT** exists in the environment, then *gawk* behaves exactly as if **--posix** had been specified on the command line. If **--lint** has been specified, *gawk* issues a warning message to this effect.

GAWK: Effective AWK Programming, Edition 3.0, published by the Free Software Foundation, 2001. The

current version of this document is available online at <http://www.gnu.org/software/gawk/manual>.

BUGS

The **-F** option is not necessary given the command line variable assignment feature; it remains only for backwards compatibility.

Syntactically invalid single character programs tend to overflow the parse stack, generating a rather unhelpful message. Such programs are surprisingly difficult to diagnose in the completely general case, and the effort to do so really is not worth it.

AUTHORS

The original version of UNIX *awk* was designed and implemented by Alfred Aho, Peter Weinberger, and Brian Kernighan of Bell Laboratories. Brian Kernighan continues to maintain and enhance it.

Paul Rubin and Jay Fenlason, of the Free Software Foundation, wrote *gawk*, to be compatible with the original version of *awk* distributed in Seventh Edition UNIX. John Woods contributed a number of bug fixes. David Trueman, with contributions from Arnold Robbins, made *gawk* compatible with the new version of UNIX *awk*. Arnold Robbins is the current maintainer.

The initial DOS port was done by Conrad Kwok and Scott Garfinkle. Scott Deifik is the current DOS maintainer. Pat Rankin did the port to VMS, and Michal Jaegermann did the port to the Atari ST. The port to OS/2 was done by Kai Uwe Rommel, with contributions and help from Darrel Hankerson. Juan M. Guerrero now maintains the OS/2 port. Fred Fish supplied support for the Amiga, and Martin Brown provided the BeOS port. Stephen Davies provided the original Tandem port, and Matthew Woehlke provided changes for Tandem's POSIX-compliant systems.

VERSION INFORMATION

This man page documents *gawk*, version 3.1.6.

BUG REPORTS

If you find a bug in *gawk*, please send electronic mail to bug-gawk@gnu.org. Please include your operating system and its revision, the version of *gawk* (from **gawk --version**), what C compiler you used to compile it, and a test program and data that are as small as possible for reproducing the problem.

Before sending a bug report, please do the following things. First, verify that you have the latest version of *gawk*. Many bugs (usually subtle ones) are fixed at each release, and if yours is out of date, the problem may already have been solved. Second, please see if setting the environment variable **LC_ALL** to **LC_ALL=C** causes things to behave as you expect. If so, it's a locale issue, and may or may not really be a bug. Finally, please read this man page and the reference manual carefully to be sure that what you think is a bug really is, instead of just a quirk in the language.

Whatever you do, do **NOT** post a bug report in **comp.lang.awk**. While the *gawk* developers occasionally read this newsgroup, posting bug reports there is an unreliable way to report bugs. Instead, please use the electronic mail addresses given above.

If you're using a GNU/Linux system or BSD-based system, you may wish to submit a bug report to the vendor of your distribution. That's fine, but please send a copy to the official email address as well, since there's no guarantee that the bug will be forwarded to the *gawk* maintainer.

ACKNOWLEDGEMENTS

Brian Kernighan of Bell Laboratories provided valuable assistance during testing and debugging. We thank him.

NAME

gecos – return the GECOS (comment) entry for a user account

SYNOPSIS

edrc/lib/gecos [**-h**]

gecos *username*

AVAILABILITY

WA2L/edrc

DESCRIPTION

return the GECOS field (=comment) of a given user.

If the user does not exist on the system (or in an equivalent coming from some server somewhere) an empty string is returned.

OPTIONS

-h print usage message.

username name of an existing user on the system.

ENVIRONMENT

-

EXIT STATUS

0 no error.

1 user does not exist.

4 usage message printed.

FILES

-

EXAMPLES

-

SEE ALSO

edrcintro(1) **gid(3)**, **group(3)**, **homedir(3)**, **uid(3)**

NOTES

NAME

getfilesystem – print the filesystem of the current working directory

SYNOPSIS

edrc/lib/getfilesystem

AVAILABILITY

WA2L/edrc

DESCRIPTION

With **getfilesystem** the filesystem (special file) is printed where the current working directory is located on.

This output is basically identical to:

```
df -k . | awk 'END{print $1}'      # Solaris, Linux
bdf . | awk 'END{print $1}'        # HP-UX
xbdf . | awk 'END{print $1}'       # all
```

but is much faster especially if there are large file systems on HP-UX.

getfilesystem is used internally by **pkg_hostname** where fast filesystem resolving is important.

OPTIONS

-

ENVIRONMENT

-

EXIT STATUS

| | |
|----------|--------------------------------------|
| 0 | filesystem could be resolved |
| 1 | error while resolving the filesystem |

FILES

/etc/mnttab on HP-UX and Solaris.

/etc/mntab on Linux.

EXAMPLES

NAME

gethostbyname – host lookup using gethostbyname() system call

SYNOPSIS

edrc/bin/gethostbyname

AVAILABILITY

WA2L/edrc

DESCRIPTION

gethostbyname is an interactive command using only the gethostbyname system call to resolve the host-name(s) and IP address(s). This ensures that the settings in the **/etc/nsswitch.conf** file are processed as the system does it. **gethostbyname** does not super-set the system settings in any kind like other resolving tools sometimes do.

To exit **gethostbyname** type *exit* at the **gethostbyname** command prompt.

The source code of **gethostbyname** is available in **edrc/src/gethostbyname.c**.

OPTIONS

-

OUTPUT INTERPRETATION

The output fields correspond to the *hostent* structure as defined in **netdb.h**.

h_error If the name server is not being used, the value of **h_errno** may not be meaningful.

1: **HOST_NOT_FOUND**

Authoritative answer host not found.

This value is returned on successful queries (what is a bit weird, of course).

2: **TRY_AGAIN**

Non-Authoritative Host not found, or SERVERFAIL.

This is usually a temporary error. The local server did not receive a response from an authoritative server. A retry at some later time may succeed. Or the queried host simply does not exist.

3: **NO_RECOVERY**

Non recoverable errors, FORMERR, REFUSED, NOTIMP.

This is a non-recoverable error.

4: NO_DATA

Valid name, no data record of requested type.

4: NO_ADDRESS

no address, look for MX record. The requested name is valid but does not have an IP address; this is not a temporary error. This means another type of request to the name server will result in an answer.

h_name The official name of the host.

h_aliases An array of alternate names for the host.

h_addrtype

The type of address being returned; always *AF_INET*.

h_length The length, in bytes, of the address.

h_addr_list

An array of network addresses for the host

EXIT STATUS

0 always

SEE ALSO

edrcintro(1), **gethostbyname(3N)**, **gethostent(3N)**, **nsswitch.conf(4)**, **resolve.conf(4)**, **resolver(4)**

BUGS

IPv6 is not supported yet.

NAME

getmountpoint – print the mountpoint of the current working directory

SYNOPSIS

edrc/lib/getmountpoint

AVAILABILITY

WA2L/edrc

DESCRIPTION

With **getmountpoint** the mount point is printed where the current working directory is located on.

This output is basically identical to:

```
df -k . | awk 'END{print $6}'      # Solaris, Linux
bdf . | awk 'END{print $6}'        # HP-UX
xbdf . | awk 'END{print $6}'       # all
```

but is much faster especially if there are large file systems on HP-UX.

OPTIONS

-

ENVIRONMENT

-

EXIT STATUS

- | | |
|----------|---------------------------------------|
| 0 | mount point could be resolved |
| 1 | error while resolving the mount point |

FILES

/etc/mnttab on HP-UX and Solaris.

/etc/mstab on Linux.

EXAMPLES

-

NAME

gid – return the numeric group-id (GID) of a group

SYNOPSIS

edrc/lib/gid [**-h**]

gid *groupname*

AVAILABILITY

WA2L/edrc

DESCRIPTION

return the numeric group-id (GID) of a given group.

If the group does not exist on the system (or in an equivalent coming from some server somewhere) an empty string is returned.

OPTIONS

-h print usage message.

groupname
name of an existing group on the system.

ENVIRONMENT

-

EXIT STATUS

0 no error.

1 group does not exist.

4 usage message printed.

NAME

glibc.version – print GLIBC version

SYNOPSIS

edrc/lib/glibc.version

edrc/lib/<OSID>/glibc.version

AVAILABILITY

WA2L/edrc

DESCRIPTION

return the GLIBC version available on the system.

OPTIONS

-

EXIT STATUS

0 no error.

106 operating system (OSID) not supported.

FILES

-

EXAMPLES

-

SEE ALSO

edrcintro(1), **ldd(1)**, **osid(3)**, **osid.probe(3)**

NOTES

Normally the GLIBC version is identical to the version of the **ldd** command.

NAME

grep, **egrep**, **fgrep**, **rgrep** – print lines matching a pattern

SYNOPSIS

```
grep [OPTIONS] PATTERN [FILE...]
grep [OPTIONS] -e PATTERN ... [FILE...]
grep [OPTIONS] -f FILE ... [FILE...]
```

DESCRIPTION

grep searches for *PATTERN* in each *FILE*. A *FILE* of “-” stands for standard input. If no *FILE* is given, recursive searches examine the working directory, and nonrecursive searches read standard input. By default, **grep** prints the matching lines.

In addition, the variant programs **egrep**, **fgrep** and **rgrep** are the same as **grep -E**, **grep -F**, and **grep -r**, respectively. These variants are deprecated, but are provided for backward compatibility.

OPTIONS**Generic Program Information**

--help Output a usage message and exit.

-V, --version
Output the version number of **grep** and exit.

Matcher Selection

-E, --extended-regexp
Interpret *PATTERN* as an extended regular expression (ERE, see below).

-F, --fixed-strings
Interpret *PATTERN* as a list of fixed strings (instead of regular expressions), separated by newlines, any of which is to be matched.

-G, --basic-regexp
Interpret *PATTERN* as a basic regular expression (BRE, see below). This is the default.

-P, --perl-regexp
Interpret the pattern as a Perl-compatible regular expression (PCRE). This is experimental and **grep -P** may warn of unimplemented features.

Matching Control

-e PATTERN, --regexp=PATTERN
Use *PATTERN* as the pattern. If this option is used multiple times or is combined with the **-f** (**--file**) option, search for all patterns given. This option can be used to protect a pattern beginning with “-”.

-f FILE, --file=FILE
Obtain patterns from *FILE*, one per line. If this option is used multiple times or is combined with the **-e** (**--regexp**) option, search for all patterns given. The empty file contains zero patterns, and therefore matches nothing.

-i, --ignore-case
Ignore case distinctions, so that characters that differ only in case match each other.

-v, --invert-match
Invert the sense of matching, to select non-matching lines.

-w, --word-regexp
Select only those lines containing matches that form whole words. The test is that the matching substring must either be at the beginning of the line, or preceded by a non-word constituent character. Similarly, it must be either at the end of the line or followed by a non-word constituent character. Word-constituent characters are letters, digits, and the underscore. This option has no effect if **-x** is also specified.

-x, --line-regexp

Select only those matches that exactly match the whole line. For a regular expression pattern, this is like parenthesizing the pattern and then surrounding it with `^` and `$`.

-y Obsolete synonym for **-i**.**General Output Control****-c, --count**

Suppress normal output; instead print a count of matching lines for each input file. With the **-v**, **--invert-match** option (see below), count non-matching lines.

--color[=WHEN], --colour[=WHEN]

Surround the matched (non-empty) strings, matching lines, context lines, file names, line numbers, byte offsets, and separators (for fields and groups of context lines) with escape sequences to display them in color on the terminal. The colors are defined by the environment variable **GREP_COLORS**. The deprecated environment variable **GREP_COLOR** is still supported, but its setting does not have priority. *WHEN* is **never**, **always**, or **auto**.

-L, --files-without-match

Suppress normal output; instead print the name of each input file from which no output would normally have been printed. The scanning will stop on the first match.

-l, --files-with-matches

Suppress normal output; instead print the name of each input file from which output would normally have been printed. The scanning will stop on the first match.

-m NUM, --max-count=NUM

Stop reading a file after *NUM* matching lines. If the input is standard input from a regular file, and *NUM* matching lines are output, **grep** ensures that the standard input is positioned to just after the last matching line before exiting, regardless of the presence of trailing context lines. This enables a calling process to resume a search. When **grep** stops after *NUM* matching lines, it outputs any trailing context lines. When the **-c** or **--count** option is also used, **grep** does not output a count greater than *NUM*. When the **-v** or **--invert-match** option is also used, **grep** stops after outputting *NUM* non-matching lines.

-o, --only-matching

Print only the matched (non-empty) parts of a matching line, with each such part on a separate output line.

-q, --quiet, --silent

Quiet; do not write anything to standard output. Exit immediately with zero status if any match is found, even if an error was detected. Also see the **-s** or **--no-messages** option.

-s, --no-messages

Suppress error messages about nonexistent or unreadable files.

Output Line Prefix Control**-b, --byte-offset**

Print the 0-based byte offset within the input file before each line of output. If **-o** (**--only-matching**) is specified, print the offset of the matching part itself.

-H, --with-filename

Print the file name for each match. This is the default when there is more than one file to search.

-h, --no-filename

Suppress the prefixing of file names on output. This is the default when there is only one file (or only standard input) to search.

--label=LABEL

Display input actually coming from standard input as input coming from file *LABEL*. This is especially useful when implementing tools like **zgrep**, e.g., **gzip -cd foo.gz | grep --label=foo -H something**. See also the **-H** option.

-n, --line-number

Prefix each line of output with the 1-based line number within its input file.

-T, --initial-tab

Make sure that the first character of actual line content lies on a tab stop, so that the alignment of tabs looks normal. This is useful with options that prefix their output to the actual content: **-H**, **-n**, and **-b**. In order to improve the probability that lines from a single file will all start at the same column, this also causes the line number and byte offset (if present) to be printed in a minimum size field width.

-u, --unix-byte-offsets

Report Unix-style byte offsets. This switch causes **grep** to report byte offsets as if the file were a Unix-style text file, i.e., with CR characters stripped off. This will produce results identical to running **grep** on a Unix machine. This option has no effect unless **-b** option is also used; it has no effect on platforms other than MS-DOS and MS-Windows.

-Z, --null

Output a zero byte (the ASCII NUL character) instead of the character that normally follows a file name. For example, **grep -IZ** outputs a zero byte after each file name instead of the usual newline. This option makes the output unambiguous, even in the presence of file names containing unusual characters like newlines. This option can be used with commands like **find -print0**, **perl -0**, **sort -z**, and **xargs -0** to process arbitrary file names, even those that contain newline characters.

Context Line Control**-A NUM, --after-context=NUM**

Print *NUM* lines of trailing context after matching lines. Places a line containing a group separator (--) between contiguous groups of matches. With the **-o** or **--only-matching** option, this has no effect and a warning is given.

-B NUM, --before-context=NUM

Print *NUM* lines of leading context before matching lines. Places a line containing a group separator (--) between contiguous groups of matches. With the **-o** or **--only-matching** option, this has no effect and a warning is given.

-C NUM, -NUM, --context=NUM

Print *NUM* lines of output context. Places a line containing a group separator (--) between contiguous groups of matches. With the **-o** or **--only-matching** option, this has no effect and a warning is given.

File and Directory Selection**-a, --text**

Process a binary file as if it were text; this is equivalent to the **--binary-files=text** option.

--binary-files=TYPE

If a file's data or metadata indicate that the file contains binary data, assume that the file is of type *TYPE*. Non-text bytes indicate binary data; these are either output bytes that are improperly encoded for the current locale, or null input bytes when the **-z** option is not given.

By default, *TYPE* is **binary**, and when **grep** discovers that a file is binary it suppresses any further output, and instead outputs either a one-line message saying that a binary file matches, or no message if there is no match.

If *TYPE* is **without-match**, when **grep** discovers that a file is binary it assumes that the rest of the file does not match; this is equivalent to the **-I** option.

If *TYPE* is **text**, **grep** processes a binary file as if it were text; this is equivalent to the **-a** option.

When *type* is **binary**, **grep** may treat non-text bytes as line terminators even without the **-z** option. This means choosing **binary** versus **text** can affect whether a pattern matches a file. For example, when *type* is **binary** the pattern **q\$** might match **q** immediately followed by a null byte, even though this is not matched when *type* is **text**. Conversely, when *type* is **binary** the pattern **.**

(period) might not match a null byte.

Warning: The **-a** option might output binary garbage, which can have nasty side effects if the output is a terminal and if the terminal driver interprets some of it as commands. On the other hand, when reading files whose text encodings are unknown, it can be helpful to use **-a** or to set **LC_ALL='C'** in the environment, in order to find more matches even if the matches are unsafe for direct display.

-D ACTION, --devices=ACTION

If an input file is a device, FIFO or socket, use *ACTION* to process it. By default, *ACTION* is **read**, which means that devices are read just as if they were ordinary files. If *ACTION* is **skip**, devices are silently skipped.

-d ACTION, --directories=ACTION

If an input file is a directory, use *ACTION* to process it. By default, *ACTION* is **read**, i.e., read directories just as if they were ordinary files. If *ACTION* is **skip**, silently skip directories. If *ACTION* is **recurse**, read all files under each directory, recursively, following symbolic links only if they are on the command line. This is equivalent to the **-r** option.

--exclude=GLOB

Skip any command-line file with a name suffix that matches the pattern *GLOB*, using wildcard matching; a name suffix is either the whole name, or any suffix starting after a */* and before a *+non-/. When searching recursively, skip any subfile whose base name matches *GLOB*; the base name is the part after the last */*. A pattern can use ***, *?*, and *[...]* as wildcards, and ** to quote a wildcard or backslash character literally.*

--exclude-from=FILE

Skip files whose base name matches any of the file-name globs read from *FILE* (using wildcard matching as described under **--exclude**).

--exclude-dir=GLOB

Skip any command-line directory with a name suffix that matches the pattern *GLOB*. When searching recursively, skip any subdirectory whose base name matches *GLOB*. Ignore any redundant trailing slashes in *GLOB*.

-I Process a binary file as if it did not contain matching data; this is equivalent to the **--binary-files=without-match** option.

--include=GLOB

Search only files whose base name matches *GLOB* (using wildcard matching as described under **--exclude**).

-r, --recursive

Read all files under each directory, recursively, following symbolic links only if they are on the command line. Note that if no file operand is given, *grep* searches the working directory. This is equivalent to the **-d recurse** option.

-R, --dereference-recursive

Read all files under each directory, recursively. Follow all symbolic links, unlike **-r**.

Other Options

--line-buffered

Use line buffering on output. This can cause a performance penalty.

-U, --binary

Treat the file(s) as binary. By default, under MS-DOS and MS-Windows, **grep** guesses whether a file is text or binary as described for the **--binary-files** option. If **grep** decides the file is a text file, it strips the CR characters from the original file contents (to make regular expressions with *^* and *\$* work correctly). Specifying **-U** overrules this guesswork, causing all files to be read and passed to the matching mechanism verbatim; if the file is a text file with CR/LF pairs at the end of each line, this will cause some regular expressions to fail. This option has no effect on platforms other than MS-DOS and MS-Windows.

-z, --null-data

Treat input and output data as sequences of lines, each terminated by a zero byte (the ASCII NUL character) instead of a newline. Like the **-Z** or **--null** option, this option can be used with commands like **sort -z** to process arbitrary file names.

REGULAR EXPRESSIONS

A regular expression is a pattern that describes a set of strings. Regular expressions are constructed analogously to arithmetic expressions, by using various operators to combine smaller expressions.

grep understands three different versions of regular expression syntax: “basic” (BRE), “extended” (ERE) and “perl” (PCRE). In GNU **grep** there is no difference in available functionality between basic and extended syntaxes. In other implementations, basic regular expressions are less powerful. The following description applies to extended regular expressions; differences for basic regular expressions are summarized afterwards. Perl-compatible regular expressions give additional functionality, and are documented in `pcresyntax(3)` and `pcrpattern(3)`, but work only if PCRE is available in the system.

The fundamental building blocks are the regular expressions that match a single character. Most characters, including all letters and digits, are regular expressions that match themselves. Any meta-character with special meaning may be quoted by preceding it with a backslash.

The period `.` matches any single character.

Character Classes and Bracket Expressions

A *bracket expression* is a list of characters enclosed by `[` and `]`. It matches any single character in that list; if the first character of the list is the caret `^` then it matches any character *not* in the list. For example, the regular expression `[0123456789]` matches any single digit.

Within a bracket expression, a *range expression* consists of two characters separated by a hyphen. It matches any single character that sorts between the two characters, inclusive, using the locale’s collating sequence and character set. For example, in the default C locale, `[a-d]` is equivalent to `[abcd]`. Many locales sort characters in dictionary order, and in these locales `[a-d]` is typically not equivalent to `[abcd]`; it might be equivalent to `[aBbCcDd]`, for example. To obtain the traditional interpretation of bracket expressions, you can use the C locale by setting the `LC_ALL` environment variable to the value `C`.

Finally, certain named classes of characters are predefined within bracket expressions, as follows. Their names are self explanatory, and they are `[:alnum:]`, `[:alpha:]`, `[:cntrl:]`, `[:digit:]`, `[:graph:]`, `[:lower:]`, `[:print:]`, `[:punct:]`, `[:space:]`, `[:upper:]`, and `[:xdigit:]`. For example, `[:alnum:]` means the character class of numbers and letters in the current locale. In the C locale and ASCII character set encoding, this is the same as `[0-9A-Za-z]`. (Note that the brackets in these class names are part of the symbolic names, and must be included in addition to the brackets delimiting the bracket expression.) Most meta-characters lose their special meaning inside bracket expressions. To include a literal `]` place it first in the list. Similarly, to include a literal `^` place it anywhere but first. Finally, to include a literal `-` place it last.

Anchoring

The caret `^` and the dollar sign `$` are meta-characters that respectively match the empty string at the beginning and end of a line.

The Backslash Character and Special Expressions

The symbols `\<` and `\>` respectively match the empty string at the beginning and end of a word. The symbol `\b` matches the empty string at the edge of a word, and `\B` matches the empty string provided it’s *not* at the edge of a word. The symbol `\w` is a synonym for `[_[:alnum:]]` and `\W` is a synonym for `[^_[:alnum:]]`.

Repetition

A regular expression may be followed by one of several repetition operators:

- ?** The preceding item is optional and matched at most once.
- *** The preceding item will be matched zero or more times.
- +** The preceding item will be matched one or more times.
- {*n*}** The preceding item is matched exactly *n* times.
- {*n*,}** The preceding item is matched *n* or more times.

- {,m}** The preceding item is matched at most *m* times. This is a GNU extension.
- {n,m}** The preceding item is matched at least *n* times, but not more than *m* times.

Concatenation

Two regular expressions may be concatenated; the resulting regular expression matches any string formed by concatenating two substrings that respectively match the concatenated expressions.

Alternation

Two regular expressions may be joined by the infix operator `|`; the resulting regular expression matches any string matching either alternate expression.

Precedence

Repetition takes precedence over concatenation, which in turn takes precedence over alternation. A whole expression may be enclosed in parentheses to override these precedence rules and form a subexpression.

Back References and Subexpressions

The back-reference `\n`, where *n* is a single digit, matches the substring previously matched by the *n*th parenthesized subexpression of the regular expression.

Basic vs Extended Regular Expressions

In basic regular expressions the meta-characters `?`, `+`, `{`, `|`, `(`, and `)` lose their special meaning; instead use the backslashed versions `\?`, `\+`, `\{`, `\|`, `\(`, and `\)`.

ENVIRONMENT VARIABLES

The behavior of **grep** is affected by the following environment variables.

The locale for category **LC_foo** is specified by examining the three environment variables **LC_ALL**, **LC_foo**, **LANG**, in that order. The first of these variables that is set specifies the locale. For example, if **LC_ALL** is not set, but **LC_MESSAGES** is set to **pt_BR**, then the Brazilian Portuguese locale is used for the **LC_MESSAGES** category. The C locale is used if none of these environment variables are set, if the locale catalog is not installed, or if **grep** was not compiled with national language support (NLS). The shell command **locale -a** lists locales that are currently available.

GREP_OPTIONS

This variable specifies default options to be placed in front of any explicit options. As this causes problems when writing portable scripts, this feature will be removed in a future release of **grep**, and **grep** warns if it is used. Please use an alias or script instead.

GREP_COLOR

This variable specifies the color used to highlight matched (non-empty) text. It is deprecated in favor of **GREP_COLORS**, but still supported. The **mt**, **ms**, and **mc** capabilities of **GREP_COLORS** have priority over it. It can only specify the color used to highlight the matching non-empty text in any matching line (a selected line when the **-v** command-line option is omitted, or a context line when **-v** is specified). The default is **01;31**, which means a bold red foreground text on the terminal's default background.

GREP_COLORS

Specifies the colors and other attributes used to highlight various parts of the output. Its value is a colon-separated list of capabilities that defaults to **ms=01;31:mc=01;31:sl=:cx=:fn=35:ln=32:bn=32:se=36** with the **rv** and **ne** boolean capabilities omitted (i.e., false). Supported capabilities are as follows.

- sl=** SGR substring for whole selected lines (i.e., matching lines when the **-v** command-line option is omitted, or non-matching lines when **-v** is specified). If however the boolean **rv** capability and the **-v** command-line option are both specified, it applies to context matching lines instead. The default is empty (i.e., the terminal's default color pair).
- cx=** SGR substring for whole context lines (i.e., non-matching lines when the **-v** command-line option is omitted, or matching lines when **-v** is specified). If however the boolean **rv** capability and the **-v** command-line option are both specified, it applies to selected non-matching lines instead. The default is empty (i.e., the terminal's default color pair).

- rv** Boolean value that reverses (swaps) the meanings of the **sl=** and **cx=** capabilities when the **-v** command-line option is specified. The default is false (i.e., the capability is omitted).
- mt=01;31** SGR substring for matching non-empty text in any matching line (i.e., a selected line when the **-v** command-line option is omitted, or a context line when **-v** is specified). Setting this is equivalent to setting both **ms=** and **mc=** at once to the same value. The default is a bold red text foreground over the current line background.
- ms=01;31** SGR substring for matching non-empty text in a selected line. (This is only used when the **-v** command-line option is omitted.) The effect of the **sl=** (or **cx=** if **rv**) capability remains active when this kicks in. The default is a bold red text foreground over the current line background.
- mc=01;31** SGR substring for matching non-empty text in a context line. (This is only used when the **-v** command-line option is specified.) The effect of the **cx=** (or **sl=** if **rv**) capability remains active when this kicks in. The default is a bold red text foreground over the current line background.
- fn=35** SGR substring for file names prefixing any content line. The default is a magenta text foreground over the terminal's default background.
- ln=32** SGR substring for line numbers prefixing any content line. The default is a green text foreground over the terminal's default background.
- bn=32** SGR substring for byte offsets prefixing any content line. The default is a green text foreground over the terminal's default background.
- se=36** SGR substring for separators that are inserted between selected line fields (:), between context line fields, (–), and between groups of adjacent lines when nonzero context is specified (––). The default is a cyan text foreground over the terminal's default background.
- ne** Boolean value that prevents clearing to the end of line using Erase in Line (EL) to Right (**\33[K**) each time a colorized item ends. This is needed on terminals on which EL is not supported. It is otherwise useful on terminals for which the **back_color_erase** (**bce**) boolean terminfo capability does not apply, when the chosen highlight colors do not affect the background, or when EL is too slow or causes too much flicker. The default is false (i.e., the capability is omitted).

Note that boolean capabilities have no **=...** part. They are omitted (i.e., false) by default and become true when specified.

See the Select Graphic Rendition (SGR) section in the documentation of the text terminal that is used for permitted values and their meaning as character attributes. These substring values are integers in decimal representation and can be concatenated with semicolons. **grep** takes care of assembling the result into a complete SGR sequence (**\33[...m**). Common values to concatenate include **1** for bold, **4** for underline, **5** for blink, **7** for inverse, **39** for default foreground color, **30** to **37** for foreground colors, **90** to **97** for 16-color mode foreground colors, **38;5;0** to **38;5;255** for 88-color and 256-color modes foreground colors, **49** for default background color, **40** to **47** for background colors, **100** to **107** for 16-color mode background colors, and **48;5;0** to **48;5;255** for 88-color and 256-color modes background colors.

LC_ALL, LC_COLLATE, LANG

These variables specify the locale for the **LC_COLLATE** category, which determines the collating sequence used to interpret range expressions like **[a–z]**.

LC_ALL, LC_CTYPE, LANG

These variables specify the locale for the **LC_CTYPE** category, which determines the type of characters, e.g., which characters are whitespace. This category also determines the character encoding, that is, whether text is encoded in UTF-8, ASCII, or some other encoding. In the C or POSIX locale, all characters are encoded as a single byte and every byte is a valid character.

LC_ALL, LC_MESSAGES, LANG

These variables specify the locale for the **LC_MESSAGES** category, which determines the language that **grep** uses for messages. The default C locale uses American English messages.

POSIXLY_CORRECT

If set, **grep** behaves as POSIX requires; otherwise, **grep** behaves more like other GNU programs. POSIX requires that options that follow file names must be treated as file names; by default, such options are permuted to the front of the operand list and are treated as options. Also, POSIX requires that unrecognized options be diagnosed as “illegal”, but since they are not really against the law the default is to diagnose them as “invalid”. **POSIXLY_CORRECT** also disables **_GNU_nonoption_argv_flags_**, described below.

_GNU_nonoption_argv_flags_

(Here *N* is **grep**’s numeric process ID.) If the *i*th character of this environment variable’s value is **1**, do not consider the *i*th operand of **grep** to be an option, even if it appears to be one. A shell can put this variable in the environment for each command it runs, specifying which operands are the results of file name wildcard expansion and therefore should not be treated as options. This behavior is available only with the GNU C library, and only when **POSIXLY_CORRECT** is not set.

EXIT STATUS

Normally the exit status is 0 if a line is selected, 1 if no lines were selected, and 2 if an error occurred. However, if the **-q** or **--quiet** or **--silent** is used and a line is selected, the exit status is 0 even if an error occurred.

BUGS**Reporting Bugs**

Email bug reports to [the bug-reporting address](mailto:bug-grep@gnu.org) (bug-grep@gnu.org). An [email archive](http://lists.gnu.org/mailman/listinfo/bug-grep) (http://lists.gnu.org/mailman/listinfo/bug-grep) and a [bug tracker](http://debbugs.gnu.org/cgi/pkgreport.cgi?package=grep) (http://debbugs.gnu.org/cgi/pkgreport.cgi?package=grep) are available.

Known Bugs

Large repetition counts in the $\{n,m\}$ construct may cause **grep** to use lots of memory. In addition, certain other obscure regular expressions require exponential time and space, and may cause **grep** to run out of memory.

Back-references are very slow, and may require exponential time.

grep(1p).

Full Documentation

A [complete manual](http://www.gnu.org/software/grep/manual/) (http://www.gnu.org/software/grep/manual/) is available. If the **info** and **grep** programs are properly installed at your site, the command

info grep

should give you access to the complete manual.

NOTES

This man page is maintained only fitfully; the full documentation is often more up-to-date.

NAME

group – return the group name for a numeric group-id (gid)

SYNOPSIS

edrc/lib/group [**-h**]

group *group-id*

AVAILABILITY

WA2L/edrc

DESCRIPTION

return the group name for a given numeric group-id (gid).

If the group does not exist on the system (or in an equivalent coming from some server somewhere) an empty string is returned.

OPTIONS

-h print usage message.

group-id numeric group id of an existing group on the system.

ENVIRONMENT

-

EXIT STATUS

0 no error.

1 group for given *group-id* does not exist.

4 usage message printed.

NAME

gs – Ghostscript (PostScript and PDF language interpreter and previewer)

SYNOPSIS

gs [*options*] [*files*] ...

DESCRIPTION

The **gs** command invokes **Ghostscript**, an interpreter of Adobe Systems' **PostScript**(tm) and **Portable Document Format** (PDF) languages. **gs** reads "files" in sequence and executes them as Ghostscript programs. After doing this, it reads further input from the standard input stream (normally the keyboard), interpreting each line separately and output to an output device (may be a file or an X11 window preview, see below). The interpreter exits gracefully when it encounters the "quit" command (either in a file or from the keyboard), at end-of-file, or at an interrupt signal (such as Control-C at the keyboard).

The interpreter recognizes many option switches, some of which are described below. Please see the usage documentation for complete information. Switches may appear anywhere in the command line and apply to all files thereafter. Invoking Ghostscript with the **-h** or **-?** switch produces a message which shows several useful switches, all the devices known to that executable, and the search path for fonts; on Unix it also shows the location of detailed documentation.

Ghostscript may be built to use many different output devices. To see which devices your executable includes, run "**gs -h**".

Unless you specify a particular device, Ghostscript normally opens the first one of those and directs output to it.

If you have installed the ghostscript-x Debian package and are under X, the default device is an X11 window (previewer), else ghostscript will use the bbox device and print on stdout the dimension of the postscript file.

So if the first one in the list is the one you want to use, just issue the command

```
gs myfile.ps
```

You can also check the set of available devices from within Ghostscript: invoke Ghostscript and type

```
devicenames ==
```

but the first device on the resulting list may not be the default device you determine with "**gs -h**". To specify "AbcXyz" as the initial output device, include the switch

```
-sDEVICE=AbcXyz
```

For example, for output to an Epson printer you might use the command

```
gs -sDEVICE=epson myfile.ps
```

The "**-sDEVICE=**" switch must precede the first mention of a file to print, and only the switch's first use has any effect.

Finally, you can specify a default device in the environment variable **GS_DEVICE**. The order of precedence for these alternatives from highest to lowest (Ghostscript uses the device defined highest in the list) is:

Some devices can support different resolutions (densities). To specify the resolution on such a printer, use the "**-r**" switch:

```
gs -sDEVICE=<device> -r<xres>x<yres>
```

For example, on a 9-pin Epson-compatible printer, you get the lowest-density (fastest) mode with

```
gs -sDEVICE=epson -r60x72
```

and the highest-density (best output quality) mode with

```
gs -sDEVICE=epson -r240x72.
```

If you select a printer as the output device, Ghostscript also allows you to choose where Ghostscript sends

the output — on Unix systems, usually to a temporary file. To send the output to a file "foo.xyz", use the switch

```
-sOutputFile=foo.xyz
```

You might want to print each page separately. To do this, send the output to a series of files "foo1.xyz, foo2.xyz, ..." using the "-sOutputFile=" switch with "%d" in a filename template:

```
-sOutputFile=foo%d.xyz
```

Each resulting file receives one page of output, and the files are numbered in sequence. "%d" is a printf format specification; you can also use a variant like "%02d".

You can also send output to a pipe. For example, to pipe output to the "**lpr**" command (which, on many Unix systems, directs it to a printer), use the option

```
-sOutputFile=%pipe%lpr
```

You can also send output to standard output:

```
-sOutputFile=--
```

or

```
-sOutputFile=%stdout%
```

In this case you must also use the **-q** switch, to prevent Ghostscript from writing messages to standard output.

To select a specific paper size, use the command line switch

```
-sPAPERSIZE=<paper_size>
```

for instance

```
-sPAPERSIZE=a4
```

or

```
-sPAPERSIZE=legal
```

Most ISO and US paper sizes are recognized. See the usage documentation for a full list, or the definitions in the initialization file "gs_statd.ps".

Ghostscript can do many things other than print or view PostScript and PDF files. For example, if you want to know the bounding box of a PostScript (or EPS) file, Ghostscript provides a special "device" that just prints out this information.

For example, using one of the example files distributed with Ghostscript,

```
gs -sDEVICE=bbbox golfer.ps
```

prints out

```
%%BoundingBox: 0 25 583 732
```

```
%%HiResBoundingBox: 0.808497 25.009496 582.994503 731.809445
```

OPTIONS

-- filename arg1 ...

Takes the next argument as a file name as usual, but takes all remaining arguments (even if they have the syntactic form of switches) and defines the name "ARGUMENTS" in "userdict" (not "systemdict") as an array of those strings, **before** running the file. When Ghostscript finishes executing the file, it exits back to the shell.

-Dname=token

-dname=token

Define a name in "systemdict" with the given definition. The token must be exactly one token (as defined by the "token" operator) and may contain no whitespace.

-Dname

- dname**
Define a name in "systemdict" with value=null.
- Sname=string**
-sname=string
Define a name in "systemdict" with a given string as value. This is different from **-d**. For example, **-dname=35** is equivalent to the program fragment
 /name 35 def
whereas **-sname=35** is equivalent to
 /name (35) def
- P**
Makes Ghostscript to look first in the current directory for library files. By default, Ghostscript no longer looks in the current directory, unless, of course, the first explicitly supplied directory is "." in **-I**. See also the **INITIALIZATION FILES** section below, and bundled **Use.htm** for detailed discussion on search paths and how Ghostscript finds files.
- q**
Quiet startup: suppress normal startup messages, and also do the equivalent of **-dQUIET**.
- gnumber1xnumber2**
Equivalent to **-dDEVICEWIDTH=number1** and **-dDEVICEHEIGHT=number2**. This is for the benefit of devices (such as X11 windows) that require (or allow) width and height to be specified.
- rnumber**
-rnumber1xnumber2
Equivalent to **-dDEVICEXRESOLUTION=number1** and **-dDEVICEYRESOLUTION=number2**. This is for the benefit of devices such as printers that support multiple X and Y resolutions. If only one number is given, it is used for both X and Y resolutions.
- Idirectories**
Adds the designated list of directories at the head of the search path for library files.
- This is not really a switch, but indicates to Ghostscript that standard input is coming from a file or a pipe and not interactively from the command line. Ghostscript reads from standard input until it reaches end-of-file, executing it like any other file, and then continues with processing the command line. When the command line has been entirely processed, Ghostscript exits rather than going into its interactive mode.

Note that the normal initialization file "gs_init.ps" makes "systemdict" read-only, so the values of names defined with **-D**, **-d**, **-S**, or **-s** cannot be changed (although, of course, they can be superseded by definitions in "userdict" or other dictionaries.)

SPECIAL NAMES

- dNOCACHE**
Disables character caching. Useful only for debugging.
- dNOBIND**
Disables the "bind" operator. Useful only for debugging.
- dNODISPLAY**
Suppresses the normal initialization of the output device. This may be useful when debugging.
- dNOPAUSE**
Disables the prompt and pause at the end of each page. This may be desirable for applications where another program is driving Ghostscript.
- dNOPLATFONTS**
Disables the use of fonts supplied by the underlying platform (for instance X Windows). This may be needed if the platform fonts look undesirably different from the scalable fonts.
- dSAFER**
Restricts file operations the job can perform. Strongly recommended for spoolers, conversion scripts or other sensitive environments where a badly written or malicious PostScript program

code must be prevented from changing important files.

-dWRITESYSTEMDICT

Leaves "systemdict" writable. This is necessary when running special utility programs, but is strongly discouraged as it bypasses normal Postscript security measures.

-sDEVICE=device

Selects an alternate initial output device, as described above.

-sOutputFile=filename

Selects an alternate output file (or pipe) for the initial output device, as described above.

SAFER MODE

The **-dSAFER** option disables the "deletefile" and "renamefile" operators and prohibits opening piped commands ("%pipe%cmd"). Only "%stdout" and "%stderr" can be opened for writing. It also disables reading from files, except for "%stdin", files given as a command line argument, and files contained in paths given by LIBPATH and FONTPATH or specified by the system params /FontResourceDir and /GenericResourceDir.

This mode also sets the .LockSafetyParams parameter of the initial output device to protect against programs that attempt to write to files using the OutputFile device parameter. Since the device parameters specified on the command line, including OutputFile, are set prior to SAFER mode, use of "-sOutputFile=..." on the command line is unrestricted.

SAFER mode prevents changing the /GenericResourceDir, /FontResourceDir, /SystemParamsPassword, and /StartJobPassword.

While SAFER mode is not the default, it is the default for many wrapper scripts such as ps2pdf and may be the default in a subsequent release of Ghostscript. Thus when running programs that need to open files or set restricted parameters you should pass the **-dNOSAFAFER** command line option or its synonym **-dDE-LAYSFAFER**.

When running with **-dNOSAFAFER** it is possible to perform a "save" followed by ".setsafe", execute a file or procedure in SAFER mode, and then use "restore" to return to NOSAFER mode. In order to prevent the save object from being restored by the foreign file or procedure, the ".runandhide" operator should be used to hide the save object from the restricted procedure.

FILES

The locations of many Ghostscript run-time files are compiled into the executable when it is built. Run "**gs -h**" to find the location of Ghostscript documentation on your system, from which you can get more details. On a Debian system they are in **/usr**.

/usr/share/ghostscript/[0-9]*.[0.9]*/*

Startup files, utilities, and basic font definitions (where [0-9]*.[0.9]* is the ghostscript version)

/usr/share/fonts/type1/gsfonts/*

More font definitions from the gsfonts package

/usr/share/doc/ghostscript/examples/*

Ghostscript demonstration files (if ghostscript-doc package is installed)

/usr/share/doc/ghostscript/*

Diverse document files (may need to install ghostscript-doc package)

INITIALIZATION FILES

When looking for the initialization files "gs_*.ps", the files related to fonts, or the file for the "run" operator, Ghostscript first tries to open the file with the name as given, using the current working directory if no directory is specified. If this fails, and the file name doesn't specify an explicit directory or drive (for instance, doesn't contain "/" on Unix systems), Ghostscript tries directories in this order:

1. the directories specified by the **-I** switches in the command line (see below), if any;
2. the directories specified by the **GS_LIB** environment variable, if any;

3. the directories specified by the **GS_LIB_DEFAULT** macro in the Ghostscript makefile when the executable was built. **GS_LIB_DEFAULT** is `"/usr/share/ghostscript/[0-9]*.[0-9]*/lib"` on a Debian system where `"[0-9]*.[0-9]*/"` represents the Ghostscript version number

Each of these (**GS_LIB_DEFAULT**, **GS_LIB**, and **-I** parameter) may be either a single directory or a list of directories separated by `":"`.

ENVIRONMENT

GS_OPTIONS

String of options to be processed before the command line options

GS_DEVICE

Used to specify an output device

GS_FONTPATH

Path names used to search for fonts

GS_LIB

Path names for initialization files and fonts

TEMP Where temporary files are made

X RESOURCES

Ghostscript, or more properly the X11 display device, looks for the following resources under the program name "Ghostscript":

borderWidth

The border width in pixels (default = 1).

borderColor

The name of the border color (default = black).

geometry

The window size and placement, `WxH+X+Y` (default is NULL).

xResolution

The number of x pixels per inch (default is computed from **WidthOfScreen** and **WidthMMOfScreen**).

yResolution

The number of y pixels per inch (default is computed from **HeightOfScreen** and **HeightMMOfScreen**).

useBackingPixmap

Determines whether backing store is to be used for saving display window (default = true).

See the usage document for a more complete list of resources. To set these resources on Unix, put them in a file such as `"~/Xresources"` in the following form:

```
Ghostscript*geometry: 612x792-0+0
Ghostscript*xResolution: 72
Ghostscript*yResolution: 72
```

Then merge these resources into the X server's resource database:

```
% xrdp -merge ~/.Xresources
```

SEE ALSO

BUGS

See <http://bugs.ghostscript.com/> and the Usenet news group comp.lang.postscript.

VERSION

This document was last revised for Ghostscript version 9.26.

AUTHOR

Artifex Software, Inc. are the primary maintainers of Ghostscript. Russell J. Lang, [gsview at ghostgum.com.au](mailto:gsview@ghostgum.com.au), is the author of most of the MS Windows code in Ghostscript.

NAME

gzip, *gunzip*, *zcat* – compress or expand files

SYNOPSIS

gzip [**-acdfhlLnNrtvV19**] [**-S suffix**] [*name ...*]

gunzip [**-acfhllNrtvV**] [**-S suffix**] [*name ...*]

zcat [**-fhLV**] [*name ...*]

DESCRIPTION

Gzip reduces the size of the named files using Lempel-Ziv coding (LZ77). Whenever possible, each file is replaced by one with the extension **.gz**, while keeping the same ownership modes, access and modification times. (The default extension is **-gz** for VMS, **z** for MSDOS, OS/2 FAT, Windows NT FAT and Atari.) If no files are specified, or if a file name is "-", the standard input is compressed to the standard output. *Gzip* will only attempt to compress regular files. In particular, it will ignore symbolic links.

If the compressed file name is too long for its file system, *gzip* truncates it. *Gzip* attempts to truncate only the parts of the file name longer than 3 characters. (A part is delimited by dots.) If the name consists of small parts only, the longest parts are truncated. For example, if file names are limited to 14 characters, *gzip.msdos.exe* is compressed to *gzi.msd.exe.gz*. Names are not truncated on systems which do not have a limit on file name length.

By default, *gzip* keeps the original file name and timestamp in the compressed file. These are used when decompressing the file with the **-N** option. This is useful when the compressed file name was truncated or when the time stamp was not preserved after a file transfer.

Compressed files can be restored to their original form using *gzip -d* or *gunzip* or *zcat*. If the original name saved in the compressed file is not suitable for its file system, a new name is constructed from the original one to make it legal.

gunzip takes a list of files on its command line and replaces each file whose name ends with **.gz**, **-gz**, **.z**, **-z**, **_z** or **.Z** and which begins with the correct magic number with an uncompressed file without the original extension. *gunzip* also recognizes the special extensions **.tgz** and **.taz** as shorthands for **.tar.gz** and **.tar.Z** respectively. When compressing, *gzip* uses the **.tgz** extension if necessary instead of truncating a file with a **.tar** extension.

gunzip can currently decompress files created by *gzip*, *zip*, *compress*, *compress -H* or *pack*. The detection of the input format is automatic. When using the first two formats, *gunzip* checks a 32 bit CRC. For *pack*, *gunzip* checks the uncompressed length. The standard *compress* format was not designed to allow consistency checks. However *gunzip* is sometimes able to detect a bad **.Z** file. If you get an error when uncompressing a **.Z** file, do not assume that the **.Z** file is correct simply because the standard *uncompress* does not complain. This generally means that the standard *uncompress* does not check its input, and happily generates garbage output. The SCO *compress -H* format (lzh compression method) does not include a CRC but also allows some consistency checks.

Files created by *zip* can be uncompressed by *gzip* only if they have a single member compressed with the 'deflation' method. This feature is only intended to help conversion of *tar.zip* files to the *tar.gz* format. To extract a *zip* file with a single member, use a command like *gunzip <foo.zip* or *gunzip -S .zip foo.zip*. To extract *zip* files with several members, use *unzip* instead of *gunzip*.

zcat is identical to *gunzip -c*. (On some systems, *zcat* may be installed as *gzcat* to preserve the original link to *compress*.) *zcat* uncompresses either a list of files on the command line or its standard input and writes the uncompressed data on standard output. *zcat* will uncompress files that have the correct magic number whether they have a **.gz** suffix or not.

Gzip uses the Lempel-Ziv algorithm used in *zip* and PKZIP. The amount of compression obtained depends on the size of the input and the distribution of common substrings. Typically, text such as source code or English is reduced by 60–70%. Compression is generally much better than that achieved by LZW (as used in *compress*), Huffman coding (as used in *pack*), or adaptive Huffman coding (*compact*).

Compression is always performed, even if the compressed file is slightly larger than the original. The worst case expansion is a few bytes for the *gzip* file header, plus 5 bytes every 32K block, or an expansion ratio of

0.015% for large files. Note that the actual number of used disk blocks almost never increases. *gzip* preserves the mode, ownership and timestamps of files when compressing or decompressing.

The *gzip* file format is specified in P. Deutsch, GZIP file format specification version 4.3, <ftp://ftp.isi.edu/in-notes/rfc1952.txt>, Internet RFC 1952 (May 1996). The *zip* deflation format is specified in P. Deutsch, DEFLATE Compressed Data Format Specification version 1.3, <ftp://ftp.isi.edu/in-notes/rfc1951.txt>, Internet RFC 1951 (May 1996).

OPTIONS

-a --ascii

Ascii text mode: convert end-of-lines using local conventions. This option is supported only on some non-Unix systems. For MSDOS, CR LF is converted to LF when compressing, and LF is converted to CR LF when decompressing.

-c --stdout --to-stdout

Write output on standard output; keep original files unchanged. If there are several input files, the output consists of a sequence of independently compressed members. To obtain better compression, concatenate all input files before compressing them.

-d --decompress --uncompress

Decompress.

-f --force

Force compression or decompression even if the file has multiple links or the corresponding file already exists, or if the compressed data is read from or written to a terminal. If the input data is not in a format recognized by *gzip*, and if the option *--stdout* is also given, copy the input data without change to the standard output: let *zcat* behave as *cat*. If *-f* is not given, and when not running in the background, *gzip* prompts to verify whether an existing file should be overwritten.

-h --help

Display a help screen and quit.

-l --list For each compressed file, list the following fields:

compressed size: size of the compressed file
uncompressed size: size of the uncompressed file
ratio: compression ratio (0.0% if unknown)
uncompressed_name: name of the uncompressed file

The uncompressed size is given as -1 for files not in gzip format, such as compressed .Z files. To get the uncompressed size for such a file, you can use:

```
zcat file.Z | wc -c
```

In combination with the *--verbose* option, the following fields are also displayed:

method: compression method
crc: the 32-bit CRC of the uncompressed data
date & time: time stamp for the uncompressed file

The compression methods currently supported are deflate, compress, lzh (SCO compress -H) and pack. The crc is given as ffffffff for a file not in gzip format.

With *--name*, the uncompressed name, date and time are those stored within the compress file if present.

With *--verbose*, the size totals and compression ratio for all files is also displayed, unless some sizes are unknown. With *--quiet*, the title and totals lines are not displayed.

-L --license

Display the *gzip* license and quit.

-n --no-name

When compressing, do not save the original file name and time stamp by default. (The original name is always saved if the name had to be truncated.) When decompressing, do not restore the original file name if present (remove only the *gzip* suffix from the compressed file name) and do not restore the original time stamp if present (copy it from the compressed file). This option is the default when decompressing.

-N --name

When compressing, always save the original file name and time stamp; this is the default. When decompressing, restore the original file name and time stamp if present. This option is useful on systems which have a limit on file name length or when the time stamp has been lost after a file transfer.

-q --quiet

Suppress all warnings.

-r --recursive

Travel the directory structure recursively. If any of the file names specified on the command line are directories, *gzip* will descend into the directory and compress all the files it finds there (or decompress them in the case of *gunzip*).

-S .suf --suffix .suf

Use suffix *.suf* instead of *.gz*. Any suffix can be given, but suffixes other than *.z* and *.gz* should be avoided to avoid confusion when files are transferred to other systems. A null suffix forces *gunzip* to try decompression on all given files regardless of suffix, as in:

```
gunzip -S "" *      (*. * for MSDOS)
```

Previous versions of *gzip* used the *.z* suffix. This was changed to avoid a conflict with *pack(1)*.

-t --test

Test. Check the compressed file integrity.

-v --verbose

Verbose. Display the name and percentage reduction for each file compressed or decompressed.

-V --version

Version. Display the version number and compilation options then quit.

-# --fast --best

Regulate the speed of compression using the specified digit #, where **-1** or **--fast** indicates the fastest compression method (less compression) and **-9** or **--best** indicates the slowest compression method (best compression). The default compression level is **-6** (that is, biased towards high compression at expense of speed).

ADVANCED USAGE

Multiple compressed files can be concatenated. In this case, *gunzip* will extract all members at once. For example:

```
gzip -c file1 > foo.gz
gzip -c file2 >> foo.gz
```

Then

```
gunzip -c foo
```

is equivalent to

```
cat file1 file2
```

In case of damage to one member of a .gz file, other members can still be recovered (if the damaged member is removed). However, you can get better compression by compressing all members at once:

```
cat file1 file2 | gzip > foo.gz
```

compresses better than

```
gzip -c file1 file2 > foo.gz
```

If you want to recompress concatenated files to get better compression, do:

```
gzip -cd old.gz | gzip > new.gz
```

If a compressed file consists of several members, the uncompressed size and CRC reported by the --list option applies to the last member only. If you need the uncompressed size for all members, you can use:

```
gzip -cd file.gz | wc -c
```

If you wish to create a single archive file with multiple members so that members can later be extracted independently, use an archiver such as tar or zip. GNU tar supports the -z option to invoke gzip transparently. gzip is designed as a complement to tar, not as a replacement.

ENVIRONMENT

The environment variable **GZIP** can hold a set of default options for *gzip*. These options are interpreted first and can be overwritten by explicit command line parameters. For example:

for sh: `GZIP="-8v --name"; export GZIP`

for csh: `setenv GZIP "-8v --name"`

for MSDOS: `set GZIP=-8v --name`

On Vax/VMS, the name of the environment variable is GZIP_OPT, to avoid a conflict with the symbol set for invocation of the program.

SEE ALSO

znew(1), zcmp(1), zmore(1), zforce(1), gzexe(1), zip(1), unzip(1), compress(1), pack(1), compact(1)

The *gzip* file format is specified in P. Deutsch, GZIP file format specification version 4.3, <<ftp://ftp.isi.edu/in-notes/rfc1952.txt>>, Internet RFC 1952 (May 1996). The *zip* deflation format is specified in P. Deutsch, DEFLATE Compressed Data Format Specification version 1.3, <<ftp://ftp.isi.edu/in-notes/rfc1951.txt>>, Internet RFC 1951 (May 1996).

DIAGNOSTICS

Exit status is normally 0; if an error occurs, exit status is 1. If a warning occurs, exit status is 2.

Usage: `gzip [-cdfhLnNrtvV19] [-S suffix] [file ...]`

Invalid options were specified on the command line.

file: not in gzip format

The file specified to *gunzip* has not been compressed.

file: Corrupt input. Use zcat to recover some data.

The compressed file has been damaged. The data up to the point of failure can be recovered using

```
zcat file > recover
```

file: compressed with *xx* bits, can only handle *yy* bits

File was compressed (using LZW) by a program that could deal with more *bits* than the decompress code on this machine. Recompress the file with gzip, which compresses better and uses less

memory.

file: already has .gz suffix -- no change

The file is assumed to be already compressed. Rename the file and try again.

file already exists; do you wish to overwrite (y or n)?

Respond "y" if you want the output file to be replaced; "n" if not.

gunzip: corrupt input

A SIGSEGV violation was detected which usually means that the input file has been corrupted.

xx.x% Percentage of the input saved by compression.

(Relevant only for **-v** and **-l**.)

-- not a regular file or directory: ignored

When the input file is not a regular file or directory, (e.g. a symbolic link, socket, FIFO, device file), it is left unaltered.

-- has *xx* other links: unchanged

The input file has links; it is left unchanged. See *ln(1)* for more information. Use the **-f** flag to force compression of multiply-linked files.

CAVEATS

When writing compressed data to a tape, it is generally necessary to pad the output with zeroes up to a block boundary. When the data is read and the whole block is passed to *gunzip* for decompression, *gunzip* detects that there is extra trailing garbage after the compressed data and emits a warning by default. You have to use the **--quiet** option to suppress the warning. This option can be set in the **GZIP** environment variable as in:

```
for sh: GZIP="-q" tar -xfz --block-compress /dev/rst0
```

```
for csh: (setenv GZIP -q; tar -xfz --block-compr /dev/rst0
```

In the above example, *gzip* is invoked implicitly by the **-z** option of GNU *tar*. Make sure that the same block size (**-b** option of *tar*) is used for reading and writing compressed data on tapes. (This example assumes you are using the GNU version of *tar*.)

BUGS

The *gzip* format represents the input size modulo 2^{32} , so the **--list** option reports incorrect uncompressed sizes and compression ratios for uncompressed files 4 GB and larger. To work around this problem, you can use the following command to discover a large uncompressed file's true size:

```
zcat file.gz | wc -c
```

The **--list** option reports sizes as **-1** and crc as **ffffff** if the compressed file is on a non seekable media.

In some rare cases, the **--best** option gives worse compression than the default compression level (**-6**). On some highly redundant files, *compress* compresses better than *gzip*.

NAME

h2 – H" free Java SQL database engine

SYNOPSIS

edrc/bin/h2 [**-help** | **-?**]

h2 [**-url** *url*] [**-driver** *driver*] [**-user** *user*] [**-password** *password*] [**-web**] [**-tool**] [**-browser**] [**-tcp**] [**-pg**]]

AVAILABILITY

WA2L/edrc

DESCRIPTION

H2 is a relational database management system written in Java. It can be embedded in Java applications or run in the client-server mode. The disk footprint (size of the jar file) is about 2.5 MB.

OPTIONS

-help usage message.

-? usage message.

-url *url* start a browser and connect to this URL

-driver *driver*
 used together with -url: the driver

-user *user* used together with -url: the user name

-password *password*
 used together with -url: the password

-web start the web server with the H2 Console

-tool start the icon or window that allows to start a browser

-browser start a browser connecting to the web server

-tcp start the TCP server

-pg start the PG server

For each server, additional options are available; for details, see the server tool.

ENVIRONMENT

See HTML H2 documentation in <http://www.h2database.com>.

EXIT STATUS

See HTML H2 documentation in <http://www.h2database.com>.

FILES

See HTML H2 documentation in <http://www.h2database.com>.

EXAMPLES

See HTML H2 documentation in <http://www.h2database.com>.

SEE ALSO

NAME

histlist – print shell history files

SYNOPSIS

edrc/lib/histlist [**-h**]

histlist [*histfile* [*number*]]

AVAILABILITY

WA2L/edrc

DESCRIPTION

print a table of history files including the resolution of usage begin, usage end, history file size and history file name.

The begin can be resolved properly only if the history file names comply to the history file names as produced by the **shell**(1) command when started outside **edrc**.

OPTIONS

-h usage message.

histfile history file. The **histlist** command searches the directory of the given *histfile* for other history files that will be listed by the command.

number number of most recent history files listed.

ENVIRONMENT**\$HISTFILE**

history file.

EXIT STATUS

0 no error

4 usage listed.

FILES

`~<USER>/eshell/sh_history/./<MIL-DATE>_<TIME>.<TTY>`
default history file.

EXAMPLES

-

SEE ALSO

edrcintro(1), **eshell(1)**, **shell(1)**

NOTES

when calling the **histlist** command within **shell(1)** or **eshell(1)** you are actually calling an alias having the definition:

```
alias histlist='\histlist $HISTFILE 100'
```

BUGS

NAME

homedir – Get Home Directory of a User

SYNOPSIS

edrc/lib/homedir [*user*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

The **homedir** command returns the logical path of a given user to standard output. In the C-shell and the Korn-shell this corresponds to **cd** *~user* . The **homedir user** command is especially useful in Bourne-shell scripts, where the above command with *~* does not work.

OPTIONS

user username of the user whose homedir has to be resolved.

EXIT STATUS

0 always

EXAMPLES

1) HOWTO use homedir to evaluate a home directory of a user

```
[ /home/user ]  
[ user@client ] [ksh]: homedir sfitools  
/apl/sfitools
```

SEE ALSO

edrcintro(1), **gid(3)**, **gecos(3)**, **group(3)**, **uid(3)**, **user(3)**

FILES

/etc/passwd
(or related NIS/NIS+ table)

NOTES

Parts of this manpage were extracted from the documentation of the **SFI-Director** and modified to fit to the **WA2L/edrc** package. See <http://sfidirector.sourceforge.net> for more information about the **SFI-Director**.

BUGS

NAME

hostaliases – return aliases for a hostname

SYNOPSIS

edrc/lib/hostaliases [**-h**]

hostaliases *hostname*

AVAILABILITY

WA2L/edrc

DESCRIPTION

return all defined aliases for a given hostname.

OPTIONS

-h print usage message.

hostname name of a host.

ENVIRONMENT

-

EXIT STATUS

0 no error.

1 no aliases found for a given host.

4 usage message printed.

NAME

hostlist – return a list of hosts

SYNOPSIS

edrc/lib/hostlist [**-h**]

hostlist

hostlist [**-g** *hostgroupname*{[,*hostgroupname*]}][**-l**]

hostlist -p

hostlist -i | -y | -j

AVAILABILITY

WA2L/edrc

DESCRIPTION

The **hostlist** command returns a list of hosts.

The intention is, that the output generated by **hostlist** is used as input for scripts or commands which compute commands/jobs on this list of hosts. Therefore there is only one source list of hosts being part of an environment and when a host is added/removed to/from it, only the **edrc/etc/hostlist.cfg** configuration file has to be adjusted and not all scripts which have to deal with a list of hosts.

hostlist can be used together with the **server_environment**(3) command in the configuration file **edrc/etc/hostlist.cfg** to enable **hostlist** to return the list of hosts that are part of a certain named server environment. E.g. the list of hosts in the PRODUCTION environment is different from the list of hosts in the DEVELOPMENT environment for an enterprise. See **hostlist.cfg**(4) for more information.

To compute different sets of hosts as returned by a call of **hostlist**, it is possible to define groups of hosts that can be accessed via a *hostgroupname*. This enables the abstraction of a group of hosts to a group name (*@HOSTGROUP*).

On complex configurations the resolution performance might decrease. To avoid this, the resolution cache can be used (**CACHE=True** in **edrc/etc/hostlist.cfg**). The cache data depends on the timestamps and file-sizes of a configurable set of files (**CACHE_DEPENDENCY=" file_1 file_2 ... file_n-1 file_n "**), the **hostlist**(3) and **server_environment**(3) command files, and the hostname as resolved by **hostname**(1). The resolution cache is read/write for the WA2L/edrc owner and read only for all other users.

OPTIONS

return the list of hosts being part of the current server environment. See also **server_environment**(3) for information about the definition of server environments.

- h** usage message.

- g** *hostgroupname_list*
 comma separated list of *hostgroupname*. The convention is, that *hostgroups* always start with the @ character.

- l** the returned list of hosts is comma separated instead of space separated (=default). This eases further processing of the output as handing over the output to the **-t** option of **rcmd**.

- p** print all configured host groups in human readable form. The item listed without a *HOSTGROUP* name is the output of **hostlist** when used without an option.

 The *HOSTGROUPS* having a name starting with an underscore (_) should **not** be used interactively, due to the fact that the convention is, that those *HOSTGROUPS* are used internally within configuration files only.

- i** print all configured host groups as Ansible inventory ini file format.

 The *HOSTGROUPS* having a name starting with an underscore (_) are *HOSTGROUPS* that are used internally in WA2L/edrc within configuration files.

- y** print all configured host groups as Ansible inventory yaml file format.

 The *HOSTGROUPS* having a name starting with an underscore (_) are *HOSTGROUPS* that are used internally in WA2L/edrc within configuration files.

- j** print all configured host groups as Ansible inventory json file format.

 The *HOSTGROUPS* having a name starting with an underscore (_) are *HOSTGROUPS* that are used internally in WA2L/edrc within configuration files.

ENVIRONMENT

-

EXIT STATUS

- 0** no error.

- 2** a file that is defined in the **CACHE_DEPENDENCY** file list does not exist.

- 4** usage printed.

- 6** configuration file **edrc/etc/hostlist.cfg** does not exist.

FILES

edrc/etc/hostlist.cfg

configuration file of **hostlist**. this file contains all host list and host group definitions.

edrc/var/cache/hostlist/

resolution cache of the **hostlist** command if the **CACHE** setting in the configuration file **edrc/etc/hostlist.cfg** is set to *True*.

edrc/var/cache/hostlist/meta

meta data for the resolution cache. This file is used to check if the cache data is still valid.

edrc/var/cache/hostlist/data

this file contains the cache data, the resolved **HOSTLIST** and **HOSTGRPS** settings for the system where **hostlist** has been executed.

edrc/var/samples/hostlist/

configuration examples for **hostlist(3)** and **server_environment(3)**.

EXAMPLES

1) command line usage example

```
[ /home/wilma ]
[ wilma@adm_db1_prod ][-ksh]: ~edrc/lib/hostlist

dcdbsi20 dcdbsi21 dcdbsi30 dcdbsi31 dcdbsi32 dcdbsi33
```

2) command line usage example using a hostgroup

```
[ /home/wilma ]
[ wilma@adm_db1_prod ][-ksh]: ~edrc/lib/hostlist -g @ADM

adm_db1_mnt adm_db1_tst adm_db1_pre adm_db1_prod
```

3) use of hostlist in configuration files

The use of **hostlist** in configuration files eases the configuration due to the fact that the target list of hosts can be centralized to one single configuration file (the **edrc/etc/hostlist.cfg** file) and changes in the server environment will be propagated to all tools used.

Example of the use of **hostlist** in the **edrc/etc/edrc.cfg** configuration file:

```
:
:

# Space separated list of hosts. To this hosts
# the files in SCRIPTS_BASEDIR will be distributed.
#
DIST_HOSTLIST="`hostlist -g @_DIST`"

:
```

:

Example of the use of **hostlist** in the **edrc/etc/passwdsyncd.cfg** configuration file:

:

:

```
# Space separated list of hosts. To this hosts
# the password information will be distributed.
#
SYNC_HOSTLIST="'hostlist'"
```

:

:

4) usage in scripts

Print uptime of all systems in a server environment.

:

:

```
targets='hostlist -l'
rcmd -n -t $targets -c "sysinfo -u" | sort
```

:

:

SEE ALSO

edrcintro(1), **hostlist.cfg**(4), **hostlistdat2cfg**(3), **rcmd**(1), **resolve_targetlist**(3), **server_environment**(3), **edrc/var/samples/hostlist/**

NOTES

The commands **rcmd**(3) and **filelist**(1) use **hostlist** internally to resolve the list of hosts being part of the server environment where logged in.

BUGS

NAME

hostlist.cfg – configuration file for hostlist

SYNOPSIS

edrc/etc/hostlist.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **hostlist** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**HOSTLIST**

Definition of hosts that are returned when invoking **hostlist** without options.

Example: HOSTLIST="dcdbsi20 dcdbsi21 dcdbsi30 dcdbsi31 dcdbsi32 dcdbsi33"

Default: HOSTLIST=""

HOSTGRPS

Definitions of groups of hosts that are returned when invoking **hostlist** with the **-g @GRP-NAME** option.

Example: HOSTGRPS="@ADM: adm_db1_mnt adm_db1_tst adm_db1_pre adm_db1_prod
@BE: dcdbsi20 dcdbsi21 dcdbsi30 dcdbsi31 dcdbsi32"

Default: HOSTGRPS=""

CACHE Set this setting to *True* to cache the resolved **HOSTLIST** and **HOSTGRPS** settings, set it to *False* to not to use a cache.

Example: CACHE=True

Default: CACHE=False

CACHE_DEPENDENCY

List of files on which the cache data depends on. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation. This setting is only active if the **CACHE** setting is set to *True*.

Example: CACHE_DEPENDENCY="etc/hostlist.cfg etc/hostlist.dat etc/server_environment.cfg"

Default: CACHE_DEPENDENCY="etc/hostlist.cfg etc/server_environment.cfg"

EXAMPLES

1) very simple configuration for one environment

This configuration contains the servers in the environment (PRODUCTION) of an enterprise where WA2L/edrc is installed. If WA2L/edrc is installed in other environments (TEST, PRE-PRODUCTION), too, a specific **edrc/etc/hostlist.cfg** configuration file has to be defined for each environment.

```
#
# Purpose of the different HOSTGRPS:
#
#   @_DIST:      Distribution group where edrc distributes when invoking t
#                 edrc 'distribute' command. Do not use this group for manu
#                 invocations of rcmd or filedist.

# List of hosts / Groups of hosts
#
HOSTLIST="dcdbsi20 dcdbsi21 dcdbsi30 dcdbsi31 dcdbsi32 dcdbsi33"
HOSTGRPS="@_DIST:
                                dcdbsi20 dcdbsi21 dcdbsi30 dcdbsi31 dcdbsi3
                                dcdbsi33
"
```

2) advanced config for multiple environments

To have a single **edrc/etc/hostlist.cfg** configuration file for all environments (TEST, PREPRODUCTION, PRODUCTION) in the enterprise the **server_environment(3)** command can be used in the configuration file. In this configuration file example the **HOSTLIST** definition is defined for each environment with the focus to the related environment and because the **HOSTGRPS** definition is identical for all environments it can be defined once. If **HOSTGRPS** are different for each environment it has to be defined for each environment, too.

```
#
# Purpose of the different HOSTGRPS:
#
```

```

#   @_DIST:      Distribution group where edrc distributes when invoking t
#                 edrc 'distribute' command. Do not use this group for manu
#                 invocations of rcmd or filedist.
#   @ALL:        All servers of the whole environment (MAINTENANCE, TEST,
#                 PREPRODUCTION and PRODUCTION)
#
# Groups of hosts
#
HOSTGRPS="@_DIST:
                                dcdbsi20 dcdbsi21 dcdbsi30 dcdbsi31 dcdbsi3
                                dcdbsi33
                                dcdbsi61 dcdbsi62 dcdbsi63 dcdbsi64
                                dcdbsi71 dcdbsi72 dcdbsi73 dcdbsi74
                                dcdbsi50
                                @ALL:
                                dcdbsi20 dcdbsi21 dcdbsi30 dcdbsi31 dcdbsi3
                                dcdbsi33
                                dcdbsi61 dcdbsi62 dcdbsi63 dcdbsi64
                                dcdbsi71 dcdbsi72 dcdbsi73 dcdbsi74
                                "

# List of hosts
#
case `server_environment` in
    PRODUCTION)
        HOSTLIST="dcdbsi20 dcdbsi21 dcdbsi30 dcdbsi31 dcdbsi32
        ;;
    PREPRODUCTION)
        HOSTLIST="dcdbsi61 dcdbsi62 dcdbsi71 dcdbsi72"
        ;;
    TEST)
        HOSTLIST="dcdbsi63 dcdbsi64 dcdbsi73 dcdbsi74"
        ;;
esac

```

3) advanced config for multiple environments with disaster recovery support

The setup in this disaster recovery scenario is, that the PREPRODUCTION is used to recover the PRODUCTION environment to.

If the file `./DISASTER_CASE` exists it is assumed that a DISASTER CASE SITUATION exists. In that case the list of hosts is returned that correlated to this situation. To make this happen the configuration `edrc/etc/server_environment.cfg` has to be replaced by a configuration file that returns PRODUCTION for the hosts being part of the former PREPRODUCTION environment.

```

# List of hosts / Groups of hosts
#
case `server_environment` in
    PRODUCTION)
        if [ -f ./DISASTER_CASE ]; then
            ##

```

```

## DISASTER CASE SITUATION
## All servers from the PREPRODUCTION are used to for
## PRODUCTION environment.
## The HOSTGRPS are restricted PREPRODUCTION host
## encapsulate the 'Disaster Recovery Environment'
## the other environments during a 'Disaster Simul
## or a 'Disaster Case'.
##
##
HOSTLIST="dcdbsi61 dcdbsi62 dcdbsi71 dcdbsi72"
HOSTGRPS="@_DIST:
                                dcdbsi61 dcdbsi62 dcdbsi7
                                dcdbsi50
                                @ALL:
                                dcdbsi61 dcdbsi62 dcdbsi7
                                "
else
##
## NORMAL OPERATION SITUATION
##
HOSTLIST="dcdbsi20 dcdbsi21 dcdbsi30 dcdbsi31 dcdbsi32
HOSTGRPS="@_DIST:
                                dcdbsi20 dcdbsi21 dcdbsi3
                                dcdbsi33
                                dcdbsi61 dcdbsi62 dcdbsi6
                                dcdbsi71 dcdbsi72 dcdbsi7
                                dcdbsi50
                                @ALL:
                                dcdbsi20 dcdbsi21 dcdbsi3
                                dcdbsi33
                                dcdbsi61 dcdbsi62 dcdbsi6
                                dcdbsi71 dcdbsi72 dcdbsi7
                                "
fi
;;

:
:

esac

```

4) define hosts in hostlist.dat

This is the definition as documented in **edrcsetup**(1m) of WA2L/edrc starting with release 1.5.43 and is also the configuration file contents that is distributed with the full application package from now on (see also: **edrc/var/samples/hostlist/07/** and **edrc/var/samples/hostlist/08/**).

To define the hosts and groups in the **hostlist.dat** file, set the **USE_HOSTLIST_DAT** setting to *True*.

```

:
:

```

```

# Set USE_HOSTLIST_DAT to True, if hosts are listed in
# the etc/hostlist.dat file, if hosts are defined directly
# in etc/hostlist.cfg, set USE_HOSTLIST_DAT to False.
#
USE_HOSTLIST_DAT=True

# Define the central administration environment in the
# format CUSTOMER.NAME as defined in server_environment.cfg.
#
CMAN_ENVIRONMENT="Highlander.ADMIN"

# Read hostlist.dat definitions as resolved.
#
if [ "$USE_HOSTLIST_DAT" = True ]; then
    case `server_environment -C`.`server_environment` in
        $CMAN_ENVIRONMENT)
            out=`hostlistdat2cfg -o -m MGRPS_LIST=@LINUX,@SOLARIS,@
            *) out=`hostlistdat2cfg -o` ;;
        esac
        . $out; removetemp -q -d `dirname ${out}`; return 0
    fi

# List of hosts when defined directly in the hostlist.cfg
# file.
#
case `server_environment -C`.`server_environment` in
    WA2L.EDRC_DVLP)
        HOSTLIST="
        "
        HOSTGRPS="@_DIST:
        @ALL:
        "
        ;;
    esac

```

NAME

hostlist.dat – list of hosts for the hostlist command

SYNOPSIS

edrc/etc/hostlist.dat

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the host list definition for the **hostlistdat2cfg** command which converts this data file to a format that can be computed by the **hostlist** command.

FILEFORMAT

The fileformat is a list of definitions that have the format

CUSTOMER;ENVIRONMENT;GROUPS;OPTIONS;HOSTS;

Rows starting with a # are considered as comments. Empty lines are allowed, too.

OPTIONS

CUSTOMER

customer name as defined in **edrc/etc/server_environment.cfg**.

ENVIRONMENT

customer environment name as defined in **edrc/etc/server_environment.cfg**.

GROUPS

space separated list of host groups.

OPTIONS

Additional options for a row. Currently this field is not resolved and should be left empty.

HOSTS

space separated list of hosts.

EXAMPLES

```
#
# etc/hostlist.dat - hostlist csv database file
#
# [00] 12.08.2008 CWa    Initial Version
#
#
# Format:
#
# <CUSTOMER>;<ENVIRONMENT>;<GROUPS>;<OPTIONS>;<HOSTS>;
#
# To verify the syntax, use: hostlistdat2cfg -a list_dat
# Only correct entries will be listed.
#
Highlander ;ADMIN          ;          ;;adm-linux adm-hpux adm-solaris;
Highlander ;REPORT        ;          ;;rpt-001 rpt-002;
ACME       ;DEVELOPMENT   ;@APP      ;;host-001 host-002;
ACME       ;DEVELOPMENT   ;@DB       ;;host-003;
ACME       ;TEST          ;          ;;host-101 host-103;
ACME       ;PREPRODUCTION ;          ;;host-201 host-203 host-205;
ACME       ;PRODUCTION    ;          ;;host-303 host-308 host-309;
ACME       ;              ;@PING     ;;ping-001 ping-002 ping-003;
#

                ub2004 \
                suse110 suse110-32 suse113 \
                suse114 suse123 suse152;
```

SEE ALSO

edrcintro(1), **hostlist(3)**, **hostlist.cfg(4)**, **hostlistdat2cfg(3)**, **server_environment(3)**, **server_environment.cfg(4)**

NOTES

the reason why the **hostlist.dat** file is converted using **hostlistdat2cfg** into a file that can be computed by the **hostlist** command is, that first the **hostlist.cfg** existed and over time it turned out to be too complicated to maintain, but a backward compatible solution was needed.

Therefore it is recommended to define the list of hosts in the **hostlist.dat** file and not any more in the **hostlist.cfg** file.

BUGS

NAME

hostlistdat2cfg – generate hostlist.cfg from hostlist.dat

SYNOPSIS

edrc/lib/hostlistdat2cfg [**-h**]

hostlistdat2cfg [**-o**]

hostlistdat2cfg [**-f** *file* ...] [*central_opt*] [*action_opt*] [*env_opt*]

central_opt ::= **-m** [[**XGRPS_PREF**=*string*] [**XGRPS_LEGACY**] [**MGRPS_LIST**=*hostgroup*list]]

action_opt ::= **-a** { [**print_cfg**] [**-o**] | **list_dat** [*type_opt*] | **list_res** [*type_opt*] }

env_opt ::= **-n** *CUSTOMER.NAME*

type_opt ::= **-t** { **table** | **csv** | **csv_header** }

AVAILABILITY

WA2L/edrc

DESCRIPTION

convert a **hostlist.dat** file that has the structure

Example:

```
#
# Format:
#
#   <CUSTOMER>; <ENVIRONMENT>; <GROUPS>; <OPTIONS>; <HOSTS>
#
ACME;DEVELOPMENT      ;@APP      ;;host-001 host-002;
ACME;DEVELOPMENT      ;@DB       ;;host-003;
ACME;TEST              ;@APP      ;;host-101 host-103;
ACME;PREPRODUCTION    ;@APP      ;;host-201 host-202 host-205;
ACME;PRODUCTION        ;@APP      ;;host-303 host-308 host-309;
```

into settings that can be used in the **hostlist.cfg** file.

This command will significantly simplify the definition of host lists of large environments and will make the more complicated constructs obsolete where using the **fmatch**(3) command in the **hostlist.cfg**(4) configuration file.

Despite the many options that the **hostlistdat2cfg** provides, normally only the **-m** and the **-o** options will be used in the **hostlist.cfg** config file. See also samples in the **edrc/var/samples/hostlist** directory.

OPTIONS

-h print usage message.

-o write configuration to temporary file and return the name of the the temporary file.

The output is written to a temporary directory that is generated by the **maketemp(3)** command internally. Therefore the tempfile can be removed using **removetemp(3)** later:

```
out=`hostlistdat2cfg -o`
. $out
removetemp -q -d `dirname ${out}`
```

-f file... a list of csv files. If this option is not specified, the **edrc/etc/hostlist.dat** file is read by default.

The csv files is a semicolon separated file having the format as explained below. Rows can span multiple lines in the file, if they end with a backslash (\).

To verify the syntax of the csv file, use the command **hostlistdat2cfg -a list_dat -f file** which will only list the correct rows.

Format:

CUSTOMER;ENVIRONMENT;GROUPS;OPTIONS;HOSTS;

Keys:

CUSTOMER

Customer name as returned by **server_environment -C**.

ENVIRONMENT

Environment name as returned by **server_environment**. If this field is left empty, the row is valid for all environments of the *CUSTOMER*.

GROUPS Space separated list of hostgroups (*@HOSTGRP*) as known from the **hostlist(3)** command.

The *GROUPS* *@ALL* and *@_DIST* are generated automatically out of all hosts specified in the *HOSTS* field for the *ENVIRONMENT*s of a *CUSTOMER*.

If certain host(s) should be excluded from the *@ALL* or *@_DIST* group, specify *-@ALL* or *-@_DIST* in the *GROUPS* field.

OPTIONS Additional options for a row. Currently this field is not resolved and should be left empty.

HOSTS space separated list of hosts.

-m [*options*]

options:

XGRPS_PREF=*string*

cross env HOSTGRPS prefix (default="")

XGRPS_LEGACY

also create legacy customer HOSTGRPS omitting **.ALL**.

MGRPS_LIST=*hostgroup**list*

comma separated HOSTGRPS to be merged.

-a *action* action:

print_cfg print the **hostlist.cfg** configuration structure. If no action is given, this is the default action.

list_dat list the data of the given csv (**hostlist.dat**) file(s). This option can be used to check if the syntax of the processed csv file(s) is correct, because only correct columns are printed.

list_res list resolved **hostlist.dat** file for the related environment. This option can also be used for further data processing.

-t *type* type:

table list in table format. If no type is given, this is the default output type.

csv list in csv format. When using this option, only the data rows are listed.

csv_header

list the header row for the **csv** output.

-n *CUSTOMER.NAME*

set the *CUSTOMER* and *ENVIRONMENT* name.

This enables to test a configuration for an certain environment without logging in to it.

If this option is not used, the default is the customer name and environment of the server where logged on as returned by **server_environment -C** (=CUSTOMER) and **server_environment** (=NAME).

ENVIRONMENT

-

EXIT STATUS

| | |
|----------|------------------------|
| 0 | no error. |
| 4 | usage message printed. |

FILES**edrc/etc/hostlist.dat**configuration file of **hostlistdat2cfg**. This file contains all host list and host group definitions.**EXAMPLES****1) print config for environment where logged on:**`hostlistdat2cfg`**2) print central management config for environment where logged on:**`hostlistdat2cfg -m`**3) print central management config for environment where logged on and merge all operating system groups (@SOLARIS, @LINUX ...) that are defined in all customer environments:**`hostlistdat2cfg -m MGRPS_LIST=@LINUX,@SOLARIS,@HPUX`

With that the local @ANY.SOLARIS group will contain all hosts that are member of @SOLARIS groups in all customer environments.

4) use hostlistdat2cfg in etc/hostlist.dat:

```
USE_HOSTLIST_DAT=True
CMAN_ENVIRONMENT="Highlander.ADMIN"

if [ "$USE_HOSTLIST_DAT" = True ]; then
  case `server_environment -C`.`server_environment` in
    $CMAN_ENVIRONMENT)
      out=`hostlistdat2cfg -o -m MGRPS_LIST=@LINUX,@SOLARIS,@HPUX`;
      *) out=`hostlistdat2cfg -o`;
    esac
  . $out; removetemp -q -d `dirname ${out}`; return 0
fi
```

5) example with complete file set server_environment.cfg, hostlist.cfg and hostlist.dat

edrc/etc/server_environment.cfg

```

NAME

html2mht – convert a HTML file to a single Web Archive file (MHT)

SYNOPSIS

edrc/lib/html2mht [**-h**]

html2mht **-i** *htmlfile* **-o** *mhtfile* [**-f**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

convert a HTML file that has referenced images to a single web archive file (mht) that contains the image files.

The MHT file can be viewed using the Microsoft Internet Explorer (TM) or an other MHT viewer.

OPTIONS

-h print usage message.

-i *htmlfile* input HTML file to be converted.

-o *mhtfile* output MHT file. To be able to read the file directly by the Microsoft Internet Explorer (TM) the *mhtfile* should be named *filename.mht* .

-f force overwriting of the output *mhtfile*.

ENVIRONMENT

-

EXIT STATUS

0 no error.

1 *mhtfile* does already exist.

2 *htmlfile* cannot be read.

- 4 usage message printed.
- 5 cannot write to output file *mhtfile*.
- 6 cannot write to output directory of *mhtfile*.

FILES

edrc/var/samples/html2mht/
example files to test **html2mht(3)**.

EXAMPLES

-

SEE ALSO

edrcintro(1), **edrc/var/samples/html2mht/**

NOTES

-

BUGS

CSS files and JavaScript files have to be included in the *htmlfile* to be converted.

AUTHOR

NAME

indent – continuous unbuffered output with an indent

SYNOPSIS

edrc/lib/indent [*width* [*output_channel*]]

(deprecated: **ident** [*width*])

AVAILABILITY

WA2L/edrc

DESCRIPTION

continuous output of characters received via **stdin** with a leading indent (*width*) on each line.

OPTIONS

width width of output indent. If not specified the default of 4 applies.

output_channel

if set to **1** the leading indent goes to **stdout** which is the default. If set to **2** the leading indent goes to **stderr**.

ENVIRONMENT

-

EXIT STATUS

0 no error.

FILES

-

EXAMPLES**1) indented output of a file**

Print a file with the standard indent of 4:

```
[ / ]
[ root@acme007 ][-sh]: cat /etc/group | indent
      root:x:0:root,HMUST
```

```
bin:x:1:root,bin,daemon
daemon:x:2:root,bin,daemon
sys:x:3:root,bin,adm
:
:
```

Print the file with a specific indent of 8:

```
[ / ]
[ root@acme007 ][-sh]: cat /etc/group | indent 8
    root:x:0:root,HMUST
    bin:x:1:root,bin,daemon
    daemon:x:2:root,bin,daemon
    sys:x:3:root,bin,adm
    :
    :
```

2) indented output in a script

In the following script produces an output as:

```
:
:
interface files ...
    csv files in '/data/incoming' ...
        /data/incoming/HR/12002.csv
        /data/incoming/HR/12003.csv
        /data/incoming/HR/12004.csv
        /data/incoming/HR/12005.csv
        /data/incoming/GL/50003.csv
        /data/incoming/GL/50004.csv
    done.
    csv files in '/data/outgoing' ...
        /data/outgoing/HR/12001.csv
        /data/outgoing/GL/50001.csv
        /data/outgoing/GL/50002.csv
    done.
done.
:
:
```

Be aware of the 'cascaded' usage of the **indent** command first to indent the output of the **find** command and then to indent the output of the whole **search_csv()** function.

To ensure, that error output of the **find** command output is also indented, the output of **find** to **stderr** has to be redirected to **stdout** using the **2>&1** redirection syntax.

```
#!/bin/sh
:
:
search_csv(){ start=$1
    echo "csv files in '$start' ..."
}
```

```

        find $start -name *.csv -print 2>&1 | indent
        echo "done."
    } # search_csv

main() {

    in=/data/incoming
    out=/data/outgoing
    :
    :
    echo "interface files ..."
    search_csv $in | indent
    search_csv $out | indent
    echo "done."
    :
    :
} # main
main $*
```

The **main()** function above could also be written as:

```

main() {

    in=/data/incoming
    out=/data/outgoing
    :
    :
    echo "interface files ..."
    {
        search_csv $in
        search_csv $out
    } | indent
    echo "done."
    :
    :
} # main
```

SEE ALSO

NAME

info – read Info documents

SYNOPSIS

info [*OPTION*]... [*MENU-ITEM*...]

DESCRIPTION

Read documentation in Info format.

OPTIONS

- apropos=***SUBJECT*
look up *SUBJECT* in all indices of all manuals.
- directory=***DIR*
add *DIR* to INFOPATH.
- dribble=***FILENAME*
remember user keystrokes in *FILENAME*.
- file=***FILENAME*
specify Info file to visit.
- help** display this help and exit.
- index-search=***STRING*
go to node pointed by index entry *STRING*.
- node=***NODENAME*
specify nodes in first visited Info file.
- output=***FILENAME*
output selected nodes to *FILENAME*.
- restore=***FILENAME*
read initial keystrokes from *FILENAME*.
- show-options, --usage**
go to command-line options node.
- subnodes**
recursively output menu items.
- vi-keys**
use vi-like and less-like key bindings.
- version**
display version information and exit.

The first non-option argument, if present, is the menu entry to start from; it is searched for in all ‘dir’ files along INFOPATH. If it is not present, info merges all ‘dir’ files and shows the result. Any remaining arguments are treated as the names of menu items relative to the initial node visited.

EXAMPLES

- info show top-level dir menu
- info emacs
start at emacs node from top-level dir
- info emacs buffers
start at buffers node within emacs manual
- info **--show-options** emacs
start at node with emacs’ command line options
- info **-f** ./foo.info
show file ./foo.info, not searching dir

REPORTING BUGS

NAME

ini – initialize environment

SYNOPSIS

ini ([-h] | -l | *application*)

edrc/lib/ini.(bash|ksh|sh|csh) ([-h] | -l | *application*)

AVAILABILITY

WA2L/edrc

DESCRIPTION

initialize the environment based on named definitions specified in **etc/env**.

Each shell has its own **ini.shell** binary to initialize the environment based on the definitions.

So it is not necessary to use different syntax for different shells, this is done by the **ini.shell** command.

Interactive usage

The interactive **ini** command is a shell alias pointing to the relating **ini.shell** command.

The alias in the **ksh** shell therefore calls the **ini.ksh** command, a C-shell would call the **ini.csh** command.

Script usage

To use the **ini** mechanism in a script, invoke the **ini.shell** command and process the output:

Bourne-Shell using a temporary file and source it:

```
ini.sh myApplication > /tmp/env.$$  
. /tmp/env.$$
```

Korn-Shell using a temporary file and source it:

```
ini.ksh myApplication > /tmp/env.$$  
. /tmp/env.$$
```

Bourne-Again-Shell using a temporary file and source it:

```
ini.bash myApplication > /tmp/env.$$  
. /tmp/env.$$
```

C-Shell using a temporary file and source it:

```
ini.csh myApplication > /tmp/env.$$  
source /tmp/env.$$
```

Bourne-Shell using **eval**:

```
eval `ini.sh myApplication`
```

Korn-Shell using **eval**:

```
eval `ini.ksh myApplication`
```

Bourne-Again-Shell using **eval**:

```
eval `ini.bash myApplication`
```

C-Shell using **eval**:

```
eval `ini.csh myApplication`
```

OPTIONS

-h usage message.

-l list all application environment definitions from the **etc/env** configuration file.

application
 application name.

ENVIRONMENT

\$BASEDIR
 base directory of the userclass tool directory.

The userclass **env** files sit in: **\$BASEDIR/etc/**.

\$HOME users \$HOME directory. The env file is: **\$HOME/.myenv**.

EXIT STATUS

2 operating system not supported.

4 usage printed.

5 application definitions listed.

6 configuration file not found.

FILES**edrc/etc/ini.cfg**configuration file for **ini**.**edrc/etc/env**environment definition configuration file for **ini**.**\$HOME/.myenv**user specific environment definition configuration file for **ini**.**\$BASEDIR/etc/env**environment definition file if **USERCLASS_SUPPORT=True**.**\$BASEDIR/etc/env. domainname**domain dependent environment definition file if **USERCLASS_SUPPORT=True**.**\$BASEDIR/etc/env. hostname**host dependent environment definition file if **USERCLASS_SUPPORT=True**.**EXAMPLES**

NAME

ini.cfg – configuration file for ini

SYNOPSIS

edrc/etc/ini.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **ini** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**USERCLASS_SUPPORT**

enable or disable USERCLASS support.

Example: USERCLASS_SUPPORT=True

Default: USERCLASS_SUPPORT=False

NAME

input – prompt for an input

SYNOPSIS

edrc/lib/input

input "*prompt*" ["*default input*" [*options*]]

AVAILABILITY

WA2L/edrc

DESCRIPTION

This command is used in scripts to prompt a user for an input.

It is possible to verify the users input using a number of options. As long as the input does not conform to the option specified the input prompt is repeated.

It is also possible to specify a default value that takes in effect when <ENTER> or <RETURN> without entering an input is pressed.

All input is logged to a logfile if the environment variable **\$EDRC_LOGFILE** is set and the **NO_LOG** option isn't set.

OPTIONS

usage message

"*prompt*" prompt to be displayed.

"*default input*"

default input. This input will be returned if the <ENTER> key is pressed without entering anything on the input prompt.

options a list of comma separated options of the list below. The input is verified against all options listed. Therefore be careful not to provide an option list that makes it impossible to enter any data (e.g. **ALPHA,DIGIT**).

NOT_NULL

null input is not accepted.

NO_LOG

do not record the input to the logfile.

NO_TRIM

do not trim whitespaces from begin and end of input. Default is to trim those whitespaces.

Hint: If the input is a whitespace and the option **NOT_NULL** is set, the input is not accepted.

NO_ECHO

do not echo the input to stdout. This is useful if you query passwords.

LOG_STARS

log stars (*****) to the logfile instead of the real input. This option should be used always if you query passwords with the **input** command.

TTY read input from **tty** and write prompt to **tty**.

MINLEN=*len*

accept only input with a minimal length of *len*.

MAXLEN=*len*

accept only input up to a maximal length of *len*.

ALPHA

accept only inputs consisting of letters (a – Z).

DIGIT accept only numbers as unsigned integer values (0 – 9).

FLOAT

accept only numbers as signed floating point values. Examples: +.125, +0.125, 0.125, 3.1415, 815, -.125, -0.125, -3.1415, -815.

ALNUM

accept only alphanumeric input (a – Z, 0 – 9).

ALNUM+SPACE

accept only alphanumeric input including spaces (a – Z, 0 – 9, ' ').

ALNUM+_

accept only alphanumeric and _ (a – Z, 0 – 9, _).

IPV4 accept only IP version 4 addresses (0.0.0.0 – 255.255.255.255).

HH:MM

accept only time values in the format HH:MM (00:00 – 24:00).

HH:MM:SS

accept only time values in the format HH:MM:SS (00:00:00 – 24:00:00).

HHH:MM

accept only time (hour:minutes) values in the format hour:MM (00:00 – 9999999:59) in contrast to HH:MM, the hours are not limited to 24 hours.

HHH:MM:SS

accept only time values in the format hour:MM:SS (00:00:00 – 9999999:59:59) in contrast to HH:MM:SS, the hours are not limited to 24 hours.

MM/DD

accept only dates (month and day) in the format MM/DD (01/01 – 12/31).

MM/DD/YYYY

accept only dates in the format MM/DD/YYYY (01/01/0000 – 12/31/9999).

DD.MM

accept only dates (day and month) in the format DD.MM (01.01 – 31.12).

DD.MM.YYYY

accept only dates in the format DD.MM.YYYY (01.01.0000 – 31.12.9999).

YYYY-MM-DD

accept only dates in the military format YYYY-MM-DD (0000-01-01 – 9999-12-31).

ENVIRONMENT**\$EDRC_LOGFILE**

the accepted input read by **input** is logged to the file specified in this environment variable (if set).

EXIT STATUS

0 no error.

2 command aborted pressing Ctrl+C.

4 usage listed.

FILES

/dev/tty terminal device file when option **TTY** is used. This device file is read if the resolution of the current pseudo device of the terminal is not possible.

EXAMPLES

The following examples are script cut-outs of Bourne-, Korn- or Bash shell scripts:

1) filename input

```
filename=`input "Package Filename" "" NOT_NULL,ALNUM+_`
```

2) input a number and log everything to a logfile

```
Logfile=/var/log/process_counts.log
EDRC_LOGFILE=$Logfile; export EDRC_LOGFILE

pause=40
ok=n

{
    while [ ok != y ]; then
        pause=`input "pause between process counts" $pause DIGIT`
        ok=`choice "input OK? <yn>" yn n`
    done

    echo "press <Ctrl>+<C> to stop"
    while [ 1 = 1 ]; do
        echo "number of processes: `ps -ef | wc -l`"
        sleep $pause
    done
} >> $Logfile
```

3) prompt for a password input

```
Logfile=/var/log/passwordchange.log
EDRC_LOGFILE=$Logfile; export EDRC_LOGFILE

new=new
verify=verify

while [ "$new" != "$verify" ]; then
    new=`input "New password" "" NOT_NULL,LOG_STARS,NO_ECHO`
    verify=`input "Retype new password" "" NOT_NULL,LOG_STARS,NO_ECHO`
done
```

SEE ALSO

NOTES

-

BUGS

The dates 09/03/1752 - 09/13/1752 are accepted, despite of the fact that those dates did never occur because it is assumed that the Gregorian Reformation took place on the 09/03/1752.

NAME

input_targets – input a list of target hosts and/or hostgroups

SYNOPSIS

edrc/lib/input_targets [*targets*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

special purpose input to query lists of hosts.

The prompt cannot be changed and is set to "Target hosts".

The input and the optional command argument is a space separated list of hosts and/or hostgroups (*@HOSTGRP*).

If hostgroups are entered, those hostgroups are resolved and the resulting list is a uniquely sorted list of target hosts. Therefore, if a host is member of one or more hostgroups and eventually entered as a separate target host, it will be listed only once in the resulting list.

If the input differs from the default, the input prompt is repeated to allow verification and modifications.

If no target list is specified in *targets*, a default target list is provided in the input prompt as it is resolved by the **hostlist**(3) command.

OPTIONS

targets space separated list of target hosts and/or hostgroups (*@HOSTGRP*).

ENVIRONMENT

-

EXIT STATUS

0 always.

NAME

ipcalc – IP Calculator

SYNOPSIS

edrc/bin/ipcalc [**--help**]

ipcalc [**options**] *address* [*/* *netmask*] [*netmask*]

ipcalc *address1-address2*

AVAILABILITY

WA2L/edrc

DESCRIPTION

ipcalc takes an IP address and netmask and calculates the resulting broadcast, network, Cisco wildcard mask, and host range. By giving a second netmask, you can design subnets and supernets. It is also intended to be a teaching tool and presents the subnetting results as easy-to-understand binary values.

Enter your netmask(s) in CIDR notation (*/25*) or dotted decimals (*255.255.255.0*). Inverse netmasks are recognized. If you omit the netmask **ipcalc** uses the default netmask for the class of your network.

Look at the space between the bits of the addresses: The bits before it are the network part of the address, the bits after it are the host part. You can see two simple facts: In a network address all host bits are zero, in a broadcast address they are all set.

The class of your network is determined by its first bits.

If your network is a private internet according to RFC 1918 this is remarked. When displaying subnets the new bits in the network part of the netmask are marked in a different color

The wildcard is the inverse netmask as used for access control lists in Cisco routers.

Do you want to split your network into subnets? Enter the address and netmask of your original network and play with the second netmask until the result matches your needs.

OPTIONS

--help usage message.

address IP-address.

netmask netmask.

- n** | **--nocolor**
do not display ANSI color codes.
- b** | **--nobinary**
suppress the bitwise output.
- c** | **--class** just print bit-count-mask of given address.
- h** | **--html** display results as HTML (not finished in this version).
- v** | **--version**
print Version.
- s** *n1 n2 n3*
split into networks of size n1, n2, n3.
- split** *n1 n2 n3*
split into networks of size n1, n2, n3.
- r** | **--range**
de-aggregate address range.

ENVIRONMENT

-

EXIT STATUS

0 always

FILES

-

EXAMPLES

1) common usage

```
ipcalc 192.168.0.1/24
ipcalc 192.168.0.1/255.255.128.0
ipcalc 192.168.0.1 255.255.128.0 255.255.192.0
ipcalc 192.168.0.1 0.0.63.255
```

2) de-aggregate address range

```
ipcalc 192.168.0.23 - 192.168.1.200
```

3) split networks into subnets

```
ipcalc 192.168.6.20 -s 200
ipcalc 192.168.6.20 -s 200 200 200
```

NAME

ipsort – filter for sorted output of IP addresses

SYNOPSIS

edrc/bin/ipsort [-h]

AVAILABILITY

WA2L/edrc

DESCRIPTION

With this command you can sort a data stream which has IP addresses in the first column.

OPTIONS

-h usage message

EXAMPLES

1. Sorted output of the /etc/hosts file

```
myhost:[1] cat /etc/hosts | ipsort
```

2. Sorted output of the NIS hosts map

```
myhost:[2] ypcat hosts | ipsort
```

3. Sorted output of the actual routing table

```
myhost:[3] netstat -rnv | ipsort
```

SEE ALSO

NAME

is_config_byhand – check if file is listed in a .config_byhand* file

SYNOPSIS

edrc/lib/is_config_byhand [-h]

is_config_byhand -f file

AVAILABILITY

WA2L/edrc

DESCRIPTION

Evaluate if a given file is listed in a **config_byhand** file. If so return 'True' else return 'False'. This command is intended to be used in **pre_exec** and **post_exec** scripts called by **sysconfig** to prevent miss-configuration when re-applying a configuration to a previously configured system.

If **sysconfig** is called with the force option (-f), **is_sysconfig_byhand** returns *False* for all files queried.

OPTIONS

-h usage message.

-f file .

ENVIRONMENT**\$SYSCONFIG_FORCE**

if the environment variable **\$SYSCONFIG_FORCE** is set to *True* **is_config_byhand** returns *False* for every file. This environment variable is set to *True* when **sysconfig** is invoked with the force (-f) option.

EXIT STATUS

0 file is listed in a **config_byhand** file. **is_config_byhand** returns *True* to **stdout** in this case.

1 file is not listed in any **config_byhand** file. **is_config_byhand** returns *False* to **stdout** in this case.

2 operating system is not supported, yet. See **osid**(3) if you get this error.

- 4 usage printed.
- 11 temporary directory could not be claimed or created in **/tmp**. Check the system temporary directory **/tmp** if you get this error, it is an indicator of system intrusion.

FILES

<root_dir>/EDRC.config_byhand <root_dir>/EDRC.config_byhand.<name>
a list of files to be protected from overwriting after the initial run of **sysconfig**.

<root_dir>/config_byhand
a list of files to be protected from overwriting after the initial run of **rmtconfig** a system configuration tool provided by the SFI-Director. You should not enter new entries into this file, it is only considered to protect systems configured with **rmtconfig** from miss-configuration.

EXAMPLES

1) usage in a post_exec script

Create a system dependent **/etc/issue** file.

```
Hostname='hostname'
Configuration='TEST CONFIGURATION - ACME, Datacenter Balsberg'
```

```
file=$SYSCONFIG_ROOTDIR/etc/issue
if [ "`is_config_byhand -f $file`" = False ]; then

    cat << EOM | apply2file -o -u bin -g bin -p 444 -f $file
```

```
`banner $Hostname`
```

```
$Configuration
```

```
#####
#   This is an ACME protected system.                               #
#   This system is for the use of authorized users only.           #
#   Individuals using this computer system without authority, or in #
#   excess of their authority, are subject to having all of their   #
#   activities on this system monitored and recorded by system     #
#   personnel.                                                       #
#                                                                     #
#   In the course of monitoring individuals improperly using this   #
#   system, or in the course of system maintenance, the activities #
#   of authorized users may also be monitored.                     #
#                                                                     #
#   Anyone using this system expressly consents to such monitoring  #
#   and is advised that if such monitoring reveals possible        #
#   evidence of criminal activity, system personnel may provide the #
#   evidence of such monitoring to law enforcement officials.       #

NAME

is_existing – test if a file or directory is existing

SYNOPSIS

edrc/lib/is_existing [**-h**]

is_existing *file* [*timeout*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

check if a *file/directory/link* etc. is existing and accessible by the calling user.

This command does not hang if for instance the NFS resource where the *file/directory/link* is located is not available.

There is the possibility to specify a timeout value when the default of 0 second is not sufficient.

OPTIONS

-h print usage message.

file file/directory/link to check if it exists.

timeout timeout in seconds.

This allows to check if a resource is existing that needs some time to get available (as an auto-mounted NFS directory).

the default timeout is 0 seconds.

ENVIRONMENT

-

EXIT STATUS

0 element exists. **True** is returned to **stdout**.

is_existing(3)

Library Commands

is_existing(3)

- 1** element is not existing or is not accessible within the given *timeout*. **False** is returned to **stdout**.
- 4** usage message printed.

NAME

is_osid – check if this is a certain Os-Id

SYNOPSIS

edrc/lib/is_osid [**-h**]

is_osid [**-n**][**-s** *scriptname*] **-o** *osid_list*

is_osid [**-s** *scriptname*] **-o** *osid_list*

AVAILABILITY

WA2L/edrc

DESCRIPTION

evaluate if the operating system id returned by **osid**(3) matches to one os-id specified by the **-o** option. This command is used to limit a script execution to supported operating systems only.

OPTIONS

-h print usage message.

-n no message output, if the operating system id of the system where the **is_osid** command is running is not listed in the *osid_list*.

-s *scriptname*
scriptname to print in the message output. In a script this setting is normally set to **\$0**.

-o *osid_list*
comma separated list of **osid**(3) that are allowed to run the command.

ENVIRONMENT

-

EXIT STATUS

0 OS is in OS-Id list.

2 OS is not in Os-Id list (OS not supported).

4 usage printed.

FILES

-

EXAMPLES

1) check if osid is HP-11 or HP-11i

```
is_osid -s $0 -o HP-11,HP-11i || exit $?
```

2) check if osid is Solaris or HP-*:

```
is_osid -s $0 -o Solaris,HP-* || exit $?
```

SEE ALSO

NAME

is_permitted – check if a functionality is permitted to be started

SYNOPSIS

edrc/lib/is_permitted [**-h**]

is_permitted *functionality* [*options*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

the main intention of this command is to check if a certain functionality is permitted for execution in contributed commands.

In recovery scripts global functionality and script functionality can be checked for startup permission.

This enables you to minimize possible by-passes of the denials defined in the **DENY_LIST** in the **edrc** config file **edrc.cfg**(4).

This allows to restrict functionality when an **edrc** configuration is used for special purposes (as: application- or operation support or to software control but don't want to give the user all freedom of changing things).

If a certain checked functionality (e.g.: */shell*) is not permitted to be started, the message

```
edrc-WARNING: execution of functionality 'shell' not permitted.
```

is displayed

OPTIONS

-h usage message.

functionality

functionality to check if it is permitted to start depending on the setting in the **DENY_LIST** of the **edrc** config file **edrc.cfg**(4).

The functionality is the string defined in the **@PROVIDES@** tag in the contributed command or general **edrc** functionalities.

To list all functionalities, invoke the **edrcperm** command in **edrc**.

Non-existing functionalities are treated as permitted.

Check if functionality of the own (e.g: edrcupgrade) contributed command is permitted to be started:

```
if [ `is_permitted seturl` = True ]; then
:
:
if
```

Check if global low-level **edrc** functionality (low level functionality has an underscore '_' in the name) is permitted to start:

```
if [ `is_permitted edit_file` = True ]; then
:
:
if
```

Check if a global **edrc** functionality is permitted to be started:

```
if [ `is_permitted /shell` = True ]; then
:
:
if

if [ `is_permitted /env.new` = True ]; then
:
:
if
```

Check if a specific functionality start of a specific contributed command is permitted:

```
if [ `is_permitted /contrib.logs.view` = True ]; then
:
:
if
```

options comma separated list or options for **is_permitted**:

NOLOG

do not log positive denial message into session log file.

ENVIRONMENT

-

EXIT STATUS

- 0** call of the functionality is permitted.
In addition **True** is returned to **stdout**.
- 1** call of the functionality is not permitted.
In addition **False** is returned to **stdout**.
- 4** usage displayed.

FILES

-

EXAMPLES

See contributed commands in **edrc/contrib/edrc/** for examples of the **is_permitted** command.

SYNOPSIS

edrc/lib/is_running [**-h**]

is_running *package*

is_running *package*{*{,package_n}*}

AVAILABILITY

WA2L/edrc

DESCRIPTION

evaluate if a given cluster package is up.

Return 'True' if it is up, otherwise return nothing, therefore this command can be used in crontab to run a certain line only if the specified cluster package is running on this host.

Example:

```
0 1 * * * [ ``/opt/edrc/lib/is_running psoftprod`` ] \  
&& /opt/psoft/bin/my_command
```

OPTIONS

-h print usage message.

package MC/Service Guard cluster package name.

ENVIRONMENT

-

EXIT STATUS

0 one of the specified package(s) is up.

1 all specified package(s) are down.

2 OS not supported.

is_running(3)

Library Commands

is_running(3)

4 usage printed.

5 package state cannot be resolved.

NAME

is_up – test if a host is up

SYNOPSIS

edrc/lib/is_up -h

is_up *host*

AVAILABILITY

WA2L/edrc

DESCRIPTION

Test if a host is up by pinging it or by connecting to alternate ports on the system.

The advantage of using **is_up** instead of **ping**(8) and **ping6**(8) is, that this command has identical usage on different operating systems.

When **ping** (ICMP echo) is not allowed/enabled to test the peer's availability **is_up** tries to connect to the ports 22 and 513-514.

OPTIONS

-h print usage message.

host name or IP address of host to test.

ENVIRONMENT

-

EXIT STATUS

- | | |
|----------|--|
| 0 | host reached. |
| 1 | host not reached. |
| 2 | operating system not supported. See osid (3) if you get this error. |
| 4 | usage message printed. |

is_up(3)

Library Commands

is_up(3)

NAME

is_user – check if command is started by a certain user

SYNOPSIS

edrc/lib/is_user [**-h**]

is_user [**-n**] [**-s** *scriptname*] **-u** *user_list*

is_user [**-s** *scriptname*] **-u** *user_list*

AVAILABILITY

WA2L/edrc

DESCRIPTION

evaluate if the user that started the command matches to one username specified by the **-u** option. This command is used to limit a script execution to supported users only.

OPTIONS

-h print usage message.

-n no message output, if the username of the user starting the command where the **is_user** command is running is not listed in the *user_list*.

-s *scriptname*
scriptname to print in the message output. In a script this setting is normally set to **\$0**.

-u *user_list*
comma separated list of usernames that are allowed to run the command.

ENVIRONMENT

-

EXIT STATUS

0 User is in user-list list.

2 User is not in user-list (command start not permitted).

4 usage printed.

FILES

-

EXAMPLES

1) check if user is fred or barney

```
is_user -s $0 -u fred,barney || exit $?
```

2) check if user is root or admin*:

```
is_user -s $0 -u root,admin* || exit $?
```

is_weekend(3)

Library Commands

is_weekend(3)

NAME

is_weekend – return True on weekends, else False

SYNOPSIS

edrc/lib/is_weekend

AVAILABILITY

WA2L/edrc

DESCRIPTION

return **True** on weekends (Saturday and Sunday). Else **False** is returned.

OPTIONS

-

ENVIRONMENT

-

EXIT STATUS

0 it is weekend (Saturday or Sunday) and **True** was returned to **stdout**

1 it is a working day (Monday ... Friday) and **False** was returned to **stdout**

NAME

is_writeable – test if a file or directory is writeable

SYNOPSIS

edrc/lib/is_writeable [-h]

is_writeable *file* | *directory*

AVAILABILITY

WA2L/edrc

DESCRIPTION

check if write access to a file or a directory is possible. Return 'True'/'0' if write access is possible, otherwise return 'False'/'1'.

OPTIONS

-h print usage message.

file file to check write access.

directory directory to check write access.

ENVIRONMENT

-

EXIT STATUS

0 write access possible. **True** is returned to **stdout**.

1 write access not possible. **False** is returned to **stdout**.

4 usage message printed.

NAME

java – start java

SYNOPSIS

edrc/bin/java [*java_options*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

search the **java** command on the system and start it.

This command avoids the need to start the **java** command with an absolute path name and therefore allows to start a **java** program identically on different systems (for example from recovery scripts).

Locations of the **java** command can be configured in the **etc/java_wrapper.cfg** configuration file.

OPTIONS

java_options

all options of the system wide installed **java** command.

ENVIRONMENT

-

EXIT STATUS

101 the **java** command was not found on the system.

106 configuration file **etc/java_wrapper.cfg** does not exist.

x exit code of the started java program or the system wide installed **java** command.

FILES

etc/java_wrapper.cfg

configuration file of **java** and **.java_wrapper** .

EXAMPLES

-

SEE ALSO

edrcintro(1), **java_wrapper(1m)**, **java_wrapper.cfg(4)**

NOTES

Hint: the **java** runtime environment (JRE) or **java** development kit (JDK) is not (and will not be) bundled with WA2L/edrc.

BUGS

-

AUTHOR

java was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

`java_wrapper` – wrap Java programs to ensure java startup

SYNOPSIS

`edrc/bin/javaprogram -> .java_wrapper`

`edrc/lib/javaprogram -> .java_wrapper`

AVAILABILITY

WA2L/edrc

DESCRIPTION

Wrap Java programs for transparent start.

java locations can be configured in the config file `java_wrapper.cfg`(4).

To start a new command thru the `.java_wrapper`, follow the following steps:

- 1.) create a symlink to the new command in the **edrc/bin/** or **edrc/lib/** directory depending on your needs:

```
[ /opt/edrc/bin ]
[ root@acme001 ] [*edrc*/bash]: ln -s .java_wrapper new_cmd
```

- 2.) install the Java program in the **edrc/lib/java/** directory.
- 2.) define the Java start options in the related **edrc/lib/java/new_cmd.javaopt** file.

OPTIONS

-

ENVIRONMENT

-

EXIT STATUS

- | | |
|------------|---|
| 101 | shell (java) not found. If java is installed on the system and you get this error, add the java location in the configuration file <code>java_wrapper.cfg</code> . |
| 102 | the Java files to be started that should be located in lib/java/ do not exist. |

106 configuration file **java_wrapper.cfg** does not exist.

107 the **.java_wrapper** was called directly.

FILES

etc/java_wrapper.cfg

configuration file for the **java_wrapper** command.

lib/java/

location of the wrapped Java programs. This files should have the file permissions *644* to show, that those scripts should not be started directly.

EXAMPLES

-

SEE ALSO

NAME

java_wrapper.cfg – configuration file for .java_wrapper

SYNOPSIS

edrc/etc/java_wrapper.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **.java_wrapper** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**JAVA_COMMAND**

Space separated search sequence to the java command.

It is supported to use wildcards in the file path.

Example: JAVA_COMMAND="

```
/opt/java1.5*/jre/bin/java
/opt/java1.4*/jre/bin/java
/opt/prm/bin/jre/bin/java
/ora/product*/jre*/bin/java
/usr/bin/java
"
```

Default: JAVA_COMMAND="

```
/usr/java/jre*/bin/java
/usr/java/jdk*/bin/java
/usr/java/jdk*/jre/bin/java
edrc/lib/$OSID/jre*/bin/java
edrc/lib/$OSID/jdk*/bin/java
```

```
    /usr/bin/java  
"
```

SEE ALSO

edrcintro(1), **java_wrapper(1)**

NAME

job – job sequencer

SYNOPSIS

edrc/bin/job [**-h** | **-V**]

job

job [**-i** *check_interval*] [**-q** *queue*]

job (**-l** | **-L**) [**-q** *queue*]

job -Q

job -r (*id* | **last**)

job [**-f**] **-s** (*id* | **last**)

job -p (*id* | **last**)

job -a [**-q** *queue*]

job -c (*id* | **last**)

AVAILABILITY

WA2L/edrc

DESCRIPTION

job sequencer.

This command can be used to serialize jobs on a UNIX system within the environment of the current user (in the user context of the user).

It has a similar user interface to the **at** command.

To define a new job, start **job**, then add the commands to be executed interactively in the **job>** prompt.

To end adding commands to a job, press **[Ctrl] + [D]** or enter a . (dot) as last command.

The advantages of this command are multiple queue support, execution of jobs in the current user environment and a logging facility.

Be aware, that the directories **edrc/bin/** and **edrc/lib/** are added to the **\$PATH** environment variable and therefore all WA2L/edrc commands are also available for use in defined jobs without the need to alter the environment beforehand.

Background

The command was developed to optimize simulation calculations where only a number of licenses are available to simultaneously perform calculation runs.

The situation was, that a user needed to wait until the calculation of a coworker has been finished to start the own calculation.

This meant that the time during off-office hours were lost when a calculation ended after office hours.

Using the **job** sequencer the calculations could be en-queued and when one calculation finished, the following job started automatically. For each simultaneous calculation an own queue was used.

So the licenses could be used most efficiently and also night times were efficiently used to run calculations.

The job sequencer was developed in year 2000 as a stand alone utility and then later integrated into WA2L/edrc.

OPTIONS

- h** usage message.
- V** print program version.
- l** list all jobs in queue.
- L** list last jobs in queue.
- Q** list all queues.
- i interval** interval of check if previous job has completed.
- r id** remove job from queue.
- s id** stab job in run state.
- p id** print job properties.
- a** print *job* execution report for accounting purposes in **CSV** format.

To pretty-print the **CSV** output, use:

```
job -a | csv list
```

To select a specific project (e.g. APOLLO), the '**csv where *projectname***' command could be used:

```
job -a | csv where APOLLO | csv list
```

To show specific columns of the **CSV** output, the '**csv select *columns***' command could be used in addition:

```
job -a | csv where APOLLO | csv select "TAG;DURATION_S" | csv list
```

-c *id* print job commands including changing to the working directory from where the job was started.

This can be used to re-run a job using:

```
job -c 10123 | job
```

last resolves to the JOB-ID of the last job enqueued by the user.

-f force stabbing of job in run state with running processes.

-q *queue* queue name if not **default**.

ENVIRONMENT

\$PATH the directories **edrc/bin/** and **edrc/lib/** are added to the **\$PATH** environment variable.

Therefore all WA2L/edrc commands are available for use in jobs.

EXIT STATUS

| | |
|-----------|---|
| 0 | no error. |
| 4 | usage printed. |
| 5 | command aborted. |
| 6 | version printed. |
| 11 | cannot create temporary directory in /tmp/ ; this might be an indicator of system intrusion. |

FILES

etc/job.cfg configuration file for the **job**, **jobwatch**, and **joblog** commands.

lib/job/FUNCTION

functions that can be used in a **job**.

Currently available *FUNCTION*s are:

JOBBANNER *text*

print a banner (that is not limited to 10 characters).

JOBTITLE *text*

print a title with ### prepended.

JOBSUBTITLE *text*

print a sub-title with === prepended.

JOBSUBSUBTITLE *text*

print a sub-sub-title with --- prepended.

JOBTAG *tag*

tag a job for accounting. A *tag* could be a specific project name to identify which job was executed for what project.

Allowed characters for a *tag* are: **a-Z, 0-9, /, =, -, _, .** and **,**.

JOBCOMPLETED ["*command*"]

set the job completion criteria to *command*:

```
:
job>JOBCOMPLETED "/opt/mycalc/bin/checkflag"
:
```

whereas the *command* needs to return **0** when the job is completed and a value different to **0** when the job is not yet completed.

If the *command* is not set, the commands to check job completion need to be provided thru **stdin**, as for example:

```
:
job>JOBCOMPLETED <<EOC
job>    if [ -f /tmp/mycalc.flag ]; then
job>        exit 0
job>    else
job>        exit 1
job>    fi
job>EOC
:
```

The job completion criteria needs to be set in cases where for instance the commands defined in the job run in the background. In this case the **job** command would report the **done** state too early.

The **JOBCOMPLETED** function should be set prior to the job workload commands.

/var/tmp/job/job.log

log file of **job**.

/var/tmp/job/

spool directory of **job**.

/var/tmp/job.seq

job *id* counter.

~/job.last job *id* of the last job enqueued.

/var/tmp/job/<JOBID>/

spool directory of a job with the id <JOBID> consisting of the following state files:

cmd commands to run in the job.

env user environment (variables).

state state of the job.

pid process id of the job.

time.enqueue

time stamp when the job was created.

time.end time stamp when the job has ended.

time.run time stamp when commands in the job were started (when the job came into the run state).

exec job execution file.

user user that created the job.

cwd current working directory from where the **job** command was issued.

compl job completion criteria resolution.

log output (**stderr** and **stdout**) of the commands in the job.

version version of the **job** command at the time when the job was created.

queue job queue.

tag job tag.

EXAMPLES

NAME

job.cfg – configuration file for job/jobwatch/joblog

SYNOPSIS

edrc/etc/job.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **job**, **jobwatch** and **joblog** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**SPOOLBASEDIR**

Location of the job spool base directory.

If this option is not set, the directory does not exist or is not writeable the **SPOOLBASEDIR** defaults to **/var/tmp**.

Example: SPOOLBASEDIR=/dat/simulator

Default: SPOOLBASEDIR=/var/tmp

COLORIZE

Colorize output of job list on terminal.

Example: COLORIZE=False

Default: COLORIZE=True

SEE ALSO

NAME

joblog – monitor log file of job sequencer

SYNOPSIS

edrc/bin/joblog [**-h** | **-V**]

joblog

joblog -j (*id* | **last**)

joblog -q [*queue*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

continuous output of the log file of the **job** sequencer.

If no *id* is specified, the main job sequencer log file is shown.

OPTIONS

-h usage message.

-V print program version.

-j *id* continuous output of the log file of the job with JOB-ID *id*.

last resolves to the last job enqueued.

-q [*queue*]
 permanent log output of **running** jobs in the given *queue*.

If the *queue* is not specified, the logs of the jobs in the **default** queue are printed.

ENVIRONMENT

-

EXIT STATUS

| | |
|-----------|---|
| 0 | no error. |
| 4 | usage printed. |
| 5 | command aborted. |
| 6 | version printed. |
| 11 | cannot create temporary directory in /tmp/ ; this might be an indicator of system intrusion. |

FILES

etc/job.cfg configuration file for the **job**, **jobwatch**, and **joblog** commands.

/var/tmp/job/job.log
main log file of **job**.

/var/tmp/job/<id>/log
log file of the job with JOB-ID *id*.

NAME

jobstart – run jobs thru a simple interface

SYNOPSIS

edrc/bin/jobstart [-h | -V

jobstart *JOBNAME*...

jobstart (-e | fun | distribute)

jobstart (-l | list | time | timeline) [*query*]

jobstart (runs | runs-days | stats | stats-days) [*query*]

jobstart (enable | disable | unlock | lock) *JOBNAME*...

jobstart (enable | disable | unlock | lock) all

jobstart print *JOBNAME*

jobstart log [*begin* [*end*]]

jobstart logswitch

AVAILABILITY

WA2L/edrc

DESCRIPTION

Start jobs using a simple interface, where a job is identified by a *JOBNAME*.

The **jobstart** command can be called manually as user **root** from the command line, but running it scheduled (i.e. from **cron** or **at**) is the main purpose.

The **jobstart** command can be started on any system where it is available. However, the *JOBNAME* is started from the system that is configured in the **JOBSTART_SYSTEM=system** setting (e.g. **JOBSTART_SYSTEM="root@acme301.acme.ch"**) in the **jobstart.cfg** configuration file.

If a job runs on a target system different to the **JOBSTART_SYSTEM**, the job needs to connect to the related target system (using **ssh-exec** for example).

Therefore the **JOBSTART_SYSTEM** acts like a hub to execute all jobs.

This to simplify jobs writing, understanding the job start mechanism and to consolidate the log output centrally.

The intention is to implement the job commands in the **jobstart.cfg** file to fulfill a specific task. The user then can start those (probably more complex) tasks using the *JOBNAME* without the need to remember command line options or dependencies.

The output of **stderr** and **stdout** is logged to the logfile, therefore it is not necessarily needed to write to a dedicated logfile from the job.

The *JOBNAME* should be in upper case and only the underscore (_) character should be used as separator.

Add additional jobs to the **jobstart.cfg** file between the

```
# v----- JOBS FOLLOW -----v #
:
:
# ^----- JOBS END -----^ #
```

markers.

See section **EXAMPLES** for example job definitions.

OPTIONS

-h usage message.

-V print configuration file name and configuration file version.

-e edit the **jobstart.cfg** file in **vi(1)** editor.

Running jobs are not affected by the editing of the **jobstart.cfg** file.

Be aware, that the configuration file is saved automatically before editing using the **vsav(1)** command internally. Therefore when a messed-up file was saved, or to check changes, the **vls(1)**, **vdiff(1)**, **vrestore(1)** etc. commands can be used to verify changes or revert to a previous version.

-l | list list all *JOBNAME*s currently defined sorted by *JOBNAME* including a short description, a reference to additional job documentation and informs if and when the *JOBNAME* is scheduled in the **crontab** of root.

The name, description and the job documentation reference is extracted from the configuration file if the job is defined as:

```
JOBNAME)      # description of the job
```

or

```
JOBNAME)      # description of the job / [REF]
```

in the **jobstart.cfg** file.

time list all *JOBNAME*s currently defined sorted by scheduled *HOURL* and *MINUTE*.

timeline list all *JOBNAME*s currently defined sorted by scheduled *HOURL* and *MINUTE* whereas all range- and list-definitions are expanded to it's planned scheduled time.

- query** wildcard expression to include only a subset of *JOBNAME*s in the output.
- print** print definition of job with given *JOBNAME*.
- fun** list special utility functions that can be used in job definitions.
- runs** overview of all jobs started yesterday and today. The report is sorted by the *END* time of the completed jobs.
- runs-days** overview of all jobs started the last number of *days*. The report is sorted by the *END* time of the completed jobs.
- runs-0** overview of all jobs started since begin. The report is sorted by the *END* time of the completed jobs.
- stats** statistics of all jobs started the last 90 days.
- Only job *RUNS* that are not skipped (due to **jobstart.cfg** configuration file syntax errors (*EXIT-CODE* = 2) or are disabled/locked (*ACTIVE* = **False**)) are *COUNTED* for job runtime statistics calculations.
- Starts of jobs that are not defined are not listed.
- stats-days** statistics of all jobs started the last number of *days*.
- stats-0** statistics of all jobs started since begin.
- log** [*begin* [*end*]]
print the **jobstart.log** file between the *begin* and *end* line number.
- distribute** distribute the **jobstart.cfg** file to the relevant nodes as defined in the **DISTRIBUTION=host_list** in the environment to keep it in sync after changes.
- The *host_list* is a comma separated list of hosts (as returned by the **hostlist -l** command).
- JOBNAME...*
start a job identified by the *JOBNAME*.
- A space separated list of *JOBNAME*s can be defined to execute several jobs in sequence. The

jobstart command stops executing a *JOBNAME* sequence as soon as a *JOBNAME* has an exit code different to **0** (success) and **98** (deactivated).

enable enable a given job with *JOBNAME* or **all** jobs to be started.

disable disable a given job with *JOBNAME* or **all** current jobs from being started.

A disabled *JOBNAME* is listed as *ACTIVE False* when listing all jobs using **jobstart list**.

unlock unlock a given job with *JOBNAME* or **all** jobs to be started.

lock lock a given job with *JOBNAME* or **all** current jobs from being started.

lock provides a second level of disabling jobs from being started beside of the **jobstart disable** *JOBNAME* command.

jobstart lock *JOBNAME* is used to rather permanently prevent a job from being started where **jobstart disable** *JOBNAME* is used to rather temporarily prevent a job from being started.

A locked *JOBNAME* is listed as *ACTIVE False* when listing all jobs using **jobstart list**.

logswitch move the contents of the current log file **jobstart.log** to **jobstart.<TIMESTAMP>.log**.

After a **logswitch** the **runs**, **stats** and **log** options can still be used to query information of all **jobstart** log files (the current **jobstart.log** and all available **jobstart.<TIMESTAMP>.log** files) without the need to know in which file the information is stored.

A log switch can significantly improve performance for queries of more recent events without losing information as a normal log rotate would.

The **jobstart logswitch** command should probably be scheduled (using **ecrontab**(1) for example).

ENVIRONMENT

\$EDRC_DEBUG_JOBSTART_JOBS

set this environment variable to **True** to switch on jobs debugging and to **False** to switch off debugging.

EXIT STATUS

0 no error.

1 error.

- 2** the configuration file has syntax errors. No jobs will be started if a syntax error is detected in the configuration file.
- 3** configuration file **edrc/etc/jobstart.cfg** not found.
- 4** usage displayed.
- 5** command aborted (using **Ctrl+C**).
- 6** config file version displayed.

- 14** *JOBNAME* definition printed.
- 16** command start not permitted. This error occurs, if **jobstart** command is started by a user different to the user defined in the optional **STARTUSER=user** setting, or the user has no permission to write to the **jobstart.log** file, the **jobstart.locked** file or the **jobstart.disabled** file.
- 98** started *JOBNAME* is deactivated (by **jobstart disable JOBNAME** or **jobstart lock JOBNAME**
- 99** supplied *JOBNAME* is not defined.

FILES

edrc/etc/jobstart.cfg

configuration file with jobs definitions.

edrc/etc/jobstart.lib

optional environment specific function library to be used in jobs.

This functions could also be added to the **jobstart.cfg** config file, but when defining the functions in **jobstart.lib** the functions are listed when **jobstart fun** is used and the comment format is:

```
# myfunction opt1 opt2 -- description
```

edrc/var/cache/jobstart/jobstart.cache
cached property data of switched log files.

edrc/var/log/jobstart.log
log file of **jobstart**.

edrc/var/settings/jobstart.disabled
list of disabled jobs. This file is maintained when using **jobstart** (**enable** | **disable**) *JOBNAME*.

edrc/var/settings/jobstart.locked
list of locked jobs. This file is maintained when using **jobstart** (**unlock** | **lock**) *JOBNAME*.

EXAMPLES

1) example job definitions

A job is a shell **case** structure, which is

```
JOBNAME)    # job description
            echo "job code goes here ..."
            ;;
```

or with a reference to additional job documentation:

```
JOBNAME)    # job description / [REF]
            echo "job code goes here ..."
            ;;
```

The example below shows the definition of the jobs *SYS2HTML* and *CRONTAB*:

```
# v----- JOBS FOLLOW -----v #
CRONTAB)    # list JOBSTART_SYSTEM crontab / crond(3)
            #
            echo "# ===== system root crontab ====="
            crontab -l
            echo "# ===== edrc root crontab ====="
            ecrontab -l
            set_exitcode 0
            ;;

SYS2HTML)   # system configuration HTML
            #
            collect='hostlist'
            outputdir=$REPORTDIR/SYS2HTML/$TODAY

            # job workload
            #
            mkdir $outputdir >/dev/null 2>&1; chmod 755 $outputdir
            sys2html -o $outputdir $collect
            set_exitcode 0
            ;;

# ^----- JOBS END -----^ #
```

2) list jobs

To list all defined jobs, output correlates to example 1):

```
[ / ]
[ root@acme301 ][*edrc*/bash]: jobstart -l
```

| ACTIVE | JOBNAME | CRON | HOURL | MINUTE | DAY | MONTH | WEEKDAY | QUEUE | DESCRIPTION | DOCREF |
|--------|----------|------|-------|--------|-----|-------|---------|---------|------------------------------|----------|
| True | CRONTAB | | | | | | | | list JOBSTART_SYSTEM crontab | crond(3) |
| True | PUBLISH | YES | 08 | 00 | * | * | 1,3 | Q02-J01 | publish documentation files | |
| True | SYS2HTML | YES | 12 | 00 | * | * | 7 | Q01-J01 | system configuration HTML | |
| True | WEBSYNC | YES | 12 | 00 | * | * | 7 | Q01-J02 | synchronize webserver data | [DLD] |

(2)

The scheduling information is resolved from the **ecrontab** and **crontab** definition on the **JOB-START_SYSTEM**:

```
[ / ]
[ root@acme301 ][*edrc*/bash]: ecrontab -l
```

```
#
# acme301:~edrc/var/spool/cron/root - root crontab
#
# [000] 06.07.2021 CWa Initial Version
#
```

```
SHELL=/bin/bash
PATH=~edrc/bin:/usr/bin:/bin
```

| #MINUTE | HOURL | DAY | MONTH | WEEKDAY | COMMAND |
|---------|--------|--------|--------|----------------|-------------------------|
| #(0-59) | (0-23) | (1-31) | (1-12) | (1=Mon, 7=Sun) | |
| 00 | 12 | * | * | 7 | jobrun SYS2HTML WEBSYNC |
| 00 | 08 | * | * | 1,3 | jobrun PUBLISH |

NOTES

Beside the operating system commands, all commands provided by the WA2L/edrc package can be used.

To use **jobstart** in an application, create a symlink to the **edrc/bin/jobstart** command with a different name:

Example:

```
ln -s ~edrc/bin/jobstart /opt/myApp/bin/jobctl
```

The **FILES** of such a **jobstart** instance are: **/opt/myApp/etc/jobctl.cfg**, **/opt/myApp/etc/jobctl.lib**, **/opt/myApp/log/jobctl.log**, **/opt/myApp/var/jobctl.disabled**, **/opt/myApp/var/jobctl.locked**, and **edrc/var/cache/jobstart/jobctl.cache**.

The setting **JOBRUN_SYSTEM=system** defines the system from where the jobs are started for an instance with any name of **jobstart** (**jobctl** in this example), as the **JOBSTART_SYSTEM=system** does for **jobstart**.

NAME

jobwatch – watch a job sequencer queue

SYNOPSIS

edrc/bin/jobwatch [**-h** | **-V**]

jobwatch [**-i** *update_interval*] [**-q** *queue* | **-Q**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

watch the state of all jobs in a given **queue**.

The output is similar to the **top**(1) operating system command.

OPTIONS

-h usage message.

-V print program version.

-i *update_interval*
 maximal interval of output list update.

The default is 60 seconds, but if a job state changes the list is updated immediately.

-q *queue* queuename if not **default**.

-Q watch status of all queues.

ENVIRONMENT

-

EXIT STATUS

0 no error.

4 usage printed.

- 5** command aborted.
- 6** version printed.
- 11** cannot create temporary directory in **/tmp/**; this might be an indicator of system intrusion.

FILES

etc/job.cfg configuration file for the **job**, **jobwatch**, and **joblog** commands.

/var/tmp/job/
spool directory of **job**.

/var/tmp/job/job.log
log file of **job**.

/var/tmp/job/.seq
job *id* counter.

/var/tmp/job/<JOBID>/
spool directory of a job with the id **<JOBID>** consisting on the following state files:

cmd commands to run in the job.

env user environment (variables).

state state of the job.

pid process id of the job.

time.enqueue
time stamp when the job was created.

time.end time stamp when the job has ended.

time.run time stamp when commands in the job were started (when the job came into the run state).

exec job execution file.

user user that created the job.

cwd current working directory from where the **job** command was issued.

compl job completion criteria resolution.

log output (**stderr** and **stdout**) of the commands in the job.

version version of the **job** command at the time when the job was created.

queue job queue.

EXAMPLES

NAME

jq – Command–line JSON processor

SYNOPSIS

jq [*options...*] *filter* [*files...*]

jq can transform JSON in various ways, by selecting, iterating, reducing and otherwise mangling JSON documents. For instance, running the command **jq 'map(.price) | add'** will take an array of JSON objects as input and return the sum of their "price" fields.

jq can accept text input as well, but by default, **jq** reads a stream of JSON entities (including numbers and other literals) from **stdin**. Whitespace is only needed to separate entities such as 1 and 2, and true and false. One or more *files* may be specified, in which case **jq** will read input from those instead.

The *options* are described in the *INVOKING JQ* section; they mostly concern input and output formatting. The *filter* is written in the jq language and specifies how to transform the input file or document.

FILTERS

A jq program is a "filter": it takes an input, and produces an output. There are a lot of builtin filters for extracting a particular field of an object, or converting a number to a string, or various other standard tasks.

Filters can be combined in various ways – you can pipe the output of one filter into another filter, or collect the output of a filter into an array.

Some filters produce multiple results, for instance there's one that produces all the elements of its input array. Piping that filter into a second runs the second filter for each element of the array. Generally, things that would be done with loops and iteration in other languages are just done by gluing filters together in jq.

It's important to remember that every filter has an input and an output. Even literals like "hello" or 42 are filters – they take an input but always produce the same literal as output. Operations that combine two filters, like addition, generally feed the same input to both and combine the results. So, you can implement an averaging filter as **add / length** – feeding the input array both to the **add** filter and the **length** filter and then performing the division.

But that's getting ahead of ourselves. :) Let's start with something simpler:

INVOKING JQ

jq filters run on a stream of JSON data. The input to jq is parsed as a sequence of whitespace-separated JSON values which are passed through the provided filter one at a time. The output(s) of the filter are written to standard out, again as a sequence of whitespace-separated JSON data.

Note: it is important to mind the shell's quoting rules. As a general rule it's best to always quote (with single-quote characters) the jq program, as too many characters with special meaning to jq are also shell meta-characters. For example, **jq "foo"** will fail on most Unix shells because that will be the same as **jq foo**, which will generally fail because **foo is not defined**. When using the Windows command shell (cmd.exe) it's best to use double quotes around your jq program when given on the command-line (instead of the **-f program-file** option), but then double-quotes in the jq program need backslash escaping.

You can affect how jq reads and writes its input and output using some command-line options:

- **--version:**
Output the jq version and exit with zero.
- **--seq:**
Use the **application/json-seq** MIME type scheme for separating JSON texts in jq's input and output. This means that an ASCII RS (record separator) character is printed before each value on output and an ASCII LF (line feed) is printed after every output. Input JSON texts that fail to parse are ignored (but warned about), discarding all subsequent input until the next RS. This more also parses the output of jq without the **--seq** option.
- **--stream:**

Parse the input in streaming fashion, outputting arrays of path and leaf values (scalars and empty arrays or empty objects). For example, `"a"` becomes `[[],"a"]`, and `[[],"a"],["b"]` becomes `[[0],[]], [[1],"a"]`, and `[[1,0],"b"]`.

This is useful for processing very large inputs. Use this in conjunction with filtering and the **reduce** and **foreach** syntax to reduce large inputs incrementally.

- **--slurp/-s:**
Instead of running the filter for each JSON object in the input, read the entire input stream into a large array and run the filter just once.
- **--raw-input/-R:**
Don't parse the input as JSON. Instead, each line of text is passed to the filter as a string. If combined with **--slurp**, then the entire input is passed to the filter as a single long string.
- **--null-input/-n:**
Don't read any input at all! Instead, the filter is run once using **null** as the input. This is useful when using jq as a simple calculator or to construct JSON data from scratch.
- **--compact-output / -c:**
By default, jq pretty-prints JSON output. Using this option will result in more compact output by instead putting each JSON object on a single line.
- **--tab:**
Use a tab for each indentation level instead of two spaces.
- **--indent n:**
Use the given number of spaces (no more than 8) for indentation.
- **--color-output / -C** and **--monochrome-output / -M:**
By default, jq outputs colored JSON if writing to a terminal. You can force it to produce color even if writing to a pipe or a file using **-C**, and disable color with **-M**.
- **--ascii-output / -a:**
jq usually outputs non-ASCII Unicode codepoints as UTF-8, even if the input specified them as escape sequences (like `"\u03bc"`). Using this option, you can force jq to produce pure ASCII output with every non-ASCII character replaced with the equivalent escape sequence.
- **--unbuffered**
Flush the output after each JSON object is printed (useful if you're piping a slow data source into jq and piping jq's output elsewhere).
- **--sort-keys / -S:**
Output the fields of each object with the keys in sorted order.
- **--raw-output / -r:**
With this option, if the filter's result is a string then it will be written directly to standard output rather than being formatted as a JSON string with quotes. This can be useful for making jq filters talk to non-JSON-based systems.
- **--join-output / -j:**
Like **-r** but jq won't print a newline after each output.
- **-f filename / --from-file filename:**
Read filter from the file rather than from a command line, like awk's **-f** option. You can also use `'#'` to make comments.

- **-Ldirectory / -L directory:**

Prepend **directory** to the search list for modules. If this option is used then no builtin search list is used. See the section on modules below.

- **-e / --exit-status:**

Sets the exit status of jq to 0 if the last output values was neither **false** nor **null**, 1 if the last output value was either **false** or **null**, or 4 if no valid result was ever produced. Normally jq exits with 2 if there was any usage problem or system error, 3 if there was a jq program compile error, or 0 if the jq program ran.

- **--arg name value:**

This option passes a value to the jq program as a predefined variable. If you run jq with **--arg foo bar**, then **\$foo** is available in the program and has the value **"bar"**. Note that **value** will be treated as a string, so **--arg foo 123** will bind **\$foo** to **"123"**.

- **--argjson name JSON-text:**

This option passes a JSON-encoded value to the jq program as a predefined variable. If you run jq with **--argjson foo 123**, then **\$foo** is available in the program and has the value **123**.

- **--slurpfile variable-name filename:**

This option reads all the JSON texts in the named file and binds an array of the parsed JSON values to the given global variable. If you run jq with **--argfile foo bar**, then **\$foo** is available in the program and has an array whose elements correspond to the texts in the file named **bar**.

- **--argfile variable-name filename:**

Do not use. Use **--slurpfile** instead.

(This option is like **--slurpfile**, but when the file has just one text, then that is used, else an array of texts is used as in **--slurpfile**.)

- **--run-tests [filename]:**

Runs the tests in the given file or standard input. This must be the last option given and does not honor all preceding options. The input consists of comment lines, empty lines, and program lines followed by one input line, as many lines of output as are expected (one per output), and a terminating empty line. Compilation failure tests start with a line containing only **"%%FAIL"**, then a line containing the program to compile, then a line containing an error message to compare to the actual.

Be warned that this option can change backwards-incompatibly.

BASIC FILTERS

•

The absolute simplest (and least interesting) filter is **..**. This is a filter that takes its input and produces it unchanged as output.

Since jq by default pretty-prints all output, this trivial program can be a useful way of formatting JSON output from, say, **curl**.

```
jq '
  "Hello, world!"
=> "Hello, world!"
```

.foo, .foo.bar

The simplest *useful* filter is **.foo**. When given a JSON object (aka dictionary or hash) as input, it produces the value at the key **"foo"**, or null if there's none present.

If the key contains special characters, you need to surround it with double quotes like this: `."foo$"`.

A filter of the form `.foo.bar` is equivalent to `.foo|.bar`.

```
jq '.foo'
{"foo": 42, "bar": "less interesting data"}
=> 42
```

```
jq '.foo'
{"notfoo": true, "alsonotfoo": false}
=> null
```

```
jq '["foo"]'
{"foo": 42}
=> 42
```

.foo?

Just like `.foo`, but does not output even an error when `.` is not an array or an object.

```
jq '.foo?'
{"foo": 42, "bar": "less interesting data"}
=> 42
```

```
jq '.foo?'
{"notfoo": true, "alsonotfoo": false}
=> null
```

```
jq '["foo"]?'
{"foo": 42}
=> 42
```

```
jq '[.foo?]'
[1,2]
=> []
```

.[<string>], .[2], .[10:15]

You can also look up fields of an object using syntax like `["foo"]` (`.foo` above is a shorthand version of this). This one works for arrays as well, if the key is an integer. Arrays are zero-based (like javascript), so `.[2]` returns the third element of the array.

The `.[10:15]` syntax can be used to return a subarray of an array or substring of a string. The array returned by `.[10:15]` will be of length 5, containing the elements from index 10 (inclusive) to index 15 (exclusive). Either index may be negative (in which case it counts backwards from the end of the array), or omitted (in which case it refers to the start or end of the array).

The `.[2]` syntax can be used to return the element at the given index. Negative indices are allowed, with `-1` referring to the last element, `-2` referring to the next to last element, and so on.

The `.foo` syntax only works for simply keys i.e. keys that are all alphanumeric characters. `.[<string>]` works with keys that contain special characters such as colons and dots. For example `["foo:bar"]` and `["foo.bar"]` work while `.foo::bar` and `.foo.bar` would not.

The `?` "operator" can also be used with the slice operator, as in `.[10:15]?`, which outputs values where the

inputs are slice-able.

```
jq '[0]'
[{"name":"JSON", "good":true}, {"name":"XML", "good":false}]
=> {"name":"JSON", "good":true}
```

```
jq '[2]'
[{"name":"JSON", "good":true}, {"name":"XML", "good":false}]
=> null
```

```
jq '[2:4]'
["a","b","c","d","e"]
=> ["c","d"]
```

```
jq '[2:4]'
"abcdefghi"
=> "cd"
```

```
jq '[:3]'
["a","b","c","d","e"]
=> ["a","b","c"]
```

```
jq '[-2:]'
["a","b","c","d","e"]
=> ["d","e"]
```

```
jq '[-2]'
[1,2,3]
=> 2
```

.[]

If you use the **.*[index]*** syntax, but omit the index entirely, it will return *all* of the elements of an array. Running **.[]** with the input **[1,2,3]** will produce the numbers as three separate results, rather than as a single array.

You can also use this on an object, and it will return all the values of the object.

```
jq '[]'
[{"name":"JSON", "good":true}, {"name":"XML", "good":false}]
=> {"name":"JSON", "good":true}, {"name":"XML", "good":false}
```

```
jq '[]'
[]
=>
```

```
jq '[]'
{"a": 1, "b": 1}
=> 1, 1
```

.[]?

Like **.[]**, but no errors will be output if **.** is not an array or object.

,

If two filters are separated by a comma, then the input will be fed into both and there will be multiple outputs: first, all of the outputs produced by the left expression, and then all of the outputs produced by the right. For instance, filter **.foo, .bar**, produces both the "foo" fields and "bar" fields as separate outputs.

```
jq ´.foo, .bar´
{"foo": 42, "bar": "something else", "baz": true}
=> 42, "something else"

jq ´.user, .projects[]´
{"user": "stedolan", "projects": ["jq", "wikiflow"]}
=> "stedolan", "jq", "wikiflow"

jq ´.[4,2]´
["a", "b", "c", "d", "e"]
=> "e", "c"
```

|

The **|** operator combines two filters by feeding the output(s) of the one on the left into the input of the one on the right. It's pretty much the same as the Unix shell's pipe, if you're used to that.

If the one on the left produces multiple results, the one on the right will be run for each of those results. So, the expression **.[] | .foo** retrieves the "foo" field of each element of the input array.

```
jq ´.[] | .name´
[{"name": "JSON", "good": true}, {"name": "XML", "good": false}]
=> "JSON", "XML"
```

TYPES AND VALUES

jq supports the same set of datatypes as JSON – numbers, strings, booleans, arrays, objects (which in JSON-speak are hashes with only string keys), and "null".

Booleans, null, strings and numbers are written the same way as in javascript. Just like everything else in jq, these simple values take an input and produce an output – **42** is a valid jq expression that takes an input, ignores it, and returns 42 instead.

Array construction – []

As in JSON, **[]** is used to construct arrays, as in **[1,2,3]**. The elements of the arrays can be any jq expression. All of the results produced by all of the expressions are collected into one big array. You can use it to construct an array out of a known quantity of values (as in **[.foo, .bar, .baz]**) or to "collect" all the results of a filter into an array (as in **[.items[].name]**)

Once you understand the **,** operator, you can look at jq's array syntax in a different light: the expression **[1,2,3]** is not using a built-in syntax for comma-separated arrays, but is instead applying the **[]** operator (collect results) to the expression **1,2,3** (which produces three different results).

If you have a filter **X** that produces four results, then the expression **[X]** will produce a single result, an array of four elements.

```
jq '[.user, .projects[]]'
  {"user":"stedolan", "projects": ["jq", "wikiflow"]}
=> ["stedolan", "jq", "wikiflow"]
```

Objects – {}

Like JSON, {} is for constructing objects (aka dictionaries or hashes), as in: {"a": 42, "b": 17}.

If the keys are "sensible" (all alphabetic characters), then the quotes can be left off. The value can be any expression (although you may need to wrap it in parentheses if it's a complicated one), which gets applied to the {} expression's input (remember, all filters have an input and an output).

```
{foo: .bar}
```

will produce the JSON object {"foo": 42} if given the JSON object {"bar":42, "baz":43}. You can use this to select particular fields of an object: if the input is an object with "user", "title", "id", and "content" fields and you just want "user" and "title", you can write

```
{user: .user, title: .title}
```

Because that's so common, there's a shortcut syntax: {user, title}.

If one of the expressions produces multiple results, multiple dictionaries will be produced. If the input's

```
{"user":"stedolan", "titles":["JQ Primer", "More JQ"]}
```

then the expression

```
{user, title: .titles[]}
```

will produce two outputs:

```
{"user":"stedolan", "title": "JQ Primer"}
{"user":"stedolan", "title": "More JQ"}
```

Putting parentheses around the key means it will be evaluated as an expression. With the same input as above,

```
{(.user): .titles}
```

produces

```

{"stedolan": ["JQ Primer", "More JQ"]}

jq `{"user, title: .titles[]}`
  {"user":"stedolan","titles":["JQ Primer", "More JQ"]}
=> {"user":"stedolan", "title": "JQ Primer"}, {"user":"stedolan", "title": "More JQ"}

jq `{(.user): .titles}`
  {"user":"stedolan","titles":["JQ Primer", "More JQ"]}
=> {"stedolan": ["JQ Primer", "More JQ"]}

```

BUILTIN OPERATORS AND FUNCTIONS

Some jq operator (for instance, `+`) do different things depending on the type of their arguments (arrays, numbers, etc.). However, jq never does implicit type conversions. If you try to add a string to an object you'll get an error message and no result.

Addition – `+`

The operator `+` takes two filters, applies them both to the same input, and adds the results together. What "adding" means depends on the types involved:

- **Numbers** are added by normal arithmetic.
- **Arrays** are added by being concatenated into a larger array.
- **Strings** are added by being joined into a larger string.
- **Objects** are added by merging, that is, inserting all the key–value pairs from both objects into a single combined object. If both objects contain a value for the same key, the object on the right of the `+` wins. (For recursive merge use the `*` operator.)

null can be added to any value, and returns the other value unchanged.

```

jq `a + 1`
  {"a": 7}
=> 8

jq `a + .b`
  {"a": [1,2], "b": [3,4]}
=> [1,2,3,4]

jq `a + null`
  {"a": 1}
=> 1

jq `a + 1`
  {}
=> 1

jq `{a: 1} + {b: 2} + {c: 3} + {a: 42}`
  null
=> {"a": 42, "b": 2, "c": 3}

```

Subtraction –

As well as normal arithmetic subtraction on numbers, the `–` operator can be used on arrays to remove all occurrences of the second array's elements from the first array.

```
jq '4 – .a'
{"a":3}
=> 1
```

```
jq '– ["xml", "yaml"]'
["xml", "yaml", "json"]
=> ["json"]
```

Multiplication, division, modulo – *, /, and %

These infix operators behave as expected when given two numbers. Division by zero raises an error. `x % y` computes x modulo y.

Multiplying a string by a number produces the concatenation of that string that many times. `"x" * 0` produces **null**.

Dividing a string by another splits the first using the second as separators.

Multiplying two objects will merge them recursively: this works like addition but if both objects contain a value for the same key, and the values are objects, the two are merged with the same strategy.

```
jq '10 / . * 3'
5
=> 6
```

```
jq '."/ ", "'
"a, b,c,d, e"
=> ["a","b,c,d","e"]
```

```
jq '{ "k": { "a": 1, "b": 2 } } * { "k": { "a": 0, "c": 3 } }'
null
=> { "k": { "a": 0, "b": 2, "c": 3 } }
```

```
jq '.[ ] | (1 / .)?'
[1,0,-1]
=> 1, -1
```

length

The builtin function **length** gets the length of various different types of value:

- The length of a **string** is the number of Unicode codepoints it contains (which will be the same as its JSON-encoded length in bytes if it's pure ASCII).
- The length of an **array** is the number of elements.
- The length of an **object** is the number of key–value pairs.
- The length of **null** is zero.

```
jq ´.[] | length´ [[1,2], "string", {"a":2}, null] => 2, 6, 1, 0
```

keys, keys_unsorted

The builtin function **keys**, when given an object, returns its keys in an array.

The keys are sorted "alphabetically", by unicode codepoint order. This is not an order that makes particular sense in any particular language, but you can count on it being the same for any two objects with the same set of keys, regardless of locale settings.

When **keys** is given an array, it returns the valid indices for that array: the integers from 0 to length-1.

The **keys_unsorted** function is just like **keys**, but if the input is an object then the keys will not be sorted, instead the keys will roughly be in insertion order.

```
jq ´keys´
  {"abc": 1, "abcd": 2, "Foo": 3}
=> ["Foo", "abc", "abcd"]
```

```
jq ´keys´
  [42,3,35]
=> [0,1,2]
```

has(key)

The builtin function **has** returns whether the input object has the given key, or the input array has an element at the given index.

has(\$key) has the same effect as checking whether **\$key** is a member of the array returned by **keys**, although **has** will be faster.

```
jq ´map(has("foo"))´
  [{"foo": 42}, {}]
=> [true, false]
```

```
jq ´map(has(2))´
  [[0,1], ["a","b","c"]]
=> [false, true]
```

in

The builtin function **in** returns the input key is in the given object, or the input index corresponds to an element in the given array. It is, essentially, an inversed version of **has**.

```
jq ´.[] | in({"foo": 42})´
  ["foo", "bar"]
=> true, false
```

```
jq ´map(in([0,1]))´
  [2, 0]
=> [false, true]
```

path(path_expression)

Outputs array representations of the given path expression in `..`. The outputs are arrays of strings (keys in objects) and/or numbers (array indices).

Path expressions are jq expressions like `.a`, but also `.[]`. There are two types of path expressions: ones that can match exactly, and ones that cannot. For example, `.a.b.c` is an exact match path expression, while `.a[].b` is not.

path(exact_path_expression) will produce the array representation of the path expression even if it does not exist in `..`, if `.` is **null** or an array or an object.

path(pattern) will produce array representations of the paths matching **pattern** if the paths exist in `..`.

Note that the path expressions are not different from normal expressions. The expression **path(..|select(type=="boolean"))** outputs all the paths to boolean values in `..`, and only those paths.

```
jq 'path(.a[0].b)'
null
=> ["a",0,"b"]

jq '[path(..)]'
{"a":[{"b":1}]}
=> [[],["a"],["a",0],["a",0,"b"]]
```

del(path_expression)

The builtin function **del** removes a key and its corresponding value from an object.

```
jq 'del(.foo)'
{"foo": 42, "bar": 9001, "baz": 42}
=> {"bar": 9001, "baz": 42}

jq 'del([1, 2])'
["foo", "bar", "baz"]
=> ["foo"]
```

to_entries, from_entries, with_entries

These functions convert between an object and an array of key–value pairs. If **to_entries** is passed an object, then for each **k: v** entry in the input, the output array includes **{"key": k, "value": v}**.

from_entries does the opposite conversion, and **with_entries(foo)** is a shorthand for **to_entries | map(foo) | from_entries**, useful for doing some operation to all keys and values of an object. **from_entries** accepts key, Key, Name, value and Value as keys.

```
jq 'to_entries'
{"a": 1, "b": 2}
=> [{"key": "a", "value": 1}, {"key": "b", "value": 2}]

jq 'from_entries'
[{"key": "a", "value": 1}, {"key": "b", "value": 2}]
=> {"a": 1, "b": 2}
```

```
jq 'with_entries(.key |= "KEY_" + .)'
  {"a": 1, "b": 2}
=> {"KEY_a": 1, "KEY_b": 2}
```

select(boolean_expression)

The function **select(foo)** produces its input unchanged if **foo** returns true for that input, and produces no output otherwise.

It's useful for filtering lists: **[1,2,3] | map(select(. >= 2))** will give you **[2,3]**.

```
jq 'map(select(. >= 2))'
  [1,5,3,0,7]
=> [5,3,7]

jq '.[] | select(.id == "second")'
  [{"id": "first", "val": 1}, {"id": "second", "val": 2}]
=> [{"id": "second", "val": 2}]
```

arrays, objects, iterables, booleans, numbers, normals, finites, strings, nulls, values, scalars

These built-ins select only inputs that are arrays, objects, iterables (arrays or objects), booleans, numbers, normal numbers, finite numbers, strings, null, non-null values, and non-iterables, respectively.

```
jq '.[]|numbers'
  [[],{}],1,"foo",null,true,false]
=> 1
```

empty

empty returns no results. None at all. Not even **null**.

It's useful on occasion. You'll know if you need it :)

```
jq '1, empty, 2'
  null
=> 1, 2

jq '[1,2,empty,3]'
  null
=> [1,2,3]
```

error(message)

Produces an error, just like **.a** applied to values other than null and objects would, but with the given message as the error's value.

\$_loc__

Produces an object with a "file" key and a "line" key, with the filename and line number where **\$_loc__** occurs, as values.

```
jq 'try error("\($__loc__)") catch .'
null
=> {"file\":"<top-level>","\line\:1}"
```

map(x), map_values(x)

For any filter **x**, **map(x)** will run that filter for each element of the input array, and produce the outputs a new array. **map(.+1)** will increment each element of an array of numbers.

Similarly, **map_values(x)** will run that filter for each element, but it will return an object when an object is passed.

map(x) is equivalent to `[.] | x`. In fact, this is how it's defined. Similarly, **map_values(x)** is defined as `[.] |= x`.

```
jq 'map(.+1)'
[1,2,3]
=> [2,3,4]

jq 'map_values(.+1)'
{"a": 1, "b": 2, "c": 3}
=> {"a": 2, "b": 3, "c": 4}
```

paths, paths(node_filter), leaf_paths

paths outputs the paths to all the elements in its input (except it does not output the empty list, representing itself).

paths(f) outputs the paths to any values for which **f** is true. That is, **paths(numbers)** outputs the paths to all numeric values.

leaf_paths is an alias of **paths(scalars)**; **leaf_paths** is *deprecated* and will be removed in the next major release.

```
jq '[paths]'
[1,[],{"a":2}]
=> [[0],[1],[1,0],[1,1],[1,1,"a"]]

jq '[paths(scalars)]'
[1,[],{"a":2}]
=> [[0],[1,1,"a"]]
```

add

The filter **add** takes as input an array, and produces as output the elements of the array added together. This might mean summed, concatenated or merged depending on the types of the elements of the input array – the rules are the same as those for the **+** operator (described above).

If the input is an empty array, **add** returns **null**.

```
jq 'add'
["a","b","c"]
=> "abc"
```

```
jq 'add'
  [1, 2, 3]
=> 6
```

```
jq 'add'
  []
=> null
```

any, any(condition), any(generator; condition)

The filter **any** takes as input an array of boolean values, and produces **true** as output if any of the the elements of the array is **true**.

If the input is an empty array, **any** returns **false**.

The **any(condition)** form applies the given condition to the elements of the input array.

The **any(generator; condition)** form applies the given condition to all the outputs of the given generator.

```
jq 'any'
  [true, false]
=> true
```

```
jq 'any'
  [false, false]
=> false
```

```
jq 'any'
  []
=> false
```

all, all(condition), all(generator; condition)

The filter **all** takes as input an array of boolean values, and produces **true** as output if all of the the elements of the array are **true**.

The **all(condition)** form applies the given condition to the elements of the input array.

The **all(generator; condition)** form applies the given condition to all the outputs of the given generator.

If the input is an empty array, **all** returns **true**.

```
jq 'all'
  [true, false]
=> false
```

```
jq 'all'
  [true, true]
=> true
```

```
jq 'all'
  []
=> true
```

[Requires 1.5] flatten, flatten(depth)

The filter **flatten** takes as input an array of nested arrays, and produces a flat array in which all arrays inside the original array have been recursively replaced by their values. You can pass an argument to it to specify how many levels of nesting to flatten.

flatten(2) is like **flatten**, but going only up to two levels deep.

```
jq 'flatten'
  [1, [2], [[3]]]
=> [1, 2, 3]

jq 'flatten(1)'
  [1, [2], [[3]]]
=> [1, 2, [3]]

jq 'flatten'
  [[]]
=> []

jq 'flatten'
  [{ "foo": "bar" }, [{ "foo": "baz" }]]
=> [{ "foo": "bar" }, { "foo": "baz" }]
```

range(upto), range(from;upto) range(from;upto;by)

The **range** function produces a range of numbers. **range(4;10)** produces 6 numbers, from 4 (inclusive) to 10 (exclusive). The numbers are produced as separate outputs. Use **[range(4;10)]** to get a range as an array.

The one argument form generates numbers from 0 to the given number, with an increment of 1.

The two argument form generates numbers from **from** to **upto** with an increment of 1.

The three argument form generates numbers **from** to **upto** with an increment of **by**.

```
jq 'range(2;4)'
  null
=> 2, 3

jq '[range(2;4)]'
  null
=> [2,3]

jq '[range(4)]'
  null
=> [0,1,2,3]

jq '[range(0;10;3)]'
  null
=> [0,3,6,9]

jq '[range(0;10;-1)]'
  null
=> []
```

```
jq '[range(0;-5;-1)]'
null
=> [0,-1,-2,-3,-4]
```

floor

The **floor** function returns the floor of its numeric input.

```
jq 'floor'
3.14159
=> 3
```

sqrt

The **sqrt** function returns the square root of its numeric input.

```
jq 'sqrt'
9
=> 3
```

tonumber

The **tonumber** function parses its input as a number. It will convert correctly-formatted strings to their numeric equivalent, leave numbers alone, and give an error on all other input.

```
jq '[] | tonumber'
[1, "1"]
=> 1, 1
```

tostring

The **tostring** function prints its input as a string. Strings are left unchanged, and all other values are JSON-encoded.

```
jq '[] | tostring'
[1, "1", [1]]
=> "1", "1", "[1]"
```

type

The **type** function returns the type of its argument as a string, which is one of null, boolean, number, string, array or object.

```
jq 'map(type)'
[0, false, [], {}, null, "hello"]
=> ["number", "boolean", "array", "object", "null", "string"]
```

infinite, nan, isinfinite, isnan, isfinite, isnormal

Some arithmetic operations can yield infinities and "not a number" (NaN) values. The **isinfinite** builtin returns **true** if its input is infinite. The **isnan** builtin returns **true** if its input is a NaN. The **infinite** builtin returns a positive infinite value. The **nan** builtin returns a NaN. The **isnormal** builtin returns true if its input is a normal number.

Note that division by zero raises an error.

Currently most arithmetic operations operating on infinities, NaNs, and sub-normals do not raise errors.

```
jq '[.] | (infinite * .) < 0'
  [-1, 1]
=> true, false

jq 'infinite, nan | type'
  null
=> "number", "number"
```

sort, sort_by(path_expression)

The **sort** functions sorts its input, which must be an array. Values are sorted in the following order:

- **null**
- **false**
- **true**
- numbers
- strings, in alphabetical order (by unicode codepoint value)
- arrays, in lexical order
- objects

The ordering for objects is a little complex: first they're compared by comparing their sets of keys (as arrays in sorted order), and if their keys are equal then the values are compared key by key.

sort may be used to sort by a particular field of an object, or by applying any jq filter.

sort_by(foo) compares two elements by comparing the result of **foo** on each element.

```
jq 'sort'
  [8,3,null,6]
=> [null,3,6,8]

jq 'sort_by(.foo)'
  [{"foo":4, "bar":10}, {"foo":3, "bar":100}, {"foo":2, "bar":1}]
=> [{"foo":2, "bar":1}, {"foo":3, "bar":100}, {"foo":4, "bar":10}]
```

group_by(path_expression)

group_by(.foo) takes as input an array, groups the elements having the same **.foo** field into separate arrays, and produces all of these arrays as elements of a larger array, sorted by the value of the **.foo** field.

Any jq expression, not just a field access, may be used in place of **.foo**. The sorting order is the same as

described in the **sort** function above.

```
jq 'group_by(.foo)'
[{"foo":1, "bar":10}, {"foo":3, "bar":100}, {"foo":1, "bar":1}]
=> [{"foo":1, "bar":10}, {"foo":1, "bar":1}], [{"foo":3, "bar":100}]
```

min, max, min_by(path_exp), max_by(path_exp)

Find the minimum or maximum element of the input array.

The **min_by(path_exp)** and **max_by(path_exp)** functions allow you to specify a particular field or property to examine, e.g. **min_by(.foo)** finds the object with the smallest **foo** field.

```
jq 'min'
[5,4,2,7]
=> 2

jq 'max_by(.foo)'
[{"foo":1, "bar":14}, {"foo":2, "bar":3}]
=> {"foo":2, "bar":3}
```

unique, unique_by(path_exp)

The **unique** function takes as input an array and produces an array of the same elements, in sorted order, with duplicates removed.

The **unique_by(path_exp)** function will keep only one element for each value obtained by applying the argument. Think of it as making an array by taking one element out of every group produced by **group**.

```
jq 'unique'
[1,2,5,3,5,3,1,3]
=> [1,2,3,5]

jq 'unique_by(.foo)'
[{"foo": 1, "bar": 2}, {"foo": 1, "bar": 3}, {"foo": 4, "bar": 5}]
=> [{"foo": 1, "bar": 2}, {"foo": 4, "bar": 5}]

jq 'unique_by(length)'
["chunky", "bacon", "kitten", "cicada", "asparagus"]
=> ["bacon", "chunky", "asparagus"]
```

reverse

This function reverses an array.

```
jq 'reverse'
[1,2,3,4]
=> [4,3,2,1]
```

contains(element)

The filter **contains(b)** will produce true if b is completely contained within the input. A string B is contained in a string A if B is a substring of A. An array B is contained in an array A if all elements in B are contained in any element in A. An object B is contained in object A if all of the values in B are contained in the value in A with the same key. All other types are assumed to be contained in each other if they are equal.

```
jq 'contains("bar")'
  "foobar"
=> true

jq 'contains(["baz", "bar"])'
  ["foobar", "foobaz", "blarp"]
=> true

jq 'contains(["bazzzz", "bar"])'
  ["foobar", "foobaz", "blarp"]
=> false

jq 'contains({foo: 12, bar: [{barp: 12}]})'
  {"foo": 12, "bar": [1,2,{"barp":12, "blip":13}]}
=> true

jq 'contains({foo: 12, bar: [{barp: 15}]})'
  {"foo": 12, "bar": [1,2,{"barp":12, "blip":13}]}
=> false
```

indices(s)

Outputs an array containing the indices in . where s occurs. The input may be an array, in which case if s is an array then the indices output will be those where all elements in . match those of s.

```
jq 'indices(",")'
  "a,b, cd, efg, hijk"
=> [3,7,12]

jq 'indices(1)'
  [0,1,2,1,3,1,4]
=> [1,3,5]

jq 'indices([1,2])'
  [0,1,2,3,1,4,2,5,1,2,6,7]
=> [1,8]
```

index(s), rindex(s)

Outputs the index of the first (**index**) or last (**rindex**) occurrence of s in the input.

```
jq 'index(",")'
```

```
"a,b, cd, efg, hijk"
=> 3
```

```
jq `rindex(", ")`
"a,b, cd, efg, hijk"
=> 12
```

inside

The filter **inside(b)** will produce true if the input is completely contained within b. It is, essentially, an inversed version of **contains**.

```
jq `inside("foobar")`
"bar"
=> true
```

```
jq `inside(["foobar", "foobaz", "blarp"])`
["baz", "bar"]
=> true
```

```
jq `inside(["foobar", "foobaz", "blarp"])`
["bazzzzz", "bar"]
=> false
```

```
jq `inside({"foo": 12, "bar": [1,2,{"barp":12, "blip":13}]})`
{"foo": 12, "bar": [{"barp": 12}]}
=> true
```

```
jq `inside({"foo": 12, "bar": [1,2,{"barp":12, "blip":13}]})`
{"foo": 12, "bar": [{"barp": 15}]}
=> false
```

startswith(str)

Outputs **true** if . starts with the given string argument.

```
jq `[.[]]|startswith("foo")`
["fo", "foo", "barfoo", "foobar", "barfoob"]
=> [false, true, false, true, false]
```

endswith(str)

Outputs **true** if . ends with the given string argument.

```
jq `[.[]]|endswith("foo")`
["foobar", "barfoo"]
=> [false, true]
```

combinations, combinations(n)

Outputs all combinations of the elements of the arrays in the input array. If given an argument **n**, it outputs all combinations of **n** repetitions of the input array.

```
jq 'combinations'
[[1,2], [3, 4]]
=> [1, 3], [1, 4], [2, 3], [2, 4]

jq 'combinations(2)'
[0, 1]
=> [0, 0], [0, 1], [1, 0], [1, 1]
```

ltrimstr(str)

Outputs its input with the given prefix string removed, if it starts with it.

```
jq '[.[]|ltrimstr("foo")]´
["fo", "foo", "barfoo", "foobar", "afoo"]
=> ["fo", "", "barfoo", "bar", "afoo"]
```

rtrimstr(str)

Outputs its input with the given suffix string removed, if it ends with it.

```
jq '[.[]|rtrimstr("foo")]´
["fo", "foo", "barfoo", "foobar", "foob"]
=> ["fo", "", "bar", "foobar", "foob"]
```

explode

Converts an input string into an array of the string's codepoint numbers.

```
jq 'explode'
"foobar"
=> [102,111,111,98,97,114]
```

implode

The inverse of explode.

```
jq 'implode'
[65, 66, 67]
=> "ABC"
```

split

Splits an input string on the separator argument.

```
jq 'split(", ")'
    "a, b,c,d, e, "
=> ["a","b,c,d","e",""]
```

join(str)

Joins the array of elements given as input, using the argument as separator. It is the inverse of **split**: that is, running **split("foo") | join("foo")** over any input string returns said input string.

```
jq 'join(", ")'
    ["a","b,c,d","e"]
=> "a, b,c,d, e"
```

ascii_lowercase, ascii_uppercase

Emit a copy of the input string with its alphabetic characters (a–z and A–Z) converted to the specified case.

while(cond; update)

The **while(cond; update)** function allows you to repeatedly apply an update to **.** until **cond** is false.

Note that **while(cond; update)** is internally defined as a recursive jq function. Recursive calls within **while** will not consume additional memory if **update** produces at most one output for each input. See advanced topics below.

```
jq '[while(<100; .*2)]'
    1
=> [1,2,4,8,16,32,64]
```

until(cond; next)

The **until(cond; next)** function allows you to repeatedly apply the expression **next**, initially to **.** then to its own output, until **cond** is true. For example, this can be used to implement a factorial function (see below).

Note that **until(cond; next)** is internally defined as a recursive jq function. Recursive calls within **until()** will not consume additional memory if **next** produces at most one output for each input. See advanced topics below.

```
jq '[.,1]|until(.[0] < 1; [.[0] - 1, .[1] * .[0]])|. [1]'
    4
=> 24
```

recurse(f), recurse, recurse(f; condition), recurse_down

The **recurse(f)** function allows you to search through a recursive structure, and extract interesting data from all levels. Suppose your input represents a filesystem:

```
{ "name": "/", "children": [
  { "name": "/bin", "children": [
    { "name": "/bin/l", "children": [] },
```

```
{ "name": "/bin/sh", "children": [] } },
{ "name": "/home", "children": [
  { "name": "/home/stephen", "children": [
    { "name": "/home/stephen/jq", "children": [] } ] } ] } }
```

Now suppose you want to extract all of the filenames present. You need to retrieve **.name**, **.children.name**, **.children[].children.name**, and so on. You can do this with:

```
recurse(children[]) | .name
```

When called without an argument, **recurse** is equivalent to **recurse(.[]?)**.

recurse(f) is identical to **recurse(f; . != null)** and can be used without concerns about recursion depth.

recurse(f; condition) is a generator which begins by emitting **.** and then emits in turn **.f**, **.f|f**, **.f|f|f**, ... so long as the computed value satisfies the condition. For example, to generate all the integers, at least in principle, one could write **recurse(+1; true)**.

For legacy reasons, **recurse_down** exists as an alias to calling **recurse** without arguments. This alias is considered *deprecated* and will be removed in the next major release.

The recursive calls in **recurse** will not consume additional memory whenever **f** produces at most a single output for each input.

```
jq 'recurse(.foo[])'
  { "foo": [{"foo": []}, {"foo": [{"foo": []}]} ] }
=> { "foo": [{"foo": []}, {"foo": [{"foo": []}]} ], {"foo": []}, {"foo": [{"foo": []}]} , {"foo": []}

jq 'recurse'
  { "a": 0, "b": [1] }
=> { "a": 0, "b": [1] }, 0, [1], 1

jq 'recurse(. * .; . < 20)'
  2
=> 2, 4, 16
```

..

Short-hand for **recurse** without arguments. This is intended to resemble the XPath **//** operator. Note that **..a** does not work; use **..|a** instead. In the example below we use **..|a?** to find all the values of object keys "a" in any object found "below" ..

```
jq '..|a?'
  [{"a": 1}]
=> 1
```

env

Outputs an object representing jq's environment.

```
jq 'env.PAGER'
null
=> "less"
```

transpose

Transpose a possibly jagged matrix (an array of arrays). Rows are padded with nulls so the result is always rectangular.

```
jq 'transpose'
[[1], [2,3]]
=> [[1,2],[null,3]]
```

bsearch(x)

bsearch(x) conducts a binary search for x in the input array. If the input is sorted and contains x, then bsearch(x) will return its index in the array; otherwise, if the array is sorted, it will return $(-1 - ix)$ where ix is an insertion point such that the array would still be sorted after the insertion of x at ix. If the array is not sorted, bsearch(x) will return an integer that is probably of no interest.

```
jq 'bsearch(0)'
[0,1]
=> 0
```

```
jq 'bsearch(0)'
[1,2,3]
=> -1
```

```
jq 'bsearch(4) as $ix | if $ix < 0 then .[-(1+$ix)] = 4 else . end'
[1,2,3]
=> [1,2,3,4]
```

String interpolation – \(\foo)

Inside a string, you can put an expression inside parens after a backslash. Whatever the expression returns will be interpolated into the string.

```
jq '"The input was \(.), which is one less than \(.+1)'"
42
=> "The input was 42, which is one less than 43"
```

Convert to/from JSON

The **tojson** and **fromjson** builtins dump values as JSON texts or parse JSON texts into values, respectively. The tojson builtin differs from tostring in that tostring returns strings unmodified, while tojson encodes strings as JSON strings.

```
jq '[.[]|tostring]'
[1, "foo", ["foo"]]
=> ["1","foo","\"foo\""]
```

```
jq '[.[]|tojson]`
  [1, "foo", ["foo"]]
=> [{"1","foo\""}, [{"foo\""}]
```

```
jq '[.[]|tojson|fromjson]`
  [1, "foo", ["foo"]]
=> [1,"foo",["foo"]]
```

Format strings and escaping

The **@foo** syntax is used to format and escape strings, which is useful for building URLs, documents in a language like HTML or XML, and so forth. **@foo** can be used as a filter on its own, the possible escapings are:

@text:

Calls **tostring**, see that function for details.

@json:

Serializes the input as JSON.

@html:

Applies HTML/XML escaping, by mapping the characters `<>&'"` to their entity equivalents **<**, **>**, **&**, **'**, **"**.

@uri:

Applies percent-encoding, by mapping all reserved URI characters to a **%XX** sequence.

@csv:

The input must be an array, and it is rendered as CSV with double quotes for strings, and quotes escaped by repetition.

@tsv:

The input must be an array, and it is rendered as TSV (tab-separated values). Each input array will be printed as a single line. Fields are separated by a single tab (ascii **0x09**). Input characters line-feed (ascii **0x0a**), carriage-return (ascii **0x0d**), tab (ascii **0x09**) and backslash (ascii **0x5c**) will be output as escape sequences **\n**, **\r**, **\t**, **** respectively.

@sh:

The input is escaped suitable for use in a command-line for a POSIX shell. If the input is an array, the output will be a series of space-separated strings.

@base64:

The input is converted to base64 as specified by RFC 4648.

This syntax can be combined with string interpolation in a useful way. You can follow a **@foo** token with a string literal. The contents of the string literal will *not* be escaped. However, all interpolations made inside that string literal will be escaped. For instance,

```
@uri "https://www.google.com/search?q=\\(.search)"
```

will produce the following output for the input **{"search":"what is jq?"}**:

```
"https://www.google.com/search?q=what%20is%20jq%3F"
```

Note that the slashes, question mark, etc. in the URL are not escaped, as they were part of the string literal.

```
jq '@html'
  "This works if x < y"
=> "This works if x &lt; y"

jq '@sh "echo \(.)"'
  "O'Hara's Ale"
=> "echo 'O\W'Hara\W's Ale'"
```

Dates

jq provides some basic date handling functionality, with some high-level and low-level builtins. In all cases these builtins deal exclusively with time in UTC.

The **fromdateiso8601** builtin parses datetimes in the ISO 8601 format to a number of seconds since the Unix epoch (1970-01-01T00:00:00Z). The **todateiso8601** builtin does the inverse.

The **fromdate** builtin parses datetime strings. Currently **fromdate** only supports ISO 8601 datetime strings, but in the future it will attempt to parse datetime strings in more formats.

The **todate** builtin is an alias for **todateiso8601**.

The **now** builtin outputs the current time, in seconds since the Unix epoch.

Low-level jq interfaces to the C-library time functions are also provided: **strptime**, **strftime**, **mktime**, and **gmtime**. Refer to your host operating system's documentation for the format strings used by **strptime** and **strftime**. Note: these are not necessarily stable interfaces in jq, particularly as to their localization functionality.

The **gmtime** builtin consumes a number of seconds since the Unix epoch and outputs a "broken down time" representation of time as an array of numbers representing (in this order): the year, the month (zero-based), the day of the month, the hour of the day, the minute of the hour, the second of the minute, the day of the week, and the day of the year — all one-based unless otherwise stated.

The **mktime** builtin consumes "broken down time" representations of time output by **gmtime** and **strptime**.

The **strptime(fmt)** builtin parses input strings matching the **fmt** argument. The output is in the "broken down time" representation consumed by **gmtime** and output by **mktime**.

The **strftime(fmt)** builtin formats a time with the given format.

The format strings for **strptime** and **strftime** are described in typical C library documentation. The format string for ISO 8601 datetime is "%Y-%m-%dT%H:%M:%SZ".

jq may not support some or all of this date functionality on some systems.

```
jq 'fromdate'
  "2015-03-05T23:51:47Z"
=> 1425599507

jq 'strptime("%Y-%m-%dT%H:%M:%SZ")'
  "2015-03-05T23:51:47Z"
=> [2015,2,5,23,51,47,4,63]

jq 'strptime("%Y-%m-%dT%H:%M:%SZ")|mktime'
  "2015-03-05T23:51:47Z"
```

=> 1425599507

CONDITIONALS AND COMPARISONS

==, !=

The expression `'a == b'` will produce `'true'` if the result of `a` and `b` are equal (that is, if they represent equivalent JSON documents) and `'false'` otherwise. In particular, strings are never considered equal to numbers. If you're coming from Javascript, jq's `==` is like Javascript's `===` – considering values equal only when they have the same type as well as the same value.

`!=` is "not equal", and `'a != b'` returns the opposite value of `'a == b'`

```
jq '.[] == 1'
[1, 1.0, "1", "banana"]
=> true, true, false, false
```

if-then-else

if A then B else C end will act the same as **B** if **A** produces a value other than false or null, but act the same as **C** otherwise.

Checking for false or null is a simpler notion of "truthiness" than is found in Javascript or Python, but it means that you'll sometimes have to be more explicit about the condition you want: you can't test whether, e.g. a string is empty using **if .name then A else B end**, you'll need something more like **if (.name | length) > 0 then A else B end** instead.

If the condition **A** produces multiple results, it is considered "true" if any of those results is not false or null. If it produces zero results, it's considered false.

More cases can be added to an if using **elif A then B** syntax.

```
jq 'if . == 0 then
```

```
"zero" elif . == 1 then "one" else "many" end' 2 => "many"
```

>, >=, <=, <

The comparison operators `>`, `>=`, `<=`, `<` return whether their left argument is greater than, greater than or equal to, less than or equal to or less than their right argument (respectively).

The ordering is the same as that described for **sort**, above.

```
jq '. < 5'
2
=> true
```

and/or/not

jq supports the normal Boolean operators and/or/not. They have the same standard of truth as if expressions – false and null are considered "false values", and anything else is a "true value".

If an operand of one of these operators produces multiple results, the operator itself will produce a result for each input.

not is in fact a builtin function rather than an operator, so it is called as a filter to which things can be piped rather than with special syntax, as in **.foo and .bar | not**.

These three only produce the values "true" and "false", and so are only useful for genuine Boolean operations, rather than the common Perl/Python/Ruby idiom of "value_that_may_be_null or default". If you want to use this form of "or", picking between two values rather than evaluating a condition, see the "///" operator below.

```
jq '42 and "a string"'
null
=> true

jq '(true, false) or false'
null
=> true, false

jq '(true, true) and (true, false)'
null
=> true, false, true, false

jq '[true, false | not]'
null
=> [false, true]
```

Alternative operator – //

A filter of the form **a // b** produces the same results as **a**, if **a** produces results other than **false** and **null**. Otherwise, **a // b** produces the same results as **b**.

This is useful for providing defaults: **.foo // 1** will evaluate to **1** if there's no **.foo** element in the input. It's similar to how **or** is sometimes used in Python (jq's **or** operator is reserved for strictly Boolean operations).

```
jq '.foo // 42'
{"foo": 19}
=> 19

jq '.foo // 42'
{}
=> 42
```

try-catch

Errors can be caught by using **try EXP catch EXP**. The first expression is executed, and if it fails then the second is executed with the error message. The output of the handler, if any, is output as if it had been the output of the expression to try.

The **try EXP** form uses **empty** as the exception handler.

```
jq 'try .a catch ". is not an object"'
true
=> ". is not an object"

jq '[.[]|try .a]'
[{}, true, {"a":1}]
=> [null, 1]
```

```
jq 'try error("some exception") catch .'
    true
=> "some exception"
```

Breaking out of control structures

A convenient use of try/catch is to break out of control structures like **reduce**, **foreach**, **while**, and so on.

For example:

```
# Repeat an expression until it raises "break" as an
# error, then stop repeating without re-raising the error.
# But if the error caught is not "break" then re-raise it.
try repeat(exp) catch .=="break" then empty else error;
```

jq has a syntax for named lexical labels to "break" or "go (back) to":

```
label $out | ... break $out ...
```

The **break \$label_name** expression will cause the program to act as though the nearest (to the left) **label \$label_name** produced **empty**.

The relationship between the **break** and corresponding **label** is lexical: the label has to be "visible" from the break.

To break out of a **reduce**, for example:

```
label $out | reduce .[] as $item (null; if .==false then break $out else ... end)
```

The following jq program produces a syntax error:

```
break $out
```

because no label **\$out** is visible.

? operator

The **?** operator, used as **EXP?**, is shorthand for **try EXP**.

```
jq '[.[]|(a)?]'
    [{}, true, {"a":1}]
=> [null, 1]
```

REGULAR EXPRESSIONS (PCRE)

jq uses the Oniguruma regular expression library, as do php, ruby, TextMate, Sublime Text, etc, so the description here will focus on jq specifics.

The jq regex filters are defined so that they can be used using one of these patterns:

```

STRING | FILTER( REGEX )
STRING | FILTER( REGEX; FLAGS )
STRING | FILTER( [REGEX] )
STRING | FILTER( [REGEX, FLAGS] )

```

where: * **STRING**, **REGEX** and **FLAGS** are jq strings and subject to jq string interpolation; * **REGEX**, after string interpolation, should be a valid PCRE regex; * **FILTER** is one of **test**, **match**, or **capture**, as described below.

FLAGS is a string consisting of one or more of the supported flags:

- **g** – Global search (find all matches, not just the first)
- **i** – Case insensitive search
- **m** – Multi line mode (‘.’ will match newlines)
- **n** – Ignore empty matches
- **p** – Both **s** and **m** modes are enabled
- **s** – Single line mode (‘^’ → ‘\A’, ‘\$’ → ‘\Z’)
- **l** – Find longest possible matches
- **x** – Extended regex format (ignore whitespace and comments)

To match whitespace in an **x** pattern use an escape such as `\s`, e.g.

- `test("a\s b", "x")`.

Note that certain flags may also be specified within **REGEX**, e.g.

- `jq -n '("test", "TEst", "teST", "TEST") | test("(?i)te(?-i)st")'`

evaluates to: true, true, false, false.

[Requires 1.5] **test(val)**, **test(regex; flags)**

Like **match**, but does not return match objects, only **true** or **false** for whether or not the regex matches the input.

```

jq 'test("foo")'
"foo"
=> true

```

```

jq '[.] | test("a b c # spaces are ignored"; "ix")'
["xabcd", "ABC"]
=> true, true

```

[Requires 1.5] **match(val)**, **match(regex; flags)**

match outputs an object for each match it finds. Matches have the following fields:

- **offset** – offset in UTF-8 codepoints from the beginning of the input

- **length** – length in UTF-8 codepoints of the match
- **string** – the string that it matched
- **captures** – an array of objects representing capturing groups.

Capturing group objects have the following fields:

- **offset** – offset in UTF-8 codepoints from the beginning of the input
- **length** – length in UTF-8 codepoints of this capturing group
- **string** – the string that was captured
- **name** – the name of the capturing group (or **null** if it was unnamed)

Capturing groups that did not match anything return an offset of `-1`

```
jq 'match("(abc)+"; "g")'
"abc abc"
=> { "offset": 0, "length": 3, "string": "abc", "captures": [{ "offset": 0, "length": 3, "string": "abc", "name": null }], { "offset": 3, "length": 3, "string": "abc", "name": null } }
```

```
jq 'match("foo")'
"foo bar foo"
=> { "offset": 0, "length": 3, "string": "foo", "captures": [] }
```

```
jq 'match(["foo", "ig"])'
"foo bar FOO"
=> { "offset": 0, "length": 3, "string": "foo", "captures": [] }, { "offset": 8, "length": 3, "string": "FOO", "captures": [] }
```

```
jq 'match("foo (?<bar123>bar)? foo"; "ig")'
"foo bar foo foo"
=> { "offset": 0, "length": 11, "string": "foo bar foo", "captures": [{ "offset": 4, "length": 3, "string": "bar", "name": "bar" }], { "offset": 11, "length": 3, "string": "foo", "name": null } }
```

```
jq '[ match(".", "g") ] | length'
"abc"
=> 3
```

[Requires 1.5] capture(val), capture(regex; flags)

Collects the named captures in a JSON object, with the name of each capture as the key, and the matched string as the corresponding value.

```
jq 'capture("(?<a>[a-z]+)-(?<n>[0-9]+)")'
"xyzy-14"
=> { "a": "xyzy", "n": "14" }
```

[Requires 1.5] scan(regex), scan(regex; flags)

Emit a stream of the non-overlapping substrings of the input that match the regex in accordance with the flags, if any have been specified. If there is no match, the stream is empty. To capture all the matches for each input string, use the idiom `[expr]`, e.g. `[scan(regex)]`.

split(regex; flags)

For backwards compatibility, **split** splits on a string, not a regex.

[Requires 1.5] splits(regex), splits(regex; flags)

These provide the same results as their **split** counterparts, but as a stream instead of an array.

[Requires 1.5] sub(regex; tostring) sub(regex; string; flags)

Emit the string obtained by replacing the first match of regex in the input string with **tostring**, after interpolation. **tostring** should be a jq string, and may contain references to named captures. The named captures are, in effect, presented as a JSON object (as constructed by **capture**) to **tostring**, so a reference to a captured variable named "x" would take the form: "(.x)".

[Requires 1.5] gsub(regex; string), gsub(regex; string; flags)

gsub is like **sub** but all the non-overlapping occurrences of the regex are replaced by the string, after interpolation.

ADVANCED FEATURES

Variables are an absolute necessity in most programming languages, but they're relegated to an "advanced feature" in jq.

In most languages, variables are the only means of passing around data. If you calculate a value, and you want to use it more than once, you'll need to store it in a variable. To pass a value to another part of the program, you'll need that part of the program to define a variable (as a function parameter, object member, or whatever) in which to place the data.

It is also possible to define functions in jq, although this is a feature whose biggest use is defining jq's standard library (many jq functions such as **map** and **find** are in fact written in jq).

jq has reduction operators, which are very powerful but a bit tricky. Again, these are mostly used internally, to define some useful bits of jq's standard library.

It may not be obvious at first, but jq is all about generators (yes, as often found in other languages). Some utilities are provided to help deal with generators.

Some minimal I/O support (besides reading JSON from standard input, and writing JSON to standard output) is available.

Finally, there is a module/library system.

Variables

In jq, all filters have an input and an output, so manual plumbing is not necessary to pass a value from one part of a program to the next. Many expressions, for instance **a + b**, pass their input to two distinct subexpressions (here **a** and **b** are both passed the same input), so variables aren't usually necessary in order to use a value twice.

For instance, calculating the average value of an array of numbers requires a few variables in most languages – at least one to hold the array, perhaps one for each element or for a loop counter. In jq, it's simply **add / length** – the **add** expression is given the array and produces its sum, and the **length** expression is given the array and produces its length.

So, there's generally a cleaner way to solve most problems in jq than defining variables. Still, sometimes they do make things easier, so jq lets you define variables using **expression as \$variable**. All variable names start with \$. Here's a slightly uglier version of the array-averaging example:

```
length as $array_length | add / $array_length
```

We'll need a more complicated problem to find a situation where using variables actually makes our lives easier.

Suppose we have an array of blog posts, with "author" and "title" fields, and another object which is used to map author usernames to real names. Our input looks like:

```
{ "posts": [{ "title": "Frist psot", "author": "anon"},
             { "title": "A well-written article", "author": "person1" }],
  "realnames": { "anon": "Anonymous Coward",
                 "person1": "Person McPherson" } }
```

We want to produce the posts with the author field containing a real name, as in:

```
{ "title": "Frist psot", "author": "Anonymous Coward" }
{ "title": "A well-written article", "author": "Person McPherson" }
```

We use a variable, `$names`, to store the `realnames` object, so that we can refer to it later when looking up author usernames:

```
.realnames as $names | .posts[] | {title, author: $names[.author]}
```

The expression **`exp as $x | ...`** means: for each value of expression **`exp`**, run the rest of the pipeline with the entire original input, and with **`$x`** set to that value. Thus **`as`** functions as something of a `foreach` loop.

Just as **`{foo}`** is a handy way of writing **`{foo: .foo}`**, so **`{foo}`** is a handy way of writing **`{foo:$foo}`**.

Multiple variables may be declared using a single **`as`** expression by providing a pattern that matches the structure of the input (this is known as "destructuring"):

```
. as {realnames: $names, posts: [$first, $second]} | ...
```

The variable declarations in array patterns (e.g., **`. as [$first, $second]`**) bind to the elements of the array in from the element at index zero on up, in order. When there is no value at the index for an array pattern element, **`null`** is bound to that variable.

Variables are scoped over the rest of the expression that defines them, so

```
.realnames as $names | (.posts[] | {title, author: $names[.author]})
```

will work, but

```
(.realnames as $names | .posts[]) | {title, author: $names[.author]}
```

won't.

For programming language theorists, it's more accurate to say that jq variables are lexically-scoped bindings. In particular there's no way to change the value of a binding; one can only setup a new binding with the same name, but which will not be visible where the old one was.

```
jq ´.bar as $x | .foo | . + $x´
{"foo":10, "bar":200}
=> 210

jq ´. as $i[[:.*2|. as $i| $i), $i]´
5
=> [10,5]

jq ´. as [$a, $b, {c: $c}] | $a + $b + $c´
[2, 3, {"c": 4, "d": 5}]
=> 9

jq ´.[] as [$a, $b] | {a: $a, b: $b}´
[[0], [0, 1], [2, 1, 0]]
=> {"a":0,"b":null}, {"a":0,"b":1}, {"a":2,"b":1}
```

Defining Functions

You can give a filter a name using "def" syntax:

```
def increment: . + 1;
```

From then on, **increment** is usable as a filter just like a builtin function (in fact, this is how some of the builtins are defined). A function may take arguments:

```
def map(f): [.] | f;
```

Arguments are passed as filters, not as values. The same argument may be referenced multiple times with different inputs (here **f** is run for each element of the input array). Arguments to a function work more like callbacks than like value arguments. This is important to understand. Consider:

```
def foo(f): f|f;
5|foo(*2)
```

The result will be 20 because **f** is ***2**, and during the first invocation of **f** . will be 5, and the second time it will be 10 (5 * 2), so the result will be 20. Function arguments are filters, and filters expect an input when invoked.

If you want the value–argument behaviour for defining simple functions, you can just use a variable:

```
def addvalue(f): f as $f | map(. + $f);
```

Or use the short–hand:

```
def addvalue($f): ...;
```

With either definition, **addvalue.foo** will add the current input's **.foo** field to each element of the array.

Multiple definitions using the same function name are allowed. Each re-definition replaces the previous one for the same number of function arguments, but only for references from functions (or main program) subsequent to the re-definition.

```
jq 'def addvalue(f): . + [f]; map(addvalue(.[]))'
  [[1,2],[10,20]]
=> [[1,2,1], [10,20,10]]

jq 'def addvalue(f): f as $x | map(. + $x); addvalue(.[])'
  [[1,2],[10,20]]
=> [[1,2,1,2], [10,20,1,2]]
```

Reduce

The **reduce** syntax in jq allows you to combine all of the results of an expression by accumulating them into a single answer. As an example, we'll pass **[3,2,1]** to this expression:

```
reduce .[] as $item (0; . + $item)
```

For each result that **.[]** produces, **. + \$item** is run to accumulate a running total, starting from 0. In this example, **.[]** produces the results 3, 2, and 1, so the effect is similar to running something like this:

```
0 | (3 as $item | . + $item) |
   (2 as $item | . + $item) |
   (1 as $item | . + $item)

jq 'reduce .[] as $item (0; . + $item)'
  [10,2,5,3]
=> 20
```

limit(n; exp)

The **limit** function extracts up to **n** outputs from **exp**.

```
jq '[limit(3;.)]'
  [0,1,2,3,4,5,6,7,8,9]
=> [0,1,2]
```

first(expr), last(expr), nth(n; expr)

The **first(expr)** and **last(expr)** functions extract the first and last values from **expr**, respectively.

The **nth(n; expr)** function extracts the **n**th value output by **expr**. This can be defined as **def nth(n; expr):**

last(limit(n + 1; expr)); Note that **nth(n; expr)** doesn't support negative values of **n**.

```
jq '[first(range(.)), last(range(.)), nth(. / 2; range(.))]'
10
=> [0,9,5]
```

first, last, nth(n)

The **first** and **last** functions extract the first and last values from any array at ..

The **nth(n)** function extracts the nth value of any array at ..

```
jq '[range(.)][first, last, nth(5)]'
10
=> [0,9,5]
```

foreach

The **foreach** syntax is similar to **reduce**, but intended to allow the construction of **limit** and reducers that produce intermediate results (see example).

The form is **foreach EXP as \$var (INIT; UPDATE; EXTRACT)**. Like **reduce**, **INIT** is evaluated once to produce a state value, then each output of **EXP** is bound to **\$var**, **UPDATE** is evaluated for each output of **EXP** with the current state and with **\$var** visible. Each value output by **UPDATE** replaces the previous state. Finally, **EXTRACT** is evaluated for each new state to extract an output of **foreach**.

This is mostly useful only for constructing **reduce**- and **limit**-like functions. But it is much more general, as it allows for partial reductions (see the example below).

```
jq 'foreach .[] as $item ([[],[]]; if $item == null then [[],[0]] else [(.[] + [$item]),[]] end; if $item == null then .[1] *
[1,2,3,4,null,"a","b",null]
=> [[1,2,3,4],["a","b"]]
```

Recursion

As described above, **recurse** uses recursion, and any jq function can be recursive. The **while** builtin is also implemented in terms of recursion.

Tail calls are optimized whenever the expression to the left of the recursive call outputs its last value. In practice this means that the expression to the left of the recursive call should not produce more than one output for each input.

For example:

```
def recurse(f): def r: ., (f | select(. != null) | r); r;

def while(cond; update):
  def _while:
    if cond then ., (update | _while) else empty end;
  _while;

def repeat(exp):
```

```
def _repeat:
  exp, _repeat;
_repeat;
```

Generators and iterators

Some jq operators and functions are actually generators in that they can produce zero, one, or more values for each input, just as one might expect in other programming languages that have generators. For example, `.[]` generates all the values in its input (which must be an array or an object), `range(0; 10)` generates the integers between 0 and 10, and so on.

Even the comma operator is a generator, generating first the values generated by the expression to the left of the comma, then for each of those, the values generated by the expression on the right of the comma.

The **empty** builtin is the generator that produces zero outputs. The **empty** builtin backtracks to the preceding generator expression.

All jq functions can be generators just by using builtin generators. It is also possible to define new generators using only recursion and the comma operator. If the recursive call(s) is(are) "in tail position" then the generator will be efficient. In the example below the recursive call by `_range` to itself is in tail position. The example shows off three advanced topics: tail recursion, generator construction, and sub-functions.

```
jq 'def range(init; upto; by): def _range: if (by > 0 and . < upto) or (by < 0 and . > upto) then ., ((.+by)|_range) else .;
  null
=> 0, 3, 6, 9

jq 'def while(cond; update): def _while: if cond then ., (update | _while) else empty end; _while; [while(<100; .*2)]'
1
=> [1,2,4,8,16,32,64]
```

MATH

jq currently only has IEEE754 double-precision (64-bit) floating point number support.

Besides simple arithmetic operators such as `+`, jq also has most standard math functions from the C math library. C math functions that take a single input argument (e.g., `sin()`) are available as zero-argument jq functions. C math functions that take two input arguments (e.g., `pow()`) are available as two-argument jq functions that ignore `..`.

Availability of standard math functions depends on the availability of the corresponding math functions in your operating system and C math library. Unavailable math functions will be defined but will raise an error.

I/O

At this time jq has minimal support for I/O, mostly in the form of control over when inputs are read. Two builtin functions are provided for this, **input** and **inputs**, that read from the same sources (e.g., `stdin`, files named on the command-line) as jq itself. These two builtins, and jq's own reading actions, can be interleaved with each other.

One builtin provides minimal output capabilities, **debug**. (Recall that a jq program's output values are always output as JSON texts on `stdout`.) The **debug** builtin can have application-specific behavior, such as for executables that use the libjq C API but aren't the jq executable itself.

input

Outputs one new input.

inputs

Outputs all remaining inputs, one by one.

This is primarily useful for reductions over a program's inputs.

debug

Causes a debug message based on the input value to be produced. The jq executable wraps the input value with ["**DEBUG:**", <input-value>] and prints that and a newline on stderr, compactly. This may change in the future.

input_filename

Returns the name of the file whose input is currently being filtered. Note that this will not work well unless jq is running in a UTF-8 locale.

input_line_number

Returns the line number of the input currently being filtered.

STREAMING

With the **--stream** option jq can parse input texts in a streaming fashion, allowing jq programs to start processing large JSON texts immediately rather than after the parse completes. If you have a single JSON text that is 1GB in size, streaming it will allow you to process it much more quickly.

However, streaming isn't easy to deal with as the jq program will have [<path>, <leaf-value>] (and a few other forms) as inputs.

Several builtins are provided to make handling streams easier.

The examples below use the the streamed form of [0,[1]], which is [[0],0],[[1,0],1],[[1,0]],[[1]].

Streaming forms include [<path>, <leaf-value>] (to indicate any scalar value, empty array, or empty object), and [<path>] (to indicate the end of an array or object). Future versions of jq run with **--stream** and **-seq** may output additional forms such as ["error message"] when an input text fails to parse.

truncate_stream(stream_expression)

Consumes a number as input and truncates the corresponding number of path elements from the left of the outputs of the given streaming expression.

```
jq '[1|truncate_stream([[0],1],[[1,0],2],[[1,0]],[[1]])]'
1
=> [[[0],2],[[0]]]
```

fromstream(stream_expression)

Outputs values corresponding to the stream expression's outputs.

```
jq 'fromstream(1|truncate_stream([[0],1],[[1,0],2],[[1,0]],[[1]]))'
null
=> [2]
```

tostream

The **tostream** builtin outputs the streamed form of its input.

```
jq '. as $dot|fromstream($dot|tostream)|==$dot'
[0,[1,{"a":1},{ "b":2}]]
=> true
```

ASSIGNMENT

Assignment works a little differently in jq than in most programming languages. jq doesn't distinguish between references to and copies of something – two objects or arrays are either equal or not equal, without any further notion of being "the same object" or "not the same object".

If an object has two fields which are arrays, **.foo** and **.bar**, and you append something to **.foo**, then **.bar** will not get bigger. Even if you've just set **.bar = .foo**. If you're used to programming in languages like Python, Java, Ruby, Javascript, etc. then you can think of it as though jq does a full deep copy of every object before it does the assignment (for performance, it doesn't actually do that, but that's the general idea).

All the assignment operators in jq have path expressions on the left-hand side.

=

The filter **.foo = 1** will take as input an object and produce as output an object with the "foo" field set to 1. There is no notion of "modifying" or "changing" something in jq – all jq values are immutable. For instance,

```
.foo = .bar | .foo.baz = 1
```

will not have the side-effect of setting **.bar.baz** to be set to 1, as the similar-looking program in Javascript, Python, Ruby or other languages would. Unlike these languages (but like Haskell and some other functional languages), there is no notion of two arrays or objects being "the same array" or "the same object". They can be equal, or not equal, but if we change one of them in no circumstances will the other change behind our backs.

This means that it's impossible to build circular values in jq (such as an array whose first element is itself). This is quite intentional, and ensures that anything a jq program can produce can be represented in JSON.

Note that the left-hand side of '=' refers to a value in **..**. Thus **\$var.foo = 1** won't work as expected (**\$var.foo** is not a valid or useful path expression in **..**); use **\$var | .foo = 1** instead.

If the right-hand side of '=' produces multiple values, then for each such value jq will set the paths on the left-hand side to the value and then it will output the modified **..**. For example, **(.a,.b)=range(2)** outputs **{"a":0,"b":0}**, then **{"a":1,"b":1}**. The "update" assignment forms (see below) do not do this.

Note too that **.a,.b=0** does not set **.a** and **.b**, but **(.a,.b)=0** sets both.

|=

As well as the assignment operator '=', jq provides the "update" operator '|=', which takes a filter on the right-hand side and works out the new value for the property of **.** being assigned to by running the old value through this expression. For instance, **.foo |= .+1** will build an object with the "foo" field set to the input's "foo" plus 1.

This example should show the difference between '=' and '|=':

Provide input **'{"a": {"b": 10}, "b": 20}'** to the programs:

```
.a = .b .a |= .b
```

The former will set the "a" field of the input to the "b" field of the input, and produce the output **{"a": 20}**. The latter will set the "a" field of the input to the "a" field's "b" field, producing **{"a": 10}**.

The left-hand side can be any general path expression; see **path()**.

Note that the left-hand side of '|=' refers to a value in **..**. Thus **\$var.foo |= . + 1** won't work as expected (**\$var.foo** is not a valid or useful path expression in **..**); use **\$var | .foo |= . + 1** instead.

If the right-hand side outputs multiple values, only the last one will be used.

```
jq '(.|select(type=="boolean")) |= if . then 1 else 0 end'
[true,false,[5,true,[true,[false]],false]]
=> [1,0,[5,1,[1,[0]],0]]
```

`+=, -=, *=, /=, %=, //=`

jq has a few operators of the form **a op= b**, which are all equivalent to **a |= . op b**. So, `+= 1` can be used to increment values.

```
jq 'foo += 1'
{"foo": 42}
=> {"foo": 43}
```

Complex assignments

Lots more things are allowed on the left-hand side of a jq assignment than in most languages. We've already seen simple field accesses on the left hand side, and it's no surprise that array accesses work just as well:

```
.posts[0].title = "JQ Manual"
```

What may come as a surprise is that the expression on the left may produce multiple results, referring to different points in the input document:

```
.posts[] | .comments |= . + ["this is great"]
```

That example appends the string "this is great" to the "comments" array of each post in the input (where the input is an object with a field "posts" which is an array of posts).

When jq encounters an assignment like `a = b`, it records the "path" taken to select a part of the input document while executing a. This path is then used to find which part of the input to change while executing the assignment. Any filter may be used on the left-hand side of an equals – whichever paths it selects from the input will be where the assignment is performed.

This is a very powerful operation. Suppose we wanted to add a comment to blog posts, using the same "blog" input above. This time, we only want to comment on the posts written by "stedolan". We can find those posts using the "select" function described earlier:

```
.posts[] | select(.author == "stedolan")
```

The paths provided by this operation point to each of the posts that "stedolan" wrote, and we can comment on each of them in the same way that we did before:

```
(.posts[] | select(.author == "stedolan") | .comments) |=
. + ["terrible."]
```

MODULES

jq has a library/module system. Modules are files whose names end in **.jq**.

Modules imported by a program are searched for in a default search path (see below). The **import** and

include directives allow the importer to alter this path.

Paths in the a search path are subject to various substitutions.

For paths starting with "~/", the user's home directory is substituted for "~".

For paths starting with "\$ORIGIN/", the path of the jq executable is substituted for "\$ORIGIN".

For paths starting with "./" or paths that are ".", the path of the including file is substituted for ".". For top-level programs given on the command-line, the current directory is used.

Import directives can optionally specify a search path to which the default is appended.

The default search path is the search path given to the **-L** command-line option, else ["~/jq", "\$ORIGIN/../lib/jq", "\$ORIGIN/../lib"].

Null and empty string path elements terminate search path processing.

A dependency with relative path "foo/bar" would be searched for in "foo/bar.jq" and "foo/bar/bar.jq" in the given search path. This is intended to allow modules to be placed in a directory along with, for example, version control files, README files, and so on, but also to allow for single-file modules.

Consecutive components with the same name are not allowed to avoid ambiguities (e.g., "foo/foo").

For example, with **-L\$HOME/.jq** a module **foo** can be found in **\$HOME/.jq/foo.jq** and **\$HOME/.jq/foo/foo.jq**.

If "\$HOME/.jq" is a file, it is sourced into the main program.

import RelativePathString as NAME [<metadata>];

Imports a module found at the given path relative to a directory in a search path. A ".jq" suffix will be added to the relative path string. The module's symbols are prefixed with "NAME::".

The optional metadata must be a constant jq expression. It should be an object with keys like "homepage" and so on. At this time jq only uses the "search" key/value of the metadata. The metadata is also made available to users via the **modulemeta** builtin.

The "search" key in the metadata, if present, should have a string or array value (array of strings); this is the search path to be prefixed to the top-level search path.

include RelativePathString [<metadata>];

Imports a module found at the given path relative to a directory in a search path as if it were included in place. A ".jq" suffix will be added to the relative path string. The module's symbols are imported into the caller's namespace as if the module's content had been included directly.

The optional metadata must be a constant jq expression. It should be an object with keys like "homepage" and so on. At this time jq only uses the "search" key/value of the metadata. The metadata is also made available to users via the **modulemeta** builtin.

import RelativePathString as \$NAME [<metadata>];

Imports a JSON file found at the given path relative to a directory in a search path. A ".json" suffix will be added to the relative path string. The file's data will be available as **\$NAME::NAME**.

The optional metadata must be a constant jq expression. It should be an object with keys like "homepage" and so on. At this time jq only uses the "search" key/value of the metadata. The metadata is also made available to users via the **modulemeta** builtin.

The "search" key in the metadata, if present, should have a string or array value (array of strings); this is the search path to be prefixed to the top-level search path.

module <metadata>;

This directive is entirely optional. It's not required for proper operation. It serves only the purpose of providing metadata that can be read with the **modulemeta** builtin.

The metadata must be a constant jq expression. It should be an object with keys like "homepage". At this time jq doesn't use this metadata, but it is made available to users via the **modulemeta** builtin.

modulemeta

Takes a module name as input and outputs the module's metadata as an object, with the module's imports (including metadata) as an array value for the "deps" key.

Programs can use this to query a module's metadata, which they could then use to, for example, search for, download, and install missing dependencies.

BUGS

Presumably. Report them or discuss them at:

<https://github.com/stedolan/jq/issues>

NAME

kalc - Programmable scientific RPN calculator

SYNOPSIS

kalc [*options*] [*commands*]

or

kalc --help | --version

DESCRIPTION

kalc is a programmable scientific calculator, using *RPN (Reverse Polish Notation)*. It includes over 200 functions and a built-in help system. **kalc** works with real numbers, complex numbers and also integers in other numeric bases. It has a complete programming language, with control-flow structures such as *if* and *while*. It has "unlimited" memory for you to store objects.

The behavior of **kalc** has been made to imitate as much as possible a HP48/HP49 calculator. This program is not, however, a HP emulator, and does not use any code from that calculator's ROM.

OPTIONS

- d <n> Display at most <n> stack levels. Specify -1 as this argument to have the whole stack shown.
- s Do not load the stack from the init file.
- m Do not load the memory from the init file.
- b Runs **kalc** in batch mode. After running the commands given in the command line, exits the program.
- help Displays a brief help message and exits successfully.
- version Displays version information and exits successfully.

Eduardo M Kalinowski <ekalin@iname.com>

SEE ALSO

bc(1), **kalc.1.pdf**, <https://wa2l-edrc.sourceforge.net/manuals/man1/kalc.1.pdf>

The **kalc User's Manual (kalc.1.pdf)** which should come with this package describes in detail usage of **kalc** and all its functions.

NAME

ksh, rksh, pfksh – KornShell, a standard/restricted command and programming language

SYNOPSIS

[**±abcefhikmnoprstuvxBCDP**] [**-R** file] [**±o** option] ... [**-**] [arg ...]

rksh [**±abcefhikmnoprstuvxBCD**] [**-R** file] [**±o** option] ... [**-**] [arg ...]

DESCRIPTION

Ksh is a command and programming language that executes commands read from a terminal or a file. *Rksh* is a restricted version of the command interpreter *ksh*; it is used to set up login names and execution environments whose capabilities are more controlled than those of the standard shell. *Rpfksh* is a profile shell version of the command interpreter *ksh*; it is used to execute commands with the attributes specified by the user's profiles (see *pfexec*(1)). See *Invocation* below for the meaning of arguments to the shell.

Definitions.

A *metacharacter* is one of the following characters:

; & () | < > new-line space tab

A *blank* is a **tab** or a **space**. An *identifier* is a sequence of letters, digits, or underscores starting with a letter or underscore. Identifiers are used as components of *variable* names. A *vname* is a sequence of one or more identifiers separated by a **.** and optionally preceded by a **..**. Vnames are used as function and variable names. A *word* is a sequence of *characters* from the character set defined by the current locale, excluding non-quoted *metacharacters*.

A *command* is a sequence of characters in the syntax of the shell language. The shell reads each command and carries out the desired action either directly or by invoking separate utilities. A built-in command is a command that is carried out by the shell itself without creating a separate process. Some commands are built-in purely for convenience and are not documented here. Built-ins that cause side effects in the shell environment and built-ins that are found before performing a path search (see *Execution* below) are documented here. For historical reasons, some of these built-ins behave differently than other built-ins and are called *special built-ins*.

Commands.

A *simple-command* is a list of variable assignments (see *Variable Assignments* below) or a sequence of *blank* separated words which may be preceded by a list of variable assignments (see *Environment* below). The first word specifies the name of the command to be executed. Except as specified below, the remaining words are passed as arguments to the invoked command. The command name is passed as argument 0 (see *exec*(2)). The *value* of a simple-command is its exit status; 0-255 if it terminates normally; 256+*signum* if it terminates abnormally (the name of the signal corresponding to the exit status can be obtained via the **-l** option of the **kill** built-in utility).

A *pipeline* is a sequence of one or more *commands* separated by **|**. The standard output of each command but the last is connected by a *pipe*(2) to the standard input of the next command. Each command, except possibly the last, is run as a separate process; the shell waits for the last command to terminate. The exit status of a pipeline is the exit status of the last command unless the **pipefail** option is enabled. Each pipeline can be preceded by the *reserved word* **!** which causes the exit status of the pipeline to become 0 if the exit status of the last command is non-zero, and 1 if the exit status of the last command is 0.

A *list* is a sequence of one or more pipelines separated by **;**, **&**, **|&**, **&&**, or **| |**, and optionally terminated by **;**, **&**, or **|&**. Of these five symbols, **;**, **&**, and **|&** have equal precedence, which is lower than that of **&&** and **| |**. The symbols **&&** and **| |** also have equal precedence. A semicolon (**;**) causes sequential execution of the preceding pipeline; an ampersand (**&**) causes asynchronous execution of the preceding pipeline (i.e., the shell does *not* wait for that pipeline to finish). The symbol **|&** causes asynchronous execution of the preceding pipeline with a two-way pipe established to the parent shell; the standard input and output of the spawned pipeline can be written to and read from by the parent shell by applying the redirection operators **<&** and **>&** with arg **p** to commands and by using **-p** option of the built-in commands **read** and **print** described later. The symbol **&&** (**| |**) causes the *list* following it to be executed only if the preceding pipeline returns a zero (non-zero) value. One or more new-lines may appear in a *list* instead of a semicolon, to delimit a command. The first *item* of the first *pipeline* of a *list* that is a simple command not

beginning with a redirection, and not occurring within a **while**, **until**, or **if** *list*, can be predated by a semicolon. This semicolon is ignored unless the **showme** option is enabled as described with the **set** built-in below.

A *command* is either a simple-command or one of the following. Unless otherwise stated, the value returned by a command is that of the last simple-command executed in the command.

for *vname* [**in** *word* ...] **;do** *list* **;done**

Each time a **for** command is executed, *vname* is set to the next *word* taken from the **in** *word* list. If **in** *word* ... is omitted, then the **for** command executes the **do** *list* once for each positional parameter that is set starting from **1** (see *Parameter Expansion* below). Execution ends when there are no more words in the list.

for (([*expr1*] ; [*expr2*] ; [*expr3*])) **;do** *list* **;done**

The arithmetic expression *expr1* is evaluated first (see *Arithmetic evaluation* below). The arithmetic expression *expr2* is repeatedly evaluated until it evaluates to zero and when non-zero, *list* is executed and the arithmetic expression *expr3* evaluated. If any expression is omitted, then it behaves as if it evaluated to 1.

select *vname* [**in** *word* ...] **;do** *list* **;done**

A **select** command prints on standard error (file descriptor 2) the set of *words*, each preceded by a number. If **in** *word* ... is omitted, then the positional parameters starting from **1** are used instead (see *Parameter Expansion* below). The **PS3** prompt is printed and a line is read from the standard input. If this line consists of the number of one of the listed *words*, then the value of the variable *vname* is set to the *word* corresponding to this number. If this line is empty, the selection list is printed again. Otherwise the value of the variable *vname* is set to *null*. The contents of the line read from standard input is saved in the variable **REPLY**. The *list* is executed for each selection until a **break** or *end-of-file* is encountered. If the **REPLY** variable is set to *null* by the execution of *list*, then the selection list is printed before displaying the **PS3** prompt for the next selection.

case *word* **in** [([*pattern* [| *pattern*] ...) *list* ;;] ... **esac**

A **case** command executes the *list* associated with the first *pattern* that matches *word*. The form of the patterns is the same as that used for file-name generation (see *File Name Generation* below). The **;;** operator causes execution of **case** to terminate. If **&** is used in place of **;;** the next subsequent list, if any, is executed.

if *list* **;then** *list* [**elif** *list* **;then** *list*] ... [**else** *list*] **fi**

The *list* following **if** is executed and, if it returns a zero exit status, the *list* following the first **then** is executed. Otherwise, the *list* following **elif** is executed and, if its value is zero, the *list* following the next **then** is executed. Failing each successive **elif** *list*, the **else** *list* is executed. If the *list* has non-zero exit status and there is no **else** *list*, then the **if** command returns a zero exit status.

while *list* **;do** *list* **;done**

until *list* **;do** *list* **;done**

A **while** command repeatedly executes the **while** *list* and, if the exit status of the last command in the *list* is zero, executes the **do** *list*; otherwise the loop terminates. If no commands in the **do** *list* are executed, then the **while** command returns a zero exit status; **until** may be used in place of **while** to negate the loop termination test.

((*expression*))

The *expression* is evaluated using the rules for arithmetic evaluation described below. If the value of the arithmetic expression is non-zero, the exit status is 0, otherwise the exit status is 1.

(*list*)

Execute *list* in a separate environment. Note, that if two adjacent open parentheses are needed for nesting, a space must be inserted to avoid evaluation as an arithmetic command as described above.

{ *list* ; }

list is simply executed. Note that unlike the metacharacters (and), { and } are *reserved words* and

must occur at the beginning of a line or after a `;` in order to be recognized.

[[*expression*]]

Evaluates *expression* and returns a zero exit status when *expression* is true. See *Conditional Expressions* below, for a description of *expression*.

function *varname* { *list* ;}

varname () { *list* ;}

Define a function which is referenced by *varname*. A function whose *varname* contains a `.` is called a discipline function and the portion of the *varname* preceding the last `.` must refer to an existing variable. The body of the function is the *list* of commands between `{` and `}`. A function defined with the **function** *varname* syntax can also be used as an argument to the `.` special built-in command to get the equivalent behavior as if the *varname*() syntax were used to define it. (See *Functions* below.)

time [*pipeline*]

If *pipeline* is omitted the user and system time for the current shell and completed child processes is printed on standard error. Otherwise, *pipeline* is executed and the elapsed time as well as the user and system time are printed on standard error. The **TIMEFORMAT** variable may be set to a format string that specifies how the timing information should be displayed. See **Shell Variables** below for a description of the **TIMEFORMAT** variable.

The following reserved words are recognized as reserved only when they are the first word of a command and are not quoted:

if then else elif fi case esac for while until do done { } function select time
[[]] !

Variable Assignments.

One or more variable assignments can start a simple command or can be arguments to the **typeset**, **export**, or **readonly** special built-in commands. The syntax for an *assignment* is of the form:

varname=*word*

varname[*word*]=*word*

No space is permitted between *varname* and the `=` or between `=` and *word*.

varname=(*assign_list*)

No space is permitted between *varname* and the `=`. An *assign_list* can be one of the following:

word ...

Indexed array assignment.

[*word*]=*word* ...

Associative array assignment. If preceded by **typeset -a** this will create an indexed array instead.

assignment ...

Compound variable assignment. This creates a compound variable *varname* with sub-variables of the form *varname.name*, where *name* is the name portion of *assignment*. The value of *varname* will contain all the assignment elements. Additional assignments made to sub-variables of *varname* will also be displayed as part of the value of *varname*. If no *assignments* are specified, *varname* will be a compound variable allowing subsequence child elements to be defined.

typeset [*options*] *assignment* ...

Nested variable assignment. Multiple assignments can be specified by separating each of them with a `;`. The previous value is unset before the assignment.

In addition, a `+=` can be used in place of the `=` to signify adding to or appending to the previous value. When `+=` is applied to an arithmetic type, *word* is evaluated as an arithmetic expression and added to the current value. When applied to a string variable, the value defined by *word* is appended to the value. For compound assignments, the previous value is not unset and the new values are appended to the current ones provided that the types are compatible.

Comments.

A word beginning with # causes that word and all the following characters up to a new-line to be ignored.

Aliasing.

The first word of each command is replaced by the text of an **alias** if an **alias** for this word has been defined. An **alias** name consists of any number of characters excluding metacharacters, quoting characters, file expansion characters, parameter expansion and command substitution characters, and =. The replacement string can contain any valid shell script including the metacharacters listed above. The first word of each command in the replaced text, other than any that are in the process of being replaced, will be tested for aliases. If the last character of the alias value is a *blank* then the word following the alias will also be checked for alias substitution. Aliases can be used to redefine built-in commands but cannot be used to redefine the reserved words listed above. Aliases can be created and listed with the **alias** command and can be removed with the **unalias** command.

Aliasing is performed when scripts are read, not while they are executed. Therefore, for an alias to take effect, the **alias** definition command has to be executed before the command which references the alias is read.

The following aliases are compiled into the shell but can be unset or redefined:

```
autoload='typeset -fu'
command='command '
fc=hist
float='typeset -IE'
functions='typeset -f'
hash='alias -t --'
history='hist -l'
integer='typeset -li'
nameref='typeset -n'
nohup='nohup '
r='hist -s'
redirect='command exec'
source='command .'
stop='kill -s STOP'
suspend='kill -s STOP $$'
times='{ { time;} 2>&1;}'
type='whence -v'
```

Tilde Substitution.

After alias substitution is performed, each word is checked to see if it begins with an unquoted ~. For tilde substitution, *word* also refers to the *word* portion of parameter expansion (see *Parameter Expansion* below). If it does, then the word up to a / is checked to see if it matches a user name in the password database (See *getpwnam(3)*.) If a match is found, the ~ and the matched login name are replaced by the login directory of the matched user. If no match is found, the original text is left unchanged. A ~ by itself, or in front of a /, is replaced by \$HOME. A ~ followed by a + or - is replaced by the value of \$PWD and \$OLDPWD respectively.

In addition, when expanding a *variable assignment*, *tilde* substitution is attempted when the value of the assignment begins with a ~, and when a ~ appears after a :. The : also terminates a ~ login name.

Command Substitution.

The standard output from a command enclosed in parentheses preceded by a dollar sign (\$()) or a pair of grave accents (` `) may be used as part or all of a word; trailing new-lines are removed. In the second (obsolete) form, the string between the quotes is processed for special quoting characters before the command is executed (see *Quoting* below). The command substitution \$(*cat file*) can be replaced by the equivalent but faster \$(*<file*). The command substitution \$(*n<#*) will expand to the current byte offset for file descriptor *n*.

Arithmetic Substitution.

An arithmetic expression enclosed in double parentheses preceded by a dollar sign (\$(())) is replaced by the value of the arithmetic expression within the double parentheses.

Process Substitution.

This feature is only available on versions of the UNIX operating system that support the **/dev/fd** directory for naming open files. Each command argument of the form **<(list)** or **>(list)** will run process *list* asynchronously connected to some file in **/dev/fd**. The name of this file will become the argument to the command. If the form with **>** is selected then writing on this file will provide input for *list*. If **<** is used, then the file passed as an argument will contain the output of the *list* process. For example,

```
paste <(cut -f1 file1) <(cut -f3 file2) | tee >(process1) >(process2)
```

cuts fields 1 and 3 from the files *file1* and *file2* respectively, *pastes* the results together, and sends it to the processes *process1* and *process2*, as well as putting it onto the standard output. Note that the file, which is passed as an argument to the command, is a UNIX *pipe*(2) so programs that expect to *lseek*(2) on the file will not work.

Parameter Expansion.

A *parameter* is a *variable*, one or more digits, or any of the characters *****, **@**, **#**, **?**, **-**, **\$**, and **!**. A *variable* is denoted by a *vname*. To create a variable whose *vname* contains a **.**, a variable whose *vname* consists of everything before the last **.** must already exist. A *variable* has a *value* and zero or more *attributes*. *Variables* can be assigned *values* and *attributes* by using the **typeset** special built-in command. The attributes supported by the shell are described later with the **typeset** special built-in command. Exported variables pass values and attributes to the environment.

The shell supports both indexed and associative arrays. An element of an array variable is referenced by a *subscript*. A *subscript* for an indexed array is denoted by an *arithmetic expression* (see *Arithmetic evaluation* below) between a **[** and a **]**. To assign values to an indexed array, use **set -A vname value ...**. The value of all subscripts must be in the range of 0 through 1,048,575. Indexed arrays need not be declared. Any reference to a variable with a valid subscript is legal and an array will be created if necessary.

An associative array is created with the **-A** option to **typeset**. A *subscript* for an associative array is denoted by a string enclosed between **[** and **]**.

Referencing any array without a subscript is equivalent to referencing the array with subscript 0.

The *value* of a *variable* may be assigned by writing:

```
vname=value [ vname=value ] ...
```

or

```
vname[subscript]=value [ vname[subscript]=value ] ...
```

Note that no space is allowed before or after the **=**.

A *nameref* is a variable that is a reference to another variable. A *nameref* is created with the **-n** attribute of **typeset**. The value of the variable at the time of the **typeset** command becomes the variable that will be referenced whenever the *nameref* variable is used. The name of a *nameref* cannot contain a **.**. When a variable or function name contains a **.**, and the portion of the name up to the first **.** matches the name of a *nameref*, the variable referred to is obtained by replacing the *nameref* portion with the name of the variable referenced by the *nameref*. If a *nameref* is used as the index of a **for** loop, a name reference is established for each item in the list. A *nameref* provides a convenient way to refer to the variable inside a function whose name is passed as an argument to a function. For example, if the name of a variable is passed as the first argument to a function, the command

```
typeset -n var=$1
```

inside the function causes references and assignments to **var** to be references and assignments to the variable whose name has been passed to the function.

If either of the floating point attributes, **-E**, or **-F**, or the integer attribute, **-i**, is set for *vname*, then the *value* is subject to arithmetic evaluation as described below.

Positional parameters, parameters denoted by a number, may be assigned values with the **set** special built-in command. Parameter **\$0** is set from argument zero when the shell is invoked.

The character **\$** is used to introduce substitutable *parameters*.

\${parameter}

The shell reads all the characters from **\${** to the matching **}** as part of the same word even if it contains braces or metacharacters. The value, if any, of the parameter is substituted. The braces are required when *parameter* is followed by a letter, digit, or underscore that is not to be interpreted as part of its name, when the variable name contains a **.**. The braces are also required when a variable is subscripted unless it is part of an Arithmetic Expression or a Conditional Expression. If *parameter* is one or more digits then it is a positional parameter. A positional parameter of more than one digit must be enclosed in braces. If *parameter* is ***** or **@**, then all the positional parameters, starting with **\$1**, are substituted (separated by a field separator character). If an array *vname* with subscript ***** or **@** is used, then the value for each of the elements is substituted, separated by the first character of the value of **IFS**.

\${#parameter}

If *parameter* is ***** or **@**, the number of positional parameters is substituted. Otherwise, the length of the value of the *parameter* is substituted.

\${#vname[*]}**\${#vname[@]}**

The number of elements in the array *vname* is substituted.

\${!vname}

Expands to the name of the variable referred to by *vname*. This will be *vname* except when *vname* is a name reference.

\${!vname[subscript]}

Expands to name of the subscript unless *subscript* is ***** or **@**. When *subscript* is *****, the list of array subscripts for *vname* is generated. For a variable that is not an array, the value is 0 if the variable is set. Otherwise it is null. When *subscript* is **@**, same as above, except that when used in double quotes, each array subscript yields a separate argument.

\${!prefix*}

Expands to the names of the variables whose names begin with *prefix*.

\${parameter:-word}

If *parameter* is set and is non-null then substitute its value; otherwise substitute *word*.

\${parameter:=word}

If *parameter* is not set or is null then set it to *word*; the value of the parameter is then substituted. Positional parameters may not be assigned to in this way.

\${parameter:?word}

If *parameter* is set and is non-null then substitute its value; otherwise, print *word* and exit from the shell (if not interactive). If *word* is omitted then a standard message is printed.

\${parameter:+word}

If *parameter* is set and is non-null then substitute *word*; otherwise substitute nothing.

In the above, *word* is not evaluated unless it is to be used as the substituted string, so that, in the following example, **pwd** is executed only if **d** is not set or is null:

```
print ${d:-$(pwd)}
```

If the colon (**:**) is omitted from the above expressions, then the shell only checks whether *parameter* is set or not.

\${parameter:offset:length}**\${parameter:offset}**

Expands to the portion of the value of *parameter* starting at the character (counting from **0**) determined by expanding *offset* as an arithmetic expression and consisting of the number of characters determined by the arithmetic expression defined by *length*. In the second form, the remainder of the value is used. If A negative *offset* counts backwards from the end of *parameter*. Note that one or more *blanks* is required in front of a minus sign to prevent the shell from interpreting the operator as **:-**. If *parameter* is ***** or **@**, or is an array name indexed by ***** or **@**, then *offset* and *length*

refer to the array index and number of elements respectively. A negative *offset* is taken relative to one greater than the highest subscript for indexed arrays. The order for associate arrays is unspecified.

\${parameter#pattern}

\${parameter##pattern}

If the shell *pattern* matches the beginning of the value of *parameter*, then the value of this expansion is the value of the *parameter* with the matched portion deleted; otherwise the value of this *parameter* is substituted. In the first form the smallest matching pattern is deleted and in the second form the largest matching pattern is deleted. When *parameter* is @, *, or an array variable with subscript @ or *, the substring operation is applied to each element in turn.

\${parameter%pattern}

\${parameter%%pattern}

If the shell *pattern* matches the end of the value of *parameter*, then the value of this expansion is the value of the *parameter* with the matched part deleted; otherwise substitute the value of *parameter*. In the first form the smallest matching pattern is deleted and in the second form the largest matching pattern is deleted. When *parameter* is @, *, or an array variable with subscript @ or *, the substring operation is applied to each element in turn.

\${parameter/pattern/string}

\${parameter//pattern/string}

\${parameter/#pattern/string}

\${parameter/%pattern/string}

Expands *parameter* and replaces the longest match of *pattern* with the given *string*. Each occurrence of *pattern* in *string* is replaced by the portion of *parameter* that matches the *n*-th sub-pattern. In the first form, only the first occurrence of *pattern* is replaced. In the second form, each match for *pattern* is replaced by the given *string*. The third form restricts the pattern match to the beginning of the string while the fourth form restricts the pattern match to the end of the string. When *string* is null, the *pattern* will be deleted and the / in front of *string* may be omitted. When *parameter* is @, *, or an array variable with subscript @ or *, the substitution operation is applied to each element in turn. In this case, the *string* portion of *word* will be re-evaluated for each element.

The following parameters are automatically set by the shell:

- #** The number of positional parameters in decimal.
- Options supplied to the shell on invocation or by the **set** command.
- ?** The decimal value returned by the last executed command.
- \$** The process number of this shell.
- _** Initially, the value of **_** is an absolute pathname of the shell or script being executed as passed in the *environment*. Subsequently it is assigned the last argument of the previous command. This parameter is not set for commands which are asynchronous. This parameter is also used to hold the name of the matching **MAIL** file when checking for mail.
- !** The process number of the last background command invoked or the most recent job put in the background with the **bg** built-in command.

.sh.command

When processing a **DEBUG** trap, this variable contains the current command line that is about to run.

.sh.edchar

This variable contains the value of the keyboard character (or sequence of characters if the first character is an ESC, ascii **033**) that has been entered when processing a **KEYBD** trap (see *Key Bindings* below). If the value is changed as part of the trap action, then the new value replaces the key (or key sequence) that caused the trap.

.sh.edcol

The character position of the cursor at the time of the most recent **KEYBD** trap.

.sh.edmode

The value is set to ESC when processing a **KEYBD** trap while in **vi** insert mode. (See *Vi Editing Mode* below.) Otherwise, **.sh.edmode** is null when processing a **KEYBD** trap.

.sh.edtext

The characters in the input buffer at the time of the most recent **KEYBD** trap. The value is null when not processing a **KEYBD** trap.

.sh.file The pathname of the file that contains the current command.

.sh.fun The name of the current function that is being executed.

.sh.match

An indexed array which stores the most recent match and sub-pattern matches after conditional pattern matches that match and after variables expansions using the operators **#**, **%**, or **/**. The **0**-th element stores the complete match and the *i*-th element stores the *i*-th submatch. The **.sh.match** variable becomes unset when the variable that has expanded is assigned a new value.

.sh.name

Set to the name of the variable at the time that a discipline function is invoked.

.sh.subscript

Set to the name subscript of the variable at the time that a discipline function is invoked.

.sh.subshell

The current depth for subshells and command substitution.

.sh.value

Set to the value of the variable at the time that the **set** or **append** discipline function is invoked.

.sh.version

Set to a value that identifies the version of this shell.

LINENO

The current line number within the script or function being executed.

OLDPWD

The previous working directory set by the **cd** command.

OPTARG

The value of the last option argument processed by the **getopts** built-in command.

OPTIND

The index of the last option argument processed by the **getopts** built-in command.

PPID The process number of the parent of the shell.

PWD The present working directory set by the **cd** command.

RANDOM

Each time this variable is referenced, a random integer, uniformly distributed between 0 and 32767, is generated. The sequence of random numbers can be initialized by assigning a numeric value to **RANDOM**.

REPLY This variable is set by the **select** statement and by the **read** built-in command when no arguments are supplied.

SECONDS

Each time this variable is referenced, the number of seconds since shell invocation is returned. If this variable is assigned a value, then the value returned upon reference will be the value that was assigned plus the number of seconds since the assignment.

The following variables are used by the shell:

CDPATH

The search path for the **cd** command.

COLUMNS

If this variable is set, the value is used to define the width of the edit window for the shell edit modes and for printing **select** lists.

EDITOR

If the **VISUAL** variable is not set, the value of this variable will be checked for the patterns as described with **VISUAL** below and the corresponding editing option (see *Special*

- Command **set** below) will be turned on.
- ENV** If this variable is set, then parameter expansion, command substitution, and arithmetic substitution are performed on the value to generate the pathname of the script that will be executed when the shell is invoked (see *Invocation* below). This file is typically used for **alias** and **function** definitions. The default value is **\$HOME/.kshrc**.
- FCEDIT** Obsolete name for the default editor name for the **hist** command. **FCEDIT** is not used when **HISTEDIT** is set.
- FIGNORE** A pattern that defines the set of filenames that will be ignored when performing filename matching.
- FPATH** The search path for function definitions. The directories in this path are searched for a file with the same name as the function or command when a function with the **-u** attribute is referenced and when a command is not found. If an executable file with the name of that command is found, then it is read and executed in the current environment. Unlike **PATH**, the current directory must be represented explicitly by **.** rather than by adjacent **:** characters or a beginning or ending **:**.
- HISTCMD** Number of the current command in the history file.
- HISTEDIT** Name for the default editor name for the **hist** command.
- HISTFILE** If this variable is set when the shell is invoked, then the value is the pathname of the file that will be used to store the command history (see *Command Re-entry* below).
- HISTSIZE** If this variable is set when the shell is invoked, then the number of previously entered commands that are accessible by this shell will be greater than or equal to this number. The default is 512.
- HOME** The default argument (home directory) for the **cd** command.
- IFS** Internal field separators, normally **space**, **tab**, and **new-line** that are used to separate the results of command substitution or parameter expansion and to separate fields with the built-in command **read**. The first character of the **IFS** variable is used to separate arguments for the **"\$*"** substitution (see *Quoting* below). Each single occurrence of an **IFS** character in the string to be split, that is not in the *isspace* character class, and any adjacent characters in **IFS** that are in the *isspace* character class, delimit a field. One or more characters in **IFS** that belong to the *isspace* character class, delimit a field. In addition, if the same *isspace* character appears consecutively inside **IFS**, this character is treated as if it were not in the *isspace* class, so that if **IFS** consists of two **tab** characters, then two adjacent **tab** characters delimit a null field.
- LANG** This variable determines the locale category for any category not specifically selected with a variable starting with **LC_** or **LANG**.
- LC_ALL** This variable overrides the value of the **LANG** variable and any other **LC_** variable.
- LC_COLLATE** This variable determines the locale category for character collation information.
- LC_CTYPE** This variable determines the locale category for character handling functions. It determines the character classes for pattern matching (see *File Name Generation* below).
- LC_NUMERIC** This variable determines the locale category for the decimal point character.
- LINES** If this variable is set, the value is used to determine the column length for printing **select** lists. Select lists will print vertically until about two-thirds of **LINES** lines are filled.
- MAIL** If this variable is set to the name of a mail file *and* the **MAILPATH** variable is not set, then the shell informs the user of arrival of mail in the specified file.

MAILCHECK

This variable specifies how often (in seconds) the shell will check for changes in the modification time of any of the files specified by the **MAILPATH** or **MAIL** variables. The default value is 600 seconds. When the time has elapsed the shell will check before issuing the next prompt.

MAILPATH

A colon (:) separated list of file names. If this variable is set, then the shell informs the user of any modifications to the specified files that have occurred within the last **MAILCHECK** seconds. Each file name can be followed by a ? and a message that will be printed. The message will undergo parameter expansion, command substitution, and arithmetic substitution with the variable **\$_** defined as the name of the file that has changed. The default message is *you have mail in \$_*.

PATH The search path for commands (see *Execution* below). The user may not change **PATH** if executing under **rksh** (except in **.profile**).

PS1 The value of this variable is expanded for parameter expansion, command substitution, and arithmetic substitution to define the primary prompt string which by default is "\$ ". The character ! in the primary prompt string is replaced by the *command* number (see *Command Re-entry* below). Two successive occurrences of ! will produce a single ! when the prompt string is printed.

PS2 Secondary prompt string, by default "> ".

PS3 Selection prompt string used within a **select** loop, by default "#? ".

PS4 The value of this variable is expanded for parameter evaluation, command substitution, and arithmetic substitution and precedes each line of an execution trace. By default, **PS4** is "+ ". In addition when **PS4** is unset, the execution trace prompt is also "+ ".

SHELL The pathname of the *shell* is kept in the environment. At invocation, if the basename of this variable is **rsh**, **rksh**, or **krsh**, then the shell becomes restricted. If it is **pfsh** or **pfksh**, then the shell becomes a profile shell (see *pfexec(1)*).

TIMEFORMAT

The value of this parameter is used as a format string specifying how the timing information for pipelines prefixed with the **time** reserved word should be displayed. The % character introduces a format sequence that is expanded to a time value or other information. The format sequences and their meanings are as follows.

| | |
|----------|---|
| % % | A literal %. |
| %[p][l]R | The elapsed time in seconds. |
| %[p][l]U | The number of CPU seconds spent in user mode. |
| %[p][l]S | The number of CPU seconds spent in system mode. |
| %P | The CPU percentage, computed as (U + S) / R. |

The braces denote optional portions. The optional *p* is a digit specifying the *precision*, the number of fractional digits after a decimal point. A value of 0 causes no decimal point or fraction to be output. At most three places after the decimal point can be displayed; values of *p* greater than 3 are treated as 3. If *p* is not specified, the value 3 is used.

The optional **l** specifies a longer format, including hours if greater than zero, minutes, and seconds of the form *HHhMMmSS.FFs*. The value of *p* determines whether or not the fraction is included.

All other characters are output without change and a trailing newline is added. If unset, the default value, `$'\nreal\t%2lR\nuser\t%2lU\nsys\t%2lS'`, is used. If the value is null, no timing information is displayed.

TMOUT

If set to a value greater than zero, **TMOUT** will be the default timeout value for the **read** built-in command. The **select** compound command terminates after **TMOUT** seconds when input is from a terminal. Otherwise, the shell will terminate if a line is not entered

within the prescribed number of seconds while reading from a terminal. (Note that the shell can be compiled with a maximum bound for this value which cannot be exceeded.)

VISUAL

If the value of this variable matches the pattern **[Vv][li]**, then the **vi** option (see Special Command **set** below) is turned on. If the value matches the pattern **gmacs**, the **gmacs** option is turned on. If the value matches the pattern **macs**, then the **emacs** option will be turned on. The value of **VISUAL** overrides the value of **EDITOR**.

The shell gives default values to **PATH**, **PS1**, **PS2**, **PS3**, **PS4**, **MAILCHECK**, **FCEDIT**, **TMOU** and **IFS**, while **HOME**, **SHELL**, **ENV**, and **MAIL** are not set at all by the shell (although **HOME** is set by *login(1)*). On some systems **MAIL** and **SHELL** are also set by *login(1)*.

Field Splitting.

After parameter expansion and command substitution, the results of substitutions are scanned for the field separator characters (those found in **IFS**) and split into distinct fields where such characters are found. Explicit null fields ("" or "") are retained. Implicit null fields (those resulting from *parameters* that have no values or command substitutions with no output) are removed.

If the **braceexpand** (**-B**) option is set then each of the fields resulting from **IFS** are checked to see if they contain one or more of the brace patterns *{*,*}*, *{l1..l2}*, *{n1..n2}*, *{n1..n2%fmt}*, *{n1..n2 ..n3}*, or *{n1..n2 ..n3%fmt}*, where *** represents any character, *l1*, *l2* are letters and *n1*, *n2*, *n3* are signed numbers and *fmt* is a format specified as used by **printf**. In each case, fields are created by prepending the characters before the **{** and appending the characters after the **}** to each of the strings generated by the characters between the **{** and **}**. The resulting fields are checked to see if they have any brace patterns.

In the first form, a field is created for each string between **{** and **,**, between **,** and **,**, and between **,** and **}**. The string represented by *** can contain embedded matching **{** and **}** without quoting. Otherwise, each **{** and **}** with *** must be quoted.

In the seconds form, *l1* and *l2* must both be either upper case or both be lower case characters in the C locale. In this case a field is created for each character from *l1* thru *l2*.

In the remaining forms, a field is created for each number starting at *n1* and continuing until it reaches *n2* incrementing *n1* by *n3*. The cases where *n3* is not specified behave as if *n3* where **1** if *n1* ≤ *n2* and **-1** otherwise. If forms which specify *%fmt* any format flags, widths and precisions can be specified and *fmt* can end in any of the specifiers **cdiouxX**. For example, *{a,z}{1..5..3%02d}{b..c}x* expands to the 8 fields, **a01bx**, **a01cx**, **a04bx**, **a04cx**, **z01bx**, **z01cx**, **z04bx** and **z4cx**.

File Name Generation.

Following splitting, each field is scanned for the characters *****, **?**, **(**, and **[** unless the **-f** option has been set. If one of these characters appears, then the word is regarded as a *pattern*. Each file name component that contains any pattern character is replaced with a lexicographically sorted set of names that matches the pattern from that directory. If no file name is found that matches the pattern, then that component of the file name is left unchanged unless the pattern is prefixed with **~(N)** in which case it is removed as described below. If **IGNORE** is set, then each file name component that matches the pattern defined by the value of **IGNORE** is ignored when generating the matching filenames. The names **.** and **..** are also ignored. If **IGNORE** is not set, the character **.** at the start of each file name component will be ignored unless the first character of the pattern corresponding to this component is the character **.** itself. Note, that for other uses of pattern matching the **/** and **.** are not treated specially.

- *** Matches any string, including the null string. When used for filename expansion, if the **globstar** option is on, two adjacent *****'s by itself will match all files and zero or more directories and subdirectories. If followed by a **/** then only directories and subdirectories will match.
- ?** Matches any single character.
- [...]** Matches any one of the enclosed characters. A pair of characters separated by **-** matches any character lexically between the pair, inclusive. If the first character following the opening **[** is a **!** then any character not enclosed is matched. A **-** can be included in the character set by putting it as the first or last character.

Within [and], character classes can be specified with the syntax `[class]` where *class* is one of the following classes defined in the ANSI-C standard: (Note that **word** is equivalent to **alnum** plus the character `_`).

alnum alpha blank cntrl digit graph lower print punct space upper word xdigit

Within [and], an equivalence class can be specified with the syntax `[=c=]` which matches all characters with the same primary collation weight (as defined by the current locale) as the character *c*.

Within [and], `[.symbol.]` matches the collating symbol *symbol*.

A *pattern-list* is a list of one or more patterns separated from each other with a `&` or `|`. A `&` signifies that all patterns must be matched whereas `|` requires that only one pattern be matched. Composite patterns can be formed with one or more of the following sub-patterns:

`?(pattern-list)`

Optionally matches any one of the given patterns.

`*(pattern-list)`

Matches zero or more occurrences of the given patterns.

`+(pattern-list)`

Matches one or more occurrences of the given patterns.

`{n}(pattern-list)`

Matches *n* occurrences of the given patterns.

`{m,n}(pattern-list)`

Matches from *m* to *n* occurrences of the given patterns. If *m* is omitted, 0 will be used. If *n* is omitted at least *m* occurrences will be matched.

`@(pattern-list)`

Matches exactly one of the given patterns.

`!(pattern-list)`

Matches anything except one of the given patterns.

By default, each pattern, or sub-pattern will match the longest string possible consistent with generating the longest overall match. If more than one match is possible, the one starting closest to the beginning of the string will be chosen. However, for each of the above compound patterns a `-` can be inserted in front of the `(` to cause the shortest match to the specified *pattern-list* to be used.

When *pattern-list* is contained within parentheses, the backslash character `\` is treated specially even when inside a character class. All ANSI-C character escapes are recognized and match the specified character. In addition the following escape sequences are recognized:

| | |
|-----------------|--|
| <code>\d</code> | Matches any character in the digit class. |
| <code>\D</code> | Matches any character not in the digit class. |
| <code>\s</code> | Matches any character in the space class. |
| <code>\S</code> | Matches any character not in the space class. |
| <code>\w</code> | Matches any character in the word class. |
| <code>\W</code> | Matches any character not in the word class. |

A pattern of the form `%(pattern-pair(s))` is a sub-pattern that can be used to match nested character expressions. Each *pattern-pair* is a two character sequence which cannot contain `&` or `|`. The first *pattern-pair* specifies the starting and ending characters for the match. Each subsequent *pattern-pair* represents the beginning and ending characters of a nested group that will be skipped over when counting starting and ending character matches. The behavior is unspecified when the first character of a *pattern-pair* is alphanumeric except for the following:

| | |
|----------|---|
| D | Causes the ending character to terminate the search for this pattern without finding a match. |
| E | Causes the ending character to be interpreted as an escape character. |
| L | Causes the ending character to be interpreted as a quote character causing all characters to be ignored when looking for a match. |
| Q | Causes the ending character to be interpreted as a quote character causing all characters other than any escape character to be ignored when looking for a match. |

Thus, `%({}Q"E)`, matches characters starting at `{` until the matching `}` is found not counting any `{` or `}` that

is inside a double quoted string or preceded by the escape character `\`. Without the `{ }` this pattern matches any C language string.

Each sub-pattern in a composite pattern is numbered, starting at 1, by the location of the `(` within the pattern. The sequence `\n`, where `n` is a single digit and `\n` comes after the `n`-th. sub-pattern, matches the same string as the sub-pattern itself.

Finally a pattern can contain sub-patterns of the form `~(options:pattern-list)`, where either *options* or *pattern-list* can be omitted. Unlike the other compound patterns, these sub-patterns are not counted in the numbered sub-patterns. If *options* is present, it can consist of one or more of the following:

- +** Enable the following options. This is the default.
- Disable the following options.
- E** The remainder of the pattern uses extended regular expression syntax like the *egrep*(1) command.
- F** The remainder of the pattern uses *fgrep*(1) expression syntax.
- G** The remainder of the pattern uses basic regular expression syntax like the *grep*(1) command.
- K** The remainder of the pattern uses shell pattern syntax. This is the default.
- N** This is ignored. However, when it is the first letter and is used with file name generation, and no matches occur, the file pattern expands to the empty string.
- i** Treat the match as case insensitive.
- g** File the longest match (greedy). This is the default.
- l** Left anchor the pattern. This is the default for **K** style patterns.
- r** Right anchor the pattern. This is the default for **K** style patterns.

If both *options* and *pattern-list* are specified, then the options apply only to *pattern-list*. Otherwise, these options remain in effect until they are disabled by a subsequent `~(...)` or at the end of the sub-pattern containing `~(...)`.

Quoting.

Each of the *metacharacters* listed earlier (see *Definitions* above) has a special meaning to the shell

- i** Treat the match as case insensitive.
- g** File the longest match (greedy). This is the default.

If both *options* and *pattern-list* are specified, then the options apply only to *pattern-list*. Otherwise, these options remain in effect until they are disabled by a subsequent `~(...)` or at the end of the sub-pattern containing `~(...)`.

Quoting.

Each of the *metacharacters* listed earlier (see *Definitions* above) has a special meaning to the shell and causes termination of a word unless quoted. A character may be *quoted* (i.e., made to stand for itself) by preceding it with a `\`. The pair `\new-line` is removed. All characters enclosed between a pair of single quote marks (`'`) that is not preceded by a `$` are quoted. A single quote cannot appear within the single quotes. A single quoted string preceded by an unquoted `$` is processed as an ANSI-C string except for the following:

- \0** Causes the remainder of the string to be ignored.
- \E** Equivalent to the escape character (ascii **033**),
- \e** Equivalent to the escape character (ascii **033**),
- \cx** Expands to the character control-*x*.
- \C[.name.]** Expands to the collating element *name*.

Inside double quote marks (`"`), parameter and command substitution occur and `\` quotes the characters `\`, ```, `"`, and `$`. A `$` in front of a double quoted string will be ignored in the "C" or "POSIX" locale, and may cause the string to be replaced by a locale specific string otherwise. The meaning of `$*` and `$@` is identical when not quoted or when used as a variable assignment value or as a file name. However, when used as a command argument, `"$*"` is equivalent to `"$1d2d..."`, where *d* is the first character of the **IFS** variable, whereas `"$@"` is equivalent to `"$1" "$2" ...`. Inside grave quote marks (```), `\` quotes the characters `\`, ```, and `$`. If the grave quotes occur within double quotes, then `\` also quotes the character `"`.

The special meaning of reserved words or aliases can be removed by quoting any character of the reserved word. The recognition of function names or built-in command names listed below cannot be altered by quoting them.

Arithmetic Evaluation.

The shell performs arithmetic evaluation for arithmetic substitution, to evaluate an arithmetic command, to evaluate an indexed array subscript, and to evaluate arguments to the built-in commands **shift** and **let**. Evaluations are performed using double precision floating point arithmetic or long double precision floating point for systems that provide this data type. Floating point constants follow the ANSI-C programming language floating point conventions. Integer constants follow the ANSI-C programming language integer constant conventions although only single byte character constants are recognized and character casts are not recognized. In addition constants can be of the form `[base#]n` where *base* is a decimal number between two and sixty-four representing the arithmetic base and *n* is a number in that base. The digits above 9 are represented by the lower case letters, the upper case letters, `@`, and `_` respectively. For bases less than or equal to 36, upper and lower case characters can be used interchangeably.

An arithmetic expression uses the same syntax, precedence, and associativity of expression as the C language. All the C language operators that apply to floating point quantities can be used. In addition, the operator `**` can be used for exponentiation. It has higher precedence than multiplication and is left associative. In addition, when the value of an arithmetic variable or sub-expression can be represented as a long integer, all C language integer arithmetic operations can be performed. Variables can be referenced by name within an arithmetic expression without using the parameter expansion syntax. When a variable is referenced, its value is evaluated as an arithmetic expression.

Any of the following math library functions that are in the C math library can be used within an arithmetic expression:

```
abs acos acosh asin asinh atan atan2 atanh cbrt copysign cos cosh erf erfc
exp exp2 expm1 fabs fdim finite floor fma fmax fmod hypot ilogb int isinf
isnan lgamma log log2 logb nearbyint nextafter nexttoward pow rint round sin
sinh sqrt tan tanh tgamma trunc
```

An internal representation of a *variable* as a double precision floating point can be specified with the `-E [n]` or `-F [n]` option of the **typeset** special built-in command. The `-E` option causes the expansion of the value to be represented using scientific notation when it is expanded. The optional option argument *n* defines the number of significant figures. The `-F` option causes the expansion to be represented as a floating decimal number when it is expanded. The optional option argument *n* defines the number of places after the decimal point in this case.

An internal integer representation of a *variable* can be specified with the `-i [n]` option of the **typeset** special built-in command. The optional option argument *n* specifies an arithmetic base to be used when expanding the variable. If you do not specify an arithmetic base, base 10 will be used.

Arithmetic evaluation is performed on the value of each assignment to a variable with the `-E`, `-F`, or `-i` attribute. Assigning a floating point number to a variable whose type is an integer causes the fractional part to be truncated.

Prompting.

When used interactively, the shell prompts with the value of **PS1** after expanding it for parameter expansion, command substitution, and arithmetic substitution, before reading a command. In addition, each single `!` in the prompt is replaced by the command number. A `!!` is required to place `!` in the prompt. If at any time a new-line is typed and further input is needed to complete a command, then the secondary prompt (i.e., the value of **PS2**) is issued.

Conditional Expressions.

A *conditional expression* is used with the `[[` compound command to test attributes of files and to compare strings. Field splitting and file name generation are not performed on the words between `[[` and `]]`. Each expression can be constructed from one or more of the following unary or binary expressions:

string True, if *string* is not null.

-a file Same as **-e** below. This is obsolete.
-b file True, if *file* exists and is a block special file.
-c file True, if *file* exists and is a character special file.
-d file True, if *file* exists and is a directory.
-e file True, if *file* exists.
-f file True, if *file* exists and is an ordinary file.
-g file True, if *file* exists and it has its setgid bit set.
-k file True, if *file* exists and it has its sticky bit set.
-n string
 True, if length of *string* is non-zero.
-o ?option
 True, if option named *option* is a valid option name.
-o option
 True, if option named *option* is on.
-p file True, if *file* exists and is a fifo special file or a pipe.
-r file True, if *file* exists and is readable by current process.
-s file True, if *file* exists and has size greater than zero.
-t fildes
 True, if file descriptor number *fildes* is open and associated with a terminal device.
-u file True, if *file* exists and it has its setuid bit set.
-w file True, if *file* exists and is writable by current process.
-x file True, if *file* exists and is executable by current process. If *file* exists and is a directory, then true if the current process has permission to search in the directory.
-z string
 True, if length of *string* is zero.
-L file True, if *file* exists and is a symbolic link.
-h file True, if *file* exists and is a symbolic link.
-N file True, if *file* exists and the modification time is greater than the last access time.
-O file True, if *file* exists and is owned by the effective user id of this process.
-G file True, if *file* exists and its group matches the effective group id of this process.
-S file True, if *file* exists and is a socket.
file1 -nt file2
 True, if *file1* exists and *file2* does not, or *file1* is newer than *file2*.
file1 -ot file2
 True, if *file2* exists and *file1* does not, or *file1* is older than *file2*.
file1 -ef file2
 True, if *file1* and *file2* exist and refer to the same file.
string == pattern
 True, if *string* matches *pattern*. Any part of *pattern* can be quoted to cause it to be matched as a string. With a successful match to a pattern, the **.sh.match** array variable will contain the match and sub-pattern matches.
string = pattern
 Same as **==** above, but is obsolete.
string != pattern
 True, if *string* does not match *pattern*. When the *string* matches the *pattern* the **.sh.match** array variable will contain the match and sub-pattern matches.
string =~ ere
 True if *string* matches the pattern **~(E)ere** where *ere* is an extended regular expression.
string1 < string2
 True, if *string1* comes before *string2* based on ASCII value of their characters.
string1 > string2
 True, if *string1* comes after *string2* based on ASCII value of their characters.
 The following obsolete arithmetic comparisons are also permitted:

exp1 **-eq** *exp2*
 True, if *exp1* is equal to *exp2*.
exp1 **-ne** *exp2*
 True, if *exp1* is not equal to *exp2*.
exp1 **-lt** *exp2*
 True, if *exp1* is less than *exp2*.
exp1 **-gt** *exp2*
 True, if *exp1* is greater than *exp2*.
exp1 **-le** *exp2*
 True, if *exp1* is less than or equal to *exp2*.
exp1 **-ge** *exp2*
 True, if *exp1* is greater than or equal to *exp2*.

In each of the above expressions, if *file* is of the form **/dev/fd/*n***, where *n* is an integer, then the test is applied to the open file whose descriptor number is *n*.

A compound expression can be constructed from these primitives by using any of the following, listed in decreasing order of precedence.

(*expression*)
 True, if *expression* is true. Used to group expressions.
! *expression*
 True if *expression* is false.
expression1 **&&** *expression2*
 True, if *expression1* and *expression2* are both true.
expression1 **||** *expression2*
 True, if either *expression1* or *expression2* is true.

Input/Output.

Before a command is executed, its input and output may be redirected using a special notation interpreted by the shell. The following may appear anywhere in a simple-command or may precede or follow a *command* and are *not* passed on to the invoked command. Command substitution, parameter expansion, and arithmetic substitution occur before *word* or *digit* is used except as noted below. File name generation occurs only if the shell is interactive and the pattern matches a single file. Field splitting is not performed.

In each of the following redirections, if *file* is of the form **/dev/sctp/host/port**, **/dev/tcp/host/port**, or **/dev/udp/host/port**, where *host* is a hostname or host address, and *port* is a service given by name or an integer port number, then the redirection attempts to make a **tcp**, **sctp** or **udp** connection to the corresponding socket.

No intervening space is allowed between the characters of redirection operators.

| | |
|--|--|
| < <i>word</i> | Use file <i>word</i> as standard input (file descriptor 0). |
| > <i>word</i> | Use file <i>word</i> as standard output (file descriptor 1). If the file does not exist then it is created. If the file exists, and the noclobber option is on, this causes an error; otherwise, it is truncated to zero length. |
| > <i>word</i> | Sames as > , except that it overrides the noclobber option. |
| >> <i>word</i> | Use file <i>word</i> as standard output. If the file exists, then output is appended to it (by first seeking to the end-of-file); otherwise, the file is created. |
| <> <i>word</i> | Open file <i>word</i> for reading and writing as standard input. |
| << [-] <i>word</i> | The shell input is read up to a line that is the same as <i>word</i> after any quoting has been removed, or to an end-of-file. No parameter substitution, command substitution, arithmetic substitution or file name generation is performed on <i>word</i> . The resulting document, called a <i>here-document</i> , becomes the standard input. If any character of <i>word</i> is quoted, then no interpretation is placed upon the characters of the document; otherwise, parameter expansion, command substitution, and arithmetic substitution occur, \new-line is ignored, and \ must be used to quote the characters \ , \$, ` . If - is appended to << , then all leading |

tabs are stripped from *word* and from the document. If # is appended to <<, then leading spaces and tabs will be stripped off the first line of the document and up to an equivalent indentation will be stripped from the remaining lines and from *word*. A tab stop is assumed to occur at every 8 columns for the purposes of determining the indentation.

| | |
|----------------------|---|
| <<< <i>word</i> | A short form of here document in which <i>word</i> becomes the contents of the here-document after any parameter expansion, command substitution, and arithmetic substitution occur. |
| <& <i>digit</i> | The standard input is duplicated from file descriptor <i>digit</i> (see <i>dup(2)</i>). Similarly for the standard output using >& <i>digit</i> . |
| <& <i>digit</i> - | The file descriptor given by <i>digit</i> is moved to standard input. Similarly for the standard output using >& <i>digit</i> -. |
| <&- | The standard input is closed. Similarly for the standard output using >&-. |
| <&p | The input from the co-process is moved to standard input. |
| >&p | The output to the co-process is moved to standard output. |
| <# (<i>expr</i>) | Evaluate arithmetic expression <i>expr</i> and position file descriptor 0 to the resulting value bytes from the start of the file. The variables CUR and EOF evaluate to the current offset and end-of-file offset respectively when evaluating <i>expr</i> . |
| ># (<i>offset</i>) | The same as <# except applies to file descriptor 1. |
| <# <i>pattern</i> | Seeks forward to the beginning of the next line containing <i>pattern</i> . |
| <## <i>pattern</i> | The same as <# except that the portion of the file that is skipped is copied to standard output. |

If one of the above is preceded by a digit, with no intervening space, then the file descriptor number referred to is that specified by the digit (instead of the default 0 or 1). If one of the above, other than >&- and the ># and <# forms, is preceded by {*varname*} with no intervening space, then a file descriptor number > 10 will be selected by the shell and stored in the variable *varname*. If >&- or the any of the ># and <# forms is preceded by {*varname*} the value of *varname* defines the file descriptor to close or position. For example:

```
... 2>&1
```

means file descriptor 2 is to be opened for writing as a duplicate of file descriptor 1 and

```
exec {n}<file
```

means open file named **file** for reading and store the file descriptor number in variable **n**.

The order in which redirections are specified is significant. The shell evaluates each redirection in terms of the (*file descriptor*, *file*) association at the time of evaluation. For example:

```
... 1>fname 2>&1
```

first associates file descriptor 1 with file *fname*. It then associates file descriptor 2 with the file associated with file descriptor 1 (i.e. *fname*). If the order of redirections were reversed, file descriptor 2 would be associated with the terminal (assuming file descriptor 1 had been) and then file descriptor 1 would be associated with file *fname*.

If a command is followed by & and job control is not active, then the default standard input for the command is the empty file **/dev/null**. Otherwise, the environment for the execution of a command contains the file descriptors of the invoking shell as modified by input/output specifications.

Environment.

The *environment* (see *environ(7)*) is a list of name-value pairs that is passed to an executed program in the same way as a normal argument list. The names must be *identifiers* and the values are character strings. The shell interacts with the environment in several ways. On invocation, the shell scans the environment and creates a variable for each name found, giving it the corresponding value and attributes and marking it *export*. Executed commands inherit the environment. If the user modifies the values of these variables or

creates new ones, using the **export** or **typeset -x** commands, they become part of the environment. The environment seen by any executed command is thus composed of any name-value pairs originally inherited by the shell, whose values may be modified by the current shell, plus any additions which must be noted in **export** or **typeset -x** commands.

The environment for any *simple-command* or function may be augmented by prefixing it with one or more variable assignments. A variable assignment argument is a word of the form *identifier=value*. Thus:

```
TERM=450 cmd args          and
(export TERM; TERM=450; cmd args)
```

are equivalent (as far as the above execution of *cmd* is concerned except for special built-in commands listed below – those that are preceded with a dagger).

If the obsolete **-k** option is set, *all* variable assignment arguments are placed in the environment, even if they occur after the command name. The following first prints **a=b c** and then **c**:

```
echo a=b c
set -k
echo a=b c
```

This feature is intended for use with scripts written for early versions of the shell and its use in new scripts is strongly discouraged. It is likely to disappear someday.

Functions.

For historical reasons, there are two ways to define functions, the *name()* syntax and the **function name** syntax, described in the *Commands* section above. Shell functions are read in and stored internally. Alias names are resolved when the function is read. Functions are executed like commands with the arguments passed as positional parameters. (See *Execution* below.)

Functions defined by the **function name** syntax and called by name execute in the same process as the caller and share all files and present working directory with the caller. Traps caught by the caller are reset to their default action inside the function. A trap condition that is not caught or ignored by the function causes the function to terminate and the condition to be passed on to the caller. A trap on **EXIT** set inside a function is executed in the environment of the caller after the function completes. Ordinarily, variables are shared between the calling program and the function. However, the **typeset** special built-in command used within a function defines local variables whose scope includes the current function. They can be passed to functions that they call in the variable assignment list that precedes the call or as arguments passed as name references. Errors within functions return control to the caller.

Functions defined with the *name()* syntax and functions defined with the **function name** syntax that are invoked with the **.** special built-in are executed in the caller's environment and share all variables and traps with the caller. Errors within these function executions cause the script that contains them to abort.

The special built-in command **return** is used to return from function calls.

Function names can be listed with the **-f** or **+f** option of the **typeset** special built-in command. The text of functions, when available, will also be listed with **-f**. Functions can be undefined with the **-f** option of the **unset** special built-in command.

Ordinarily, functions are unset when the shell executes a shell script. Functions that need to be defined across separate invocations of the shell should be placed in a directory and the **FPATH** variable should contain the name of this directory. They may also be specified in the **ENV** file.

Discipline Functions.

Each variable can have zero or more discipline functions associated with it. The shell initially understands the discipline names **get**, **set**, **append**, and **unset** but on most systems others can be added at run time via the C programming interface extension provided by the **builtin** built-in utility. If the **get** discipline is defined for a variable, it is invoked whenever the given variable is referenced. If the variable **.sh.value** is assigned a value inside the discipline function, the referenced variable will evaluate to this value instead. If the **set** discipline is defined for a variable, it is invoked whenever the given variable is assigned a value. If the **append** discipline is defined for a variable, it is invoked whenever a value is appended to the given variable. The variable **.sh.value** is given the value of the variable before invoking the discipline, and the

variable will be assigned the value of **.sh.value** after the discipline completes. If **.sh.value** is unset inside the discipline, then that value is unchanged. If the **unset** discipline is defined for a variable, it is invoked whenever the given variable is unset. The variable will not be unset unless it is unset explicitly from within this discipline function.

The variable **.sh.name** contains the name of the variable for which the discipline function is called, **.sh.subscript** is the subscript of the variable, and **.sh.value** will contain the value being assigned inside the **set** discipline function. For the **set** discipline, changing **.sh.value** will change the value that gets assigned.

Jobs.

If the **monitor** option of the **set** command is turned on, an interactive shell associates a *job* with each pipeline. It keeps a table of current jobs, printed by the **jobs** command, and assigns them small integer numbers. When a job is started asynchronously with **&**, the shell prints a line which looks like:

```
[1] 1234
```

indicating that the job which was started asynchronously was job number 1 and had one (top-level) process, whose process id was 1234.

This paragraph and the next require features that are not in all versions of UNIX and may not apply. If you are running a job and wish to do something else you may hit the key **^Z** (control-Z) which sends a **STOP** signal to the current job. The shell will then normally indicate that the job has been 'Stopped', and print another prompt. You can then manipulate the state of this job, putting it in the background with the **bg** command, or run some other commands and then eventually bring the job back into the foreground with the foreground command **fg**. A **^Z** takes effect immediately and is like an interrupt in that pending output and unread input are discarded when it is typed.

A job being run in the background will stop if it tries to read from the terminal. Background jobs are normally allowed to produce output, but this can be disabled by giving the command **stty tostop**. If you set this **tty** option, then background jobs will stop when they try to produce output like they do when they try to read input.

There are several ways to refer to jobs in the shell. A job can be referred to by the process id of any process of the job or by one of the following:

%number

The job with the given number.

%string

Any job whose command line begins with *string*.

%?string

Any job whose command line contains *string*.

% %

Current job.

%+

Equivalent to **% %**.

%-

Previous job.

The shell learns immediately whenever a process changes state. It normally informs you whenever a job becomes blocked so that no further progress is possible, but only just before it prints a prompt. This is done so that it does not otherwise disturb your work. The **notify** option of the **set** command causes the shell to print these job change messages as soon as they occur.

When the **monitor** option is on, each background job that completes triggers any trap set for **CHLD**.

When you try to leave the shell while jobs are running or stopped, you will be warned that 'You have stopped(running) jobs.' You may use the **jobs** command to see what they are. If you immediately try to exit again, the shell will not warn you a second time, and the stopped jobs will be terminated. When a login shell receives a HUP signal, it sends a HUP signal to each job that has not been disowned with the **disown** built-in command described below.

Signals.

The **INT** and **QUIT** signals for an invoked command are ignored if the command is followed by **&** and the **monitor** option is not active. Otherwise, signals have the values inherited by the shell from its parent (but see also the **trap** built-in command below).

Execution.

Each time a command is read, the above substitutions are carried out. If the command name matches one of the *Special Built-in Commands* listed below, it is executed within the current shell process. Next, the command name is checked to see if it matches a user defined function. If it does, the positional parameters are saved and then reset to the arguments of the *function* call. A function is also executed in the current shell process. When the *function* completes or issues a **return**, the positional parameter list is restored. For functions defined with the **function name** syntax, any trap set on **EXIT** within the function is executed. The exit value of a *function* is the value of the last command executed. If a command name is not a *special built-in command* or a user defined *function*, but it is one of the built-in commands listed below, it is executed in the current shell process.

The shell variable **PATH** defines the search path for the directory containing the command. Alternative directory names are separated by a colon (:). The default path is **/bin:/usr/bin:** (specifying **/bin**, **/usr/bin**, and the current directory in that order). The current directory can be specified by two or more adjacent colons, or by a colon at the beginning or end of the path list. If the command name contains a **/**, then the search path is not used. Otherwise, each directory in the path is searched for an executable file of the given name that is not a directory. If found, and if the shell determines that there is a built-in version of a command corresponding to a given pathname, this built-in is invoked in the current process. If found, and this directory is also contained in the value of the **FPATH** variable, then this file is loaded into the current shell environment as if it were the argument to the **.** command except that only preset aliases are expanded, and a function of the given name is executed as described above. If not found, and the file **.paths** is found, and this file contains a line of the form **FPATH=path** where *path* names an existing directory, and this directory contains a file of the given name, then this file is loaded into the current shell environment as if it were the argument to the **.** special built-in command and a function of the given name is executed. Otherwise, if found, a process is created and an attempt is made to execute the command via *exec(2)*.

When an executable is found, the directory where it is found in is searched for a file named **.paths**. If this file is found and it contains a line of the form **BUILTIN_LIB=value**, then the library named by *value* will be searched for as if it were an option argument to **builtin -f**, and if it contains a built-in of the specified name this will be executed instead of a command by this name. Otherwise, if this file is found and it contains a line of the form *name=value* in the first or second line, then the environment variable *name* is modified by prepending the directory specified by *value* to the directory list. If *value* is not an absolute directory, then it specifies a directory relative to the directory that the executable was found. If the environment variable *name* does not already exist it will be added to the environment list for the specified command.

If the file has execute permission but is not an **a.out** file, it is assumed to be a file containing shell commands. A separate shell is spawned to read it. All non-exported variables are removed in this case. If the shell command file doesn't have read permission, or if the *setuid* and/or *setgid* bits are set on the file, then the shell executes an agent whose job it is to set up the permissions and execute the shell with the shell command file passed down as an open file. A parenthesized command is executed in a sub-shell without removing non-exported variables.

Command Re-entry.

The text of the last **HISTSIZE** (default 512) commands entered from a terminal device is saved in a *history* file. The file **\$HOME/sh_history** is used if the **HISTFILE** variable is not set or if the file it names is not writable. A shell can access the commands of all *interactive* shells which use the same named **HISTFILE**. The built-in command **hist** is used to list or edit a portion of this file. The portion of the file to be edited or listed can be selected by number or by giving the first character or characters of the command. A single command or range of commands can be specified. If you do not specify an editor program as an argument to **hist** then the value of the variable **HISTEDIT** is used. If **HISTEDIT** is unset, the obsolete variable **FCEDIT** is used. If **FCEDIT** is not defined, then **/bin/ed** is used. The edited command(s) is printed and re-executed upon leaving the editor unless you quit without writing. The **-s** option (and in obsolete versions, the editor name **-**) is used to skip the editing phase and to re-execute the command. In this case a substitution parameter of the form *old=new* can be used to modify the command before execution. For example, with the preset alias **r**, which is aliased to **'hist -s'**, typing **'r bad=good c'** will re-execute the most recent command which starts with the letter **c**, replacing the first occurrence of the string **bad** with the string **good**.

In-line Editing Options.

Normally, each command line entered from a terminal device is simply typed followed by a **new-line** ('RETURN' or 'LINE FEED'). If either the **emacs**, **gmacs**, or **vi** option is active, the user can edit the command line. To be in either of these edit modes **set** the corresponding option. An editing option is automatically selected each time the **VISUAL** or **EDITOR** variable is assigned a value ending in either of these option names.

The editing features require that the user's terminal accept 'RETURN' as carriage return without line feed and that a space (' ') must overwrite the current character on the screen.

Unless the **multiline** option is on, the editing modes implement a concept where the user is looking through a window at the current line. The window width is the value of **COLUMNS** if it is defined, otherwise 80. If the window width is too small to display the prompt and leave at least 8 columns to enter input, the prompt is truncated from the left. If the line is longer than the window width minus two, a mark is displayed at the end of the window to notify the user. As the cursor moves and reaches the window boundaries the window will be centered about the cursor. The mark is a > (<, *) if the line extends on the right (left, both) side(s) of the window.

The search commands in each edit mode provide access to the history file. Only strings are matched, not patterns, although a leading ^ in the string restricts the match to begin at the first character in the line.

Each of the edit modes has an operation to list the files or commands that match a partially entered word. When applied to the first word on the line, or the first word after a ;, |, &, or (, and the word does not begin with ~ or contain a /, the list of aliases, functions, and executable commands defined by the **PATH** variable that could match the partial word is displayed. Otherwise, the list of files that match the given word is displayed. If the partially entered word does not contain any file expansion characters, a * is appended before generating these lists. After displaying the generated list, the input line is redrawn. These operations are called command name listing and file name listing, respectively. There are additional operations, referred to as command name completion and file name completion, which compute the list of matching commands or files, but instead of printing the list, replace the current word with a complete or partial match. For file name completion, if the match is unique, a / is appended if the file is a directory and a space is appended if the file is not a directory. Otherwise, the longest common prefix for all the matching files replaces the word. For command name completion, only the portion of the file names after the last / are used to find the longest command prefix. If only a single name matches this prefix, then the word is replaced with the command name followed by a space. When using a *tab* for completion that does not yield a unique match, a subsequent *tab* will provide a numbered list of matching alternatives. A specific selection can be made by entering the selection number followed by a *tab*.

Key Bindings.

The **KEYBD** trap can be used to intercept keys as they are typed and change the characters that are actually seen by the shell. This trap is executed after each character (or sequence of characters when the first character is ESC) is entered while reading from a terminal. The variable **.sh.edchar** contains the character or character sequence which generated the trap. Changing the value of **.sh.edchar** in the trap action causes the shell to behave as if the new value were entered from the keyboard rather than the original value.

The variable **.sh.edcol** is set to the input column number of the cursor at the time of the input. The variable **.sh.edmode** is set to ESC when in **vi** insert mode (see below) and is null otherwise. By prepending **\${.sh.editmode}** to a value assigned to **.sh.edchar** it will cause the shell to change to control mode if it is not already in this mode.

This trap is not invoked for characters entered as arguments to editing directives, or while reading input for a character search.

Emacs Editing Mode.

This mode is entered by enabling either the **emacs** or **gmacs** option. The only difference between these two modes is the way they handle ^T. To edit, the user moves the cursor to the point needing correction and then inserts or deletes characters or words as needed. All the editing commands are control characters or escape sequences. The notation for control characters is caret (^) followed by the character. For example, ^F is the notation for control F. This is entered by depressing 'f' while holding down the 'CTRL'

(control) key. The ‘SHIFT’ key is *not* depressed. (The notation `^?` indicates the DEL (delete) key.)

The notation for escape sequences is **M-** followed by a character. For example, **M-f** (pronounced Meta f) is entered by depressing ESC (ascii **033**) followed by ‘f’. (**M-F** would be the notation for ESC followed by ‘SHIFT’ (capital) ‘F’.)

All edit commands operate from any place on the line (not just at the beginning). Neither the ‘RETURN’ nor the ‘LINE FEED’ key is entered after edit commands except when noted.

| | |
|-----------------|--|
| ^F | Move cursor forward (right) one character. |
| M-[C | Move cursor forward (right) one character. |
| M-f | Move cursor forward one word. (The emacs editor’s idea of a word is a string of characters consisting of only letters, digits and underscores.) |
| ^B | Move cursor backward (left) one character. |
| M-[D | Move cursor backward (left) one character. |
| M-b | Move cursor backward one word. |
| ^A | Move cursor to start of line. |
| M-[H | Move cursor to start of line. |
| ^E | Move cursor to end of line. |
| M-[Y | Move cursor to end of line. |
| ^]char | Move cursor forward to character <i>char</i> on current line. |
| M-^]char | Move cursor backward to character <i>char</i> on current line. |
| ^XX | Interchange the cursor and mark. |
| <i>erase</i> | (User defined erase character as defined by the <i>stty</i> (1) command, usually ^H or # .) Delete previous character. |
| <i>lnext</i> | (User defined literal next character as defined by the <i>stty</i> (1) command, or ^V if not defined.) Removes the next character’s editing features (if any). |
| ^D | Delete current character. |
| M-d | Delete current word. |
| M-^H | (Meta-backspace) Delete previous word. |
| M-h | Delete previous word. |
| M-^? | (Meta-DEL) Delete previous word (if your interrupt character is ^? (DEL, the default) then this command will not work). |
| ^T | Transpose current character with previous character and advance the cursor in <i>emacs</i> mode. Transpose two previous characters in <i>gmacs</i> mode. |
| ^C | Capitalize current character. |
| M-c | Capitalize current word. |
| M-l | Change the current word to lower case. |
| ^K | Delete from the cursor to the end of the line. If preceded by a numerical parameter whose value is less than the current cursor position, then delete from given position up to the cursor. If preceded by a numerical parameter whose value is greater than the current cursor position, then delete from cursor up to given cursor position. |
| ^W | Kill from the cursor to the mark. |
| M-p | Push the region from the cursor to the mark on the stack. |
| <i>kill</i> | (User defined kill character as defined by the <i>stty</i> command, usually ^G or @ .) Kill the entire current line. If two <i>kill</i> characters are entered in succession, all kill characters from then on cause a line feed (useful when using paper terminals). |
| ^Y | Restore last item removed from line. (Yank item back to the line.) |
| ^L | Line feed and print current line. |
| M-^L | Clear the screen. |
| ^@ | (Null character) Set mark. |
| M-space | (Meta space) Set mark. |
| ^J | (New line) Execute the current line. |
| ^M | (Return) Execute the current line. |
| <i>eof</i> | End-of-file character, normally ^D , is processed as an End-of-file only if the current line is null. |

| | |
|------------------|---|
| ^P | Fetch previous command. Each time ^P is entered the previous command back in time is accessed. Moves back one line when not on the first line of a multi-line command. |
| M-[A | Equivalent to ^P . |
| M-< | Fetch the least recent (oldest) history line. |
| M-> | Fetch the most recent (youngest) history line. |
| ^N | Fetch next command line. Each time ^N is entered the next command line forward in time is accessed. |
| M-[B | Equivalent to ^N . |
| ^Rstring | Reverse search history for a previous command line containing <i>string</i> . If a parameter of zero is given, the search is forward. <i>String</i> is terminated by a 'RETURN' or 'NEW LINE'. If <i>string</i> is preceded by a ^, the matched line must begin with <i>string</i> . If <i>string</i> is omitted, then the next command line containing the most recent <i>string</i> is accessed. In this case a parameter of zero reverses the direction of the search. |
| ^O | Operate – Execute the current line and fetch the next line relative to current line from the history file. |
| M-digits | (Escape) Define numeric parameter, the digits are taken as a parameter to the next command. The commands that accept a parameter are ^F , ^B , <i>erase</i> , ^C , ^D , ^K , ^R , ^P , ^N , ^] , M- , M-^] , M-^_ , M-= , M-b , M-c , M-d , M-f , M-h , M-l and M-^H . |
| M-letter | Soft-key – Your alias list is searched for an alias by the name <i>_letter</i> and if an alias of this name is defined, its value will be inserted on the input queue. The <i>letter</i> must not be one of the above meta-functions. |
| M-[letter | Soft-key – Your alias list is searched for an alias by the name <i>__letter</i> and if an alias of this name is defined, its value will be inserted on the input queue. This can be used to program function keys on many terminals. |
| M- | The last word of the previous command is inserted on the line. If preceded by a numeric parameter, the value of this parameter determines which word to insert rather than the last word. |
| M-^_ | Same as M- . |
| M-* | Attempt file name generation on the current word. An asterisk is appended if the word doesn't match any file or contain any special pattern characters. |
| M-ESC | Command or file name completion as described above. |
| ^I tab | Attempts command or file name completion as described above. If a partial completion occurs, repeating this will behave as if M-= were entered. If no match is found or entered after <i>space</i> , a <i>tab</i> is inserted. |
| M-= | If not preceded by a numeric parameter, it generates the list of matching commands or file names as described above. Otherwise, the word under the cursor is replaced by the item corresponding to the value of the numeric parameter from the most recently generated command or file list. If the cursor is not on a word, it is inserted instead. |
| ^U | Multiply parameter of next command by 4. |
| \ | Escape next character. Editing characters, the user's erase, kill and interrupt (normally ^?) characters may be entered in a command line or in a search string if preceded by a \ . The \ removes the next character's editing features (if any). |
| M-^V | Display version of the shell. |
| M-# | If the line does not begin with a # , a # is inserted at the beginning of the line and after each new-line, and the line is entered. This causes a comment to be inserted in the history file. If the line begins with a # , the # is deleted and one # after each new-line is also deleted. |

Vi Editing Mode.

There are two typing modes. Initially, when you enter a command you are in the *input* mode. To edit, the user enters *control* mode by typing ESC (**033**) and moves the cursor to the point needing correction and then inserts or deletes characters or words as needed. Most control commands accept an optional repeat *count* prior to the command.

When in **vi** mode on most systems, canonical processing is initially enabled and the command will be echoed again if the speed is 1200 baud or greater and it contains any control characters or less than one second has elapsed since the prompt was printed. The ESC character terminates canonical processing for the

remainder of the command and the user can then modify the command line. This scheme has the advantages of canonical processing with the type-ahead echoing of raw mode.

If the option **viraw** is also set, the terminal will always have canonical processing disabled. This mode is implicit for systems that do not support two alternate end of line delimiters, and may be helpful for certain terminals.

Input Edit Commands

By default the editor is in input mode.

| | |
|---------------|---|
| <i>erase</i> | (User defined erase character as defined by the <code>stty</code> command, usually ^H or #) Delete previous character. |
| ^W | Delete the previous blank separated word. On some systems the viraw option may be required for this to work. |
| <i>eof</i> | As the first character of the line causes the shell to terminate unless the ignoreeof option is set. Otherwise this character is ignored. |
| <i>lnext</i> | (User defined literal next character as defined by the <code>stty(1)</code> or ^V if not defined.) Removes the next character's editing features (if any). On some systems the viraw option may be required for this to work. |
| \ | Escape the next <i>erase</i> or <i>kill</i> character. |
| ^I tab | Attempts command or file name completion as described above and returns to input mode. If a partial completion occurs, repeating this will behave as if = were entered from control mode. If no match is found or entered after <i>space</i> , a <i>tab</i> is inserted. |

Motion Edit Commands

These commands will move the cursor.

| | |
|--------------------------|--|
| <i>[count]</i> l | Cursor forward (right) one character. |
| <i>[count]</i> [C | Cursor forward (right) one character. |
| <i>[count]</i> w | Cursor forward one alpha-numeric word. |
| <i>[count]</i> W | Cursor to the beginning of the next word that follows a blank. |
| <i>[count]</i> e | Cursor to end of word. |
| <i>[count]</i> E | Cursor to end of the current blank delimited word. |
| <i>[count]</i> h | Cursor backward (left) one character. |
| <i>[count]</i> [D | Cursor backward (left) one character. |
| <i>[count]</i> b | Cursor backward one word. |
| <i>[count]</i> B | Cursor to preceding blank separated word. |
| <i>[count]</i> | Cursor to column <i>count</i> . |
| <i>[count]</i> fc | Find the next character <i>c</i> in the current line. |
| <i>[count]</i> Fc | Find the previous character <i>c</i> in the current line. |
| <i>[count]</i> tc | Equivalent to f followed by h . |
| <i>[count]</i> Tc | Equivalent to F followed by l . |
| <i>[count]</i> ; | Repeats <i>count</i> times, the last single character find command, f , F , t , or T . |
| <i>[count]</i> , | Reverses the last single character find command <i>count</i> times. |
| 0 | Cursor to start of line. |
| ^ | Cursor to start of line. |
| [H | Cursor to first non-blank character in line. |
| \$ | Cursor to end of line. |
| [Y | Cursor to end of line. |
| % | Moves to balancing (,), { , }, [, or]. If cursor is not on one of the above characters, the remainder of the line is searched for the first occurrence of one of the above characters first. |

Search Edit Commands

These commands access your command history.

| | |
|--------------------------|--|
| <i>[count]</i> k | Fetch previous command. Each time k is entered the previous command back in time is accessed. |
| <i>[count]</i> - | Equivalent to k . |
| <i>[count]</i> [A | Equivalent to k . |

| | |
|-------------------|--|
| [count]j | Fetch next command. Each time j is entered the next command forward in time is accessed. |
| [count]+ | Equivalent to j . |
| [count][B] | Equivalent to j . |
| [count]G | The command number <i>count</i> is fetched. The default is the least recent history command. |
| /string | Search backward through history for a previous command containing <i>string</i> . <i>String</i> is terminated by a 'RETURN' or 'NEW LINE'. If <i>string</i> is preceded by a ^, the matched line must begin with <i>string</i> . If <i>string</i> is null, the previous string will be used. |
| ?string | Same as / except that search will be in the forward direction. |
| n | Search for next match of the last pattern to / or ? commands. |
| N | Search for next match of the last pattern to / or ? , but in reverse direction. |

Text Modification Edit Commands

These commands will modify the line.

a Enter input mode and enter text after the current character.

A Append text to the end of the line. Equivalent to **\$a**.

[count]c*motion*

c[*count*]*motion*

Delete current character through the character that *motion* would move the cursor to and enter input mode. If *motion* is **c**, the entire line will be deleted and input mode entered.

C Delete the current character through the end of line and enter input mode. Equivalent to **c\$**.

S Equivalent to **cc**.

[count]s Replace characters under the cursor in input mode.

D Delete the current character through the end of line. Equivalent to **d\$**.

[count]d*motion*

d[*count*]*motion*

Delete current character through the character that *motion* would move to. If *motion* is **d**, the entire line will be deleted.

i Enter input mode and insert text before the current character.

I Insert text before the beginning of the line. Equivalent to **0i**.

[count]P Place the previous text modification before the cursor.

[count]p Place the previous text modification after the cursor.

R Enter input mode and replace characters on the screen with characters you type overlay fashion.

[count]rc Replace the *count* character(s) starting at the current cursor position with *c*, and advance the cursor.

[count]x Delete current character.

[count]X Delete preceding character.

[count]. Repeat the previous text modification command.

[count]~ Invert the case of the *count* character(s) starting at the current cursor position and advance the cursor.

[count]_ Causes the *count* word of the previous command to be appended and input mode entered. The last word is used if *count* is omitted.

***** Causes an ***** to be appended to the current word and file name generation attempted. If no match is found, it rings the bell. Otherwise, the word is replaced by the matching pattern and input mode is entered.

**** Command or file name completion as described above.

Other Edit Commands

Miscellaneous commands.

[count]y*motion*

| | |
|---------------------------------------|--|
| y <i>[count]</i> <i>motion</i> | Yank current character through character that <i>motion</i> would move the cursor to and puts them into the delete buffer. The text and cursor are unchanged. |
| yy | Yanks the entire line. |
| Y | Yanks from current position to end of line. Equivalent to y\$. |
| u | Undo the last text modifying command. |
| U | Undo all the text modifying commands performed on the line. |
| [count]v | Returns the command hist -e \${VISUAL:-\${EDITOR:-vi}} <i>count</i> in the input buffer. If <i>count</i> is omitted, then the current line is used. |
| ^L | Line feed and print current line. Has effect only in control mode. |
| ^J | (New line) Execute the current line, regardless of mode. |
| ^M | (Return) Execute the current line, regardless of mode. |
| # | If the first character of the command is a #, then this command deletes this # and each # that follows a newline. Otherwise, sends the line after inserting a # in front of each line in the command. Useful for causing the current line to be inserted in the history as a comment and uncommenting previously commented commands in the history file. |
| [count]= | If <i>count</i> is not specified, it generates the list of matching commands or file names as described above. Otherwise, the word under the the cursor is replaced by the <i>count</i> item from the most recently generated command or file list. If the cursor is not on a word, it is inserted instead. |
| @letter | Your alias list is searched for an alias by the name <i>_letter</i> and if an alias of this name is defined, its value will be inserted on the input queue for processing. |
| ^V | Display version of the shell. |

Built-in Commands.

The following simple-commands are executed in the shell process. Input/Output redirection is permitted. Unless otherwise indicated, the output is written on file descriptor 1 and the exit status, when there is no syntax error, is zero. Except for **:**, **true**, **false**, **echo**, **newgrp**, and **login**, all built-in commands accept **--** to indicate end of options. They also interpret the option **--man** as a request to display the man page onto standard error and **-?** as a help request which prints a *usage* message on standard error. Commands that are preceded by one or two † symbols are special built-in commands and are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. They are not valid function names.
5. Words following a command preceded by †† that are in the format of a variable assignment are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and field splitting and file name generation are not performed.

† : [*arg* ...]

The command only expands parameters.

† .*name* [*arg* ...]

If *name* is a function defined with the **function** *name* reserved word syntax, the function is executed in the current environment (as if it had been defined with the *name()* syntax.) Otherwise if *name* refers to a file, the file is read in its entirety and the commands are executed in the current shell environment. The search path specified by **PATH** is used to find the directory containing the file. If any arguments *arg* are given, they become the positional parameters while processing the . command and the original positional parameters are restored upon completion. Otherwise the positional parameters are unchanged. The exit status is the exit status of the last command executed.

†† **alias** [**-ptx**] [*name* [*=value*]] ...

alias with no arguments prints the list of aliases in the form *name=value* on standard output. The **-p** option causes the word **alias** to be inserted before each one. When one or more arguments are

given, an *alias* is defined for each *name* whose *value* is given. A trailing space in *value* causes the next word to be checked for alias substitution. The obsolete **-t** option is used to set and list tracked aliases. The value of a tracked alias is the full pathname corresponding to the given *name*. The value becomes undefined when the value of **PATH** is reset but the alias remains tracked. Without the **-t** option, for each *name* in the argument list for which no *value* is given, the name and value of the alias is printed. The obsolete **-x** option has no effect. The exit status is non-zero if a *name* is given, but no value, and no alias has been defined for the *name*.

bg [*job*...]

This command is only on systems that support job control. Puts each specified *job* into the background. The current job is put in the background if *job* is not specified. See *Jobs* for a description of the format of *job*.

† break [*n*]

Exit from the enclosing **for**, **while**, **until**, or **select** loop, if any. If *n* is specified, then break *n* levels.

builtin [**-ds**] [**-f file**] [*name*...]

If *name* is not specified, and no **-f** option is specified, the built-ins are printed on standard output. The **-s** option prints only the special built-ins. Otherwise, each *name* represents the pathname whose basename is the name of the built-in. The entry point function name is determined by prepending **b_** to the built-in name. The ISO C/C++ prototype is **b_mycommand(int argc, char *argv[], void *context)** for the builtin command *mycommand* where *argv* is array an of *argc* elements and context is an optional pointer to a **Shell_t** structure as described in **<ast/shell.h>**.

Special built-ins cannot be bound to a pathname or deleted. The **-d** option deletes each of the given built-ins. On systems that support dynamic loading, the **-f** option names a shared library containing the code for built-ins. The shared library prefix and/or suffix, which depend on the system, can be omitted. Once a library is loaded, its symbols become available for subsequent invocations of **builtin**. Multiple libraries can be specified with separate invocations of the **builtin** command. Libraries are searched in the reverse order in which they are specified. When a library is loaded, it looks for a function in the library whose name is **lib_init()** and invokes this function with an argument of **0**.

cd [**-LP**] [*arg*]

cd [**-LP**] *old new*

This command can be in either of two forms. In the first form it changes the current directory to *arg*. If *arg* is **-** the directory is changed to the previous directory. The shell variable **HOME** is the default *arg*. The variable **PWD** is set to the current directory. The shell variable **CDPATH** defines the search path for the directory containing *arg*. Alternative directory names are separated by a colon (:). The default path is **<null>** (specifying the current directory). Note that the current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If *arg* begins with a / then the search path is not used. Otherwise, each directory in the path is searched for *arg*.

The second form of **cd** substitutes the string *new* for the string *old* in the current directory name, **PWD**, and tries to change to this new directory.

By default, symbolic link names are treated literally when finding the directory name. This is equivalent to the **-L** option. The **-P** option causes symbolic links to be resolved when determining the directory. The last instance of **-L** or **-P** on the command line determines which method is used.

The **cd** command may not be executed by **rksh**. **rksh93**.

command [**-pvxV**] *name* [*arg*...]

Without the **-v** or **-V** options, **command** executes *name* with the arguments given by *arg*. The **-p** option causes a default path to be searched rather than the one defined by the value of **PATH**. Functions will not be searched for when finding *name*. In addition, if *name* refers to a special

built-in, none of the special properties associated with the leading daggers will be honored. (For example, the predefined alias **redirect=command exec** prevents a script from terminating when an invalid redirection is given.) With the **-x** option, if command execution would result in a failure because there are too many arguments, **errno E2BIG**, the shell will invoke command *name* multiple times with a subset of the arguments on each invocation. Arguments that occur prior to the first word that expands to multiple arguments and after the last word that expands to multiple arguments will be passed on each invocation. The exit status will be the maximum invocation exit status. With the **-v** option, **command** is equivalent to the built-in **whence** command described below. The **-V** option causes **command** to act like **whence -v**.

† **continue** [*n*]

Resume the next iteration of the enclosing **for**, **while**, **until**, or **select** loop. If *n* is specified, then resume at the *n*-th enclosing loop.

disown [*job*...]

Causes the shell not to send a HUP signal to each given *job*, or all active jobs if *job* is omitted, when a login shell terminates.

echo [*arg*...]

When the first *arg* does not begin with a **-**, and none of the arguments contain a ****, then **echo** prints each of its arguments separated by a space and terminated by a new-line. Otherwise, the behavior of **echo** is system dependent and **print** or **printf** described below should be used. See *echo(1)* for usage and description.

† **eval** [*arg*...]

The arguments are read as input to the shell and the resulting command(s) executed.

† **exec** [**-c**] [**-a** *name*] [*arg*...]

If *arg* is given, the command specified by the arguments is executed in place of this shell without creating a new process. The **-c** option causes the environment to be cleared before applying variable assignments associated with the **exec** invocation. The **-a** option causes *name* rather than the first *arg*, to become **argv[0]** for the new process. Input/output arguments may appear and affect the current process. If *arg* is not given, the effect of this command is to modify file descriptors as prescribed by the input/output redirection list. In this case, any file descriptor numbers greater than 2 that are opened with this mechanism are closed when invoking another program.

† **exit** [*n*]

Causes the shell to exit with the exit status specified by *n*. The value will be the least significant 8 bits of the specified status. If *n* is omitted, then the exit status is that of the last command executed. An end-of-file will also cause the shell to exit except for a shell which has the **ignoreeof** option (see **set** below) turned on.

†† **export** [**-p**] [*name*[=*value*]]...

If *name* is not given, the names and values of each variable with the export attribute are printed with the values quoted in a manner that allows them to be re-input. The **-p** option causes the word **export** to be inserted before each one. Otherwise, the given *names* are marked for automatic export to the *environment* of subsequently-executed commands.

false Does nothing, and exits 1. Used with **until** for infinite loops.

fg [*job*...]

This command is only on systems that support job control. Each *job* specified is brought to the foreground and waited for in the specified order. Otherwise, the current job is brought into the foreground. See *Jobs* for a description of the format of *job*.

getconf [*name* [*pathname*]]

Prints the current value of the configuration parameter given by *name*. The configuration parameters are defined by the IEEE POSIX 1003.1 and IEEE POSIX 1003.2 standards. (See *pathconf(2)* and *sysconf(2)*.) The *pathname* argument is required for parameters whose value depends on the location in the file system. If no arguments are given, **getconf** prints the names and values of the

current configuration parameters. The pathname */* is used for each of the parameters that requires *pathname*.

getopts [**-a** *name*] *optstring* *vname* [*arg* ...]

Checks *arg* for legal options. If *arg* is omitted, the positional parameters are used. An option argument begins with a + or a -. An option not beginning with + or - or the argument -- ends the options. Options beginning with + are only recognized when *optstring* begins with a +. *optstring* contains the letters that **getopts** recognizes. If a letter is followed by a :, that option is expected to have an argument. The options can be separated from the argument by blanks. The option -? causes **getopts** to generate a usage message on standard error. The -a argument can be used to specify the name to use for the usage message, which defaults to \$0.

getopts places the next option letter it finds inside variable *vname* each time it is invoked. The option letter will be prepended with a + when *arg* begins with a +. The index of the next *arg* is stored in **OPTIND**. The option argument, if any, gets stored in **OPTARG**.

A leading : in *optstring* causes **getopts** to store the letter of an invalid option in **OPTARG**, and to set *vname* to ? for an unknown option and to : when a required option argument is missing. Otherwise, **getopts** prints an error message. The exit status is non-zero when there are no more options.

There is no way to specify any of the options :, +, -, ?, [, and]. The option # can only be specified as the first option.

hist [**-e** *ename*] [**-nlr**] [*first* [*last*]]

hist -s [*old=new*] [*command*]

In the first form, a range of commands from *first* to *last* is selected from the last **HISTSIZE** commands that were typed at the terminal. The arguments *first* and *last* may be specified as a number or as a string. A string is used to locate the most recent command starting with the given string. A negative number is used as an offset to the current command number. If the -l option is selected, the commands are listed on standard output. Otherwise, the editor program *ename* is invoked on a file containing these keyboard commands. If *ename* is not supplied, then the value of the variable **HISTEDIT** is used. If **HISTEDIT** is not set, then **FCEDIT** (default **/bin/ed**) is used as the editor. When editing is complete, the edited command(s) is executed if the changes have been saved. If *last* is not specified, then it will be set to *first*. If *first* is not specified, the default is the previous command for editing and -16 for listing. The option -r reverses the order of the commands and the option -n suppresses command numbers when listing. In the second form, *command* is interpreted as *first* described above and defaults to the last command executed. The resulting command is executed after the optional substitution *old=new* is performed.

jobs [**-lnp**] [*job* ...]

Lists information about each given job; or all active jobs if *job* is omitted. The -l option lists process ids in addition to the normal information. The -n option only displays jobs that have stopped or exited since last notified. The -p option causes only the process group to be listed. See *Jobs* for a description of the format of *job*.

kill [**-s** *signame*] *job* ...

kill [**-n** *signum*] *job* ...

kill -l [*sig* ...]

Sends either the TERM (terminate) signal or the specified signal to the specified jobs or processes. Signals are either given by number with the -n option or by name with the -s option (as given in <signal.h>, stripped of the prefix "SIG" with the exception that SIGCLD is named CHLD). For backward compatibility, the n and s can be omitted and the number or name placed immediately after the -. If the signal being sent is TERM (terminate) or HUP (hangup), then the job or process will be sent a CONT (continue) signal if it is stopped. The argument *job* can be the process id of a process that is not a member of one of the active jobs. See *Jobs* for a description of the format of *job*. In the third form, **kill -l**, if *sig* is not specified, the signal names are listed. Otherwise, for each *sig* that is a name, the corresponding signal number is listed. For each *sig* that is a number,

the signal name corresponding to the least significant 8 bits of *sig* is listed.

let *arg* ...

Each *arg* is a separate *arithmetic expression* to be evaluated. See *Arithmetic Evaluation* above, for a description of arithmetic expression evaluation.

The exit status is 0 if the value of the last expression is non-zero, and 1 otherwise.

† **newgrp** [*arg* ...]

Equivalent to **exec /bin/newgrp** *arg* ...

print [**-Renprs**] [**-u** *unit*] [**-f** *format*] [*arg* ...]

With no options or with option **-** or **--**, each *arg* is printed on standard output. The **-f** option causes the arguments to be printed as described by **printf**. In this case, any **e**, **n**, **r**, **R** options are ignored. Otherwise, unless the **-R** or **-r**, are specified, the following escape conventions will be applied:

| | |
|------------|---|
| \a | The alert character (ascii 07). |
| \b | The backspace character (ascii 010). |
| \c | Causes print to end without processing more arguments and not adding a new-line. |
| \f | The formfeed character (ascii 014). |
| \n | The new-line character (ascii 012). |
| \r | The carriage return character (ascii 015). |
| \t | The tab character (ascii 011). |
| \v | The vertical tab character (ascii 013). |
| \E | The escape character (ascii 033). |
| \ | The backslash character \ . |
| \0x | The character defined by the 1, 2, or 3-digit octal string given by <i>x</i> . |

The **-R** option will print all subsequent arguments and options other than **-n**. The **-e** causes the above escape conventions to be applied. This is the default behavior. It reverses the effect of an earlier **-r**. The **-p** option causes the arguments to be written onto the pipe of the process spawned with **|&** instead of standard output. The **-s** option causes the arguments to be written onto the history file instead of standard output. The **-u** option can be used to specify a one digit file descriptor unit number *unit* on which the output will be placed. The default is 1. If the option **-n** is used, no **new-line** is added to the output.

printf *format* [*arg* ...]

The arguments *arg* are printed on standard output in accordance with the ANSI-C formatting rules associated with the format string *format*. If the number of arguments exceeds the number of format specifications, the **format** string is reused to format remaining arguments. The following extensions can also be used: A **%b** format can be used instead of **%s** to cause escape sequences in the corresponding *arg* to be expanded as described in **print**. A **%B** option causes each of the arguments to be treated as variable names and the binary value of variable will be printed. This is most useful for variables whose attribute is **-b**. A **%H** format can be used instead of **%s** to cause characters in *arg* that are special in HTML and XML to be output as their entity name. A **%P** format can be used instead of **%s** to cause *arg* to be interpreted as an extended regular expression and be printed as a shell pattern. A **%R** format can be used instead of **%s** to cause *arg* to be interpreted as a shell pattern and to be printed as an extended regular expression. A **%q** format can be used instead of **%s** to cause the resulting string to be quoted in a manner than can be reinput to the shell. A **%(date-format)T** format can be used to treat an argument as a date/time string and to format the date/time according to the *date-format* as defined for the **date(1)** command. A **%Z** format will output a byte whose value is 0. The precision field of the **%d** format can be followed by a **.** and the output base. In this case, the **#** flag character causes *base#* to be prepended. The **#** flag when used with the **d** specifier without an output base, causes the output to be displayed in thousands units with one of the suffixes **k M G T P E** to indicate the unit. The **#** flag when used with the **i** specifier causes the output to be displayed in 1024 with one of the suffixes **Ki Mi Gi Ti Pi Ei** to indicate the unit. The **=** flag has been added to center the output within the specified field width.

pwd [**-LP**]

Outputs the value of the current working directory. The **-L** option is the default; it prints the logical name of the current directory. If the **-P** option is given, all symbolic links are resolved from the name. The last instance of **-L** or **-P** on the command line determines which method is used.

read [**-Aprs**] [**-d delim**] [**-n n**] [[**-N n**] [[**-t timeout**] [**-u unit**] [*vname*?*prompt*] [*vname* ...]

The shell input mechanism. One line is read and is broken up into fields using the characters in **IFS** as separators. The escape character, ****, is used to remove any special meaning for the next character and for line continuation. The **-d** option causes the read to continue to the first character of *delim* rather than new-line. The **-n** option causes at most *n* bytes to read rather a full line but will return when reading from a slow device as soon as any characters have been read. The **-N** option causes exactly *n* to be read unless an end-of-file has been encountered or the read times out because of the **-t** option. In raw mode, **-r**, the **** character is not treated specially. The first field is assigned to the first *vname*, the second field to the second *vname*, etc., with leftover fields assigned to the last *vname*. When *vname* has the binary attribute and **-n** or **-N** is specified, the bytes that are read are stored directly into the variable. If the **-v** is specified, then the value of the first *vname* will be used as a default value when reading from a terminal device. The **-A** option causes the variable *vname* to be unset and each field that is read to be stored in successive elements of the indexed array *vname*. The **-p** option causes the input line to be taken from the input pipe of a process spawned by the shell using **|&**. If the **-s** option is present, the input will be saved as a command in the history file. The option **-u** can be used to specify a one digit file descriptor unit *unit* to read from. The file descriptor can be opened with the **exec** special built-in command. The default value of unit *n* is 0. The option **-t** is used to specify a timeout in seconds when reading from a terminal or pipe. If *vname* is omitted, then **REPLY** is used as the default *vname*. An end-of-file with the **-p** option causes cleanup for this process so that another can be spawned. If the first argument contains a **?**, the remainder of this word is used as a *prompt* on standard error when the shell is interactive. The exit status is 0 unless an end-of-file is encountered or **read** has timed out.

†† **readonly** [**-p**] [*vname*[=*value*]] ...

If *vname* is not given, the names and values of each variable with the readonly attribute is printed with the values quoted in a manner that allows them to be re-inputted. The **-p** option causes the word **readonly** to be inserted before each one. Otherwise, the given *vnames* are marked readonly and these names cannot be changed by subsequent assignment.

† **return** [*n*]

Causes a shell *function* or **.** script to return to the invoking script with the exit status specified by *n*. The value will be the least significant 8 bits of the specified status. If *n* is omitted, then the return status is that of the last command executed. If **return** is invoked while not in a *function* or a **.** script, then it behaves the same as **exit**.

† **set** [**±CGabefhkmnoprstuvx**] [**±o** [*option*]] ... [**±A** *vname*] [*arg* ...]

The options for this command have meaning as follows:

- A** Array assignment. Unset the variable *vname* and assign values sequentially from the *arg* list. If **+A** is used, the variable *vname* is not unset first.
- B** Enable brace pattern field generation. This is the default behavior.
- C** Prevents redirection **>** from truncating existing files. Files that are created are opened with the **O_EXCL** mode. Requires **>|** to truncate a file when turned on.
- G** Causes the pattern ****** by itself to match files and zero or more directories and sub-directories when used for file name generation. If followed by a **/** only directories and sub-directories are matched.
- a** All subsequent variables that are defined are automatically exported.
- b** Prints job completion messages as soon as a background job changes state rather than waiting for the next prompt.
- e** If a command has a non-zero exit status, execute the **ERR** trap, if set, and exit. This mode is disabled while reading profiles.

- f** Disables file name generation.
- h** Each command becomes a tracked alias when first encountered.
- k** (Obsolete). All variable assignment arguments are placed in the environment for a command, not just those that precede the command name.
- m** Background jobs will run in a separate process group and a line will print upon completion. The exit status of background jobs is reported in a completion message. On systems with job control, this option is turned on automatically for interactive shells.
- n** Read commands and check them for syntax errors, but do not execute them. Ignored for interactive shells.
- o** The following argument can be one of the following option names:
 - allexport** Same as **-a**.
 - errexit** Same as **-e**.
 - bgnice** All background jobs are run at a lower priority. This is the default mode.
 - braceexpand** Same as **-B**.
 - emacs** Puts you in an *emacs* style in-line editor for command entry.
 - globstar** Same as **-G**.
 - gmacs** Puts you in a *gmacs* style in-line editor for command entry.
 - ignoreeof** The shell will not exit on end-of-file. The command **exit** must be used.
 - keyword** Same as **-k**.
 - markdirs** All directory names resulting from file name generation have a trailing **/** appended.
 - monitor** Same as **-m**.
 - multiline** The built-in editors will use multiple lines on the screen for lines that are longer than the width of the screen. This may not work for all terminals.
 - noclobber** Same as **-C**.
 - noexec** Same as **-n**.
 - noglob** Same as **-f**.
 - nolog** Do not save function definitions in the history file.
 - notify** Same as **-b**.
 - nounset** Same as **-u**.
 - pipefail** A pipeline will not complete until all components of the pipeline have completed, and the return value will be the value of the last non-zero command to fail or zero if no command has failed.
 - showme** When enabled, simple commands or pipelines preceded by a semicolon (**;**) will be displayed as if the **xtrace** option were enabled but will not be executed. Otherwise, the leading **;** will be ignored.
 - privileged** Same as **-p**.
 - verbose** Same as **-v**.
 - trackall** Same as **-h**.
 - vi** Puts you in insert mode of a *vi* style in-line editor until you hit the escape character **033**. This puts you in control mode. A return sends the line.
 - viraw** Each character is processed as it is typed in *vi* mode.
 - xtrace** Same as **-x**.
- p** Disables processing of the **\$HOME/.profile** file and uses the file **/etc/suid_profile** instead of the **ENV** file. This mode is on whenever the effective uid (gid) is not equal to

the real uid (gid). Turning this off causes the effective uid and gid to be set to the real uid and gid.

- r** Enables the restricted shell. This option cannot be unset once set.
- s** Sort the positional parameters lexicographically.
- t** (Obsolete). Exit after reading and executing one command.
- u** Treat unset parameters as an error when substituting.
- v** Print shell input lines as they are read.
- x** Print commands and their arguments as they are executed.
- Do not change any of the options; useful in setting **\$1** to a value beginning with **-**. If no arguments follow this option then the positional parameters are unset.

As an obsolete feature, if the first *arg* is **-** then the **-x** and **-v** options are turned off and the next *arg* is treated as the first argument. Using **+** rather than **-** causes these options to be turned off. These options can also be used upon invocation of the shell. The current set of options may be found in **\$-**. Unless **-A** is specified, the remaining arguments are positional parameters and are assigned, in order, to **\$1 \$2 ...**. If no arguments are given, then the names and values of all variables are printed on the standard output.

† **shift** [*n*]

The positional parameters from **\$n+1 ...** are renamed **\$1 ...**, default *n* is 1. The parameter *n* can be any arithmetic expression that evaluates to a non-negative number less than or equal to **\$#**.

sleep *seconds*

Suspends execution for the number of decimal seconds or fractions of a second given by *seconds*.

† **trap** [**-p**] [*action*] [*sig*] ...

The **-p** option causes the trap action associated with each trap as specified by the arguments to be printed with appropriate quoting. Otherwise, *action* will be processed as if it were an argument to **eval** when the shell receives signal(s) *sig*. Each *sig* can be given as a number or as the name of the signal. Trap commands are executed in order of signal number. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. If *action* is omitted and the first *sig* is a number, or if *action* is **-**, then the trap(s) for each *sig* are reset to their original values. If *action* is the null string then this signal is ignored by the shell and by the commands it invokes. If *sig* is **ERR** then *action* will be executed whenever a command has a non-zero exit status. If *sig* is **DEBUG** then *action* will be executed before each command. The variable **.sh.command** will contain the contents of the current command line when *action* is running. If *sig* is **0** or **EXIT** and the **trap** statement is executed inside the body of a function defined with the **function name** syntax, then the command *action* is executed after the function completes. If *sig* is **0** or **EXIT** for a **trap** set outside any function then the command *action* is executed on exit from the shell. If *sig* is **KEYBD**, then *action* will be executed whenever a key is read while in **emacs**, **gmacs**, or **vi** mode. The **trap** command with no arguments prints a list of commands associated with each signal number.

true Does nothing, and exits 0. Used with **while** for infinite loops.

†† **typeset** [**±AHflabnprtux**] [**±EFLRZi**[*n*]] [*vname*[*=value*]] ...

Sets attributes and values for shell variables and functions. When invoked inside a function defined with the **function name** syntax, a new instance of the variable *vname* is created, and the variable's value and type are restored when the function completes. The following list of attributes may be specified:

- A** Declares *vname* to be an associative array. Subscripts are strings rather than arithmetic expressions.
- a** Declares *vname* to be an indexed array. This is optional unless except for compound variable assignments.
- E** Declares *vname* to be a double precision floating point number. If *n* is non-zero, it defines the number of significant figures that are used when expanding *vname*. Otherwise, ten significant figures will be used.

- F** Declares *vname* to be a double precision floating point number. If *n* is non-zero, it defines the number of places after the decimal point that are used when expanding *vname*. Otherwise ten places after the decimal point will be used.
- H** This option provides UNIX to host-name file mapping on non-UNIX machines.
- L** Left justify and remove leading blanks from *value*. If *n* is non-zero, it defines the width of the field, otherwise it is determined by the width of the value of first assignment. When the variable is assigned to, it is filled on the right with blanks or truncated, if necessary, to fit into the field. The **-R** option is turned off.
- R** Right justify and fill with leading blanks. If *n* is non-zero, it defines the width of the field, otherwise it is determined by the width of the value of first assignment. The field is left filled with blanks or truncated from the end if the variable is reassigned. The **-L** option is turned off.
- Z** Right justify and fill with leading zeros if the first non-blank character is a digit and the **-L** option has not been set. Remove leading zeros if the **-L** option is also set. If *n* is non-zero, it defines the width of the field, otherwise it is determined by the width of the value of first assignment.
- f** The names refer to function names rather than variable names. No assignments can be made and the only other valid options are **-t**, **-u** and **-x**. The **-t** option turns on execution tracing for this function. The **-u** option causes this function to be marked undefined. The **FPATH** variable will be searched to find the function definition when the function is referenced. If no options other than **-f** is specified, then the function definition will be displayed on standard output. If **+f** is specified, then a line containing the function name followed by a shell comment containing the line number and path name of the file where this function was defined, if any, is displayed.
- b** The variable can hold any number of bytes of data. The data can be text or binary. The value is represented by the base64 encoding of the data. If **-Z** is also specified, the size in bytes of the data in the buffer will be determined by the size associated with the **-Z**. If the base64 string assigned results in more data, it will be truncated. Otherwise, it will be filled with bytes whose value is zero. The **printf** format **%B** can be used to output the actual data in this buffer instead of the base64 encoding of the data.
- i** Declares *vname* to be represented internally as integer. The right hand side of an assignment is evaluated as an arithmetic expression when assigning to an integer. If *n* is non-zero, it defines the output arithmetic base, otherwise the output base will be ten.
- l** All upper-case characters are converted to lower-case. The upper-case option, **-u**, is turned off.
- n** Declares *vname* to be a reference to the variable whose name is defined by the value of variable *vname*. This is usually used to reference a variable inside a function whose name has been passed as an argument.
- r** The given *vnames* are marked readonly and these names cannot be changed by subsequent assignment.
- t** Tags the variables. Tags are user definable and have no special meaning to the shell.
- u** All lower-case characters are converted to upper-case. The lower-case option, **-l**, is turned off.
- x** The given *vnames* are marked for automatic export to the *environment* of subsequently-executed commands. Variables whose names contain a **.** cannot be exported.

The **-i** attribute cannot be specified along with **-R**, **-L**, **-Z**, or **-f**.

Using **+** rather than **-** causes these options to be turned off. If no *vname* arguments are given, a list of *vnames* (and optionally the *values*) of the *variables* is printed. (Using **+** rather than **-** keeps the values from being printed.) The **-p** option causes **typeset** followed by the option letters to be printed before each name rather than the names of the options. If any option other than **-p** is given, only those variables which have all of the given options are printed. Otherwise, the *vnames* and *attributes* of all *variables* that have attributes are printed.

ulimit [**-HSacdfmnpstv**] [*limit*]

Set or display a resource limit. The available resource limits are listed below. Many systems do not support one or more of these limits. The limit for a specified resource is set when *limit* is specified. The value of *limit* can be a number in the unit specified below with each resource, or the value **unlimited**. The **-H** and **-S** options specify whether the hard limit or the soft limit for the given resource is set. A hard limit cannot be increased once it is set. A soft limit can be increased up to the value of the hard limit. If neither the **H** nor **S** option is specified, the limit applies to both. The current resource limit is printed when *limit* is omitted. In this case, the soft limit is printed unless **H** is specified. When more than one resource is specified, then the limit name and unit is printed before the value.

- a** Lists all of the current resource limits.
- c** The number of 512-byte blocks on the size of core dumps.
- d** The number of K-bytes on the size of the data area.
- f** The number of 512-byte blocks on files that can be written by the current process or by child processes (files of any size may be read).
- m** The number of K-bytes on the size of physical memory.
- n** The number of file descriptors plus 1.
- p** The number of 512-byte blocks for pipe buffering.
- s** The number of K-bytes on the size of the stack area.
- t** The number of CPU seconds to be used by each process.
- v** The number of K-bytes for virtual memory.

If no option is given, **-f** is assumed.

umask [**-S**] [*mask*]

The user file-creation mask is set to *mask* (see *umask(2)*). *mask* can either be an octal number or a symbolic value as described in *chmod(1)*. If a symbolic value is given, the new umask value is the complement of the result of applying *mask* to the complement of the previous umask value. If *mask* is omitted, the current value of the mask is printed. The **-S** option causes the mode to be printed as a symbolic value. Otherwise, the mask is printed in octal.

† **unalias** [**-a**] *name* ...

The aliases given by the list of *names* are removed from the alias list. The **-a** option causes all the aliases to be unset.

† **unset** [**-fnv**] *vname* ...

The variables given by the list of *vnames* are unassigned, i.e., their values and attributes are erased. Readonly variables cannot be unset. If the **-f** option is set, then the names refer to *function* names. If the **-v** option is set, then the names refer to *variable* names. The **-f** option overrides **-v**. If **-n** is set and *name* is a name reference, then *name* will be unset rather than the variable that it references. The default is equivalent to **-v**. Unsetting **LINENO**, **MAILCHECK**, **OPTARG**, **OPTIND**, **RANDOM**, **SECONDS**, **TMOUT**, and **_** removes their special meaning even if they are subsequently assigned to.

wait [*job* ...]

Wait for the specified *job* and report its termination status. If *job* is not given, then all currently active child processes are waited for. The exit status from this command is that of the last process waited for if *job* is specified; otherwise it is zero. See *Jobs* for a description of the format of *job*.

whence [**-afpv**] *name* ...

For each *name*, indicate how it would be interpreted if used as a command name.

The **-v** option produces a more verbose report. The **-f** option skips the search for functions. The **-p** option does a path search for *name* even if *name* is an alias, a function, or a reserved word. The **-p** option turns off the **-v** option. The **-a** option is similar to the **-v** option but causes all interpretations of the given name to be reported.

Invocation.

If the shell is invoked by *exec*(2), and the first character of argument zero (**\$0**) is **-**, then the shell is assumed to be a *login* shell and commands are read from **/etc/profile** and then from either **.profile** in the current directory or **\$HOME/.profile**, if either file exists. Next, for interactive shells, commands are read from the file named by performing parameter expansion, command substitution, and arithmetic substitution on the value of the environment variable **ENV** if the file exists. If the **-s** option is not present and *arg* and a file by the name of *arg* exists, then it reads and executes this script. Otherwise, if the first *arg* does not contain a */*, a path search is performed on the first *arg* to determine the name of the script to execute. The script *arg* must have execute permission and any *setuid* and *setgid* settings will be ignored. If the script is not found on the path, *arg* is processed as if it named a built-in command or function. Commands are then read as described below; the following options are interpreted by the shell when it is invoked:

- c** If the **-c** option is present, then commands are read from the first *arg*. Any remaining arguments become positional parameters starting at **0**.
- s** If the **-s** option is present or if no arguments remain, then commands are read from the standard input. Shell output, except for the output of the *Special Commands* listed above, is written to file descriptor 2.
- i** If the **-i** option is present or if the shell input and output are attached to a terminal (as told by *tcgetattr*(2)), then this shell is *interactive*. In this case **TERM** is ignored (so that **kill 0** does not kill an interactive shell) and **INTR** is caught and ignored (so that **wait** is interruptible). In all cases, **QUIT** is ignored by the shell.
- r** If the **-r** option is present, the shell is a restricted shell.
- D** A list of all double quoted strings that are preceded by a **\$** will be printed on standard output and the shell will exit. This set of strings will be subject to language translation when the locale is not C or POSIX. No commands will be executed.
- P** If **-P** or **-o profile** is present, the shell is a profile shell (see *pfexec*(1)).
- R filename** The **-R filename** option is used to generate a cross reference database that can be used by a separate utility to find definitions and references for variables and commands.

The remaining options and arguments are described under the **set** command above. An optional **-** as the first argument is ignored.

Rksh Only.

Rksh is used to set up login names and execution environments whose capabilities are more controlled than those of the standard shell. The actions of **rksh** are identical to those of **ksh**, except that the following are disallowed:

- Unsetting the restricted option.
- changing directory (see *cd*(1)),
- setting or unsetting the value or attributes of **SHELL**, **ENV**, **FPATH**, or **PATH**,
- specifying path or command names containing */*,
- redirecting output (**>**, **>|**, **<>**, and **>>**).
- adding or deleting built-in commands.
- using **command -p** to invoke a command.

The restrictions above are enforced after **.profile** and the **ENV** files are interpreted.

When a command to be executed is found to be a shell procedure, **rksh** invokes *ksh* to execute it. Thus, it is possible to provide to the end-user shell procedures that have access to the full power of the standard shell, while imposing a limited menu of commands; this scheme assumes that the end-user does not have write and execute permissions in the same directory.

The net effect of these rules is that the writer of the **.profile** has complete control over user actions, by performing guaranteed setup actions and leaving the user in an appropriate directory (probably *not* the login directory).

The system administrator often sets up a directory of commands (e.g., **/usr/rbin**) that can be safely invoked by **rksh**.

EXIT STATUS

Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. If the shell is being used non-interactively, then execution of the shell file is abandoned unless the error occurs inside a subshell in which case the subshell is abandoned. Otherwise, the shell returns the exit status of the last command executed (see also the **exit** command above). Run time errors detected by the shell are reported by printing the command or function name and the error condition. If the line number that the error occurred on is greater than one, then the line number is also printed in square brackets (**[]**) after the command or function name.

FILES

/etc/profile The system wide initialization file, executed for login shells.

\$HOME/.profile

The personal initialization file, executed for login shells after **/etc/profile**.

\$HOME/.kshrc

Default personal initialization file, executed for interactive shells when **ENV** is not set.

/etc/suid_profile

Alternative initialization file, executed when instead of personal initialization file when the real and effective user or group id do not match.

/dev/null

NULL device

POSIX – Part 2: Shell and Utilities, IEEE Std 1003.2-1992, ISO/IEC 9945-2, IEEE, 1993.

CAVEATS

If a command is executed, and then a command with the same name is installed in a directory in the search path before the directory where the original command was found, the shell will continue to *exec* the original command. Use the **-t** option of the **alias** command to correct this situation.

Some very old shell scripts contain a **^** as a synonym for the pipe character **|**.

Using the **hist** built-in command within a compound command will cause the whole command to disappear from the history file.

The built-in command **.file** reads the whole file before any commands are executed. Therefore, **alias** and **unalias** commands in the file will not apply to any commands defined in the file.

Traps are not processed while a job is waiting for a foreground process. Thus, a trap on **CHLD** won't be executed until the foreground job terminates.

It is a good idea to leave a space after the comma operator in arithmetic expressions to prevent the comma from being interpreted as the decimal point character in certain locales.

NAME

ksh_wrapper – wrap Korn- and Bourne Again Shell scripts in a Bourne shell

SYNOPSIS

edrc/bin/kshscript -> .ksh_wrapper

edrc/lib/kshscript -> .ksh_wrapper

edrc/sbin/kshscript -> .ksh_wrapper

edrc/lib/kshell

AVAILABILITY

WA2L/edrc

DESCRIPTION

wrap Korn- and Bourne Again shell scripts to avoid using `#!/bin/ksh` in the magic key. However, due to the fact that some scripts need Korn shell functionality either **ksh** or **bash** has to be installed in `/bin/`, `/sbin/`, `/usr/contrib/bin/` or `/usr/local/bin/`.

Further **ksh** / **bash** locations can be configured in the config file **ksh_wrapper.cfg**.

To start a new command thru the **.ksh_wrapper**, follow the following steps:

- 1.) create a symlink to the new command in the **edrc/sbin/**, **edrc/bin/** or **edrc/lib/** directory depending on your needs:

```
[ /opt/edrc/bin ]
[ root@acme001 ][*edrc*/bash]: ln -s .ksh_wrapper new_cmd
```

- 2.) install the ksh script in the **edrc/lib/ksh/** directory:

```
[ /opt/edrc/lib/ksh ]
[ root@acme001 ][*edrc*/bash]: vi new_cmd

[ /opt/edrc/lib/ksh ]
[ root@acme001 ][*edrc*/bash]: chmod 644 new_cmd
```

The command **edrc/lib/kshell** returns the path of the Korn- or Bourne Again shell available on the system. The path resolution and configuration file is the same as in **.ksh_wrapper**.

OPTIONS

edrc/lib/kshell

print path to **ksh** or **bash**.

edrc/bin/.ksh_wrapper

wrapper for **ksh** / **bash** scripts in **edrc/bin/**.

edrc/lib/.ksh_wrapper

wrapper for **ksh** / **bash** scripts in **edrc/lib/**.

ENVIRONMENT

-

EXIT STATUS

- | | |
|------------|--|
| 101 | shell (ksh or bash) not found. If ksh or bash is installed on the system and you get this error, add the shell location in the configuration file ksh_wrapper.cfg . |
| 102 | the Korn-Shell script to be started that should be located in lib/ksh/ does not exist. |
| 103 | user calling the command has no permission to access/execute the called <i>daemon_command</i> . |
| 106 | configuration file ksh_wrapper.cfg does not exist. |
| 107 | the .ksh_wrapper was called directly. |

FILES

etc/ksh_wrapper.cfg

configuration file for the **.ksh_wrapper** command.

lib/ksh/

location of the wrapped Korn-/Bourne Again shell scripts. This files should have the file permissions *644* to show, that those scripts must not be started directly.

NAME

kshrc – shell initialization file

SYNOPSIS

edrc/etc/kshrc

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the main configuration file (rc-file) for the **shell**(1), the **eshell**(1) and the **edrc** '**shell**' command.

Do not edit this file, it will be patched with the WA2L/edrc file; define your customization and settings to the **etc/shell.cfg** file.

FILEFORMAT

The fileformat is a ksh/bash script file.

Rows starting with a **#** are considered as comments. Empty lines are allowed, too.

OPTIONS

-

EXAMPLES

-

SEE ALSO

NAME

ksh_wrapper – wrap Korn- and Bourne Again Shell scripts in a Bourne shell

SYNOPSIS

edrc/bin/kshscript -> **.ksh_wrapper**

edrc/lib/kshscript -> **.ksh_wrapper**

edrc/sbin/kshscript -> **.ksh_wrapper**

edrc/lib/kshell

AVAILABILITY

WA2L/edrc

DESCRIPTION

wrap Korn- and Bourne Again shell scripts to avoid using `#!/bin/ksh` in the magic key. However, due to the fact that some scripts need Korn shell functionality either **ksh** or **bash** has to be installed in `/bin/`, `/sbin/`, `/usr/contrib/bin/` or `/usr/local/bin/`.

Further **ksh** / **bash** locations can be configured in the config file **ksh_wrapper.cfg**.

To start a new command thru the **.ksh_wrapper**, follow the following steps:

- 1.) create a symlink to the new command in the **edrc/sbin/**, **edrc/bin/** or **edrc/lib/** directory depending on your needs:

```
[ /opt/edrc/bin ]
[ root@acme001 ][*edrc*/bash]: ln -s .ksh_wrapper new_cmd
```

- 2.) install the ksh script in the **edrc/lib/ksh/** directory:

```
[ /opt/edrc/lib/ksh ]
[ root@acme001 ][*edrc*/bash]: vi new_cmd

[ /opt/edrc/lib/ksh ]
[ root@acme001 ][*edrc*/bash]: chmod 644 new_cmd
```

The command **edrc/lib/kshell** returns the path of the Korn- or Bourne Again shell available on the system. The path resolution and configuration file is the same as in **.ksh_wrapper**.

OPTIONS

edrc/lib/kshell

print path to **ksh** or **bash**.

edrc/bin/.ksh_wrapper

wrapper for **ksh** / **bash** scripts in **edrc/bin/**.

edrc/lib/.ksh_wrapper

wrapper for **ksh** / **bash** scripts in **edrc/lib/**.

ENVIRONMENT

-

EXIT STATUS

- | | |
|------------|--|
| 101 | shell (ksh or bash) not found. If ksh or bash is installed on the system and you get this error, add the shell location in the configuration file ksh_wrapper.cfg . |
| 102 | the Korn-Shell script to be started that should be located in lib/ksh/ does not exist. |
| 103 | user calling the command has no permission to access/execute the called <i>daemon_command</i> . |
| 106 | configuration file ksh_wrapper.cfg does not exist. |
| 107 | the .ksh_wrapper was called directly. |

FILES

NAME

ksh_wrapper.cfg – configuration file for .ksh_wrapper

SYNOPSIS

edrc/etc/ksh_wrapper.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **.ksh_wrapper** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**SEARCH_PATH**

Colon separated search path where to search for the **ksh** or **bash** interpreter.

The path defined here is prepended to the default.

Example: SEARCH_PATH="/bin:/sbin:/usr/local/bin"

Default: SEARCH_PATH="/bin:/sbin:/usr/local/bin"

SEE ALSO

edrcintro(1), ksh_wrapper(1)

NAME

`leo` – commandline interface to <http://dict.leo.org/>.

SYNOPSIS

```
leo [-slmcfuphdv] [<term>]
```

DESCRIPTION

leo is a commandline interface to the german/english/french dictionary on <http://dict.leo.org/>. It supports almost all features which the website supports, plus more.

Results will be printed to the terminal. By default the searched key word will be highlighted (which can be turned off, see below).

To get faster results, **leo** is able to cache queries if you repeatedly use the same query.

leo acts as a standard webbrowser as your mozilla or what so ever does, it connects to the website, executes the query, parses the HTML result and finally prints it somewhat nicely formatted to the terminal.

As of this writing **leo** acts as:

```
Mozilla/5.0 (Windows; U; Windows NT 5.1; de; rv:1.8.1.9) Gecko/20071025 Firefox/1.
```

OPTIONS

`-s --spelltolerance`

Allow spelling errors.

Possible values: **standard**, **on** or **off**.

Default setting: **standard**.

`-m --morphology`

Provide morphology information.

Possible values: **standard**, **none** or **forcedAll**.

Default setting: **standard**.

`-c --chartolerance`

Allow umlaut alternatives.

Possible values: **fuzzy**, **exact** or **relaxed**.

Default: **relaxed**.

`-l --language`

Translation direction.

Possible values: **en**, **fr**, **de2en**, **en2de**, **de2fr** or **fr2de**.

en and **fr** do select the translation direction automatically.

Default: **en**.

`-n --noescapechars`

Don't use escapes for highlighting.

Default: do highlighting.

Controllable via config file too. See below.

No highlighting will be used if STDOUT is not connected to a terminal.

`-f --force`

Don't use the query cache.

Default: use the cache.

This option has no effect if **use_cache** is turned off in the config file.

- `-u --user`
Specify the http proxy user to use if your proxy requires authentication. Read the 'PROXY' section for more details.
- `-p --passwd`
Specify the cleartext password to use with http proxy authentication.
This is not recommended and just implemented for completeness.
- `-h --help`
Display this help and exit.
- `-v --version`
Display version information and exit.
- `-d --debug`
Enable debugging output (a lot of it, beware!), which will be printed to STDERR. If you find a bug you must supply the debugging output along with your bugreport.

term is the key word which you want to translate. If the term contains white spaces quote it using double quotes.

If the **term** parameter is not specified, **leo** will read it from STDIN.

CONFIG

leo reads a config file **.leo** in your home directory if it exists. The following variables are supported:

use_latin

Turns on conversion of UTF8 characters to their latin* encoding.

Default setting (if not given): **yes**.

use_cache

Controls the use of the cache (see later).

Possible values: **yes** or **no**.

Default setting(if not given): **yes**.

If the commandline option **-f** or **--force** has been set then the cache will not be used for the query and if for this query exists an entry in the cache it will be removed from it.

use_color

Controls the use of escape sequences in the terminal output to highlight the key-word in the result.

Possible values: **yes** or **no**.

Default setting(if not given): **yes**.

You can set this option via commandline too: **-n** or **--noescapechars**.

The config option has higher precedence.

user_agent

You may modify the user agent as **leo** identifies itself on the target site. The default is:

```
User-Agent: Mozilla/5.0 (compatible; Konqueror/3.3.1; X11)
```

CACHING

leo supports caching of queries for faster results if you repeatedly use the same query. A query consists of the given **term** (the key word or string) plus the translation option settings.

If you, for example, execute once the following query:

```
% leo langnase
```

and somewhere later:

```
% leo -c exact
```

then **leo** will treat the latter query as a different one than the previous one, because *dict.leo.org* behaves different when different translation options are given.

PROXY

leo can be used with a HTTP proxy service. For this to work, you only have to set the environment variable **http_proxy**. It has the following format:

```
PROTO://[USER:PASSWD@]SERVER[:PORT]
```

The only supported protocol is **http**. If your proxy works without authentication, you can omit the **user:passwd** part. If no port is specified, **80** will be used.

Here is an example (for bash):

```
export http_proxy=http://172.16.120.120:3128
```

and an example with authentication credentials:

```
export http_proxy=http://max:34dwe2@172.16.120.120:3128
```

As security is always important, I have to warn you, that other users on the same machine can read your environment using the 'ps -e ..' command, so this is not recommended.

The most secure way for proxy authentication is just to specify the server+port with **http_proxy** but no credentials, and instead use the **-u** commandline parameter to specify a user (do not use **-p** to specify the password, this will also be readyble in process listing). In this case, **leo** will ask you interactively for the password. It will try its best to hide it from being displayed when you type it (as most such routines in other tools do it as well), it this fails (e.g. because you do not have the 'stty' tool installed), the password will be read from STDIN.

FILES

```
~/.leo           the config file for leo. Not required.
~/.leo-CACHE.db* the cache file.
```

AUTHOR

Thomas Linden <tom@daemon.de>.

BUGS

leo depends on <http://dict.leo.org/>. It may break **leo** if they change something on the site. Therefore be so kind and inform me if you encounter some weird behavior of **leo**. In most cases it is not a bug of **leo** itself, it is a website change on <http://dict.leo.org/>.

In such a case repeat the failed query and use the commandline flag **-d** (which enables debugging) and send the full output to me, thanks.

COPYRIGHT

leo copyleft 2000–2014 Thomas Linden. All rights reserved.

<http://dict.leo.org/> copyright (c) 1995–2014 LEO Dictionary Team.

The search results returned by **leo** are based on the work of the people at LEO.org. Thanks for the great work.

Some time ago they told me that they are disagreed with **leo**, or in other words: from their point of view **leo** seems to break copyright law in some or another way.

I thought a long time about this, but I must deny this. **leo** acts as a simple web client, just like mozilla, IE or even lynx are doing. They are providing the service to the public so I use my favorite web browser to make use of it. In fact my favorite browser to view dict.leo.org is **leo**. There is nothing wrong with that. IMHO.

If you disagree or are asked by the LEO team to stop using **leo** you may decide this for yourself. I in my case wrote kinda browser, what is not prohibited. At least not today.

VERSION

This is the manpage for **leo** version **1.39**.

NAME

libexpect – programmed dialogue library with interactive programs

DESCRIPTION

This library contains functions that allow Expect to be used as a Tcl extension or to be used directly from C or C++ (without Tcl). Adding Expect as a Tcl extension is very short and simple, so that will be covered first.

SYNOPSIS

```
#include expect_tcl.h
Expect_Init(interp);
```

```
cc files... -lexpect5.20 -ltcl7.5 -lm
```

Note: library versions may differ in the actual release.

The Expect_Init function adds expect commands to the named interpreter. It avoids overwriting commands that already exist, however aliases beginning with "exp_" are always created for expect commands. So for example, "send" can be used as "exp_send".

Generally, you should only call Expect commands via Tcl_Eval. Certain auxiliary functions may be called directly. They are summarized below. They may be useful in constructing your own main. Look at the file exp_main_exp.c in the Expect distribution as a prototype main. Another prototype is tclAppInit.c in the Tcl source distribution. A prototype for working with Tk is in exp_main_tk.c in the Expect distribution.

```
int exp_cmdlinecmds;
int exp_interactive;
FILE *exp_cmdfile;
char *exp_cmdfilename;
int exp_tcl_debugger_available;

void exp_parse_argv(Tcl_Interp *,int argc,char **argv);
int exp_interpreter(Tcl_Interp *);
void exp_interpret_cmdfile(Tcl_Interp *,FILE *);
void exp_interpret_cmdfilename(Tcl_Interp *,char *);
void exp_interpret_rcfiles(Tcl_Interp *,int my_rc,int sys_rc);
char *exp_cook(char *s,int *len);
void (*exp_app_exit)EXP_PROTO((Tcl_Interp *));
void exp_exit(Tcl_Interp *,int status);
void exp_exit_handlers(Tcl_Interp *);
void exp_error(Tcl_Interp,char *,...);
```

exp_cmdlinecmds is 1 if Expect has been invoked with commands on the program command-line (using "-c" for example). **exp_interactive** is 1 if Expect has been invoked with the -i flag or if no commands or script is being invoked. **exp_cmdfile** is a stream from which Expect will read commands. **exp_cmdfilename** is the name of a file which Expect will open and read commands from. **exp_tcl_debugger_available** is 1 if the debugger has been armed.

exp_parse_argv reads the representation of the command line. Based on what is found, any of the other variables listed here are initialized appropriately. **exp_interpreter** interactively prompts the user for commands and evaluates them. **exp_interpret_cmdfile** reads the given stream and evaluates any commands found. **exp_interpret_cmdfilename** opens the named file and evaluates any commands found. **exp_interpret_rcfiles** reads and evaluates the .rc files. If my_rc is zero, then ~/.expectrc is skipped. If sys_rc is zero, then the system-wide expectrc file is skipped. **exp_cook** returns a static buffer containing the argument reproduced with newlines replaced by carriage-return linefeed sequences. The primary purpose of this is to allow messages to be produced without worrying about whether the terminal is in raw mode or cooked

mode. If length is zero, it is computed via strlen. **exp_error** is a printf-like function that writes the result to interp->result.

SYNOPSIS

```
#include <expect.h>
```

```
int
exp_spawnl(file, arg0 [, arg1, ..., argn] (char *)0);
char *file;
char *arg0, *arg1, ... *argn;
```

```
int
exp_spawnv(file,argv);
char *file, *argv[ ];
```

```
int
exp_spawnfd(fd);
int fd;
```

```
FILE *
exp_popen(command);
char *command;
```

```
extern int exp_pid;
extern int exp_ttyinit;
extern int exp_ttycopy;
extern int exp_console;
extern char *exp_stty_init;
extern void (*exp_close_in_child)();
extern void (*exp_child_exec_prelude)();
extern void exp_close_tcl_files();
```

```
cc files... -lexpect -ltcl -lm
```

DESCRIPTION

exp_spawnl and **exp_spawnv** fork a new process so that its stdin, stdout, and stderr can be written and read by the current process. *file* is the name of a file to be executed. The *arg* pointers are null-terminated strings. Following the style of `execve()`, *arg0* (or *argv[0]*) is customarily a duplicate of the name of the file.

Four interfaces are available, **exp_spawnl** is useful when the number of arguments is known at compile time. **exp_spawnv** is useful when the number of arguments is not known at compile time. **exp_spawnfd** is useful when an open file descriptor is already available as a source. **exp_popen** is explained later on.

If the process is successfully created, a file descriptor is returned which corresponds to the process's stdin, stdout and stderr. A stream may be associated with the file descriptor by using `fdopen()`. (This should almost certainly be followed by `setbuf()` to unbuffer the I/O.)

Closing the file descriptor will typically be detected by the process as an EOF. Once such a process exits, it should be waited upon (via `wait`) in order to free up the kernel process slot. (Some systems allow you to avoid this if you ignore the SIGCHLD signal).

exp_popen is yet another interface, styled after `popen()`. It takes a Bourne shell command line, and returns a stream that corresponds to the process's stdin, stdout and stderr. The actual implementation of **exp_popen** below demonstrates **exp_spawnl**.

```
FILE *
exp_popen(program)
```

```

char *program;
{
    FILE *fp;
    int ec;

    if (0 > (ec = exp_spawnl("sh", "sh", "-c", program, (char *)0)))
        return(0);
    if (NULL == (fp = fdopen(ec, "r+"))) return(0);
    setbuf(fp, (char *)0);
    return(fp);
}

```

After a process is started, the variable **exp_pid** is set to the process-id of the new process. The variable **exp_pty_slave_name** is set to the name of the slave side of the pty.

The spawn functions use a pty to communicate with the process. By default, the pty is initialized the same way as the user's tty (if possible, i.e., if the environment has a controlling terminal.) This initialization can be skipped by setting **exp_ttycopy** to 0.

The pty is further initialized to some system wide defaults if **exp_ttyinit** is non-zero. The default is generally comparable to "stty sane".

The tty setting can be further modified by setting the variable **exp_stty_init**. This variable is interpreted in the style of stty arguments. For example, **exp_stty_init** = "sane"; repeats the default initialization.

On some systems, it is possible to redirect console output to ptys. If this is supported, you can force the next spawn to obtain the console output by setting the variable **exp_console** to 1.

Between the time a process is started and the new program is given control, the spawn functions can clean up the environment by closing file descriptors. By default, the only file descriptors closed are ones internal to Expect and any marked "close-on-exec".

If needed, you can close additional file descriptors by creating an appropriate function and assigning it to **exp_close_in_child**. The function will be called after the fork and before the exec. (This also modifies the behavior of the spawn command in Expect.)

If you are also using Tcl, it may be convenient to use the function **exp_close_tcl_files** which closes all files between the default standard file descriptors and the highest descriptor known to Tcl. (Expect does this.)

The function **exp_child_exec_prelude** is the last function called prior to the actual exec in the child. You can redefine this for effects such as manipulating the uid or the signals.

IF YOU WANT TO ALLOCATE YOUR OWN PTY

```

extern int exp_autoalloctype;
extern int exp_pty[2];

```

The spawn functions use a pty to communicate with the process. By default, a pty is automatically allocated each time a process is spawned. If you want to allocate ptys yourself, before calling one of the spawn functions, set **exp_autoalloctype** to 0, **exp_pty[0]** to the master pty file descriptor and **exp_pty[1]** to the slave pty file descriptor. The expect library will not do any pty initializations (e.g., **exp_stty_init** will not be used). The slave pty file descriptor will be automatically closed when the process is spawned. After the process is started, all further communication takes place with the master pty file descriptor.

exp_spawnl and **exp_spawnv** duplicate the shell's actions in searching for an executable file in a list of directories. The directory list is obtained from the environment.

EXPECT PROCESSING

While it is possible to use `read()` to read information from a process spawned by `exp_spawnl` or `exp_spawnv`, more convenient functions are provided. They are as follows:

```
int
exp_expectl(fd,type1,pattern1,[re1,],value1,type2,...,exp_end);
int fd;
enum exp_type type;
char *pattern1, *pattern2, ...;
regex *re1, *re2, ...;
int value1, value2, ...;
```

```
int
exp_fexpectl(fp,type1,pattern1,[re1,]value1,type2,...,exp_end);
FILE *fp;
enum exp_type type;
char *pattern1, *pattern2, ...;
regex *re1, *re2, ...;
int value1, value2, ...;
```

```
enum exp_type {
    exp_end,
    exp_glob,
    exp_exact,
    exp_regex,
    exp_compiled,
    exp_null,
};
```

```
struct exp_case {
    char *pattern;
    regex *re;
    enum exp_type type;
    int value;
};
```

```
int
exp_expectv(fd,cases);
int fd;
struct exp_case *cases;
```

```
int
exp_fexpectv(fp,cases);
FILE *fp;
struct exp_case *cases;
```

```
extern int exp_timeout;
extern char *exp_match;
extern char *exp_match_end;
extern char *exp_buffer;
extern char *exp_buffer_end;
extern int exp_match_max;
extern int exp_full_buffer;
extern int exp_remove_nulls;
```

The functions wait until the output from a process matches one of the patterns, a specified time period has passed, or an EOF is seen.

The first argument to each function is either a file descriptor or a stream. Successive sets of arguments describe patterns and associated integer values to return when the pattern matches.

The type argument is one of four values. `exp_end` indicates that no more patterns appear. `exp_glob` indicates that the pattern is a glob-style string pattern. `exp_exact` indicates that the pattern is an exact string. `exp_regexp` indicates that the pattern is a regexp-style string pattern. `exp_compiled` indicates that the pattern is a regexp-style string pattern, and that its compiled form is also provided. `exp_null` indicates that the pattern is a null (for debugging purposes, a string pattern must also follow).

If the compiled form is not provided with the functions `exp_expectl` and `exp_fexpectl`, any pattern compilation done internally is thrown away after the function returns. The functions `exp_expectv` and `exp_fexpectv` will automatically compile patterns and will not throw them away. Instead, they must be discarded by the user, by calling `free` on each pattern. It is only necessary to discard them, the last time the cases are used.

Regexp subpatterns matched are stored in the compiled regexp. Assuming "re" contains a compiled regexp, the matched string can be found in `re->startp[0]`. The match substrings (according to the parentheses) in the original pattern can be found in `re->startp[1]`, `re->startp[2]`, and so on, up to `re->startp[9]`. The corresponding strings ends are `re->endp[x]` where x is that same index as for the string start.

The type `exp_null` matches if a null appears in the input. The variable `exp_remove_nulls` must be set to 0 to prevent nulls from being automatically stripped. By default, `exp_remove_nulls` is set to 1 and nulls are automatically stripped.

`exp_expectv` and `exp_fexpectv` are useful when the number of patterns is not known in advance. In this case, the sets are provided in an array. The end of the array is denoted by a struct `exp_case` with type `exp_end`. For the rest of this discussion, these functions will be referred to generically as *expect*.

If a pattern matches, then the corresponding integer value is returned. Values need not be unique, however they should be positive to avoid being mistaken for `EXP_EOF`, `EXP_TIMEOUT`, or `EXP_FULLBUFFER`. Upon EOF or timeout, the value `EXP_EOF` or `EXP_TIMEOUT` is returned. The default timeout period is 10 seconds but may be changed by setting the variable `exp_timeout`. A value of -1 disables a timeout from occurring. A value of 0 causes the expect function to return immediately (i.e., poll) after one `read()`. However it must be preceded by a function such as `select`, `poll`, or an event manager callback to guarantee that there is data to be read.

If the variable `exp_full_buffer` is 1, then `EXP_FULLBUFFER` is returned if `exp_buffer` fills with no pattern having matched.

When the expect function returns, `exp_buffer` points to the buffer of characters that was being considered for matching. `exp_buffer_end` points to one past the last character in `exp_buffer`. If a match occurred, `exp_match` points into `exp_buffer` where the match began. `exp_match_end` points to one character past where the match ended.

Each time new input arrives, it is compared to each pattern in the order they are listed. Thus, you may test for absence of a match by making the last pattern something guaranteed to appear, such as a prompt. In situations where there is no prompt, you must check for `EXP_TIMEOUT` (just like you would if you were interacting manually). More philosophy and strategies on specifying **expect** patterns can be found in the documentation on the **expect** program itself. See SEE ALSO below.

Patterns are the usual C-shell-style regular expressions. For example, the following fragment looks for a successful login, such as from a telnet dialogue.

```
switch (exp_expectl(
    exp_glob,"connected",CONN,
    exp_glob,"busy",BUSY,
```

```

        exp_glob,"failed",ABORT,
        exp_glob,"invalid password",ABORT,
        exp_end)) {
    case CONN:      /* logged in successfully */
        break;
    case BUSY:      /* couldn't log in at the moment */
        break;
    case EXP_TIMEOUT:
    case ABORT:     /* can't log in at any moment! */
        break;
    default: /* problem with expect */
    }

```

Asterisks (as in the example above) are a useful shorthand for omitting line-termination characters and other detail. Patterns must match the entire output of the current process (since the previous read on the descriptor or stream). More than 2000 bytes of output can force earlier bytes to be "forgotten". This may be changed by setting the variable **exp_match_max**. Note that excessively large values can slow down the pattern matcher.

RUNNING IN THE BACKGROUND

```

extern int exp_disconnected;
int exp_disconnect();

```

It is possible to move a process into the background after it has begun running. A typical use for this is to read passwords and then go into the background to sleep before using the passwords to do real work.

To move a process into the background, fork, call `exp_disconnect()` in the child process and `exit()` in the parent process. This disassociates your process from the controlling terminal. If you wish to move a process into the background in a different way, you must set the variable `exp_disconnected` to 1. This allows processes spawned after this point to be started correctly.

MULTIPLEXING

By default, the expect functions block inside of a read on a single file descriptor. If you want to wait on patterns from multiple file descriptors, use `select`, `poll`, or an event manager. They will tell you what file descriptor is ready to read.

When a file descriptor is ready to read, you can use the expect functions to do one and only read by setting timeout to 0.

SLAVE CONTROL

```

void
exp_slave_control(fd,enable)
int fd;
int enable;

```

Pty trapping is normally done automatically by the expect functions. However, if you want to issue an `ioctl`, for example, directly on the slave device, you should temporarily disable trapping.

Pty trapping can be controlled with `exp_slave_control`. The first argument is the file descriptor corresponding to the spawned process. The second argument is a 0 if trapping is to be disabled and 1 if it is to be enabled.

ERRORS

All functions indicate errors by returning -1 and setting `errno`.

Errors that occur after the spawn functions fork (e.g., attempting to spawn a non-existent program) are

written to the process's stderr, and will be read by the first **expect**.

SIGNALS

```
extern int exp_reading;
extern jmp_buf exp_readenv;
```

expect uses alarm() to timeout, thus if you generate alarms during **expect**, it will timeout prematurely.

Internally, **expect** calls read() which can be interrupted by signals. If you define signal handlers, you can choose to restart or abort **expect**'s internal read. The variable, **exp_reading**, is true if (and only if) **expect**'s read has been interrupted. longjmp(exp_readenv,EXP_ABORT) will abort the read. longjmp(exp_readenv,EXP_RESTART) will restart the read.

LOGGING

```
extern int exp_loguser;
extern int exp_logfile_all
extern FILE *exp_logfile;
```

If **exp_loguser** is nonzero, **expect** sends any output from the spawned process to stdout. Since interactive programs typically echo their input, this usually suffices to show both sides of the conversation. If **exp_logfile** is also nonzero, this same output is written to the stream defined by **exp_logfile**. If **exp_logfile_all** is non-zero, **exp_logfile** is written regardless of the value of **exp_loguser**.

DEBUGGING

While I consider the library to be easy to use, I think that the standalone expect program is much, much, easier to use than working with the C compiler and its usual edit, compile, debug cycle. Unlike typical C programs, most of the debugging isn't getting the C compiler to accept your programs - rather, it is getting the dialogue correct. Also, translating scripts from expect to C is usually not necessary. For example, the speed of interactive dialogues is virtually never an issue. So please try the standalone 'expect' program first. I suspect it is a more appropriate solution for most people than the library.

Nonetheless, if you feel compelled to debug in C, here are some tools to help you.

```
extern int exp_is_debugging;
extern FILE *exp_debugfile;
```

While expect dialogues seem very intuitive, trying to codify them in a program can reveal many surprises in a program's interface. Therefore a variety of debugging aids are available. They are controlled by the above variables, all 0 by default.

Debugging information internal to **expect** is sent to stderr when **exp_is_debugging** is non-zero. The debugging information includes every character received, and every attempt made to match the current input against the patterns. In addition, non-printable characters are translated to a printable form. For example, a control-C appears as a caret followed by a C. If **exp_logfile** is non-zero, this information is also written to that stream.

If **exp_debugfile** is non-zero, all normal and debugging information is written to that stream, regardless of the value of **exp_is_debugging**.

CAVEATS

The stream versions of the **expect** functions are much slower than the file descriptor versions because there is no way to portably read an unknown number of bytes without the potential of timing out. Thus, characters are read one at a time. You are therefore strongly encouraged to use the file descriptor versions of **expect** (although, automated versions of interactive programs don't usually demand high speed anyway).

You can actually get the best of both worlds, writing with the usual stream functions and reading with the file descriptor versions of **expect** as long as you don't attempt to intermix other stream input functions (e.g., fgetc). To do this, pass fileno(stream) as the file descriptor each time. Fortunately, there is little reason to

use anything but the **expect** functions when reading from interactive programs.

There is no matching `exp_pclose` to `exp_popen` (unlike `popen` and `pclose`). It only takes two functions to close down a connection (`fclose()` followed by waiting on the `pid`), but it is not uncommon to separate these two actions by large time intervals, so the function seems of little value.

If you are running on a Cray running Unicos (all I know for sure from experience), you must run your compiled program as `root` or `setuid`. The problem is that the Cray only allows `root` processes to open `ptys`. You should observe as much precautions as possible: If you don't need permissions, `setuid(0)` only immediately before calling one of the `spawn` functions and immediately set it back afterwards.

Normally, **spawn** takes little time to execute. If you notice `spawn` taking a significant amount of time, it is probably encountering `ptys` that are wedged. A number of tests are run on `ptys` to avoid entanglements with errant processes. (These take 10 seconds per wedged `pty`.) Running `expect` with the `-d` option will show if **expect** is encountering many `ptys` in odd states. If you cannot kill the processes to which these `ptys` are attached, your only recourse may be to reboot.

BUGS

The **exp_fexpect** functions don't work at all under HP-UX - it appears to be a bug in `getc`. Follow the advice (above) about using the **exp_expect** functions (which doesn't need to call `getc`). If you fix the problem (before I do - please check the latest release) let me know.

SEE ALSO

An alternative to this library is the **expect** program. **expect** interprets scripts written in a high-level language which direct the dialogue. In addition, the user can take control and interact directly when desired. If it is not absolutely necessary to write your own C program, it is much easier to use **expect** to perform the entire interaction. It is described further in the following references:

"expect: Curing Those Uncontrollable Fits of Interactivity" by Don Libes, Proceedings of the Summer 1990 USENIX Conference, Anaheim, California, June 11-15, 1990.

"Using expect to Automate System Administration Tasks" by Don Libes, Proceedings of the 1990 USENIX Large Installation Systems Administration Conference, Colorado Springs, Colorado, October 17-19, 1990.

`expect(1)`, `alarm(3)`, `read(2)`, `write(2)`, `fdopen(3)`, `execve(2)`, `execvp(3)`, `longjmp(3)`, `pty(4)`.

There are several examples C programs in the test directory of **expect**'s source distribution which use the `expect` library.

AUTHOR

Don Libes, `libes@nist.gov`, National Institute of Standards and Technology

ACKNOWLEDGEMENTS

Thanks to John Ousterhout (UCBerkeley) for supplying the pattern matcher.

Design and implementation of the **expect** library was paid for by the U.S. government and is therefore in the public domain. However the author and NIST would like credit if this program and documentation or portions of them are used.

NAME

lbanner – make posters in large letters

SYNOPSIS

edrc/lib/lbanner [**-h**]

lbanner [**-s** *size*] [**-r** *rotate*] [**-c** *character*] **-t** "*banner text*"

AVAILABILITY

WA2L/edrc

DESCRIPTION

print an ASCII banner as the **banner**(3) command does, but allow more options, as character size, fill character and banner orientation.

OPTIONS

-h usage message.

-s *size* size of the letters (**1** ... **5**).

-r *rotate* orientation of the banner (**v** = vertical, **h** = horizontal).

-c *character* character to be used to build the banner letters.

-t "*banner text*"
string to be printed in large letters. The qotes are only needed when a multiple word string has to be printed.

ENVIRONMENT

-

EXIT STATUS

0 no error.

4 usage displayed.

NAME

lgcheckd – daemon to check, classify and report logfile content

SYNOPSIS

edrc/bin/lgcheckd [**-h** | **-V**]

lgcheckd -a (**start** | **stop** | **status**)

lgcheckd -a (**defined** | **monitored**)

lgcheckd -a ([no]collect | [no]ifstart)

lgcheckd -a (**refresh** | **reset**)

lgcheckd -a report

cat logfile | **lgcpattern** [**-s**] *patternfile*

cat logfile | **lgcpattern -p**

AVAILABILITY

WA2L/edrc

DESCRIPTION

NOTE: The **lgcheckd** daemon is a more efficient and leaner version of the **logcheckd(1m)** command. It is recommended to use **lgcheckd** for new setups.

With **lgcheckd** logfiles can be analyzed and the content can be classified to different levels of importance.

During analysis the timestamp when a certain log entry has been discovered is added to the collected analysis output.

The levels used to classify the logfile content can be defined in pattern files which are related to one or more logfiles to be analyzed.

Files listed in the **LOGFILE OPTIONS** section of the configuration file must not exist at start of the **lgcheckd**. However, as soon as such a file appears it is monitored.

The generated HTML 'Log File Check' report allows easy navigation in the report and provides a view of all matched log file entries per level of importance for a reporting period.

Only existing files or files that once existed during a reporting period will be listed in the report.

The HTML report is also suited for viewing with the **lynx(1)** browser.

lgcheckd is able to communicate to other commands for each matched logfile entry via the **INTERFACES** mechanism, which can be configured in the **lgcheckd.cfg** configuration file. Using interfaces, it is therefore

possible to forward discovered matches to a monitoring system that might not have a very sophisticated logfile analysis functionality.

lgcheckd will not fill up the file system where the log data is collected. If file space gets short during log file analysis the log file match data collection is suspended until sufficient disk space is available again (and will then resume automatically).

The suspension applies as soon as the free space is lower then **20** times the current size of the **state.db**, whereas this number can be changed in the config file using the **SUSPENDTRIGGER=number** setting. During the suspension the log files are still analysed, the matches are counted and the interfaces are started.

OPTIONS

-h usage message.

-V print daemon version.

-a action:

start start the log check daemon **lgcheckd** in the background. It is possible to start one daemon per system.

stop stop a running **lgcheckd** daemon.

report create a 'Log File Check' report for the period since the last report generation.

When invoking the **report** action, the current log collection run is ended, the log match data is deleted (depending on the **CLEAN_COLLECT** setting in the configuration file) and a new collection run is started.

All log files ever monitored are listed in the report.

However, if a log file has no matches in the current log collection run, '**<no pattern matches>**' is shown in the **Logfiles** section of the report.

When logfiles have matches, but during it's occurrence the log file match collection was suspended, the related match counts are shown in the **Overview** section of the report. In that case in the **Logfiles** section '**<no data available>**' is shown as long during the whole collect run duration no other matches were recorded.

The produced report file name is printed plain to **stdout** to allow easy capturing and further processing (as mailing the report using **mail_file(1)**).

reset initialize the **lgcheckd** daemon. All state information, collected logfile content match data, all counters and trend information will be cleared.

status check if a **lgcheckd** is running (EXIT STATUS: **14**), not running (EXIT STATUS: **15**) or is shutting down (EXIT STATUS **18**) on the system.

defined

list the logfiles defined in the **lgcheckd.cfg** (respectively **logcheckd.cfg**) config file.

monitored

list the currently monitored logfiles including additional information of the current- and past collection runs.

When the **lgcheckd** experiences heavy load due to many log entries that have to be analysed, it switches temporarily from **SINGLE** to **BURST** write mode. Whereas in **SINGLE** mode match counts and log matches are immediately written to the database, in **BURST** mode the daemon delays writing to the database and then writes the information in larger chunks to it. This to increase performance.

Therefore the information shown when using **-a monitored** is not up to date while the daemon is in **BURST** mode.

nocollect

disable collecting of matched logfile data. The matches are nevertheless counted when the collection is disabled.

collect enable collecting of matched logfile data.

noifstart

disable the start of interfaces on related log file data match.

ifstart enable the start of interfaces on related log file data match.

refresh force the resolution of log files to monitor.

The interval of checking for new log files that appeared based on the definition in the configuration file is **5** minutes.

lgcpattern *patternfile*

utility to help to define, verify and optimize a **logcheckd.pattern(4)** file. This utility replaces the similar functionality '**logcheckd -a verify patternfile check_levels**' as provided by **logcheckd(1m)**.

See **lgcpattern(3)** for more information.

ENVIRONMENT

-

EXIT STATUS

0 no error.

- 1** neither configfile **etc/lgcheckd.cfg** nor **etc/logcheckd.cfg** exists.
- 4** usage listed.
- 5** program version printed.
- 14** daemon running.
- 15** daemon not running.
- 18** daemon is shutting down.

FILES

etc/lgcheckd.cfg

configuration file of **lgcheckd**, see **lgcheckd.cfg(4)**, **logcheckd.pattern(4)** and **logcheckd.interface(3)** for more information.

The **GENERAL OPTIONS** options are loaded on daemon start, the **LOGFILE OPTIONS** options are loaded on daemon start and are re-evaluated in an interval of **300** seconds or when the **lgcheckd -a refresh** command is invoked.

The provided template file **var/samples/templates/lgcheck.cfg** contains the settings computed by the **lgcheckd** only and should be used as starting point for configuration of new setups if the legacy log checking daemon **logcheckd** was not used before.

(etc/logcheckd.cfg)

configuration file of **logcheckd**.

If the file **etc/lgcheckd.cfg** does not exist the **lgcheckd** reads this file without disadvantages. However, the **lgcheckd** computes the leaner set of options as documented in **lgcheckd.cfg(4)**.

lib/logcheckd/

This directory contains additional files used by **lgcheckd**.

lib/logcheckd/database/state.ddl

SQL data definition language (DDL) file to create the **state.db**.

lib/logcheckd/interface/

This directory contains the interfaces which allow **lgcheckd** to communicate to other tools.

lib/logcheckd/interface/<interfacefile>

Interface that communicates with other software.

See **logcheckd.interface(3)** for more information.

var/cache/logcheckd/

cache data for **lgcheckd**.

var/log/lgcheckd.log

logfile of **lgcheckd**.

var/logcheckd/pattern/

Location of the pattern files used for logfile analysis.

var/logcheckd/pattern/<patternfile>

Pattern file that can be used on multiple operating systems for logfile analysis.

The needed pattern files are loaded on on daemon start and if changed re-loaded in an interval of **300** seconds or when the **lgcheckd -a refresh** command is invoked.

See **logcheckd.pattern(3)** for more information.

var/logcheckd/pattern/<patternfile>.<OSID>

Pattern file for a specific operating system.

In the config file **etc/lgcheckd.cfg** the pattern file is specified *without* the **<OSID>** part. **lgcheckd** first checks if an operating system dependent pattern file exists and then uses the non-operating system dependent pattern file. This eases up configuration and enables to have identical configuration files across different operating systems.

See **logcheckd.pattern(3)** for more information.

var/logcheckd/pattern/lgcheckd

Pattern file to alert **lgcheckd** own events.

var/logcheckd/iconfig/

Location of the configuration files for the interfaces.

var/logcheckd/iconfig/<interfacefile>.cfg

Configuration file of the interfaces located in the **lib/logcheckd/interface/** directory.

See **logcheckd.interface(3)** for more information.

var/logcheckd/iconfig/lgcheckd.cfg

Configuration file of the **lgcheckd** interface used to send alert mails on events in the logfile **var/log/lgcheckd.log** of the **lgcheckd** only.

var/logcheckd/state/

Persistent state information of the **lgcheckd** daemon. All information herein is maintained by the **lgcheckd** command, do not edit it by hand.

var/logcheckd/state/state.db

database that contains all state information and collection data of the **lgcheckd**. The **state.db** is a SQLite (see: **sqlite(1)**) database.

var/logcheckd/report/

Default report output directory.

var/logcheckd/report/logcheck.<hostname>.<timestamp>.html

Report file generated invoking the **lgcheckd -a report** command.

The report is also suited for viewing with the **lynx(1)** browser.

var/samples/templates/lgcheck.cfg

Template configuration file for **lgcheckd**.

EXAMPLES

1) an example pattern file

In this example the logfile of **su(1)** command which allows to switch the user is checked. **su** writes successful user switches in the logfile as:

```
SU 06/05 11:03 + ta barney-root
```

unsuccessful attempts are logged as:

```
SU 06/05 11:03 - ta barney-root
```

The Log Check report in this example should exclude all successful switches of the *root* user to any user, due to the fact that we trust the *root* user:

```
[EXCLUDE]
```

```
. * + . * root-.*$
```

Non-successful tries to switch to the *root* user are classified to the *HIGH* section:

```
[HIGH]
```

```
. * - .*-root$
```

Successful switches to *root* are classified as *MEDIUM* because the user doing the switch knows the password and the assumption here is, that the user knows this password by purpose:

```
[MEDIUM]
```

```
. * + .*-root$
```

Non-successful switches to other users as *root* are also classified as *MEDIUM* due to the fact that the abuse of a *non-root* user has less impact as the abuse of the *root* user, but it also might be a brute force attack to get access to a user login:

```
. * -
```

All remaining entries are classified to the *VERIFY* section:

```
[VERIFY]
```

```
. *
```

The complete pattern file:

```
[ /root ]
[ root@acme001 ][-sh]: cat -n /opt/edrc/var/logcheckd/pattern/su

01 #
02 # logcheckd/pattern/su - logfile analysis pattern file for: su
03 #
04 # [00] 25.04.2008 CWa Initial Version
05 #
06
07 [EXCLUDE]
08
09 .* + .* root-.*$
10
11 [HIGH]
12
13 .* - .*-root$
14
15 [MEDIUM]
16
17 .* + .*-root$
18 .* -
19
20 [LOW]
21
22
23
24 [VERIFY]
25
26 .*
```

2) start the lgcheckd daemon

```
[ /root ]
[ root@acme001 ][-sh]: lgcheckd -a start
```

lgcheckd - a log file checking and reporting daemon, by Chr. Walther

lgcheckd-INFO: start daemon.

3) check lgcheckd status

```
[ /root ]
[ root@acme001 ][-sh]: lgcheckd -a status
```

lgcheckd - a log file checking and reporting daemon, by Chr. Walther

lgcheckd-INFO: daemon is not running, collection is 'enabled', interfaces

4) create a 'Log File Check' report

```
[ /root ]
[ root@acme001 ][-sh]: lgcheckd -a report

lgcheckd - a log file checking and reporting daemon, by Chr. Walther

lgcheckd-INFO: create report for collect run '13'.
lgcheckd-INFO: report file is '/opt/edrc/var/logcheckd/report/logcheck.ac
lgcheckd-INFO: collection match data for collect run '13' deleted.
lgcheckd-INFO: active collect run is now '14'.
done.
```

5) stop lgcheckd

```
[ /root ]
[ root@acme001 ][-sh]: lgcheckd -a stop

lgcheckd - a log file checking and reporting daemon, by Chr. Walther

lgcheckd-INFO: daemon not running.
```

6) reset lgcheckd

```
[ /root ]
[ root@acme001 ][-sh]: lgcheckd -a reset

lgcheckd - a log file checking and reporting daemon, by Chr. Walther

lgcheckd-INFO: daemon database initialized.
```

SEE ALSO

edrcintro(1), **osid(3)**, **crontab(1)**, **ecrontab(1)**, **edrcinit(1m)**, **egrep(1)**, **jobstart(1)**, **lgcheckd.cfg(4)**, **lgcheckd.state.db(4)**, **lgcpattern(3)**, **logcheckd.interface(3)**, **logcheckd.pattern(4)**, **logtail(1)**, **lynx(1)**, **sqlite(1)**, **tpl(1)**

NOTES

The **lgcheckd** daemon is a more efficient and leaner version of the **logcheckd(1m)** command. It is recommended to use **lgcheckd** for new setups

The **lgcheckd** can be started using **edrcinit(1m)**, for which the service handler **WA2Ledrc.lgcheckd** is available.

BUGS

NAME

lgcheckd.cfg – configuration file for lgcheckd

SYNOPSIS

edrc/etc/lgcheckd.cfg
(**edrc/etc/logcheckd.cfg**)

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **lgcheckd** command.

The **lgcheckd** daemon can compute the configuration file **edrc/etc/logcheckd.cfg** of the **logcheckd (1m)** command for easy effortless migration (see also: **USE_LEGACY_COMMAND=False** in **logcheckd.cfg(4)**).

However, the **lgcheckd** command computes only the options as documented in this manual page.

FILEFORMAT

Rows starting with a **#** are considered as comments.

The fileformat for the '**GENERAL OPTIONS**' is **OPTION=VALUE**

Between the **OPTION**, the **=** and the **VALUE** are no spaces.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a **VALUE**.

For the '**LOGFILES OPTIONS**', the fileformat is *field ; field ; field ; field ; field ; field ;* (ensure, that between the *field* and the separator **;** are no spaces).

OPTIONS**GENERAL OPTIONS****ALERT_MAIL_TO**

Recipient of the alert mail. Multiple recipients have to be specified as a comma separated list. If no **ALERT_MAIL_TO** is set, there is no alert mail sent on filesystem shortage and on resumption of log collection.

Example: **ALERT_MAIL_TO=fred.flintstone@acme.ch,support@acme.ch**

Default: **ALERT_MAIL_TO=""**

COLLECT

If this setting is set to *True* the log match data collection is enabled on startup and the matches are saved to the **state.db** for later analysis and reporting, if set to **False** log match data collection is disabled.

Be aware, that command line definitions using **lgcheckd -a [no]collect** has preference.

Example: COLLECT=False

Default: COLLECT=True

INTERFACESTART

If this setting is set to *True* the interfaces defined in the **INTERFACES=...** definition are started on positive match, when set to **False** the interfaces are not started on positive match.

Be aware, that command line definitions using **lgcheckd -a [no]ifstart** has preference.

Example: INTERFACESTART=False

Default: INTERFACESTART=True

CLEAN_COLLECT

If this setting is set to *True* the collected logfile match data is removed after report creation. However, the match count information is retained.

Example: CLEAN_COLLECT=False

Default: CLEAN_COLLECT=True

REPORTDIR

Directory where the 'Log File Check' reports are written to. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation.

Example: REPORTDIR=/dat/report/ACME/LOGCHECK

Example: REPORTDIR=var/www/report/rpt/007/ACME/LOGCHECK

Default: REPORTDIR=var/logcheckd/report

INTERFACES

Interfaces to be executed when a certain check level matches. The setting is a space separated list of entries in the format: *<interface>:<LEVEL1>,<LEVEL2>*

Example: INTERFACES="mail:HIGH CAUnicenter:HIGH,MEDIUM"

Default: INTERFACES=""

SUSPENDTRIGGER

If the free space of the file system on which the **state.db** resides is lower then

`'size of state.db' * SUSPENDTRIGGER`

the collection of log file matches is suspended.

Example: SUSPENDTRIGGER=5

Default: SUSPENDTRIGGER=20

LOGFILES OPTIONS

List of logfiles to be checked for patterns.

It is not needed to restart the lgcheckd when logfile entries are added.

Pattern files can be added and modified during **lgcheckd** runtime.

In all other cases the **lgcheckd** needs to be restarted.

The format of the logfiles specification is:

resolve_mode ; patternfile ; interfaces ; res ; res ; logfile ;

(ensure, that between the *field* and the separator *;* are no spaces)

where the fields have the following content:

resolve_mode

the resolve mode needs to be set to **eval** or **dfft**.

However, it makes no difference in how the entries are computed, the *resolve_mode* field exists to be backward compatible to the configuration file for the **logcheckd(1m)** command.

patternfile pattern file. The pattern files are located in the **var/logcheckd/pattern** directory. If an operating system dependent pattern file with the name **<patternfile>.<OSID>** exists (e.g. **Cron.Solaris**), this file will be used for logfile analysis, else the pattern file as specified (e.g. **Cron**) will be used.

interfaces Interfaces to be executed when a certain check level matches for a certain logfile. The setting is a space separated list of entries in the format: **<interface>:<LEVEL1>,<LEVEL2>**. If the *interfaces* column is set for a logfile, the setting in the **INTERFACES** option is ignored for that logfile.

res reserved for future use, leave it empty.

logfile logfile to analyze.

In general the logfile has to be specified with an absolute path name.

However, if a relative path is specified, it is relative to the root of the WA2L/edrc installation (as returned by the **aproot(3)** command).

Example:

```
dflt;WA2Ledrc;;;var/log/edrc.log;
dflt;lgcheckd;;;var/log/lgcheckd.log;
dflt;All;;;etc/rc.log;
eval;MCSG;;;etc/cmcluster/*/*.cntl.log;
dflt;sudo;;;var/adm/sudo.log;
dflt;Samba;;;var/opt/samba/log.smbd;
dflt;syslog;;;var/adm/syslog/syslog.log;
```

FILES

var/samples/templates/lgcheck.cfg

Template configuration file for **lgcheckd**.

NAME

state.db – lgcheckd database state.db

SYNOPSIS

edrc/var/logcheckd/state/state.db

AVAILABILITY

WA2L/edrc

DESCRIPTION

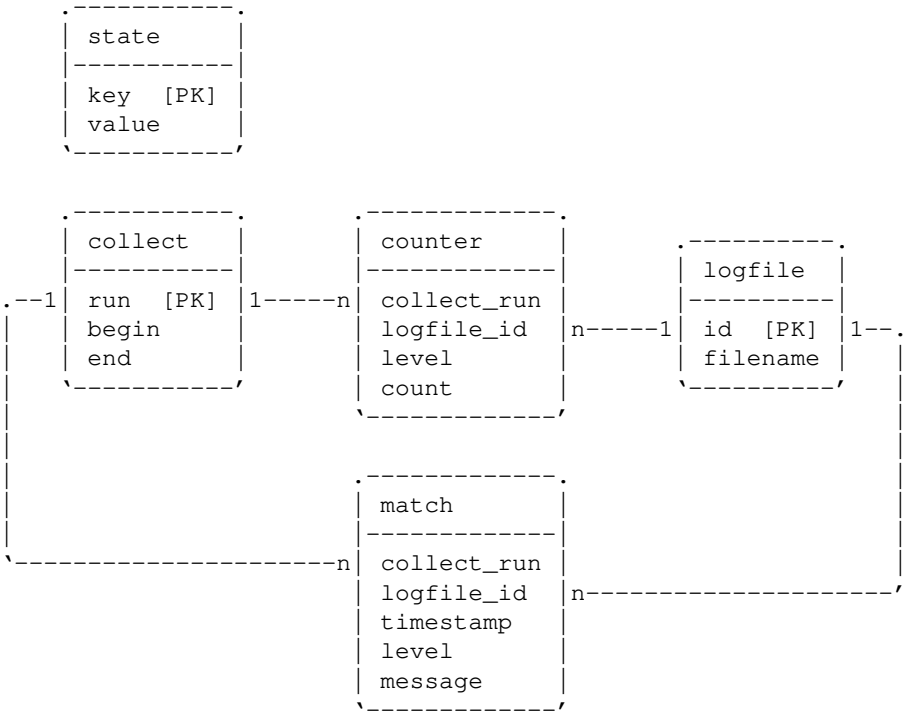

The **state.db** is the database that contains all volatile information of the log check daemon **lgcheckd**(1m).

FILEFORMAT

This is the ER (Entity Relationship) diagram of the **state.db** SQLite database that is used to store all log monitoring data of the log check daemon **lgcheckd**(1m).

The **[PK]** field is the primary key, **1---n** is a 'one to any' relationship.

All primary keys are unique in this data model.

| | |
|----------------|---|
| state | this table contains state information of the lgcheckd . |
| collect | <p>in this table the collect run properties are kept. Only one run is active, which is represented by an empty <i>end</i> field.</p> <p>Collect run entries are never deleted.</p> |
| logfile | the logfile table contains an index of all log files ever monitored. |
| counter | here all counts for matching patterns for each [LEVEL] are saved. Counters are never deleted. |
| match | <p>here the matching log file message data (except data of [EXCLUDE] sections and IGNORED messages) are saved. When a report is created (using -a report) the collected data of the related collection run is deleted by default.</p> <p>The data collection can be disabled using the COLLECT=False setting in the daemon configuration file or using the -a nocollect option on the command line.</p> <p>Data collection is automatically suspended when the available storage on the filesystem where the state.db resides gets tight. A suspended collection is automatically resumed after sufficient storage is available, again.</p> <p>If data collection is disabled or suspended the matches are still counted and saved to the counter table.</p> |

OPTIONS

-

FILES

| | |
|---|--|
| lib/logcheckd/database/state.ddl | SQL file to generate the SQLite database. |
| var/logcheckd/state/state.db | SQLite main database file. |
| var/logcheckd/state/state.db-wal | <p>this file is the Write-Ahead Log. It temporarily stores the changes made to the database. When a transaction is committed, the changes are appended to the wal file. Eventually, these changes are transferred (checkpointed) from the wal file back into the main database file.</p> |
| var/logcheckd/state/state.db-shm | <p>this file is the Shared Memory File. It is used to coordinate access between multiple database connections in WAL mode. The shared memory file is used to store the index of transactions in the wal file and to handle concurrency control.</p> |

NAME

lgcpattern – check/verify a logcheckd and lgcheckd pattern file definition

SYNOPSIS

edrc/lib/lgcpattern [**-h**]

cat logfile | **lgcpattern** [**-s** | **-i**] *patternfile*

lgcpattern [**-s** | **-i**] *patternfile* < *logfile*

cat logfile | **lgcpattern** (**-p** | **-P**)

lgcpattern (**-p** | **-P**) < *logfile*

AVAILABILITY

WA2L/edrc

DESCRIPTION

utility to help to define a **logcheckd.pattern**(4) file.

OPTIONS

-h print usage message.

-s print match statistics for each pattern.

This output can be used to re-arrange the pattern sequence in the pattern file for best performance.

-i print only the **[IGNORED]** log lines, the lines that do not match to any pattern.

-p produce patterns from *logfile* stream to be used in *patternfiles*.

The output is reduced by a leading time stamp, characters that are special to regular expressions are escaped and numbers are replaced by related regular expressions.

-P as the **-p** option, but also print the commented (**#** ...) original log message line before the related pattern.

patternfile pattern file name as present in the pattern file directory.

Please note that the pattern file including an operating system id **osid**(3) has to be specified. This allows to also check pattern files of operating systems different to the one logged-on to be

checked.

logfile log file stream to check the *patternfile* against.

ENVIRONMENT

-

EXIT STATUS

| | |
|----------|------------------------------|
| 0 | no error. |
| 1 | pattern file does not exist. |
| 4 | usage message printed. |

FILES

edrc/var/logcheckd/pattern/
pattern file directory.

edrc/var/logcheckd/pattern/*patternfile*
pattern file to check/analyse/verify against a log file data stream.

EXAMPLES

1) Analyze parts of a log file

Use the last 10 lines of the **/var/log/syslog** log file and check it against the **syslog.Linux-64** pattern file.

This to see which message match against the *patternfile* and for which no matches exist (**=[IGNORED]**) and for which matches patterns are probably missing (**=[VERIFY]**).

```
tail -10 /var/log/syslog | \
lgcpattern syslog.Linux-64
```

2) Analyze pattern file definition

Use the last 10000 lines of the **/var/log/syslog** log file to verify the **syslog.Linux-64** pattern file.

This to see a statistics of message-match counts to patterns in the *patternfile*.

This result can be used to possibly rearrange the pattern sequence to improve analysis efficiency.

```
tail -10000 /var/log/syslog | \
lgcpattern -s syslog.Linux-64
```

3) Generate patterns based on a log file

Use the last 10 lines of the **/var/log/syslog** log file to generate patterns for the log lines.

Each "patternized" line is prepended by a commented original message line to ease up pattern definition.

```
tail -10 /var/log/syslog | \
lgcpattern -P
```

4) Generate unique patterns based on a log file

Use the last 10 lines of the **/var/log/syslog** log file to generate unique patterns for the log lines.

```
tail -10 /var/log/syslog | \
lgcpattern -p | sort -u
```

5) Generate patterns for un-categorized log entries

Use the last 500 lines of the **/var/log/syslog** log file to generate a list of unique patterns for the log lines that are currently not matched by any pattern of the pattern file **syslog.Linux-64**.

```
tail -500 /var/log/syslog | \
lgcpattern -i syslog.Linux-64 | \
lgcpattern -p | sort -u
```

NAME

listtemp – list state of temporary directories in a directory

SYNOPSIS

edrc/lib/listtemp [-h]

listtemp -d *directory*

AVAILABILITY

WA2L/edrc

DESCRIPTION

list the state of all temporary directories, that are created in a certain directory.

The output is a list that provides the following information:

IS_ACTIVE

True = the process that created the directory is still running;

False = the process that created the directory is not running any more.

If an entry is marked as **False** the process that created the temporary directory is no longer running and the temporary directory can be removed without side effects.

DIRECTORY

the temporary directory.

CREATED

date and time when the temporary directory was created.

COMMAND

command name that created the directory.

PID

process id of the process that created the directory.

USER

name of the user that created the temporary directory.

PROCESS

process name of the process that created the directory.

OPTIONS

-h usage message.

-d *directory*
directory where to start to search for temporary directories.

ENVIRONMENT

-

EXIT STATUS

0 no error.

3 directory specified in the **-d** option does not exist.

4 usage message listed.

FILES

.maketemp.flagfile
flagfile located in the temporary directory containing the state information about the command that created the temporary directory. This file is created by **maketemp(3)** and is also read by **removetemp(3)** when removing the temporary directory.

EXAMPLES

-

SEE ALSO

edrcintro(1), **maketemp(3)**, **purgetemp(3)**, **removetemp(3)**

NAME

llcomp – list the files contained in a compressed archive file

SYNOPSIS

edrc/bin/llcomp [**-h**]

llcomp *file*

AVAILABILITY

WA2L/edrc

DESCRIPTION

With **llcomp** you can list the files included in a compressed archive without decompressing the whole archive file. The output of **llcomp** is more detailed then the output of the **lscomp** command. Note, that the output of **llcomp** differs depending on the archive format, while the output of **lscomp** is identical for all supported archives.

OPTIONS

-h usage message

file filename of the compressed archive file. This file is a file with the suffixes **.tgz**, **.tar.gz**, **.tar.bz**, **.tar.bz2**, **.tar.Z**, **.tar.zip**, **.cpio**, **.cpio.gz**, **.cpio.bz**, **.cpio.bz2**, **.cpio.xz**, **.cpio.Z**, **.cpio.zip**, **.depot.gz**, **.depot**, **.epub**, **.zip**, **.jar**, **.whl**, **.rock**, **.rpm**, **.deb** or **.bw**.

EXIT STATUS

- 1** specified archive file not found.
- 2** file format of specified archive file not recognized. The file format is determined by the file suffix only.
- 4** usage displayed.
- 6** error while decompressing a compressed archive. This error occurs if the file is not compressed with the command that is normally assigned with the file suffix.
For instance: the file **my_archive.tar.gz** was not really compressed with **gzip** or the file is corrupt.
- 7** error while accessing file list in archive. This error occurs if the file is not archived with the command that is normally assigned to the file suffix.
For instance: the file **my_archive.tar.gz** was not really a compressed **tar** file or the tar archive

is corrupt.

NAME

locate – list files in databases that match a pattern

SYNOPSIS

```
locate [-d path | --database=path] [-e | -E | --[non-]existing] [-i | --ignore-case] [-0 | --null] [-c |
--count] [-w | --wholename] [-b | --basename] [-l N | --limit=N] [-S | --statistics] [-r | --regex ]
[--regextype R] [--max-database-age D] [-P | -H | --nofollow] [-L | --follow] [--version] [-A | --all]
[-p | --print] [--help] pattern...
```

DESCRIPTION

This manual page documents the GNU version of **locate**. For each given pattern, **locate** searches one or more databases of file names and displays the file names that contain the pattern. Patterns can contain shell-style metacharacters: ‘*’, ‘?’, and ‘[]’. The metacharacters do not treat ‘/’ or ‘.’ specially. Therefore, a pattern ‘foo*bar’ can match a file name that contains ‘foo3/bar’, and a pattern ‘*duck*’ can match a file name that contains ‘lake/.ducky’. Patterns that contain metacharacters should be quoted to protect them from expansion by the shell.

If a pattern is a plain string — it contains no metacharacters — **locate** displays all file names in the database that contain that string anywhere. If a pattern does contain metacharacters, **locate** only displays file names that match the pattern exactly. As a result, patterns that contain metacharacters should usually begin with a ‘*’, and will most often end with one as well. The exceptions are patterns that are intended to explicitly match the beginning or end of a file name.

The file name databases contain lists of files that were on the system when the databases were last updated. The system administrator can choose the file name of the default database, the frequency with which the databases are updated, and the directories for which they contain entries; see **updatedb(1)**.

If **locate**’s output is going to a terminal, unusual characters in the output are escaped in the same way as for the **--print** action of the **find** command. If the output is not going to a terminal, file names are printed exactly as-is.

OPTIONS

-0, --null

Use ASCII NUL as a separator, instead of newline.

-A, --all

Print only names which match all non-option arguments, not those matching one or more non-option arguments.

-b, --basename

Results are considered to match if the pattern specified matches the final component of the name of a file as listed in the database. This final component is usually referred to as the ‘base name’.

-c, --count

Instead of printing the matched filenames, just print the total number of matches we found, unless **--print** (**-p**) is also present.

-d path, --database=path

Instead of searching the default file name database, search the file name databases in *path*, which is a colon-separated list of database file names. You can also use the environment variable **LOCATE_PATH** to set the list of database files to search. The option overrides the environment variable if both are used. Empty elements in the path are taken to be synonyms for the file name of the default database. A database can be supplied on stdin, using ‘-’ as an element of *path*. If more than one element of *path* is ‘-’, later instances are ignored (and a warning message is printed).

The file name database format changed starting with GNU **find** and **locate** version 4.0 to allow machines with different byte orderings to share the databases. This version of **locate** can automatically recognize and read databases produced for older versions of GNU **locate** or Unix versions of **locate** or **find**. Support for the old locate database format will be discontinued in a future release.

- e, --existing*
Only print out such names that currently exist (instead of such names that existed when the database was created). Note that this may slow down the program a lot, if there are many matches in the database. If you are using this option within a program, please note that it is possible for the file to be deleted after **locate** has checked that it exists, but before you use it.
- E, --non-existing*
Only print out such names that currently do not exist (instead of such names that existed when the database was created). Note that this may slow down the program a lot, if there are many matches in the database.
- help* Print a summary of the options to **locate** and exit.
- i, --ignore-case*
Ignore case distinctions in both the pattern and the file names.
- l N, --limit=N*
Limit the number of matches to N. If a limit is set via this option, the number of results printed for the *-c* option will never be larger than this number.
- L, --follow*
If testing for the existence of files (with the *-e* or *-E* options), consider broken symbolic links to be non-existing. This is the default.
- max-database-age D*
Normally, **locate** will issue a warning message when it searches a database which is more than 8 days old. This option changes that value to something other than 8. The effect of specifying a negative value is undefined.
- m, --mmap*
Accepted but does nothing, for compatibility with BSD **locate**.
- P, -H, --nofollow*
If testing for the existence of files (with the *-e* or *-E* options), treat broken symbolic links as if they were existing files. The *-H* form of this option is provided purely for similarity with **find**; the use of *-P* is recommended over *-H*.
- p, --print*
Print search results when they normally would not, because of the presence of *--statistics* (*-S*) or *--count* (*-c*).
- r, --regex*
The pattern specified on the command line is understood to be a regular expression, as opposed to a glob pattern. The Regular expressions work in the same way as in **emacs** except for the fact that "." will match a newline. GNU **find** uses the same regular expressions. Filenames whose full paths match the specified regular expression are printed (or, in the case of the *-c* option, counted). If you wish to anchor your regular expression at the ends of the full path name, then as is usual with regular expressions, you should use the characters *^* and *\$* to signify this.
- regextype R*
Use regular expression dialect R. Supported dialects include 'findutils-default', 'posix-awk', 'posix-basic', 'posix-egrep', 'posix-extended', 'posix-minimal-basic', 'awk', 'ed', 'egrep', 'emacs', 'gnu-awk', 'grep' and 'sed'. See the Texinfo documentation for a detailed explanation of these dialects.
- s, --stdio*
Accepted but does nothing, for compatibility with BSD **locate**.
- S, --statistics*
Print various statistics about each locate database and then exit without performing a search, unless non-option arguments are given. For compatibility with BSD, *-S* is accepted as a synonym for *--statistics*. However, the output of **locate** *-S* is different for the GNU and BSD

implementations of **locate**.

--version

Print the version number of **locate** and exit.

-w, --wholename

Match against the whole name of the file as listed in the database. This is the default.

ENVIRONMENT

LOCATE_PATH

Colon-separated list of databases to search. If the value has a leading or trailing colon, or has two colons in a row, you may get results that vary between different versions of **locate**.

HISTORY

The **locate** program started life as the BSD fast find program, contributed to BSD by James A. Woods. This was described by his paper *Finding Files Fast* which was published in *Usenix ;login:*, Vol 8, No 1, February/March, 1983, pp. 8-10. When the **find** program began to assume a default **-print** action if no action was specified, this changed the interpretation of **find pattern**. The BSD developers therefore moved the fast find functionality into **locate**. The GNU implementation of **locate** appears to be derived from the same code.

Significant changes to **locate** in reverse order:

- 4.3.7 Byte-order independent support for old database format
- 4.3.3 **locate -i** supports multi-byte characters correctly
Introduced **--max_db_age**
- 4.3.2 Support for the **slocate** database format
- 4.2.22 Introduced the **--all** option
- 4.2.15 Introduced the **--regex** option
- 4.2.14 Introduced options **-L, -P, -H**
- 4.2.12 Empty items in **LOCATE_PATH** now indicate the default database
- 4.2.11 Introduced the **--statistics** option
- 4.2.4 Introduced **--count** and **--limit**
- 4.2.0 Glob characters cause matching against the whole file name
- 4.0 Introduced the **LOCATE02** database format
- 3.7 **Locate** can search multiple databases

BUGS

The **locate** database correctly handles filenames containing newlines, but only if the system's **sort** command has a working **-z** option. If you suspect that **locate** may need to return filenames containing newlines, consider using its **--null** option.

NAME

locatedb – front-compressed file name database

DESCRIPTION

This manual page documents the format of file name databases for the GNU version of **locate**. The file name databases contain lists of files that were in particular directory trees when the databases were last updated.

There can be multiple databases. Users can select which databases **locate** searches using an environment variable or command line option; see **locate(1)**. The system administrator can choose the file name of the default database, the frequency with which the databases are updated, and the directories for which they contain entries. Normally, file name databases are updated by running the **updatedb** program periodically, typically nightly; see **updatedb(1)**.

GNU LOCATE02 database format

This is the default format of databases produced by **updatedb**. The **updatedb** program runs **frcode** to compress the list of file names using front-compression, which reduces the database size by a factor of 4 to 5. Front-compression (also known as incremental encoding) works as follows.

The database entries are a sorted list (case-insensitively, for users' convenience). Since the list is sorted, each entry is likely to share a prefix (initial string) with the previous entry. Each database entry begins with a signed offset-differential count byte, which is the additional number of characters of prefix of the preceding entry to use beyond the number that the preceding entry is using of its predecessor. (The counts can be negative.) Following the count is a null-terminated ASCII remainder — the part of the name that follows the shared prefix.

If the offset-differential count is larger than can be stored in a signed byte (± 127), the byte has the value 0x80 (binary 10000000) and the actual count follows in a 2-byte word, with the high byte first (network byte order). This count can also be negative (the sign bit being in the first of the two bytes).

Every database begins with a dummy entry for a file called 'LOCATE02', which **locate** checks for to ensure that the database file has the correct format; it ignores the entry in doing the search.

Databases cannot be concatenated together, even if the first (dummy) entry is trimmed from all but the first database. This is because the offset-differential count in the first entry of the second and following databases will be wrong.

In the future, the data within the locate database may not be sorted in any particular order. To obtain sorted results, pipe the output of **locate** through **sort -f**.

slocate database format

The **slocate** program uses a database format similar to, but not quite the same as, GNU **locate**. The first byte of the database specifies its *security level*. If the security level is 0, **slocate** will read, match and print filenames on the basis of the information in the database only. However, if the security level byte is 1, **slocate** omits entries from its output if the invoking user is unable to access them. The second byte of the database is zero. The second byte is followed by the first database entry. The first entry in the database is not preceded by any differential count or dummy entry. Instead the differential count for the first item is assumed to be zero.

Starting with the second entry (if any) in the database, data is interpreted as for the GNU LOCATE02 format.

Old Locate Database format

There is also an old database format, used by Unix **locate** and **find** programs and earlier releases of the GNU ones. **updatedb** runs programs called **bigram** and **code** to produce old-format databases. The old format differs from the above description in the following ways. Instead of each entry starting with an offset-differential count byte and ending with a null, byte values from 0 through 28 indicate offset-differential counts from -14 through 14. The byte value indicating that a long offset-differential count follows is 0x1e (30), not 0x80. The long counts are stored in host byte order, which is not necessarily network byte order, and host integer word size, which is usually 4 bytes. They also represent a count 14 less than their value. The database lines have no termination byte; the start of the next line is indicated by its first byte having a

value ≤ 30 .

In addition, instead of starting with a dummy entry, the old database format starts with a 256 byte table containing the 128 most common bigrams in the file list. A bigram is a pair of adjacent bytes. Bytes in the database that have the high bit set are indexes (with the high bit cleared) into the bigram table. The bigram and offset-differential count coding makes these databases 20–25% smaller than the new format, but makes them not 8-bit clean. Any byte in a file name that is in the ranges used for the special codes is replaced in the database by a question mark, which not coincidentally is the shell wildcard to match a single character.

EXAMPLE

Input to **frcode**:

```
/usr/src
/usr/src/cmd/aardvark.c
/usr/src/cmd/armadillo.c
/usr/tmp/zoo
```

Length of the longest prefix of the preceding entry to share:

```
0 /usr/src
8 /cmd/aardvark.c
14 rmadillo.c
5 tmp/zoo
```

Output from **frcode**, with trailing nulls changed to newlines and count bytes made printable:

```
0 LOCATE02
0 /usr/src
8 /cmd/aardvark.c
6 rmadillo.c
-9 tmp/zoo
```

(6 = 14 - 8, and -9 = 5 - 14)

NAME

locations.cfg – locations configuration file

SYNOPSIS

etc/locations.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the location definition for the **locations** command.

FILEFORMAT

The fileformat is a list of definitions that have the format

COUNTRY;TIMEZONE;COMPANY;CITY;COMMENTS;WORKTIME_FROM;WORKTIME_TO;

Rows starting with a **#** are considered as comments. Empty lines are allowed, too.

OPTIONS

COUNTRY

Country of the (company) location.

TIMEZONE

Timezone where the location is in.

See **etc/timezone.dat** for a list of time zones.

COMPANY

Company or organization name.

CITY

City of the company or organization.

COMMENTS

Comments.

WORKTIME_FROM

time when the working time in the location starts. The time is the local time in the timezone as set in the *TIMEZONE* field.

WORKTIME_TO

time when the working time in the location ends. The time is the local time in the timezone as set in the *TIMEZONE* field.

The *WORKTIME_FROM* and *WORKTIME_TO* fields are used together with the *TIMEZONE* to resolve if a certain location is currently on duty.

NAME

log – write a message to a logfile

SYNOPSIS

edrc/lib/log *level* "*message text*"

log -h

AVAILABILITY

WA2L/edrc

DESCRIPTION

This command is used in scripts to write a standardized message to a log file.

The message is appended to a logfile and has the format:

YYYY-MM-DD HH:MM:SS [<Session>] <Scriptname>-<LEVEL>: <message text>

Example:

2008-12-14 14:00:05 [SAT_6031] my_script-ERROR: dir '/dat/report/myreport' does not exist.

The **<Scriptname>** is derived from the **\$EDRC_SCRIPTNAME** environment variable, the **<LEVEL>** is the upper case of the *level* string given as the first option of the command. The **<Session>** is derived from the **\$EDRC_SESSION** environment variable if set, else the process id of the calling script is logged. The message text is written as received from the other options of the command.

OPTIONS

level

Message level. The string given here is printed in upper case. There is no restriction in the *level* strings, a convention used in commands within WA2L/edrc is:

INFO Information messages.

ERROR

An error occurred, that questions the correct output or function of the command. An error has to be corrected to ensure that the command can complete successfully.

WARNING

A non critical malfunction of the command occurred. Often a **WARNING** can be ignored, but in some occasions a warning can also lead to a minor reduction in output quality. A warning has to be analyzed and rated by the user.

FATAL

A fatal error is a condition that has to be analyzed and that needs user intervention and correction to ensure proper functionality.

message text

message to be printed.

ENVIRONMENT**\$EDRC_SCRIPTNAME**

scriptname that is printed in the **<Scriptname>** part of the output.

\$EDRC_LOGFILE

logfile where the log entries are appended to.

\$TZ

time zone.

EXIT STATUS

0 no error.

4 usage listed.

EXAMPLES

The following examples are script cut-outs of Bourne-, Korn- or Bash shell scripts:

1) common usage

```
EDRC_SCRIPTNAME=`basename $0`; export EDRC_SCRIPTNAME
EDRC_LOGFILE=/var/log/`basename $0`.log; export EDRC_LOGFILE

log INFO "command started"
```

2) set a session usage

```
EDRC_SCRIPTNAME=`basename $0`; export EDRC_SCRIPTNAME
EDRC_LOGFILE=/var/log/`basename $0`.log; export EDRC_LOGFILE
EDRC_SESSION=SAT_6031; export EDRC_SESSION

log INFO "command started"
```

NAME

logcat – cat remote- or local (time-stamped) log file(s)

SYNOPSIS

edrc/bin/logcat [**-h** | **-p**]

logcat *file* ...

logcat [[*user@*]*host*:]*file* ...

logcat [*options*] [**-f** "*from_ts*"] [**-t** "*to_ts*"] [[*user@*]*host*:]*file* ...

logcat [*options*] [**-f** "*from_ts*"] [**-t** "*to_ts*" **-t** "*to_ts*"] [[*user@*]*host*:]*file* ...

lcat ...

options ::= [**-l** *localuser*] [**-M**] [**-s** *num*] [**-NUM**] [**-T** *id*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

cat selected time range (from/to) in log *files*.

If the log file has time stamps, the data between a *from* and *to* time stamp is selected and **cated**.

Hint: To **grep** in log files with time stamps, use the **loggrep**(1) command directly instead of piping the output of **logcat**(1) to **grep** or **egrep**.

When there are no time stamps in the log file, or the time stamp format is not recognized, the whole log file data is **cated**.

The first **97** lines of the log file are used to resolve the time stamp format used in a particular file.

Beside text log file(s), **logcat** can handle file(s) which are **zipped** (**.zip**), **compressed** (**.Z**), **gzipped** (**.gz**), **bzip2ed** (**.bz**, **.bz2**, **.bzip2**) or **xzed** (**.xz**) directly.

To increase performance on scanning large log files which are bigger then **100 MByte**, only the last **1'000'000** lines are analysed. To force to nevertheless analyse the whole file, specify **-0** in the **-NUM** option.

FROM/TO DATA SELECTION

The **-f** "*from_ts*" and **-t** "*to_ts*" time stamps have to be specified in military format ("**2021-01-18 20:57:10**").

The following abbreviations and defaults apply (examples when executed on **Monday, 2021-01-18**):

| specified from/to_ts | resulting from_ts | resulting to_ts |
|----------------------|---------------------|---------------------|
| | 2021-01-18 00:00:00 | 2021-01-18 23:59:59 |
| 13:45 | 2021-01-18 13:45:00 | 2021-01-18 13:45:59 |
| 13:45:55 | 2021-01-18 13:45:55 | 2021-01-18 13:45:55 |
| 16 | 2021-01-16 00:00:00 | 2021-01-16 23:59:59 |
| 01-16 | 2021-01-16 00:00:00 | 2021-01-16 23:59:59 |
| 05-30 | 2020-05-30 00:00:00 | 2020-05-30 23:59:59 |
| 2020 | 2020-01-01 00:00:00 | 2020-12-31 23:59:59 |
| 2020-03 | 2020-03-01 00:00:00 | 2020-03-31 23:59:59 |
| 2020-03-27 | 2020-03-27 00:00:00 | 2020-03-27 23:59:59 |
| 2020-03-27 13 | 2020-03-27 13:00:00 | 2020-03-27 13:59:59 |
| 2020-03-27 13:45 | 2020-03-27 13:45:00 | 2020-03-27 13:45:59 |
| 2020-03-27 13:45:12 | 2020-03-27 13:45:12 | 2021-03-27 13:45:12 |
| yesterday | 2021-01-17 00:00:00 | 2021-01-17 23:59:59 |
| mon | 2021-01-11 00:00:00 | 2021-01-11 23:59:59 |
| tue | 2021-01-12 00:00:00 | 2021-01-12 23:59:59 |
| wed | 2021-01-13 00:00:00 | 2021-01-13 23:59:59 |
| thu | 2021-01-14 00:00:00 | 2021-01-14 23:59:59 |
| fri | 2021-01-15 00:00:00 | 2021-01-15 23:59:59 |
| sat | 2021-01-16 00:00:00 | 2021-01-16 23:59:59 |
| sun | 2021-01-17 00:00:00 | 2021-01-17 23:59:59 |

LOG FILE TIME STAMP FORMATS

The following time stamps are recognized (per log file):

- 1) 2021-01-30 23:59:59
- 2) 2021/01/30-23:59:59
- 3) Jan 30 23:59:59
- 4) ---- 2021-01-30 23:59:59 ----
- 5) 12/16-11:34:21
- 6) Nov 18, 2019 9:44:43 PM
Apr 15, 2020 10:50:51 AM
- 7) End-Date: 2021-01-15 10:06:29
Start-Date: 2021-01-15 10:06:35
- 8) [18/Jan/2021:10:51:23 +0100]
- 9) 2021/01/30 23:59:59
- 10) ----BEGIN: Mon Nov 18 19:51:51 UTC 2019

- 23) error 2021-02-13 06:12:51
info 2021-02-13 06:12:51
- 24) ERROR: apport (pid 593) Fri Feb 1 23:09:19 2019

OPTIONS

- h** usage message.
- p** print the timestamp formats known by **logcat**, some example files where that timestamp format has been discovered and the regular expression that is used to identify the timestamp.
- l *localuser***
use the local user *localuser* to initiate the connection.
- s *num*** use the first *num* lines of the logfile for timestamp format detection.

-NUM analyse the last *NUM* lines, instead of the whole file.

On large log files that exceed **100 MByte**, only the last **1'000'000** rows are scanned, whereas the first **4007** lines are here used to resolve the time stamp format.

To force to scan nevertheless the whole log file, specify **-0** here.

-f "from_ts"

start of data selection in military (=ISO) format, an abbreviated date or time specification as listed in the table in section **DESCRIPTION** or a past weekday (as: **yesterday, mon, tue, wed, thu, fri, sat, sun**).

Default is the current date at **00:00:00** (example: "**2021-01-18 00:00:00**").

-t "to_ts"

end of data selection in military (=ISO) format, an abbreviated date or time specification as listed in the table in section **DESCRIPTION** or a past weekday (as: **yesterday, mon, tue, wed, thu, fri, sat, sun**).

Default is current date at **23:59:59** (example: "**2021-01-18 23:59:59**").

-M

print meta data of **logcat** results to file descriptor **3**.

Example:

```
LOGGREGP_FROM="2020-03-27 13:45:00"
LOGGREGP_TO="2020-03-27 18:00:00"
LOGGREGP_COUNT="68312"
LOGGREGP_BEGIN="2020-03-27 13:50:18"
LOGGREGP_END="2020-03-27 17:58:36"
LOGGREGP_DURATION="000:04:13:24"
```

This output can be used to set variables in a script:

```
#!/bin/sh

logcat -M -f "2020-03-27 13:45:00" -t "2020-03-27 18:00:00" \
    starting ~edrc/var/log/edrc.log 3>/tmp/meta.out

. /tmp/meta.out
echo "ENTRIES: $LOGGREGP_COUNT between $LOGGREGP_BEGIN and $LOGGREGP_END"
```

[[user@]host:]file

remote- or local file.

If a **-** is specified as a *file* option, data is read from **stdin**.

Beside text files, the specified *file* can also be **zipped** (**.zip**), **compressed** (**.Z**), **gzipped** (**.gz**), **bzip2ed** (**.bz**, **.bz2**, **.bzip2**) or **xzed** (**.xz**).

ENVIRONMENT**\$LOGGREG_FROM**

from_ts as specified on the command line. However, the command line option **-f** "*from_ts*" has preference.

\$LOGGREG_TO

to_ts as specified on the command line. However, the command line option **-t** "*to_ts*" has preference.

EXIT STATUS

0

2 error occurred.

4 usage printed.

5 command has been aborted.

11 could not claim a temporary directory in **/tmp/**.

FILES

-

EXAMPLES

-

SEE ALSO

edrcintro(1), **cat(1)**, **edrcsetup(1m)**, **egrep(1)**, **grep(1)**, **loggrep(1)**, **rcat(1)**, **regexintro(4)**, **ssh-exec(1)**, **ssh-exec.cfg(4)**

NOTES

logcat uses **rcat(1)** internally to get the remote- and local files.

A call to **lcat** ... is identical to a call to the **logcat** ... command.

logcat is a simplified use (or shortcut) to the **loggrep** command to display the whole section between two timestamps without **grep**ing the log contents. That's why some (environment) variables also for **logcat** have the **LOGGREG_...** prefix.

NAME

logcheckd – daemon to check, classify and report logfile content

SYNOPSIS

edrc/bin/logcheckd [**-h**]

logcheckd -a (**start** | **stop** | **report** | **reset** | **status** | **defined** | **monitored**)

cat logfile | **logcheckd -a verify patternfile check_levels**

AVAILABILITY

WA2L/edrc

DESCRIPTION

NOTE: The **lgcheckd** daemon is a more efficient and leaner version of the **logcheckd(1m)** command. It is recommended to use **lgcheckd(1m)** at least for new setups.

With **logcheckd** logfiles can be analyzed and the content can be classified to different levels of importance.

During analysis the timestamp when a certain log entry has been discovered is added to the collected analysis output.

The levels used to classify the logfile content can be defined in pattern files which are related to one or more logfiles to be analyzed.

The generated HTML report allows easy navigation in the report and provides an index of the number of selected rows (=hits) per level of importance in an overview section of the report.

To allow judgement of the number of hits the absolute number of hits are also normalized to 'hits per day' (hits/day) which then are less dependent of the reporting period and can be compared to the hits/day of the last analysis period and a calculated hits trend.

The trend is calculated as:

$$\text{trend_new} = (0.75 * \text{trend_last}) + (0.25 * \text{hits_last})$$

This means that the past goes into the trend calculation with three quarters and the last run goes into the trend with a weight of one quarter. This causes to approach a good prediction of expected future logfile content hits.

The generated report can be kept on the file system, but the main purpose is to send it per mail to system administration personnel which will get a good overview of the log situation on the system.

For compliance the report contains a random compliance code that is used to prove that the report has been viewed. To help the administrative personnel and to enable a consistent compliance procedure the generated report provides a '**send report view confirmation mail**' hyperlink that prepares a compliance mail when clicking on it having the compliance code in the subject line. So in the mailbox it is easy to see which

reports have been viewed by sorting it by subject.

logcheckd will not fill up the file system where the log data is collected and reported. If file space will be short during log file analysis the analysis is suspended until sufficient disk space is available again and will then resume automatically. A report will also only be generated if sufficient free space is available. The following suspension criteria applies:

$$\{1.5 * lsize\} > \{available - (available + used) / 100 * MIN_FREESPACE\}$$

For a logfile analysis, the "lsize" is the total size of the logfile to be analyzed; for a report creation, the "lsize" is the size of all collected matches of the collect run for which the report should be generated.

logcheckd is also able to communicate to other commands for each matched logfile entry via the **INTERFACES** mechanism, which can be configured in the **logcheckd.cfg** configuration file. Using interfaces, it is therefore possible to forward discovered matches to a monitoring system that might not have a very sophisticated logfile analysis functionality.

REPORT STRUCTURE

The generated report is structured into the following sections:

General General information about the report. This section contains the following information:

Customer

Name of the Customer.

Environment

Name and description of the environment of which the host is part of.

Hostname

Hostname where the report has been generated.

Report Name of the report.

Report ID

Unique ID of the report.

Report Period

Period (date and time from, date and time to) that is covered by the report. To allow easy calculations the duration in seconds is provided, too.

Date Date when the report has been generated.

Generated by

Path and name of the command and user that generated (and mailed) the report.

Confirmation Code

Random confirmation code for compliance usage.

Compliance

Hyperlink providing an email with a structured subject and content that can be mailed to a compliance recipient.

Overview Overview of all logfiles that existed during the 'Report Period'. This section contains the following information:

Current (hits absolute)

Absolute number of hits per defined level and absolute number of ignored logfile rows during the 'Reporting Period'.

Current (hits/day)

Number of hits per defined level and number of ignored logfile rows during the 'Reporting Period' converted into hits per day.

Last (hits/day)

Number of hits per defined level and number of ignored logfile rows during the last 'Reporting Period' converted into hits per day.

Trend (hits/day)

Trend of hits per defined level and number of ignored logfile rows calculated based on all past reports.

Logfile Name and size of the logfile.

Logfiles All captured logfile rows sorted by logfile and defined level.

Footline Information about the **logcheckd** version used to generate the report.

OPTIONS

-h usage message.

-a action:

start

start the log check daemon **logcheckd** in the background. It is possible to start one daemon per system.

stop

stop a running **logcheckd** daemon.

report

create a LogCheck report for the period since the last report generation. If an email address is defined in the **REPORT_MAIL_TO** setting in the config file **etc/logcheckd.cfg** the report will be mailed to the recipient(s) defined in **REPORT_MAIL_TO**, **REPORT_MAIL_CC** and **REPORT_MAIL_BCC**.

reset

initialize the **logcheckd** daemon. All state information, collected logfile content hits, all counters and trend information will be cleared. If you configured to keep the logfile collection hits (**CLEAN_COLLECT=False**) all collect runs are removed. If you configured to keep the generated reports after mailing them (**CLEAN_REPORT=False**) the reports will be moved to the **REPORT-DIR/\$TODAY** directory.

status check if a **logcheckd** is running (EXIT STATUS: 14) or not running (EXIT STATUS: 15) on the system.

defined

list the logfiles defined in the **logcheckd.cfg** config file.

monitored

list the currently monitored logfiles including some additional information.

verify *patternfile check_levels*

verify the *check_levels* of the *patternfile* for the *logfile* piped into **logcheckd**. This option can be used to check if the settings made in a pattern file lead into the expected results. *check_levels* is a comma separated list of levels to be checked. This is equal to the **CHECK_LEVELS** setting in the **logcheckd.cfg** configuration file. When verifying a *patternfile* no timing information is added to the output.

ENVIRONMENT

-

SIGNALS

The following signals are handled by **logcheckd**. Do not use other signals as those listed below, as long as you do not really know what you are doing and what the consequences are. In general there is no need to invoke those signals by your own, this signals are used for inter process communication of **logcheckd**.

TERM kill the process without an argument (**kill PID**). Issuing this signal, the daemon will end.

EXIT STATUS

- 0** no error.
- 1** configfile **etc/logcheckd.cfg** does not exist.
- 2** operating system is not supported. See **osid(3)** if you get this error.
- 3** pattern file does not exist. This exit status is returned only when calling **logcheckd** with the **-a verify** option.

- 4 usage listed.
- 5 **logcheckd** has been aborted issuing <Ctrl>+<C>. This applies only when using the options **-a stop**, **-a reset** or **-a report**.
- 6 cannot write to **REPORTDIR**.
- 7 cannot write to **COLLECTDIR**.
- 8 cannot write to the **logcheckd** logfile.
- 9 cannot write to **LOCKDIR**.
- 10 directory **PATTERNDIR** does not exist.
- 11 a temporary directory could not be claimed or created in **/var/tmp**. Check the system temporary directory **/var/tmp** if you get this error, it is an indicator of system intrusion.
- 12 ambiguous pattern file name. This error only occurs if **logcheckd** is called with the **-a verify** option. During daemon operation logfile specifications containing ambiguous pattern file names are ignored and the daemon does not exit.
- 13 report creation failed.
- 14 daemon running.
- 15 daemon not running.
- 16 directory **INTERFACECONFIGDIR** does not exist.
- 17 not all interfaces, as specified in **INTERFACES** in the **logcheckd.cfg** config file, can be accessed. An interface has to be executable for the root user.

FILES

etc/logcheckd.cfg

configuration file of **logcheckd**, see **logcheckd.cfg(4)**, **logcheckd.pattern(4)** and **logcheckd.style(4)** for more information. The logfile options are reloaded in the interval defined in **CHECK_INTERVAL**, therefore logfiles can be added, modified and removed from the list without restarting the **logcheckd** daemon. When a logfile is removed, it will not be checked from that moment on, but it will be included in the first report generated afterwards.

lib/logcheckd/

This directory contains additional files used by **logcheckd**.

lib/logcheckd/style/

This directory contains the stylesheets used by the **logcheckd** when a HTML report is generated.

lib/logcheckd/style/WA2L.css

Default style sheet when generating the report.

lib/logcheckd/interface/

This directory contains the interfaces which allow **logcheckd** to communicate to other tools.

lib/logcheckd/interface/<interfacefile>

Interface that communicates with other software. See **logcheckd.interface(3)** for more information.

var/log/logcheckd.log

logfile of **logcheckd**. The location of the logfile can be configured in the **etc/logcheckd.cfg** config file.

var/logcheckd/pattern/

Location of the pattern files used for logfile analysis.

var/logcheckd/pattern/<patternfile>

Pattern file that can be used on multiple operating systems for logfile analysis.

var/logcheckd/pattern/<patternfile>.<OSID>

Pattern file for a specific operating system.

In the config file **etc/logcheckd.cfg** the pattern file is specified *without* the **<OSID>** part. **logcheckd** first checks if a operating system dependent pattern file exists and then uses the non-operating system dependent pattern file. This eases up configuration and enables to have identical configuration files across different operating systems.

var/logcheckd/iconfig/

Location of the configuration files for the interfaces.

var/logcheckd/iconfig/<interfacefile>.cfg

Configuration file of the interfaces located in the **lib/logcheckd/interface/** directory. See **logcheckd.interface(3)** for more information.

var/logcheckd/collect/

Default collect directory.

var/logcheckd/collect/<collect_run>/

This directory contains the collected logfile entries (hits) of all checked logfiles for a certain collect run.

var/logcheckd/collect/<collect_run>/<logfile_number>.excluded

Number of excluded ([EXCLUDE] section) rows of a checked logfile.

var/logcheckd/collect/<collect_run>/<logfile_number>.ignored

Number of ignored rows of a checked logfile.

var/logcheckd/collect/<collect_run>/<logfile_number>.<LEVEL>

Selected rows of a logfile for a certain *LEVEL* as configured in the pattern file. See also **logcheckd.pattern(4)** for more information about pattern files.

var/logcheckd/collect/<collect_run>/ts.begin

Begin timestamp of a logfile analysis / reporting period.

var/logcheckd/collect/<collect_run>/ts.end

End timestamp of a logfile reporting period..

var/logcheckd/state/

Persistent state information of the **logcheckd** daemon. All information herein is maintained by the **logcheckd** command, do not edit it by hand.

var/logcheckd/state/index

Index of all configured logfiles that have been found on the system.

var/logcheckd/state/collect.seq

Counter of collect runs.

var/logcheckd/state/report.seq

Counter of generated reports.

var/logcheckd/state/files/

File properties that have to be saved across collect runs.

var/logcheckd/state/files/<logfile_number>.inode

Inode number of a checked logfile.

var/logcheckd/state/files/<logfile_number>.rows

Number of rows of a checked logfile.

var/logcheckd/state/files/<logfile_number>.size

Size in kBytes (1 kByte = 1024 Bytes) of a checked logfile.

var/logcheckd/state/files/<logfile_number>.<LEVEL>.hits.last

Number of hits per day of a logfile for a certain *LEVEL*.

var/logcheckd/state/files/<logfile_number>.<LEVEL>.hits.trend

Trend of hits per day of a logfile for a certain *LEVEL*.

var/logcheckd/state/files/<logfile_number>.ignored.last

Number of ignored logfile rows per day of the last reporting period.

var/logcheckd/state/files/<logfile_number>.ignored.trend

Trend of number of ignored rows per day.

var/logcheckd/state/files/<logfile_number>.excluded.last

Number of excluded logfile rows per day of the last reporting period.

var/logcheckd/state/files/<logfile_number>.excluded.trend

Trend of number of excluded rows per day.

var/logcheckd/report/

Default report output directory.

<REPORTDIR>/<customer>_<report>_<environment_name>_<report_id>.html

Report file if it is saved.

var/samples/templates/logcheck.cfg

Template configuration file for **logcheckd**.

EXAMPLES

1) verify a pattern file

In this example the logfile of **su(1)** command which allows to switch the user is checked. **su** writes successful user switches in the logfile as:

```
SU 06/05 11:03 + ta barney-root
```

unsuccessful attempts are logged as:

```
SU 06/05 11:03 - ta barney-root
```

The LogCheck report in this example should exclude all successful switches of the *root* user to any user, due to the fact that we trust the *root* user:

```
[EXCLUDE]
```

```
. * + . * root-. * $
```

Non-successful tries to switch to the *root* user are classified to the *HIGH* section:

```
[HIGH]
```

```
. * - . *-root $
```

Successful switches to *root* are classified as *MEDIUM* because the user doing the switch knows the password and the assumption here is, that the user knows this password by purpose:

```
[MEDIUM]
```

```
. * + . *-root $
```

Non-successful switches to other users as *root* are also classified as *MEDIUM* due to the fact that the abuse of a *non-root* user has less impact as the abuse of the *root* user, but it also might be a brute force attack to get access to a user login:

```
. * -
```

All remaining entries are classified to the *VERIFY* section:

```
[VERIFY]
```

```
. *
```

Later when running **logcheckd** as daemon the *VERIFY* and *EXCLUDE* sections will only be collected/reported when they are listed in the **CHECK_LEVELS** setting (e.g: **CHECK_LEVELS=HIGH,MEDIUM,LOW,VERIFY,EXCLUDE**) in the config file **logcheckd.cfg**(4).

```

NAME

logcheckd.cfg – configuration file for logcheckd and lgcheckd

SYNOPSIS

edrc/etc/logcheckd.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **logcheckd** command.

FILEFORMAT

Rows starting with a **#** are considered as comments.

The fileformat for the '**GENERAL OPTIONS**' and the '**REPORT OPTIONS**' is **OPTION=VALUE**

Between the **OPTION**, the **=** and the **VALUE** are no spaces.

You should not comment out any **OPTION**. If you like to use default settings simply do not specify a **VALUE**.

For the '**LOGFILES OPTIONS**', the fileformat is *field ; field ; field ; field ; field ; field ;* (ensure, that between the *field* and the separator **;** are no spaces).

OPTIONS**GENERAL OPTIONS****USE_LEGACY_COMMAND**

If this setting is set to *True* the **logcheckd** command is started, if it is set to **False** the new variant **lgcheckd** is started when invoking the **logcheckd** command.

Example: USE_LEGACY_COMMAND=False

Default: USE_LEGACY_COMMAND=True

LOG

Log output dir of logcheckd. If you specify a relative path name the path is relative to the root of the EDRC installation.

Example: LOG=/var/opt/ACME/log

Default: LOG=var/log

LOCKDIR

Lock dir of logcheckd. If you specify a relative path name the path is relative to the root of the EDRC installation. In General it is not recommended to set the lockdir within EDRC, locate it in a system own directory.

Example: LOCKDIR=/var/run/logcheckd

Default: LOCKDIR=var/lock

CHECK_INTERVAL

Interval of **logcheckd** in seconds.

Example: CHECK_INTERVAL=30

Default: CHECK_INTERVAL=10

ANALYSIS_SUSPENSION

If the free space in the **COLLECTDIR** is not sufficient to analyze a logfile (the available free space must be 1.5 times the size of the logfile to be analyzed), the logfile analysis of the logfile is suspended for the number of seconds specified in this setting. When the **ANALYSIS_SUSPENSION** is elapsed, the free space is checked again. The logfile analysis will be suspended as long as the free space is not sufficient. When sufficient space is made available, the logfile analysis is resumed automatically.

Example: ANALYSIS_SUSPENSION=600

Default: ANALYSIS_SUSPENSION=300

MIN_FREESPACE

Minimum free disk space in percent (%) in the filesystem where the **COLLECTDIR** and the **REPORTDIR** resides. This is the watermark that is considered when checking the free space and which causes a analysis suspension or a "insufficient free space" message when generating a report. Beside to avoid file system fill ups, this setting is used to avoid monitoring alerts when a certain filesystem fill up level is reached.

Example: MIN_FREESPACE=5

Default: MIN_FREESPACE=15

INIT_MODE

Mode on initial startup when a logfile has not been analyzed before. Set *FromBeginning* to analyze the logfile from the beginning, set *FromEnd* to analyze logfile beginning at the file end.

Example: INIT_MODE=FromBeginning

Default: INIT_MODE=FromEnd

REPORTDIR

Directory where the LOGCHECK reports are written to. If you specify a relative path name the path is relative to the root of the EDRC installation.

Example: REPORTDIR=/dat/report/ACME/logcheck

Default: REPORTDIR=/var/logcheckd/report

CLEAN_REPORT

If this setting is set to *True* the report output file is removed after sending it.

Example: CLEAN_REPORT=True

Default: CLEAN_REPORT=False

COMPRESS_REPORTMAIL

If set to *True* the report is attached as a zipped file to the report mail.

Example: COMPRESS_REPORTMAIL=True

Default: COMPRESS_REPORTMAIL=False

COMPRESS_SUFFIX

Compressed attachment file suffix.

Example: COMPRESS_SUFFIX=.ACME.zip

Default: COMPRESS_SUFFIX=.zip

COMPANY

Company. This String will be added to the zipfile comment.

Example: COMPANY="ACME Information Business GmbH, Switzerland"

Default: COMPANY=""

REPORT_STYLE

Report style definition.

Example: REPORT_STYLE=WA2L.css

Default: REPORT_STYLE=WA2L.css

REPORT_NUMBER_START

First report number.

Example: REPORT_NUMBER_START=50000

Default: REPORT_NUMBER_START=10000

CLEAN_COLLECT

If this setting is set to *True* the report output file is removed after sending it.

Example: CLEAN_COLLECT=False

Default: CLEAN_COLLECT=True

COLLECTDIR

Directory where the log hits are collected to. If you specify a relative path name the path is relative to the root of the EDRC installation.

Example: COLLECTDIR=var/logcheckd/collect

Default: COLLECTDIR=var/logcheckd/collect

PATTERNDIR

Directory where the pattern files are saved. If you specify a relative path name the path is relative to the root of the EDRC installation.

Example: PATTERNDIR=var/logcheckd/pattern

Default: PATTERNDIR=var/logcheckd/pattern

CHECK_LEVELS

Check the listed levels only. This levels should to be defined in the pattern files to have an effect.

Example: CHECK_LEVELS=HIGH,MEDIUM,LOW,EXCLUDE

Default: CHECK_LEVELS=HIGH,MEDIUM,LOW

INTERFACECONFIGDIR

Directory where the interface configuration files are saved. If you specify a relative path name the path is relative to the root of the WA2L/edrc installation.

Example: INTERFACECONFIGDIR=var/logcheckd/iconfig

Default: INTERFACECONFIGDIR=var/logcheckd/iconfig

INTERFACES

Interfaces to be executed when a certain check level matches. The setting is a space separated list of entries in the format: *<interface>:<LEVEL1>,<LEVEL2>* .

Example: INTERFACES="mail:HIGH CAUnicenter:HIGH,MEDIUM"

Default: INTERFACES=""

ALERT_MAIL_TO

Recipient of the alert mail. Multiple recipients have to be specified as a comma separated list. If no **ALERT_MAIL_TO** is set, there is no alert mail sent on filesystem shortage and on resumption of log analysis.

Example: ALERT_MAIL_TO=fred.flintstone@acme.ch,support@acme.ch

Default: ALERT_MAIL_TO=""

ALERT_MAIL_SECTION

Section as displayed in the report mail subject line.

Example: ALERT_MAIL_SECTION="system alert"

Default: ALERT_MAIL_SECTION="system alert"

REPORT OPTIONS

REPORT_CUSTOMER

Customer.

Example: REPORT_CUSTOMER='server_environment -C'

Default: REPORT_CUSTOMER='server_environment -C'

REPORT_NAME

Name of the report.

Example: REPORT_NAME=LOGCHECK

Default: REPORT_NAME=LOGCHECK

REPORT_SECTION

Section as displayed in the report mail subject line.

Example: REPORT_SECTION=logcheck

Default: REPORT_SECTION=logcheck

REPORT_SERVER_ENVIRONMENT

Server environment where the report is generated.

Example: `REPORT_SERVER_ENVIRONMENT='server_environment'`

Default: `REPORT_SERVER_ENVIRONMENT='server_environment'`

REPORT_SERVER_ENVIRONMENT_DESCRIPTION

Server environment description where the report is generated.

Example: `REPORT_SERVER_ENVIRONMENT_DESCRIPTION='server_environment -d'`

Default: `REPORT_SERVER_ENVIRONMENT_DESCRIPTION='server_environment -d'`

REPORT_MAIL_FROM

Sender of the report mail.

Example: `REPORT_MAIL_FROM=support@acme.ch`

Default: `REPORT_MAIL_FROM=${USER}@'hostname'`

REPORT_MAIL_TO

Recipient of the report mail. If multiple recipients have to be specified as comma separated list.

Example: `REPORT_MAIL_TO=fred.flintstone@acme.ch,support@acme.ch`

Default: `REPORT_MAIL_TO=""`

REPORT_MAIL_CC

Carbon copy recipient of the report mail. If multiple recipients have to be specified as comma separated list.

Example: `REPORT_MAIL_CC=donald.duck@acme.ch,daisy.duck@acme.ch`

Default: `REPORT_MAIL_CC=""`

REPORT_MAIL_BCC

Blind carbon copy recipient of the report mail. If multiple recipients have to be specified as comma separated list.

Example: `REPORT_MAIL_BCC=dagobert.duck@acme.ch`

Default: `REPORT_MAIL_BCC=""`

REPORT_MAIL_CONFIRMATION_TO

Recipient of the confirmation mail.

Example: `REPORT_MAIL_CONFIRMATION_TO=support@acme.ch`

Default: REPORT_MAIL_CONFIRMATION_TO=""

LOGFILES OPTIONS

Logfiles. List of logfiles to be checked for patterns. Only existing files or files that once existed during a reporting period will be listed in the report. It is not needed to restart the logcheckd when logfile entries are modified, added or removed. Pattern file content can also be modified during logcheckd runtime.

The format of the logfiles specification is:

resolve_mode ; *patternfile* ; *res* ; *res* ; *res* ; *logfile* ;

(ensure, that between the *field* and the separator ; are no spaces)

where the fields have the following content:

resolve_mode

how to resolve the filename:

eval evaluate the filename dynamically. The variables \$HOSTNAME, \$TODAY, \$YEAR, \$MONTH and \$DAY are allowed to be used in filenames in the **eval** mode.

dflt take the filename precisely as specified

patternfile pattern file. The pattern files are located in the **var/logcheckd/pattern** directory. If an operating system dependent pattern file with the name **<patternfile>.<OSID>** exists (e.g. **Cron.Solaris**), this file will be used for logfile analysis, else the pattern file as specified (e.g. **Cron**) will be used.

res reserved for future use, leave it empty.

logfile logfile to analyze. The logfile has to be specified with an absolute path name.

Example:

```
dflt;WA2Ledrc;;;/opt/edrc/var/log/edrc.log;
dflt;All;;;/etc/rc.log;
eval;MCSG;;;/etc/cmcluster/*/*.cntl.log;
dflt;sudo;;;/var/adm/sudo.log;
dflt;Samba;;;/var/opt/samba/log.smbd;
dflt;syslog;;;/var/adm/syslog/syslog.log;
```

FILES

var/samples/templates/logcheck.cfg

NAME

logcheckd.interface – interfaces for logcheckd and lgcheckd

SYNOPSIS

edrc/lib/logcheckd/interface/<interfacefile>

AVAILABILITY

WA2L/edrc

DESCRIPTION

the **INTERFACE** mechanism of **logcheckd** and **lgcheckd** allows **logcheckd** and **lgcheckd** to communicate to other programs for a matching log entry.

The **INTERFACE** receives the matching log entry thru **stdin**, the following environment variables are exported to the **INTERFACE**: **\$APPROOT**, **\$SERVER_ENVIRONMENT_NAME**, **\$SERVER_ENVIRONMENT_CUSTOMER**, **\$SERVER_ENVIRONMENT_DESCRIPTION**, **\$INTERFACE_CFG**, **\$TIMESTAMP**, **\$LOGFILE**, and **\$LEVEL**.

OPTIONS

-

ENVIRONMENT

\$INTERFACE_CFG

configuration file of the **INTERFACE**.

\$TIMESTAMP

timestamp of the matching logfile entry.

\$LOGFILE

name of the logfile containing the matching logfile entry.

\$LEVEL

matched level as defined in the **logcheckd.pattern**(4) file.

\$APPROOT

root directory of the WA2L/edrc installation as returned by the **approot**(3) command.

\$SERVER_ENVIRONMENT_NAME

server environment name as returned by the **server_environment**(3) command.

\$SERVER_ENVIRONMENT_CUSTOMER

server environment customer as returned by the **server_environment(3)** command.

\$SERVER_ENVIRONMENT_DESCRIPTION

server environment description as returned by the **server_environment(3)** command.

EXIT STATUS

0 always.

The exit status of an interface is not resolved by the **logcheckd** and **lgcheckd**.

FILES

edrc/var/logcheckd/iconfig/<interfacefile>.cfg

configuration file for the interface allowing to write a configurable interface.

EXAMPLES**1. Simple example interface:**

This example **INTERFACE** saves all matching log entries to an output file that is configured in the **edrc/var/logcheckd/iconfig/Example.cfg**.

Interface configuration (**edrc/var/logcheckd/iconfig/Example.cfg**):

```
#
# logcheckd/iconfig/Example.cfg - configuration for logcheckd interface
#
# [00] 23.05.2009 CWa Initial Version
#

# Output file for interface
#
INTERFACE_OUTPUTFILE=/tmp/$EDRC_SCRIPTNAME.out
```

Interface implementation (**edrc/lib/logcheckd/interface/Example**):

```
#!/bin/sh
#
# Example - logcheckd interface: simple Example
#
# [00] 23.05.2009 CWa Initial Version
# [01] 28.05.2009 CWa ++
#

# Const
. $INTERFACE_CFG
Outputfile=$INTERFACE_OUTPUTFILE
```

```

# run -- run the interface command
#
run() {
    cat <<EOM >> $Outputfile
--
    TIMESTAMP=$TIMESTAMP
    LEVEL=$LEVEL
    LOGFILE=$LOGFILE
    EOM

    cat - >> $Outputfile
} # run

```

```

# Main -- Main
#
main() {
    case $LEVEL in
        HIGH)
            run
            ;;
        *)
            run
            ;;
    esac
} # main
main

```

2. Other example interfaces:

See directory: **edrc/lib/logcheckd/interface/**.

NAME

logcheckd.pattern – patternfile for logfile analysis in logcheckd and lgcheckd

SYNOPSIS

edrc/var/logcheckd/pattern/<patternfile>

AVAILABILITY

WA2L/edrc

DESCRIPTION

The pattern file is used to define the analysis of logfiles.

FILEFORMAT

The pattern file is a list of regular expression patterns divided into sections. Empty lines and lines starting with a # are considered as comments.

[SECTION_1]

pattern_11
pattern_12
pattern_1n

[SECTION_2]

pattern_21
pattern_22
pattern_2n

[SECTION_n]

pattern_n1
pattern_n2
pattern_nn

The sections and patterns are processed in the sequence listed. If a pattern matches for a logfile entry, the remaining patterns are not processed any more. Therefore it enhances performance if patterns that will match more often are listed at the beginning of a section, if possible.

Hint: a section with the identical name can appear multiple times in a pattern file.

The patterns are POSIX 1003.2 regular expressions as processed by **egrep**(1).

All logfile entries that are not matched are ignored and are counted as IGNORED.

The special section **[EXCLUDE]** can be used to exclude logfile entries from analysis. Excluded logfile

entries are not reported in the 'Logfiles' section of the LOGCHECK report, but are counted and reported in the 'Overview' section.

Because the sections are processed by **logcheckd(1m)** and **lgcheckd(1m)** in the order as defined in the pattern file, the **[EXCLUDE]** section will often be the first section in the pattern file to have the wanted effect.

The **[EXCLUDE]** section also enables you to reuse rule files already defined for the **logcheck(1)** command written by Craig H. Rowland, <crowland@psionic.com>.

The advantage of using the **[EXCLUDE]** section is, that the current logfile can be used as information baseline and all entries that are not significant to be reported can be excluded; all remaining entries can be classified, the pattern **.*** can be used to catch all remaining entries. Doing this unknown entries, which might be of interest, are not missed.

See also **EXAMPLES** section to see how to use the **[EXCLUDE]** section.

OPTIONS

-

EXAMPLES

See also **logcheckd(1m)** and **lgcheckd(1m)**.

1) example pattern file

See explanation of this pattern file in **logcheckd(1m)** and **lgcheckd(1m)** example 1) in section **EXAMPLES**.

```
#

NAME

logcheckd.style – stylefile for logfile analysis in logcheckd

SYNOPSIS

edrc/lib/logcheckd/style/<stylefile>.css

AVAILABILITY

WA2L/edrc

DESCRIPTION

The style file is used to define the look of the LOGCHECK report.

It enables the user to define the own look of a report if needed.

The style file is included directly into the LOGCHECK report to ensure that the style definition takes effect independent of the file location.

With the **REPORT_STYLE** setting in the **logcheckd.cfg** config file it is possible to define a style sheet different from the default.

FILEFORMAT

The style file format complies to the definitions of the cascading style sheets (css).

OPTIONS

Below the style definitions special to the LOGCHECK report are explained.

REPORT

h1 Report title.

h2 Section titles:

h2.general Title of section '**General**'.

h2.overview Title of section '**Overview**'.

h2.logfiles Title of section '**Logfiles**'.

div.created
text in the footline of the report that contains the 'created by ...' text.

GENERAL SECTION
pre.general
Text in the '**General**' section.

OVERVIEW SECTION
table.overview
Overview table.

table.overview th.current
Table header of '**Current (hits)**' counter rows.

table.overview th.current_normalized
Table header of '**Current (hits/day)**' counter rows.

table.overview th.last
Table header of '**Last (hits/day)**' counter rows.

table.overview th.trend
Table header of '**Trend (hits/day)**' counter rows.

table.overview th.logfile
Table header of '**Logfile**' rows.

table.overview th.gap
Gap between overview table header columns.

table.overview td.current
Table cell of '**Current (hits)**' counter rows.

table.overview td.current a.marked
Current hit counts that are bigger then zero.

table.overview td.current a.normal
Current hit counts that are equal to zero.

table.overview td.current_normalized
Table cell of '**Current (hits/day)**' counter rows.

table.overview td.last
Table cell of '**Last (hits/day)**' counter rows.

table.overview td.trend
Table cell of '**Trend (hits/day)**' counter rows.

table.overview td.logfile

Table cell of '**Logfile NAME**' rows.

table.overview td.logsize

Table cell of '**Logfile SIZE**' rows.

table.overview td.gap

Gap between overview table data columns.

LOGFILES SECTION

h3 Logfile names in the '**Logfiles**' section.

h4 Level titles in the '**Logfiles**' section.

pre.logfiles

Selected logfile content in the.

pre.logfiles span.timing

Timing information in the selected logfile content.

pre.logfiles span.separator

Separator between timing information and the selected logfile content.

FILES**edrc/lib/logcheckd/style/WA2L.css**

Default style definition for the LOGCHECK report. Do not change this file if you like to change the report look, create an own **.css** file, otherwise your changes will be lost after an upgrade of WA2L/edrc.

NAME

logcut – shorten logfiles

SYNOPSIS

edrc/bin/logcut [**-h** | **-p**]

logcut [**-s** *size*] **-c**

AVAILABILITY

WA2L/edrc

DESCRIPTION

logcut is used to shorten logfiles on a UNIX/Linux system. The logfile is shortened if a configurable row limit is reached. This limit can be set for each logfile.

To avoid to fill up a file system with logfiles this command may be placed in crontab and scheduled to run on a regular basis. See the **EXAMPLES** section for examples.

OPTIONS

-h the usage message.

-p print logfiles report.

-c cut/shorten the logfiles.

-s *size* size in rows. If specified, this command line option overrides the **LOGSIZE=** and **LOG[n]=** setting in the configuration file.

EXAMPLES

1. crontab entry to run logcut in a two hour interval:

```
# run logcut in a 2 hour interval
#
0 0,2,4,6,8,10,12,14,16,18,20,22 * * * [ -x /opt/edrc/bin/logcut ] \
&& /opt/edrc/bin/logcut -c >/dev/null 2>&1
```

FILES

etc/logcut.cfg
configuration file of **logcut** .

var/log/logcut.log
Logfile of **logcut** .

RETURN STATE

- | | |
|---|--|
| 0 | No error. |
| 2 | configuration file <i>logcut.cfg</i> does not exist. |
| 4 | usage listed. |
| 5 | program aborted (Ctrl-C, ...). |

SEE ALSO

edrcintro(1), **logcut.cfg(4)**

NOTES

logcut is derived from the **emlogcut** comand which is part of the EM-1/emtools module within EM-1, the EVENT-MANAGER-1 software package developed by Christian Walther. With EM-1 you can manage and resolve sports events. This is a database application based on Linux and PostgreSQL and provides an ASCII and a WEB interface, as well as many functions to manage a sports event and calculate rank lists and bills in an efficient way. For questions about EM-1 contact the author of EM-1: wa2l@users.sourceforge.net .

BUGS

-

AUTHOR

logcut was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net .

NAME

logcut.cfg – configuration file for logcut

SYNOPSIS

edrc/etc/logcut.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **logcut** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You have to set all settings, no default values apply.

OPTIONS**LOGSIZE**

Default logfile length in rows if no specific length is specified in the **LOG[n]** settings.

Example: LOGSIZE=20000

Default: LOGSIZE=

LOG[n] Logfile(s) to shorten. The logfiles have to be specified as an absolute path name. Each logfile to be shorten needs a **LOG[n]** entry with an own number (*n*).

The format of the **LOG[n]** entries is: **LOG[n]=size:logfile**

Example: LOG[01]=100000:~edrc/var/log/edrc.log

Default: LOG[01]=

SEE ALSO

logcut(1), **edrcintro(1)**

NOTES

-

BUGS

No default values apply, therefore ensure to specify all settings.

AUTHOR

logcut.cfg was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net.

NAME

loggrep – grep in remote- or local (time-stamped) log file(s)

SYNOPSIS

edrc/bin/loggrep [**-h** | **-p**]

loggrep *regex file ...*

loggrep *regex* [[*user@*]*host*:]*file ...*

loggrep [*options*] [**-f** "*from_ts*"] [**-t** "*to_ts*"] [*egrep_options*] *regex* [[*user@*]*host*:]*file ...*

loggrep [*options*] [**-f** "*from_ts*"] [**-t** "*to_ts*" **-t** "*to_ts*"] [*egrep_options*] *regex* [[*user@*]*host*:]*file ...*

lgrep ...

options ::= [**-l** *localuser*] [**-M**] [**-s** *num*] [**-NUM**] [**-T** *id*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

grep selected time range (from/to) in log *files*.

If the log file has time stamps, the data between a *from* and *to* time stamp is selected and **grep**ed by the specified *regex*.

When there are no time stamps in the log file, or the time stamp format is not recognized, the whole log file data is **grep**ed

The first **97** lines of the log file are used to resolve the time stamp format used in a particular file.

Beside text log file(s), **loggrep** can handle file(s) which are **zipped** (**.zip**), **compressed** (**.Z**), **gzipped** (**.gz**), **bzip2ed** (**.bz**, **.bz2**, **.bzip2**) or **xzed** (**.xz**) directly.

To increase performance on scanning large log files which are bigger then **100 MByte**, only the last **1'000'000** lines are analysed. To force to nevertheless analyse the whole file, specify **-0** in the **-NUM** option.

FROM/TO DATA SELECTION

The **-f** "*from_ts*" and **-t** "*to_ts*" time stamps have to be specified in military format ("**2021-01-18 20:57:10**").

The following abbreviations and defaults apply (examples when executed on **Monday, 2021-01-18**):

| specified from/to_ts | resulting from_ts | resulting to_ts |
|----------------------|---------------------|---------------------|
| | 2021-01-18 00:00:00 | 2021-01-18 23:59:59 |
| 13:45 | 2021-01-18 13:45:00 | 2021-01-18 13:45:59 |
| 13:45:55 | 2021-01-18 13:45:55 | 2021-01-18 13:45:55 |
| 16 | 2021-01-16 00:00:00 | 2021-01-16 23:59:59 |
| 01-16 | 2021-01-16 00:00:00 | 2021-01-16 23:59:59 |
| 05-30 | 2020-05-30 00:00:00 | 2020-05-30 23:59:59 |
| 2020 | 2020-01-01 00:00:00 | 2020-12-31 23:59:59 |
| 2020-03 | 2020-03-01 00:00:00 | 2020-03-31 23:59:59 |
| 2020-03-27 | 2020-03-27 00:00:00 | 2020-03-27 23:59:59 |
| 2020-03-27 13 | 2020-03-27 13:00:00 | 2020-03-27 13:59:59 |
| 2020-03-27 13:45 | 2020-03-27 13:45:00 | 2020-03-27 13:45:59 |
| 2020-03-27 13:45:12 | 2020-03-27 13:45:12 | 2021-03-27 13:45:12 |
| yesterday | 2021-01-17 00:00:00 | 2021-01-17 23:59:59 |
| mon | 2021-01-11 00:00:00 | 2021-01-11 23:59:59 |
| tue | 2021-01-12 00:00:00 | 2021-01-12 23:59:59 |
| wed | 2021-01-13 00:00:00 | 2021-01-13 23:59:59 |
| thu | 2021-01-14 00:00:00 | 2021-01-14 23:59:59 |
| fri | 2021-01-15 00:00:00 | 2021-01-15 23:59:59 |

- 22)** Log time: 2018-08-18 21:10:09
- 23)** error 2021-02-13 06:12:51
info 2021-02-13 06:12:51
- 24)** ERROR: apport (pid 593) Fri Feb 1 23:09:19 2019

OPTIONS

- h** usage message.
- p** print the timestamp formats known by **loggrep**, some example files where that timestamp format has been discovered and the regular expression that is used to identify the timestamp.
- l *localuser*** use the local user *localuser* to initiate the connection.
- s *num*** use the first *num* lines of the logfile for timestamp format detection.
- NUM** analyse the last *NUM* lines, instead of the whole file.

On large log files that exceed **100 MByte**, only the last **1'000'000** rows are scanned, whereas the first **4007** lines are here used to resolve the time stamp format.

To force to scan nevertheless the whole log file, specify `-0` here.

-f "*from_ts*"

start of data selection in military (=ISO) format, an abbreviated date or time specification as listed in the table in section **DESCRIPTION** or a past weekday (as: **yesterday**, **mon**, **tue**, **wed**, **thu**, **fri**, **sat**, **sun**).

Default is the current date at **00:00:00** (example: "**2021-01-18 00:00:00**").

-t "*to_ts*"

end of data selection in military (=ISO) format, an abbreviated date or time specification as listed in the table in section **DESCRIPTION** or a past weekday (as: **yesterday**, **mon**, **tue**, **wed**, **thu**, **fri**, **sat**, **sun**).

Default is current date at **23:59:59** (example: "**2021-01-18 23:59:59**").

-M

print meta data of **loggrep** results to file descriptor **3**.

Example:

```
LOGGREP_FROM="2020-03-27 13:45:00"
LOGGREP_TO="2020-03-27 18:00:00"
LOGGREP_COUNT="68312"
LOGGREP_BEGIN="2020-03-27 13:50:18"
LOGGREP_END="2020-03-27 17:58:36"
LOGGREP_DURATION="000:04:13:24"
```

This output can be used to set variables in a script:

```
#!/bin/sh

loggrep -M -f "2020-03-27 13:45:00" -t "2020-03-27 18:00:00" \
    starting ~edrc/var/log/edrc.log 3>/tmp/meta.out

. /tmp/meta.out
echo "ENTRIES: $LOGGREP_COUNT between $LOGGREP_BEGIN and $LOGGREP_END"
```

egrep_options

options of the **egrep**(1) command.

If options of the **egrep**(1) have a second argument, specify the argument without a space (eg: specify **-m5** and not **-m 5**).

See **egrep**(1) for a description of the available **egrep** options.

regex

regular expression *PATTERN* as understood by **egrep** respectively **grep -E**.

[[user@]host:]file

remote- or local file.

If a `-` is specified as a *file* option, data is read from **stdin**.

Beside text files, the specified *file* can also be **zipped** (**.zip**), **compressed** (**.Z**), **gzipped** (**.gz**), **bzip2ed** (**.bz**, **.bz2**, **.bzip2**) or **xzed** (**.xz**).

ENVIRONMENT

\$LOGGREG_FROM

from_ts as specified on the command line. However, the command line option **-f** "*from_ts*" has preference.

\$LOGGREG_TO

to_ts as specified on the command line. However, the command line option **-t** "*to_ts*" has preference.

EXIT STATUS

- 0** *regex* is found in at least one of the listed files. no error.
- 1** *regex* is not found in any of the listed files.
- 2** error occurred.
- 4** usage printed.
- 5** command has been aborted.
- 11** could not claim a temporary directory in **/tmp/**.

NAME

logrotate – rotate logfiles

SYNOPSIS

edrc/bin/logrotate [**-h**]

logrotate -f *file* [**-r** *number_of_saves*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

logrotate rotates logfiles on the system. The permissions and the file handle of the logfile (*file*) are preserved.

The *file* is saved to *file.<number>* where the **<number>** counts from **1** to *number_of_saves*.

The newest version of the file is the one having the lowest number, the oldest file has the highest number.

If the specified *file* does not exist, the already saved versions are not rotated.

OPTIONS

-h usage message.

-f *log_file* logfile to be rotated.

-r *number_of_saves*
number of rotated files that are kept on the filesystem.

ENVIRONMENT

-

EXIT STATUS

0 no error.

1 specified *file* to be rotated does not exist.

- 2** cannot write to logfile of **logrotate**.
- 3** configfile **logrotate.cfg** does not exist.
- 4** usage printed.

FILES

etc/logrotate.cfg

configuration file of **logrotate**, see **logrotate.cfg(4)** for more information.

var/log/logrotate.log

default logfile of **logrotate**.

EXAMPLES

NAME

logrotate.cfg – configuration file for logrotate

SYNOPSIS

edrc/etc/logrotate.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **logrotate** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS**LOGBASE**

basedir of the logrotate logfile (**logrotate.log**).

Example: LOGBASE='homedir ACME'/log

Default: LOGBASE='approot'/var/log

DEFAULT_SAVES

Default number of file generations kept. This setting applies if the **-r number_of_saves** option is not specified on the command line.

Example: DEFAULT_SAVES=5

Default: DEFAULT_SAVES=10

SEE ALSO

NAME

logtail – tail a log file out of a list of defined logfiles

SYNOPSIS

edrc/bin/logtail [**-h**]

logtail [*select*]

logtail [**-t**] [**-c** | **-C**] [*select*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

give a selection of common logfiles to be tailed (**tail -f *selected_logfile***). The files to be listed in the selection list can be defined in a user dependent or system wide configuration file.

The config file can list logfiles using the wild cards as known from the **ls(1)** command. The list is resolved prior to each start of **logtail** and only the files that exist on the system and are readable by the user are listed in the selection list.

This enables the user to have an identical configuration file for all servers and operating systems.

To load a log file into a viewer (**view**), instead of the continuous file output of **logtail**, use the **logview(1)** command.

OPTIONS

- t** add a high resolution timestamp to the output allowing timing information display on logfiles without timestamps.
- c** colorize **tailed** output based on **logcheckd.pattern(4)** files.
- C** prepend [*LEVEL*] to the colorizes **tailed** output based on **logcheckd.pattern(4)** files.
- select* select files from logfile list.

ENVIRONMENT**\$APPROOT**

root directory of the application as resolved by **approot(3)**. This variable can be used in the log files configuration files to point to the root of the WA2L/edrc installation. Therefore for example the **~edrc/var/log/edrc.log** definition can be replaced with

\$APPROOT/var/log/edrc.log with the result that **logview** also lists the logfile when no **edrc** user is defined on the system.

\$LOGTAIL_LEVELMODE

set the appearance of the [*LEVEL*] effective when using the **-C option**.

Possible settings are: **light**, **bold**, **invers**, **red**, **green**, **magenta**, **blue**, **cyan** and **yellow**, whereas the default is **bold**.

EXIT STATUS

0 no error.

FILES

\$HOME/.log_files

definition of files to be listed in the selection. Only the root user should list the files in this config file.

\$HOME/.mylog_files

definition of files to be listed in the selection. For non-root users, this file should be used to define the log files instead of **.log_files** due to the preservation of *.my** files when using the **mkuser(3)** and/or **makeuser(3)** commands.

etc/log_files.cfg

system wide definition of log files. This file is read when the files **\$HOME/.log_files** and **\$HOME/.mylog_files** do not exist.

etc/lgcheckd.cfg

configuration file of **lgcheckd(1m)** to resolve the pattern file for a selected log file.

etc/logcheckd.cfg

configuration file of **logcheckd(1m)** to resolve the pattern file for a selected log file. This file is read, if the **etc/lgcheckd.cfg** does not exist.

var/logcheckd/pattern/

pattern files.

var/logcheckd/pattern/logtail

default pattern file, if no pattern file could be resolved.

EXAMPLES

1) common usage

Configuration file example:

```
#
# log_files.cfg - configuration file for logtail and logview
#
# [00] 08.08.2004 CWa Initial Version
#
$APPROOT/var/log/edrc.log
$APPROOT/var/log/pack.log
$APPROOT/var/log/patchinstall.log
$APPROOT/var/log/filedist.log
$APPROOT/var/log/rcmd.log
$APPROOT/var/log/sysconfig.log
$APPROOT/var/log/shttpd_*.log
/etc/cmcluster/*/*.log
/etc/shutdownlog
~ACME/log/sap_instance.log
/opt/patrol/log/*.log
/var/adm/cron/log
/var/log/boot.log
/var/log/cron
/var/log/cups/access_log
/var/log/cups/error_log
/var/log/dmesg
/var/log/httpd/*
/var/log/lastlog
/var/log/maillog
/var/log/messages
/var/adm/messages
/var/log/samba/log.nmbd
```

Example usage:

```
[ /home/barney ]
[ barney@acme001 ][bash]: logtail

1) /opt/edrc/var/log/edrc.log

NAME

logview – view a log file out of a list of defined logfiles

SYNOPSIS

edrc/bin/logview [**-h**]

logview [*select*]

AVAILABILITY

WA2L/edrc

DESCRIPTION

give a selection of common logfiles to be viewed (**view** *selected_logfile*). The files to be listed in the selection list can be defined in a user dependent or system wide configuration file.

The config file can list logfiles using the wild cards as known from the **ls**(1) command. The list is resolved prior to each start of **logview** and only the files that exist on the system and are readable by the user are listed in the selection list.

This enables the user to have an identical configuration file for all servers and operating systems.

To continuously print a log file (**tail -f**), instead of loading the file into the viewer of **logview**, use the **log-tail**(1) command.

OPTIONS

-h print usage message,

select select files from list of files.

ENVIRONMENT**\$APPROOT**

root directory of the application as resolved by **approot**(3). This variable can be used in the log files configuration files to point to the root of the WA2L/edrc installation. Therefore for example the **~edrc/var/log/edrc.log** definition can be replaced with **\$APPROOT/var/log/edrc.log** with the result that **logview** also lists the logfile when no **edrc** user is defined on the system.

EXIT STATUS

0 no error.

4 usage message printed.

FILES

\$HOME/.log_files

definition of files to be listed in the selection. Only the root user should list the files in this config file.

\$HOME/.mylog_files

definition of files to be listed in the selection. For non-root users, this file should be used to define the log files instead of **.log_files** due to the preservation of *.my** files when using the **mkuser(3)** and/or **makeuser(3)** commands.

etc/log_files.cfg

system wide definition of log files. This file is read when the files **\$HOME/.log_files** and **\$HOME/.mylog_files** do not exist.

etc/exrc settings for the **view** read only editor.

EXAMPLES

1) common usage

Configuration file example:

```
#
# log_files.cfg - configuration file for logview and logview
#
# [00] 08.08.2004 CWa Initial Version
#
$APPROOT/var/log/edrc.log
$APPROOT/var/log/pack.log
$APPROOT/var/log/patchinstall.log
$APPROOT/var/log/filedist.log
$APPROOT/var/log/rcmd.log
$APPROOT/var/log/sysconfig.log
$APPROOT/var/log/shutdown.log
/etc/cmcluster/*/*.log
/etc/shutdownlog
~ACME/log/sap_instance.log
/opt/patrol/log/*.log
/var/adm/cron/log
/var/log/boot.log
/var/log/cron
/var/log/cups/access_log
/var/log/cups/error_log
/var/log/dmesg
/var/log/httpd/*
/var/log/lastlog
/var/log/maillog
/var/log/messages
```

```
/var/adm/messages
/var/log/samba/log.nmbd
```

Example usage:

```
[ /home/barney ]
[ barney@acme001 ][bash]: logview

1) /opt/edrc/var/log/edrc.log
2) /opt/edrc/var/log/pack.log
3) /opt/edrc/var/log/patchinstall.log
4) /opt/edrc/var/log/sysconfig.log
5) /opt/ACME/log/sap_instance.log
6) /var/log/boot.log
7) /var/log/cron
8) /var/log/dmesg
9) /var/log/httpd/access_log
10) /var/log/httpd/access_log.1
11) /var/log/httpd/access_log.2
12) /var/log/httpd/access_log.3
13) /var/log/httpd/access_log.4
14) /var/log/httpd/error_log
15) /var/log/httpd/error_log.1
:
41) /var/opt/ACME/log/useradm.log
42) /var/opt/ACME/log/watchdog.log
43) /var/opt/samba/log.smb.rh7mzv7t001
select log:6
```

```
1 Jan 14 14:01:00 rh7mzv7t001 CROND[27550]: (root) CMD (run-parts /et
2 Jan 14 15:01:00 rh7mzv7t001 CROND[27913]: (root) CMD (run-parts /et
3 Jan 14 16:01:00 rh7mzv7t001 CROND[28276]: (root) CMD (run-parts /et
4 Jan 14 18:01:00 rh7mzv7t001 CROND[29478]: (root) CMD (run-parts /et
~
~
```

NAME

log_files.cfg – log files definition for logfiles and logtail

SYNOPSIS

edrc/etc/log_files.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the log file definition for the **logview** and **logtail** commands.

FILEFORMAT

The fileformat is a plain list of log files, where wildcards, the tilde (~) and the variables documented in the **OPTIONS** section are supported.

The log files must not exist on the system, the **logview** and **logtail** commands resolve the existing log files and only presents the existing ones to the user; therefore the **log_files.cfg** can be kept identical on all systems.

Rows starting with a # are considered as comments. Empty lines are allowed, too.

OPTIONS**\$APPROOT**

root of the WA2L/edrc package installation, as returned by the **aproot(3)** command.

EXAMPLES

```
#
# log_files.cfg - configuration file for logtail and logview
#
# [00] 08.08.2004 CWa   Initial Version
#
$APPROOT/var/log/edrc.log
$APPROOT/var/log/pack.log
$APPROOT/var/log/patchinstall.log
$APPROOT/var/log/filedist.log
$APPROOT/var/log/rcmd.log
$APPROOT/var/log/sysconfig.log
$APPROOT/var/log/shttpd_*.log
/etc/cmcluster/*/*.log
/etc/shutdownlog
~ACME/log/sap_instance.log
```

```
/opt/patrol/log/*.log
/var/adm/cron/log
/var/log/boot.log
/var/log/cron
/var/log/cups/access_log
/var/log/cups/error_log
/var/log/dmesg
/var/log/httpd/*
/var/log/lastlog
/var/log/maillog
/var/log/messages
/var/adm/messages
/var/log/samba/log.nmbd
```

NAME

lots – long term data save handling

SYNOPSIS

edrc/bin/lots [**-h**]

lots [**-c** *configfile*] **-a** (**collect** [**-d** *datalist*] | **save** | **execute**) [**-i** *identitylist*]

lots [**-c** *configfile*] **-a** (**lock** | **purge**)

lots [**-c** *configfile*] **-a** **clear** **-j** *jobname*

lots [**-c** *configfile*] **-a** (**list_action** | **list_session** | **list_collect** | **list_save** | **list_lock** | **list_purge** | **list_clear**) [**-f** *from_date*][**-t** *to_date*]

lots [**-c** *configfile*] **-a** **list_jobs** [**-d** *datalist*]

lots [**-c** *configfile*] **-a** (**list_datalist** | **list_schedule** | **list_volume**)

lots [**-c** *configfile*] **-a** (**print_job** **-j** *jobname* | **print_log** [**-f** *from_date*][**-t** *to_date*] | **print_logtail** | **print_session** **-s** *sessionname*)

AVAILABILITY

WA2L/edrc

DESCRIPTION

lots is used to copy data in an organized and automated fashion to a long term storage device. On this device the data is locked.

lots locks the data by setting the access time of the saved data to the future point in time (current day + *RETENTION*) and removes the write flag of all files and directories to be locked. If the long term data storage is a file system on a NetAPP filer having a 'SnapLock Enterprise' volume or a 'SnapLock Compliance' volume, the data cannot be removed from Unix until the *RETENTION* is expired. If **lots** is used on a normal file system not having this functionality, the root user can delete the data, but it is still ensured, that non-root users cannot view, list or even remove the saved data.

The source path where the data comes from, the permissions of the path and other properties are saved and recorded to ensure a data restore even if the user base has changed since the data save.

After the expiration of the *RETENTION* + *DATA_PURGE_LAG*, the **lots** command purges (=removes) the expired data and the disk space is freed up.

The following four steps are performed during the life cycle of a long term data save:

1) collect

This step is executed once for each *DATALIST* whose schedule in **schedule.dat** matches for the current day and whose *HOSTNAME* setting matches to the host where the **lots** command is

started.

A new job is created and the file and directory names to be saved as defined in the **datalist.dat** file are collected and stored in the newly created job. Be aware, that the **lots** release that created a job is always saved in the job, too (**VERSION** property when printing the job).

This job will in the following steps be passes thru several phases during the whole information life cycle. The job information can be displayed using the ' **lots -a print_job -j jobname** ' command.

In this step no data is saved. When the **collect** action is completed, the job is in the **save** phase.

If multiple schedule definitions of a **DATALIST** match at a certain day, only the schedule definition having the highest **RETENTION** value will be executed, this to use the disk space economically. A scheduled **DATALIST** is only executed once a day unless the **RETENTION** in the **schedule.dat** is increased.

A job that is in the **save** phase can be removed using the ' **lots -a clear -j jobname** ' command.

2) save

This step is executed for all jobs that are in the **save** phase based on the resolved hostname in the **collect** step.

In this step the files found in the **collect** step are copied to the long term data save location as defined in the **volume.dat** file. The save can be performed with or without compression. The compression method has to be defined in the **schedule.dat** file.

When the **save** action is completed, the job is in the **lock** phase.

A job that is in the **lock** phase can be removed using the ' **lots -a clear -j jobname** ' command. All data that has been saved will also be removed from the long term storage.

3) lock

This step is executed for all jobs that are in the **lock** phase, the **save** phase completed with a **SAVESTATE** of **OK** and the number of days as defined in the **DATA_LOCK_LAG** setting in the **lots.cfg** file are expired.

The lock delay enables the system administrative personnel to react on unwanted conditions, as: inconsistency of saved data, errors in definitions which cause too much data to be saved (=waste of disk space) and other reasons.

The **DATA_LOCK_LAG** should be defined carefully and the implications have to be known by the administrative personnel operating the long term data save setup. If, for instance, the **DATA_LOCK_LAG** is set to 7, the administrator has after the **save** seven days time to react on a malfunction and to correct it. But during this time it is also possible to delete the saved data, what can be a risk, too.

When a job is in the **lock** phase, but the previous phase (**save**) did not complete with a **SAVESTATE** equal to **OK**, the **lock** action for the related job will be skipped and the data will not be locked. This means, that the job will remain in the **lock** phase until it is cleared using the ' **lots -a clear -j jobname** ' command. This avoids the locking of saved data of unsuccessful **save** actions.

When the **lock** action is completed, the job is in the **purge** phase.

A job that is in the **purge** phase cannot be removed any more using the '**lots -a clear -j job-name**' command, because on the long term storage the data is locked and **lots** must wait for the expiration of the lock to remove the data related to the locked job.

4) purge

This step is executed for all jobs that are in the **purge** phase after *RETENTION* + *DATA_PURGE_LAG* is expired.

The **purge** action removes the data related to the job on the long term storage and the disk space is therefore freed up.

When the **purge** action is completed, the job is in the **expired** phase and will remain there for ever for reference and compliance proof purposes.

The **DATA_PURGE_LAG** has only to be defined greater than 0, if it is experienced, that the system clocks of the server(s) accessing the long term storage (using **lots**) and the 'Compliance Clock' of the long term data storage device are not completely in sync. The purge of the data is delayed by the number of days defined in this setting. This to ensure smooth data purging.

This four steps (**collect**, **save**, **lock**, **purge**) can be executed separately using the commands:

- 1) **lots -a collect**
- 2) **lots -a save**
- 3) **lots -a lock**
- 4) **lots -a purge**

but the normal case is using the '**lots -a execute**' command which executes all steps in one session in sequence.

In a productive automated setup, the '**lots -a execute**' command will normally be called via a **cron** entry that starts **lots** once each day.

It is supported to access the same long term storage in parallel from multiple hosts. In this case the **VARDIR** as defined in the **lots.cfg** file and the **lots.cfg** file itself should be located also centrally on the long term storage to allow the most convenient operations. It is anyway recommendable to put the **VARDIR** and the **lots.cfg** config file also on the long term storage device to have the configuration and state information separated from the server to always secure this information and to be independent from server crashes and server re-installations which might occur during the life cycle of the data stored for a long time on the long term data storage. For central secure setup as suggested here, see the **EXAMPLES** section.

Each invocation of '**lots -a action**' creates a session. A session represents all command output and can be displayed for verification and compliance proof. Session logs are kept forever and can be displayed using the '**lots -a print_session -s sessionname**' command. To evaluate the sessions related to a job, use the '**lots -a list_(action|collect|save|lock|purge|clear)**' command.

To resolve the data save location for a job of a certain *DATALIST*, use the commands:

- 1) **lots -a list_jobs [-d datalist]**
- 2) **lots -a print_job -j jobname**

The **lots** command currently does not provide a data restore interface. Therefore the restore of the saved files is performed using the normal operating system commands (**cp**, **cpio**, **unzip**, **bzip2 -d**, **gzip -d**,

uncompress) and after the restore the permissions have to be adjusted based on the information queried using the **print_job** action as described above also using the operating system commands (**chmod**, **chown**, **chgrp**).

OPTIONS

-h usage message. Here the revision of **lots** is also displayed.

-c *config_file*
configuration file.

-i *identitylist*
comma separated list of identities (=hostnames) of the **lots** command.
If this option is not specified and the environment variable **\$LOTS_IDENTITIES** is not set, the identities of the **lots** command are all hostnames under which the host where **lots** is started is known. Using the **-i** option it can be defined on which *HOSTNAME* settings in the **schedule.dat** file the **lots** command reacts.

Example, when **-i adm_oral_tst** is used:

```
:
resolve identities of this host ...
    adm_oral_tst
done.
:
```

Example, when the **-i** option is not used and the **\$LOTS_IDENTITIES** environment variable is not set (the *adm_oral_tst* hostname is a cluster package that is currently running on the host):

```
:
resolve identities of this host ...
    adm_oral_tst acme001 loghost localhost
done.
:
```

-a action:

collect [**-d** *datalist*] [**-i** *identitylist*]
collect data of scheduled *datalist*(s).

save [**-i** *identitylist*]
save data that has been collected to the long term storage.

lock
lock data on the long term storage from modification.

purge
remove data whose locks (retention) have been expired from long term storage.

clear -j *jobname*

remove a job and the data saved (if any). It is only possible to clear a job in the **save** and **lock** phases. When a job is cleared that has the biggest retention for a datalist for the current date, it is possible to perform another **collect** action of the related schedule.

execute [-i *identitylist*]

perform all four long term data save steps (**collect**, **save**, **lock**, **purge**) in one step.

list_action [-f *from_date*] [-t *to_date*]

list all performed actions between the *from_date* and the *to_date*.

If the *from_date* is not specified, the actions are listed from the beginning to the *to_date*. If the *to_date* is not entered, the actions are listed from the *from_date* to the end. If neither of the two dates are specified all actions are listed.

list_session [-f *from_date*] [-t *to_date*]

list all saved sessions between the *from_date* and the *to_date*.

If the *from_date* is not specified, the sessions are listed from the beginning to the *to_date*. If the *to_date* is not entered, the sessions are listed from the *from_date* to the end. If neither of the two dates are specified all sessions are listed.

list_collect [-f *from_date*] [-t *to_date*]

list only the **collect** actions between the *from_date* and the *to_date*.

If the *from_date* is not specified, the **collect** actions are listed from the beginning to the *to_date*. If the *to_date* is not entered, the **collect** actions are listed from the *from_date* to the end. If neither of the two dates are specified all **collect** actions are listed.

list_save [-f *from_date*] [-t *to_date*]

list only the **save** actions between the *from_date* and the *to_date*.

If the *from_date* is not specified, the **save** actions are listed from the beginning to the *to_date*. If the *to_date* is not entered, the **save** actions are listed from the *from_date* to the end. If neither of the two dates are specified all **save** actions are listed.

list_lock [-f *from_date*] [-t *to_date*]

list only the **lock** actions between the *from_date* and the *to_date*.

If the *from_date* is not specified, the **lock** actions are listed from the beginning to the *to_date*. If the *to_date* is not entered, the **lock** actions are listed from the *from_date* to the end. If neither of the two dates are specified all **lock** actions are listed.

list_purge [-f *from_date*] [-t *to_date*]

list only the **purge** actions between the *from_date* and the *to_date*.

If the *from_date* is not specified, the **purge** actions are listed from the beginning to the *to_date*. If the *to_date* is not entered, the **purge** actions are listed from the *from_date* to the end. If neither of the two dates are specified all **purge** actions are listed.

list_clear [-f *from_date*] [-t *to_date*]

list only the **clear** actions between the *from_date* and the *to_date*.

If the *from_date* is not specified, the **clear** actions are listed from the beginning to the *to_date*. If the *to_date* is not entered, the **clear** actions are listed from the *from_date*

to the end. If neither of the two dates are specified all **clear** actions are listed.

list_jobs [-d *datalist*]

list the jobs and the phase where the job is in. If the **-d *datalist*** is not specified, all jobs are listed.

list_datalist

list all valid datalist definitions. See also **datalist.dat(4)** for more information about the datalist format.

list_schedule

list all valid schedule definitions. See also **schedule.dat(4)** for more information about the schedule format.

list_volume

list all valid volume definitions. See also **volume.dat(4)** for more information about the volume format.

print_job -j *jobname*

print all properties of a certain job. Use this option to print the path of the saved data.

GENERAL JOB PROPERTIES:

PHASE phase the job is currently in.

HOSTNAME

hostname where the data of a matching schedule has been collected and saved.

VERSION

version of **lots** that created the related job.

JOBNAME

name of the job. This name has to be specified in the **-j** option when required.

DATALIST

scheduled datalist name of the job.

DATALIST_DESCRIPTION

free text description of the **DATALIST** as defined in the **datalist.dat** file at the time of job creation.

TIMEZONE

time zone as returned by **timezone(3)** at the time of job creation.

SCHEDULE

schedule in **schedule.dat** which matched at the time of job creation.

SCHEDULE_DESCRIPTION

free text description of the **SCHEDULE** as defined in the **schedule.dat** file at the time of job creation.

RETENTION

effective data retention in days as defined in the **schedule.dat** file at the time of job creation.

COMPRESSION

compression method of the saved data as defined in the **schedule.dat** file at the time of job creation.

COLLECTTIMESTAMP

timestamp (seconds since the epoch) when the data to be saved has been collected. This property will be seen when the job is in the phase **save**, **lock**, **purge** or **expired**.

COLLECTTIMEDAT

this is the human readable format of **COLLECTTIMESTAMP**.

COLLECTSTATE

state of the **collect** action. This property will be seen when the job is in the phase **save**, **lock**, **purge** or **expired**.

LOCKTIMESTAMP

timestamp (seconds since the epoch) when the data to be saved will be locked. This property will be seen when the job is in the phase **save**, **lock**, **purge** or **expired**.

LOCKTIMEDAT

this is the human readable format of **LOCKTIMESTAMP**.

LOCKSTATE

state of the **lock** action. This property will be seen when the job is in the phase **purge** or **expired**.

SAVETIMESTAMP

timestamp (seconds since the epoch) when the data has been saved. This property will be seen when the job is in the phase **lock**, **purge** or **expired**.

SAFETIMEDAT

this is the human readable format of **SAVETIMESTAMP**.

SAVESTATE

state of the **save** action. This property will be seen when the job is in the phase **lock**, **purge** or **expired**.

PURGETIMESTAMP

timestamp (seconds since the epoch) when the data has been purged. This property will be seen when the job is in the phase **expired**.

If the **PURGESTATE** is *RETRY*, this property will also be seen when the job is in the phase **purge**.

PURGETIMEDAT

this is the human readable format of **PURGETIMESTAMP**.

If the **PURGESTATE** is *RETRY*, this property will also be seen when the job is in the phase **purge**.

PURGESTATE

state of the **purge** action. This property will normally be seen when the job is in the phase **expired**.

If the **PURGESTATE** is *RETRY*, this property will also be seen when the job is in the phase **purge**. The *RETRY* **PURGESTATE** shows, that the **purge** action was not completely successful. The purging of the data of a job with this condition will be repeated in subsequent calls of **lots** until it succeeds.

DATA SAVE INFORMATION:**SAVE_BASEDIR**

to this directory (on the long term storage) the data of the related job is saved to. In normal cases only one directory is listed here, but in special cases there might be listed multiple directories. This property will only have content when the job is in the phase **lock** or **purge**.

FILENAME

filename and path of the saved source file. This property will only have content when data to be saved as defined in **datalist.dat** has been found on the system when collecting the data.

SAVE_SUFFIX

suffix of the saved file. This suffix correlates to the chosen compression method as printed in the **COMPRESSION** property.

A file to be restored can therefore be accessed concatenating the properties **SAVE_BASEDIR** + **FILENAME** + **SAVE_SUFFIX**.

SIZE

size of the source file in bytes.

USER

file owner name of the source file. The numeric user ID is stored with the file.

GROUP

file group name of the source file. The numeric group ID is stored with the file.

PERMISSIONS

symbolic representation of the source file's permissions as displayed by the **ls(1)** command.

PERM numeric representation of the source file's permissions which can be used with the **chmod(1)** command.

MTIME modification time of the source file in military format.

print_log [**-f** *from_date*] [**-t** *to_date*]

print the master log between the *from_date* and the *to_date*.

If the *from_date* is not specified, the log file is printed from the beginning to the *to_date*. If the *to_date* is not entered, the log file is printed from the *from_date* beginning to the end. If neither of the two dates is specified the whole log is printed.

print_logtail

display a continuous master log output.

print_session -s *sessionname*

print the session log output. Each output of **lots** is saved and due to compliance reasons never deleted. To evaluate the session name related to a certain action or a sequence of actions, use **list_action**, **list_collect**, **list_save**, **list_lock**, **list_purge**, **list_clear** or **print_log**.

-f *from_date*

begin date in the military format **YYYY-MM-DD**. To compute dates in this format, see: **input(3)**, **seconds(3)**, **timer(1)**, **today(3)**, **tomorrow(3)**, **yesterday(3)**.

-t *to_date*

end date in the military format **YYYY-MM-DD**. To compute dates in this format, see: **input(3)**, **seconds(3)**, **timer(1)**, **today(3)**, **tomorrow(3)**, **yesterday(3)**.

-j *jobname*

name of a **lots** job in the format **YYYY-MM-DD_hh.mm.ss**.

-s *sessionname*

name of a **lots** session in the format **YYYY-MM-DD_hh.mm.ss**.

-d *datalist*

name of a datalist as specified in **datalist.dat** and **schedule.dat**.

ENVIRONMENT**\$LOTS_CONFIGFILE**

configuration file of **lots**. The **-c** *configfile* command line option has preference. If the configuration file specified in **\$LOTS_CONFIGFILE** does not exist, the default configuration file **edrc/etc/lots.cfg** is read.

\$LOTS_IDENTITIES

comma separated list of identities (=hostnames) of the **lots** command. The **-i identitylist** option has preference.

EXIT STATUS

- 0** no error.
- 1** configuration file does not exist.
- 2** session could not be created. If you get this error, check the file systems where the **VARDIR/log** directory resides. See also **lots.cfg(4)**.
- 4** Usage printed.
- 5** **lots** aborted pressing <Ctrl>+<C>.
- 6** job as specified in **-j jobname** not found.
- 7** session as specified in **-s sessionname** not found.
- 8** cannot write to logfile.
- 9** cannot write to **VARDIR**.
- 10** a job to be cleared does not exist or is not in the **save** or **lock** phases.

FILES

The **VARDIR** can be defined in the **lots.cfg** file. Default is **edrc/var/lots**.

edrc/etc/lots.cfg

default **lots** configuration file.

VARDIR/log/lots.master.log

logfile of **lots**.

Do not modify or shorten this file.

VARDIR/log/lots.session.<SESSIONNAME>.log.gz

session logfile of **lots**. Display session logs using the ' **lots -a print_session -s sessionname** ' command. Do not modify or delete any of this files.

VARDIR/locks/

lockfiles, do not edit them by hand.

VARDIR/objects/datalist.dat

data save definition. In this file it is defined which set of files and directories are saved using one handle (datalist).

VARDIR/objects/schedule.dat

schedule, retention and compression definition. In this file it is defined which datalist is scheduled to be saved on which date.

VARDIR/objects/volume.dat

definition of data save volume destinations. With this file it is possible to locate long term data saves to different destinations.

VARDIR/spool/save/<JOBNAME>.job

jobs in the **save** phase. Do not access job files directly, always use the **-a print_job** action to query job information, due to the fact that certain job information is resolved by **lots** while printing the job and some job properties are constructed for certain job VERSIONs due to functionality enhancements of **lots**.

VARDIR/spool/lock/<JOBNAME>.job

jobs in the **lock** phase. Do not access job files directly, always use the **-a print_job** action to query job information, due to the fact that certain job information is resolved by **lots** while printing the job and some job properties are constructed for certain job VERSIONs due to functionality enhancements of **lots**.

VARDIR/spool/purge/<JOBNAME>.job

jobs in the **purge** phase. Do not access job files directly, always use the **-a print_job** action to query job information, due to the fact that certain job information is resolved by **lots** while printing the job and some job properties are constructed for certain job VERSIONs due to functionality enhancements of **lots**.

VARDIR/spool/expired/<JOBNAME>.job

jobs in the **expired** phase. Do not access job files directly, always use the **-a print_job** action to query job information, due to the fact that certain job information is resolved by **lots** while printing the job and some job properties are constructed for certain job VERSIONs due to functionality enhancements of **lots**.

VARDIR/state/action

record of all performed actions. Do not modify or shorten this file.

VARDIR/state/diskusage

record of used disk space. This information is used to create reports.

VARDIR/state/performance

record of durations and data throughput. This information is used to calculate forecasts and create performance reports.

<VOLUME_PATH>/<YEAR>/<MMDD>/<DATALIST>/<COUNTER>/data/

SAVE_BASEDIR directory on the long term storage device where the data as defined in a datalist is saved to.

<VOLUME_PATH>/<YEAR>/<MMDD>/<DATALIST>/<COUNTER>/meta/<JOBNAME>.job
 copy of the job file as located in **VARDIR/spool/lock/<JOBNAME>.job** or **VARDIR/spool/purge/<JOBNAME>.job** depending on the phase where the job currently is in. On a severe emergency situation where the information in the **VARDIR/spool/lock/** and/or **VARDIR/spool/purge/** directories is lost without having a backup, the state of the **lots** jobs in the **lock** and **purge** phases, which are the most critical ones, can be reconstructed by copying the job files from **<VOLUME_PATH>/<YEAR>/<MMDD>/<DATALIST>/<COUNTER>/meta/** back to the **VARDIR/spool/lock/** or **VARDIR/spool/purge/** directories. The meta data of saved data is also locked with the identical retention as the data, therefore this information is secured.

EXAMPLES

-

SEE ALSO

edrcintro(1), lots.cfg(4), datalist.dat(4), schedule.dat(4), volume.dat(4), bzip2(1), chmod(1), chown(1), compress(1), cpio(1), gzip(1), input(3), ls(1), seconds(3), timer(1), timezone(3), today(3), tomorrow(3), unzip(1), yesterday(3), zip(1).

NOTES

The NetAPP filers are able to provide the following SnapLock variants, based on the licenses applied:

SnapLock Enterprise:

Is a trusted administrator mode. In this mode a volume containing non-expired locked data can be destroyed by an NetAPP administrator on the NetAPP filer.

SnapLock Compliance:

Is a untrusted administrator mode. In this mode a volume containing non-expired locked data can not be destroyed on the NetAPP filer. This results in the risk, that on program malfunction or handling errors on the SnapLock volume, a big amount of disk space could be wasted without the possibility to clean up the data and to free up the wasted disk space.

BUGS

Abort handling is fully tested under HP-11ia only. Therefore when running **lots** on other operating systems, refrain from aborting a running **lots** session if possible. However, the expected side effects are not severe.

NAME

lots.cfg – configuration file for lots

SYNOPSIS

edrc/etc/lots.cfg
\$LOTS_CONFIGFILE

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **lots** command.

FILEFORMAT

Rows starting with a **#** are considered as comments.

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the **=** and the **VALUE** are no spaces.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a **VALUE**.

OPTIONS

VARDIR location of the **edrc/var/lots** directory containing all state and log information. When the **VARDIR** is changed from the default location it has to be ensured that the whole structure of the **VARDIR** is present at the altered location. Ensure that the directory permissions are identical to the ones as set at the default location.

See also description in **lots(1m)** concerning this topic.

Example: **VARDIR=/dat/worm_all/var/lots**

Default: **VARDIR=edrc/var/lots**

LOG Log output dir of lots. If you specify a relative path name the path is relative to the **VARDIR** setting.

Example: **LOG=/var/opt/lots/log**

Default: **LOG=\$VARDIR/log**

DATA_LOCK_LAG

Number of days after the lock is carried out on the copied data. This is to allow corrective intervention prior to the data locking.

If the **DATA_LOCK_LAG** is bigger then the **RETENTION_MAX** setting, the effective **DATA_LOCK_LAG** is adjusted to the value of **RETENTION_MAX**.

See also description in **lots**(1m) concerning this topic.

Example: **DATA_LOCK_LAG=7**

Default: **DATA_LOCK_LAG=30**

DATA_PURGE_LAG

Number of days by which the removal of data to be purged is delayed. This is to allow smooth data purge if the operating system clocks and the compliance clocks on the storage devices are not completely in sync.

See also description in **lots**(1m) concerning this topic.

Example: **DATA_PURGE_LAG=7**

Default: **DATA_PURGE_LAG=0**

RETENTION_MIN

Minimum retention in days. Specified retentions in **schedule.dat** that are lower then this watermark will be adjusted automatically to this minimum.

Example: **RETENTION_MIN=150**

Default: **RETENTION_MIN=1**

RETENTION_MAX

Maximum retention in days. Specified retentions in **schedule.dat** that are higher then this watermark will be adjusted automatically to this maximum.

Example: **RETENTION_MAX=1460**

Default: **RETENTION_MAX=60**

LOCK_TIMEOUT

timeout in seconds. This is the maximum lifetime of a job-, datalist and session lock. This setting has to be adjusted only, if the data processing duration exceeds the default.

The **LOCK_TIMEOUT** should not exceed the minimum scheduling interval of any datalist defined.

Important: Do not confound this setting with the settings concerning the retention and the locking of saved data.

Example: LOCK_TIMEOUT=82800

Default: LOCK_TIMEOUT=79200

FORECAST_DATAPOINTS

Number of most recent data points that should be used to calculate the various forecasts. If this setting is set to 0 all available data points are considered.

Example: FORECAST_DATAPOINTS=100

Default: FORECAST_DATAPOINTS=0

NAME

lotsctl – start edrc with a special lots (longterm data save) control configuration

SYNOPSIS

edrc/bin/lotsctl [**-h** | **-V**]

lotsctl [**-s**] [**-t**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

Short start of **edrc** with an other configuration which points to an own script tree. Internally **lotsctl** calls **edrc -c edrc.lotsctl.cfg -n LOTSCTL_@ID@** .

lotsctl stands for " 'L**O**ng**T**erm data **S**ave **C**on**T**ro**L**' " .

The session name (as shown in the menu) is automatically set to **LOTSCTL_<id>** . Where **<id>** is the process id of the started **edrc** instance if not already a session with the same name exists, if so the **<id>** is set to a random number.

If additional short starts are needed, create a symlink from the new short start command to **sat** (see section **EXAMPLES**).

OPTIONS

-h usage message.

-V print version and patch level of **edrc** . For an explanation of the release numbering system see **edrcrevision(1)**.

-s silent startup. Startup without showing the EDRC banner.

-t no terminal initialization. Sometimes the terminal initialization causes unwanted behavior. To skip terminal initialization, invoke **edrc** with this option.

ENVIRONMENT

-

EXIT STATUS

see **edrc(1m)** .

FILES**etc/edrc.lotsctl.cfg**

configuration file of **lotsctl**, see **edrc.cfg(4)** for more information.

etc/lotsctl.cfg

global configuration for the lotsctl menu tree.

scripts/lotsctl/_env

root env file for the lotsctl menu tree. Use the **env** edrc command to edit the env file.

Other files see section **FILES** in **edrc(1m)** .

EXAMPLES**1) create a new short start**

This creates a new short start command **new_shortstart** that will load the configuration file **edrc.new_shortstart.cfg** . The session name will automatically be set to **NEW_SHORTSTART_<id>** .

```
[ /root ]
[ root@rh7mzv7t001 ] [bash]: cd ~edrc/bin

[ /opt/edrc/bin ]
[ root@rh7mzv7t001 ] [bash]: ln -s sat new_shortstart
```

NAME

logctl.cfg – configuration file for logctl

SYNOPSIS

edrc/etc/logctl.cfg

AVAILABILITY

WA2L/edrc

DESCRIPTION

This is the configuration file for the **logctl** command.

FILEFORMAT

The fileformat is **OPTION=VALUE**

Between the **OPTION**, the = and the *VALUE* are no spaces.

Rows starting with a # are considered as comments.

You should not comment out any **OPTION** If you like to use default settings simply do not specify a *VALUE*.

OPTIONS

The "Example PROD:" represents a possible productive configuration, where the directory **/dat/worm_all** is located on a SnapLock drive. The "Example EDRC:" is an installation, which can be used for test purposes. All original directories are used and are located within WA2L/edrc

LOTS_HOME

This setting points to the lots software installation directory. This setting allows to point to an alternate base directory for testing purposes. Therefore for normal operations, this should be set to the installation directory of WA2L/edrc.

Example PROD: LOTS_HOME="‘aproot’"

Example EDRC: LOTS_HOME="‘aproot’"

Default: LOTS_HOME="‘aproot’"

LOTS_VAR

Var directory of lots. This setting should point to the long term data storage to ensure independence from the server(s) where lots runs. This to avoid state information loss on possible

server re-installations and to be able to run lots from multiple servers against the same long term data storage.

Example PROD: `LOTS_VAR="/dat/worm_all/var/lots"`

Example EDRC: `LOTS_VAR="$LOTS_HOME/var/lots"`

Default: `LOTS_VAR="`aproot`/var/lots"`

LOTS_CONFIGFILE

Active configuration file of lots. This file should also be located on the long term storage due to the same reasons as the **LOTS_VAR** setting.

Example PROD: `LOTS_CONFIGFILE="/dat/worm_all/etc/lots.cfg"`

Example EDRC: `LOTS_CONFIGFILE="$LOTS_HOME/etc/lots.cfg"`

Default: `LOTS_CONFIGFILE="`aproot`/etc/lots.cfg"`

GLUP_CONFIGFILE

The **glup.cfg** file defines settings for the billing report that is created on a monthly basis based on the number of computed jobs. This setting only affects the 'stat -> rb' menu point.

Example PROD: `GLUP_CONFIGFILE="/dat/worm_all/etc/glup.cfg"`

Default EDRC: -

Default: -

REPORT_BASEDIR

Directory to save specific reports generated in the 'stats' menu.

Example PROD: `REPORT_BASEDIR="/dat/report/`server_environment`-C"`

Example EDRC: -

Default: `REPORT_BASEDIR="/var/report/`server_environment`-C"`

TRUNK_DEFAULT

Default trunk target for the 'colo' menu. For a description of the trunk default target syntax, see trunk description in **edrc(1m)**.

Example PROD: `TRUNK_DEFAULT="adm_ora1_tst"`

Example EDRC: `TRUNK_DEFAULT="`hostlist` | awk '{print $1}'"`

Default: `TRUNK_DEFAULT=""`

TRUNK_TARGETS

Trunk targets for the 'colo' menu. For a description of the trunk target syntax, see trunk description in **edrc**(1m).

Example PROD:

```
TRUNK_TARGETS="
    adm_oral_tst%-%MSSQL%saves:adm_oral_tst
    rcat_oral_tst%-%Oracle%saves:rcat_oral_tst
    asys_app1_tst%-%Misc%saves:asys_app1_tst
"
```

Example EDRC: TRUNK_TARGETS="'hostlist' 'hostname'"

Default: TRUNK_TARGETS=""

NAME

lscomp – list the files contained in a compressed archive file

SYNOPSIS

edrc/bin/lscomp [-h]

lscomp *file*

AVAILABILITY

WA2L/edrc

DESCRIPTION

With **lscomp** you can list the files included in a compressed archive without decompressing the whole archive file. To view a more detailed filelist you should use the **llcomp** command.

OPTIONS

-h usage message

file filename of the compressed archive file. This file is a file with the suffixes **.tgz**, **.tar.gz**, **.tar.bz**, **.tar.bz2**, **.tar.Z**, **.tar.zip**, **.cpio**, **.cpio.gz**, **.cpio.bz**, **.cpio.bz2**, **.cpio.xz**, **.cpio.Z**, **.cpio.zip**, **.depot.gz**, **.depot**, **.epub**, **.zip**, **.jar**, **.whl**, **.rock**, **.rpm**, **.deb** or **.bw**.

EXIT STATUS

- | | |
|----------|--|
| 1 | specified archive file not found. |
| 2 | file format of specified archive file not recognized. The file format is determined by the file suffix only. |
| 4 | usage displayed. |
| 6 | error while decompressing a compressed archive. This error occurs if the file is not compressed with the command that is normally assigned with the file suffix. For instance: the file my_archive.tar.gz was not really compressed with gzip or the file is corrupt. |
| 7 | error while accessing file list in archive. This error occurs if the file is not archived with the command that is normally assigned to the file suffix. For instance: the file my_archive.tar.gz was not really a compressed tar file or the tar archive is corrupt. |

NAME

lscp – print list with cp-commands in the current working directory

SYNOPSIS

edrc/bin/lscp [**ls_options**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

Print a list of **cp** commands with files in the current working directory to stdout. This is useful if many filenames have to be copied to different filenames.

The common usage is to invoke **lscp**, redirect the output to a temporary file, load the temporary file into **vi**, modify the filenames with the editing functionality of **vi** and then execute the commands in the temporary file. With this procedure it is very effective to copy many files to different filenames.

This functionality might be used often when integrating a new application into a disaster recovery solution thru copying an existing application recovery sequence. In this case many files have to be copied, but the content might be identical in many cases.

OPTIONS

ls_options all native **ls** options.

EXIT STATUS

x the exit status of **cp**.

EXAMPLES

1) common

lscp usage:

```
lscp > a; vi a; sh a; rm a
```

SEE ALSO

edrcintro(1), **ls(1)**, **lsmv(1)**, **cp(1)**

BUGS

-

AUTHOR

lscp was developed by Christian Walther. Send suggestions and bug reports to wa2l@users.sourceforge.net

NAME

lsmv – print list with mv-commands in the current working directory

SYNOPSIS

edrc/bin/lsmv [**ls_options**]

AVAILABILITY

WA2L/edrc

DESCRIPTION

Print a list of **mv** commands with files in the current working directory to stdout. This is useful if many filenames have to be adjusted.

The common usage is to invoke **lsmv**, redirect the output to a temporary file, load the temporary file into **vi**, modify the filenames with the editing functionality of **vi** and then execute the commands in the temporary file. With this procedure it is very effective to rename many files.

This functionality might be used often when integrating a new application into a disaster recovery solution thru copying an existing application recovery sequence. In this case many files have to be renamed, but the content might be identical in many cases.

OPTIONS

ls_options all native **ls** options.

EXIT STATUS

x the exit status of **mv**.

EXAMPLES

1) common

lsmv usage:

```
lsmv > a; vi a; sh a; rm a
```

SEE ALSO

edrcintro(1), **ls(1)**, **lsdp(1)**, **mv(1)**

NAME

lsOf – list open files

SYNOPSIS

```
lsOf [ -?abChKlnNOPRtUvVX ] [ -A A ] [ -c c ] [ +c c ] [ +|-d d ] [ +|-D D ] [ +|-e s ] [ +|-E ] [ +|-f
[cfgGn] ] [ -F [ff] ] [ -g [s] ] [ -i [ij] ] [ -k k ] [ +|-L [ll] ] [ +|-m m ] [ +|-M ] [ -o [o] ] [ -p s ] [ +|-r
[t[m<fnt>]] ] [ -s [p:s] ] [ -S [t] ] [ -T [t] ] [ -u s ] [ +|-w ] [ -x [fl] ] [ -z [z] ] [ -Z [Z] ] [ -- ] [names]
```

DESCRIPTION

LsOf revision 4.88 lists on its standard output file information about files opened by processes for the following UNIX dialects:

Apple Darwin 9 and Mac OS X 10.[567]
 FreeBSD 8.[234], 9.0, 10.0 and 11.0 for AMD64-based systems
 Linux 2.1.72 and above for x86-based systems
 Solaris 9, 10 and 11

(See the **DISTRIBUTION** section of this manual page for information on how to obtain the latest *lsOf* revision.)

An open file may be a regular file, a directory, a block special file, a character special file, an executing text reference, a library, a stream or a network file (Internet socket, NFS file or UNIX domain socket.) A specific file or all the files in a file system may be selected by path.

Instead of a formatted display, *lsOf* will produce output that can be parsed by other programs. See the **-F**, option description, and the **OUTPUT FOR OTHER PROGRAMS** section for more information.

In addition to producing a single output list, *lsOf* will run in repeat mode. In repeat mode it will produce output, delay, then repeat the output operation until stopped with an interrupt or quit signal. See the **+|-r** [*t*[*m*<*fnt*>]] option description for more information.

OPTIONS

In the absence of any options, *lsOf* lists all open files belonging to all active processes.

If any list request option is specified, other list requests must be specifically requested – e.g., if **-U** is specified for the listing of UNIX socket files, NFS files won't be listed unless **-N** is also specified; or if a user list is specified with the **-u** option, UNIX domain socket files, belonging to users not in the list, won't be listed unless the **-U** option is also specified.

Normally list options that are specifically stated are ORed – i.e., specifying the **-i** option without an address and the **-ufoo** option produces a listing of all network files OR files belonging to processes owned by user “foo”. The exceptions are:

- 1) the ‘^’ (negated) login name or user ID (UID), specified with the **-u** option;
- 2) the ‘^’ (negated) process ID (PID), specified with the **-p** option;
- 3) the ‘^’ (negated) process group ID (PGID), specified with the **-g** option;
- 4) the ‘^’ (negated) command, specified with the **-c** option;
- 5) the ‘^’ negated TCP or UDP protocol state names, specified with the **-s** [*p:s*] option.

Since they represent exclusions, they are applied without ORing or ANDing and take effect before any other selection criteria are applied.

The **-a** option may be used to AND the selections. For example, specifying **-a**, **-U**, and **-ufoo** produces a listing of only UNIX socket files that belong to processes owned by user “foo”.

Caution: the **-a** option causes all list selection options to be ANDed; it can't be used to cause ANDing of

selected pairs of selection options by placing it between them, even though its placement there is acceptable. Wherever **-a** is placed, it causes the ANDing of all selection options.

Items of the same selection set – command names, file descriptors, network addresses, process identifiers, user identifiers, zone names, security contexts – are joined in a single ORed set and applied before the result participates in ANDing. Thus, for example, specifying **-i@aaa.bbb**, **-i@ccc.ddd**, **-a**, and **-ufff,ggg** will select the listing of files that belong to either login “fff” OR “ggg” AND have network connections to either host aaa.bbb OR ccc.ddd.

Options may be grouped together following a single prefix -- e.g., the option set “**-a -b -C**” may be stated as **-abC**. However, since values are optional following **+-f**, **-F**, **-g**, **-i**, **+-L**, **-o**, **+-r**, **-s**, **-S**, **-T**, **-x** and **-z**, when you have no values for them be careful that the following character isn’t ambiguous. For example, **-Fn** might represent the **-F** and **-n** options, or it might represent the **n** field identifier character following the **-F** option. When ambiguity is possible, start a new option with a ‘-’ character – e.g., “**-F -n**”. If the next option is a file name, follow the possibly ambiguous option with “**--**” – e.g., “**-F -- name**”.

Either the ‘+’ or the ‘-’ prefix may be applied to a group of options. Options that don’t take on separate meanings for each prefix – e.g., **-i** – may be grouped under either prefix. Thus, for example, “**+M -i**” may be stated as “**+Mi**” and the group means the same as the separate options. Be careful of prefix grouping when one or more options in the group does take on separate meanings under different prefixes – e.g., **+-M**; “**-iM**” is not the same request as “**-i +M**”. When in doubt, use separate options with appropriate prefixes.

-? -h These two equivalent options select a usage (help) output list. *Lsof* displays a shortened form of this output when it detects an error in the options supplied to it, after it has displayed messages explaining each error. (Escape the ‘?’ character as your shell requires.)

-a causes list selection options to be ANDed, as described above.

-A A is available on systems configured for AFS whose AFS kernel code is implemented via dynamic modules. It allows the *lsof* user to specify *A* as an alternate name list file where the kernel addresses of the dynamic modules might be found. See the *lsof* FAQ (The **FAQ** section gives its location.) for more information about dynamic modules, their symbols, and how they affect *lsof*.

-b causes *lsof* to avoid kernel functions that might block – *lstat(2)*, *readlink(2)*, and *stat(2)*.

See the **BLOCKS AND TIMEOUTS** and **AVOIDING KERNEL BLOCKS** sections for information on using this option.

-c c selects the listing of files for processes executing the command that begins with the characters of *c*. Multiple commands may be specified, using multiple **-c** options. They are joined in a single ORed set before participating in AND option selection.

If *c* begins with a ‘^’, then the following characters specify a command name whose processes are to be ignored (excluded.)

If *c* begins and ends with a slash (/), the characters between the slashes are interpreted as a regular expression. Shell meta-characters in the regular expression must be quoted to prevent their interpretation by the shell. The closing slash may be followed by these modifiers:

| | |
|---|--|
| b | the regular expression is a basic one. |
| i | ignore the case of letters. |
| x | the regular expression is an extended one (default). |

See the *lsof* FAQ (The **FAQ** section gives its location.) for more information on basic and extended regular expressions.

The simple command specification is tested first. If that test fails, the command regular expression is applied. If the simple command test succeeds, the command regular expression test isn’t made. This may result in “no command found for regex:” messages when *lsof*’s **-V** option is

specified.

+c *w* defines the maximum number of initial characters of the name, supplied by the UNIX dialect, of the UNIX command associated with a process to be printed in the COMMAND column. (The *lsOf* default is nine.)

Note that many UNIX dialects do not supply all command name characters to *lsOf* in the files and structures from which *lsOf* obtains command name. Often dialects limit the number of characters supplied in those sources. For example, Linux 2.4.27 and Solaris 9 both limit command name length to 16 characters.

If *w* is zero ('0'), all command characters supplied to *lsOf* by the UNIX dialect will be printed.

If *w* is less than the length of the column title, "COMMAND", it will be raised to that length.

-C disables the reporting of any path name components from the kernel's name cache. See the **KERNEL NAME CACHE** section for more information.

+d *s* causes *lsOf* to search for all open instances of directory *s* and the files and directories it contains at its top level. **+d** does NOT descend the directory tree, rooted at *s*. The **+D** *D* option may be used to request a full-descent directory tree search, rooted at directory *D*.

Processing of the **+d** option does not follow symbolic links within *s* unless the **-x** or **-x l** option is also specified. Nor does it search for open files on file system mount points on subdirectories of *s* unless the **-x** or **-x f** option is also specified.

Note: the authority of the user of this option limits it to searching for files that the user has permission to examine with the system *stat(2)* function.

-d *s* specifies a list of file descriptors (FDs) to exclude from or include in the output listing. The file descriptors are specified in the comma-separated set *s* – e.g., "cwd,1,3", "^6,^2". (There should be no spaces in the set.)

The list is an exclusion list if all entries of the set begin with '^'. It is an inclusion list if no entry begins with '^'. Mixed lists are not permitted.

A file descriptor number range may be in the set as long as neither member is empty, both members are numbers, and the ending member is larger than the starting one – e.g., "0-7" or "3-10". Ranges may be specified for exclusion if they have the '^' prefix – e.g., "^0-7" excludes all file descriptors 0 through 7.

Multiple file descriptor numbers are joined in a single ORed set before participating in AND option selection.

When there are exclusion and inclusion members in the set, *lsOf* reports them as errors and exits with a non-zero return code.

See the description of File Descriptor (FD) output values in the **OUTPUT** section for more information on file descriptor names.

+D *D* causes *lsOf* to search for all open instances of directory *D* and all the files and directories it contains to its complete depth.

Processing of the **+D** option does not follow symbolic links within *D* unless the **-x** or **-x l** option is also specified. Nor does it search for open files on file system mount points on subdirectories of *D* unless the **-x** or **-x f** option is also specified.

Note: the authority of the user of this option limits it to searching for files that the user has permission to examine with the system *stat(2)* function.

Further note: *lsOf* may process this option slowly and require a large amount of dynamic memory to do it. This is because it must descend the entire directory tree, rooted at *D*, calling *stat(2)* for each file and directory, building a list of all the files it finds, and searching that list for a match with every open file. When directory *D* is large, these steps can take a long time, so use this option prudently.

-D D directs *lsOf*'s use of the device cache file. The use of this option is sometimes restricted. See the **DEVICE CACHE FILE** section and the sections that follow it for more information on this option.

-D must be followed by a function letter; the function letter may optionally be followed by a path name. *Lsof* recognizes these function letters:

- ?** – report device cache file paths
- b** – build the device cache file
- i** – ignore the device cache file
- r** – read the device cache file
- u** – read and update the device cache file

The **b**, **r**, and **u** functions, accompanied by a path name, are sometimes restricted. When these functions are restricted, they will not appear in the description of the **-D** option that accompanies **-h** or **-?** option output. See the **DEVICE CACHE FILE** section and the sections that follow it for more information on these functions and when they're restricted.

The **?** function reports the read-only and write paths that *lsOf* can use for the device cache file, the names of any environment variables whose values *lsOf* will examine when forming the device cache file path, and the format for the personal device cache file path. (Escape the '?' character as your shell requires.)

When available, the **b**, **r**, and **u** functions may be followed by the device cache file's path. The standard default is *.lsOf_hostname* in the home directory of the real user ID that executes *lsOf*, but this could have been changed when *lsOf* was configured and compiled. (The output of the **-h** and **-?** options show the current default prefix – e.g., “.lsOf”). The suffix, *hostname*, is the first component of the host's name returned by *gethostname(2)*.

When available, the **b** function directs *lsOf* to build a new device cache file at the default or specified path.

The **i** function directs *lsOf* to ignore the default device cache file and obtain its information about devices via direct calls to the kernel.

The **r** function directs *lsOf* to read the device cache at the default or specified path, but prevents it from creating a new device cache file when none exists or the existing one is improperly structured. The **r** function, when specified without a path name, prevents *lsOf* from updating an incorrect or outdated device cache file, or creating a new one in its place. The **r** function is always available when it is specified without a path name argument; it may be restricted by the permissions of the *lsOf* process.

When available, the **u** function directs *lsOf* to read the device cache file at the default or specified path, if possible, and to rebuild it, if necessary. This is the default device cache file function when no **-D** option has been specified.

+|-e s exempts the file system whose path name is *s* from being subjected to kernel function calls that might block. The **+e** option exempts *stat(2)*, *lstat(2)* and most *readlink(2)* kernel function calls. The **-e** option exempts only *stat(2)* and *lstat(2)* kernel function calls. Multiple file systems may be specified with separate **+|-e** specifications and each may have *readlink(2)* calls exempted or not.

This option is currently implemented only for Linux.

CAUTION: this option can easily be mis-applied to other than the file system of interest, because it uses path name rather than the more reliable device and inode numbers. (Device and inode numbers are acquired via the potentially blocking *stat(2)* kernel call and are thus not available, but see the **+|-m m** option as a possible alternative way to supply device numbers.) **Use this option with great care and fully specify the path name of the file system to be exempted.**

When open files on exempted file systems are reported, it may not be possible to obtain all their information. Therefore, some information columns will be blank, the characters “UNKN” preface the values in the TYPE column, and the applicable exemption option is added in parentheses to the end of the NAME column. (Some device number information might be made available via the **+|-m m** option.)

+|-E **+E** specifies that Linux files should be displayed with endpoint information and the files of the endpoints should also be displayed.

Endpoint information is displayed in the NAME column in the form “*PID,cmd,FDmode*”. *PID* is the endpoint process ID; *cmd* is the endpoint process command; *FD* is the endpoint file’s descriptor; and *mode* is the endpoint file’s access mode. Multiple occurrences of this information can appear in a file’s NAME column.

-E specifies that Linux pipe files should only be displayed with endpoint information.

+|-f [cfgGn]

f by itself clarifies how path name arguments are to be interpreted. When followed by **c**, **f**, **g**, **G**, or **n** in any combination it specifies that the listing of kernel file structure information is to be enabled (‘+’) or inhibited (‘-’).

Normally a path name argument is taken to be a file system name if it matches a mounted-on directory name reported by *mount*(8), or if it represents a block device, named in the *mount* output and associated with a mounted directory name. When **+f** is specified, all path name arguments will be taken to be file system names, and *lsOf* will complain if any are not. This can be useful, for example, when the file system name (mounted-on device) isn’t a block device. This happens for some CD-ROM file systems.

When **-f** is specified by itself, all path name arguments will be taken to be simple files. Thus, for example, the “**-f -- /**” arguments direct *lsOf* to search for open files with a ‘/’ path name, not all open files in the ‘/’ (root) file system.

Be careful to make sure **+f** and **-f** are properly terminated and aren’t followed by a character (e.g., of the file or file system name) that might be taken as a parameter. For example, use “**--**” after **+f** and **-f** as in these examples.

```
$ lsOf +f -- /file/system/name
$ lsOf -f -- /file/name
```

The listing of information from kernel file structures, requested with the **+f [cfgGn]** option form, is normally inhibited, and is not available in whole or part for some dialects – e.g., /proc-based Linux kernels below 2.6.22. When the prefix to **f** is a plus sign (‘+’), these characters request file structure information:

| | |
|----------|---|
| c | file structure use count (not Linux) |
| f | file structure address (not Linux) |
| g | file flag abbreviations (Linux 2.6.22 and up) |
| G | file flags in hexadecimal (Linux 2.6.22 and up) |
| n | file structure node address (not Linux) |

When the prefix is minus (‘-’) the same characters disable the listing of the indicated values.

File structure addresses, use counts, flags, and node addresses may be used to detect more readily identical files inherited by child processes and identical files in use by different processes. *lsOf* column output can be sorted by output columns holding the values and listed to identify identical file use, or *lsOf* field output can be parsed by an AWK or Perl post-filter script, or by a C program.

-Ff specifies a character list, *f*, that selects the fields to be output for processing by another program, and the character that terminates each output field. Each field to be output is specified with a single character in *f*. The field terminator defaults to NL, but may be changed to NUL (000). See the **OUTPUT FOR OTHER PROGRAMS** section for a description of the field

identification characters and the field output process.

When the field selection character list is empty, all standard fields are selected (except the raw device field, security context and zone field for compatibility reasons) and the NL field terminator is used.

When the field selection character list contains only a zero ('0'), all fields are selected (except the raw device field for compatibility reasons) and the NUL terminator character is used.

Other combinations of fields and their associated field terminator character must be set with explicit entries in *f*, as described in the **OUTPUT FOR OTHER PROGRAMS** section.

When a field selection character identifies an item *lsOf* does not normally list – e.g., PPID, selected with **-R** – specification of the field character – e.g., **“-FR”** – also selects the listing of the item.

When the field selection character list contains the single character '?', *lsOf* will display a help list of the field identification characters. (Escape the '?' character as your shell requires.)

-g [*s*] excludes or selects the listing of files for the processes whose optional process group IDentification (PGID) numbers are in the comma-separated set *s* – e.g., “123” or “123,456”. (There should be no spaces in the set.)

PGID numbers that begin with '^' (negation) represent exclusions.

Multiple PGID numbers are joined in a single ORed set before participating in AND option selection. However, PGID exclusions are applied without ORing or ANDing and take effect before other selection criteria are applied.

The **-g** option also enables the output display of PGID numbers. When specified without a PGID set that's all it does.

-i [*i*] selects the listing of files any of whose Internet address matches the address specified in *i*. If no address is specified, this option selects the listing of all Internet and x.25 (HP-UX) network files.

If **-i4** or **-i6** is specified with no following address, only files of the indicated IP version, IPv4 or IPv6, are displayed. (An IPv6 specification may be used only if the dialects supports IPv6, as indicated by “[46]” and “IPv[46]” in *lsOf*'s **-h** or **-?** output.) Sequentially specifying **-i4**, followed by **-i6** is the same as specifying **-i**, and vice-versa. Specifying **-i4**, or **-i6** after **-i** is the same as specifying **-i4** or **-i6** by itself.

Multiple addresses (up to a limit of 100) may be specified with multiple **-i** options. (A port number or service name range is counted as one address.) They are joined in a single ORed set before participating in AND option selection.

An Internet address is specified in the form (Items in square brackets are optional.):

[46][*protocol*][@*hostname* | *hostaddr*][:*service* | *port*]

where:

46 specifies the IP version, IPv4 or IPv6
that applies to the following address.
'6' may be specified only if the UNIX
dialect supports IPv6. If neither '4' nor
'6' is specified, the following address
applies to all IP versions.
protocol is a protocol name – **TCP**, **UDP**
hostname is an Internet host name. Unless a
specific IP version is specified, open
network files associated with host names
of all versions will be selected.
hostaddr is a numeric Internet IPv4 address in

dot form; or an IPv6 numeric address in colon form, enclosed in brackets, if the UNIX dialect supports IPv6. When an IP version is selected, only its numeric addresses may be specified.

service is an */etc/services* name – e.g., **smtp** – or a list of them.

port is a port number, or a list of them.

IPv6 options may be used only if the UNIX dialect supports IPv6. To see if the dialect supports IPv6, run *lsOf* and specify the **-h** or **-?** (help) option. If the displayed description of the **-i** option contains “[46]” and “IPv[46]”, IPv6 is supported.

IPv4 host names and addresses may not be specified if network file selection is limited to IPv6 with **-i 6**. IPv6 host names and addresses may not be specified if network file selection is limited to IPv4 with **-i 4**. When an open IPv4 network file’s address is mapped in an IPv6 address, the open file’s type will be IPv6, not IPv4, and its display will be selected by ‘6’, not ‘4’.

At least one address component – **4**, **6**, *protocol*, *hostname*, *hostaddr*, or *service* – must be supplied. The ‘@’ character, leading the host specification, is always required; as is the ‘:’, leading the port specification. Specify either *hostname* or *hostaddr*. Specify either *service* name list or *port* number list. If a *service* name list is specified, the *protocol* may also need to be specified if the TCP, UDP and UDPLITE port numbers for the service name are different. Use any case – lower or upper – for *protocol*.

Service names and *port* numbers may be combined in a list whose entries are separated by commas and whose numeric range entries are separated by minus signs. There may be no embedded spaces, and all service names must belong to the specified *protocol*. Since service names may contain embedded minus signs, the starting entry of a range can’t be a service name; it can be a port number, however.

Here are some sample addresses:

```
-i6 – IPv6 only
TCP:25 – TCP and port 25
@1.2.3.4 – Internet IPv4 host address 1.2.3.4
@[3ffe:1ebc::1]:1234 – Internet IPv6 host address
3ffe:1ebc::1, port 1234
UDP:who – UDP who service port
TCP@lsOf.itap:513 – TCP, port 513 and host name lsOf.itap
tcp@foo:1-10,smtp,99 – TCP, ports 1 through 10,
service name smtp, port 99, host name foo
tcp@bar:1-smtp – TCP, ports 1 through smtp, host bar
:time – either TCP, UDP or UDPLITE time service port
```

-K selects the listing of tasks (threads) of processes, on dialects where task (thread) reporting is supported. (If help output – i.e., the output of the **-h** or **-?** options – shows this option, then task (thread) reporting is supported by the dialect.)

When **-K** and **-a** are both specified on Linux, and the tasks of a main process are selected by other options, the main process will also be listed as though it were a task, but without a task ID. (See the description of the TID column in the **OUTPUT** section.)

Where the FreeBSD version supports threads, all threads will be listed with their IDs.

In general threads and tasks inherit the files of the caller, but may close some and open others, so *lsOf* always reports all the open files of threads and tasks.

-k k specifies a kernel name list file, *k*, in place of */vmunix*, */mach*, etc. **-k** is not available under AIX on the IBM RISC/System 6000.

- l** inhibits the conversion of user ID numbers to login names. It is also useful when login name lookup is working improperly or slowly.
- +|-L [*l*]** enables (+) or disables (-) the listing of file link counts, where they are available – e.g., they aren't available for sockets, or most FIFOs and pipes.
- When **+L** is specified without a following number, all link counts will be listed. When **-L** is specified (the default), no link counts will be listed.
- When **+L** is followed by a number, only files having a link count less than that number will be listed. (No number may follow **-L**.) A specification of the form “**+L1**” will select open files that have been unlinked. A specification of the form “**+aL1 <file_system>**” will select unlinked open files on the specified file system.
- For other link count comparisons, use field output (**-F**) and a post-processing script or program.
- +|-m m** specifies an alternate kernel memory file or activates mount table supplement processing.
- The option form **-m m** specifies a kernel memory file, *m*, in place of */dev/kmem* or */dev/mem* – e.g., a crash dump file.
- The option form **+m** requests that a mount supplement file be written to the standard output file. All other options are silently ignored.
- There will be a line in the mount supplement file for each mounted file system, containing the mounted file system directory, followed by a single space, followed by the device number in hexadecimal “0x” format – e.g.,
- / 0x801*
- Lsof* can use the mount supplement file to get device numbers for file systems when it can't get them via *stat(2)* or *lstat(2)*.
- The option form **+m m** identifies *m* as a mount supplement file.
- Note: the **+m** and **+m m** options are not available for all supported dialects. Check the output of *lsof*'s **-h** or **-?** options to see if the **+m** and **+m m** options are available.
- +|-M** Enables (+) or disables (-) the reporting of portmapper registrations for local TCP, UDP and UDPLITE ports, where port mapping is supported. (See the last paragraph of this option description for information about where portmapper registration reporting is supported.)
- The default reporting mode is set by the *lsof* builder with the `HASPMAPENABLED` #define in the dialect's `machine.h` header file; *lsof* is distributed with the `HASPMAPENABLED` #define deactivated, so portmapper reporting is disabled by default and must be requested with **+M**. Specifying *lsof*'s **-h** or **-?** option will report the default mode. Disabling portmapper registration when it is already disabled or enabling it when already enabled is acceptable. When portmapper registration reporting is enabled, *lsof* displays the portmapper registration (if any) for local TCP, UDP or UDPLITE ports in square brackets immediately following the port numbers or service names – e.g., “:1234[name]” or “:name[100083]”. The registration information may be a name or number, depending on what the registering program supplied to the portmapper when it registered the port.
- When portmapper registration reporting is enabled, *lsof* may run a little more slowly or even become blocked when access to the portmapper becomes congested or stopped. Reverse the reporting mode to determine if portmapper registration reporting is slowing or blocking *lsof*.
- For purposes of portmapper registration reporting *lsof* considers a TCP, UDP or UDPLITE port local if: it is found in the local part of its containing kernel structure; or if it is located in the foreign part of its containing kernel structure and the local and foreign Internet addresses are the same; or if it is located in the foreign part of its containing kernel structure and the foreign Internet address is `INADDR_LOOPBACK` (127.0.0.1). This rule may make *lsof* ignore some foreign ports on machines with multiple interfaces when the foreign Internet address is on a different interface from the local one.

See the *lsuf* FAQ (The **FAQ** section gives its location.) for further discussion of portmapper registration reporting issues.

Portmapper registration reporting is supported only on dialects that have RPC header files. (Some Linux distributions with Glibc 2.14 do not have them.) When portmapper registration reporting is supported, the **-h** or **-?** help output will show the **+|-M** option.

- n** inhibits the conversion of network numbers to host names for network files. Inhibiting conversion may make *lsuf* run faster. It is also useful when host name lookup is not working properly.
- N** selects the listing of NFS files.

- o** directs *lsuf* to display file offset at all times. It causes the SIZE/OFF output column title to be changed to OFFSET. Note: on some UNIX dialects *lsuf* can't obtain accurate or consistent file offset information from its kernel data sources, sometimes just for particular kinds of files (e.g., socket files.) Consult the *lsuf* FAQ (The **FAQ** section gives its location.) for more information.

The **-o** and **-s** options are mutually exclusive; they can't both be specified. When neither is specified, *lsuf* displays whatever value – size or offset – is appropriate and available for the type of the file.

- o o** defines the number of decimal digits (*o*) to be printed after the “0t” for a file offset before the form is switched to “0x...”. An *o* value of zero (unlimited) directs *lsuf* to use the “0t” form for all offset output.

This option does NOT direct *lsuf* to display offset at all times; specify **-o** (without a trailing number) to do that. **-o o** only specifies the number of digits after “0t” in either mixed size and offset or offset-only output. Thus, for example, to direct *lsuf* to display offset at all times with a decimal digit count of 10, use:

```
-o -o 10
```

or

```
-oo10
```

The default number of digits allowed after “0t” is normally 8, but may have been changed by the *lsuf* builder. Consult the description of the **-o o** option in the output of the **-h** or **-?** option to determine the default that is in effect.

- O** directs *lsuf* to bypass the strategy it uses to avoid being blocked by some kernel operations – i.e., doing them in forked child processes. See the **BLOCKS AND TIMEOUTS** and **AVOIDING KERNEL BLOCKS** sections for more information on kernel operations that may block *lsuf*.

While use of this option will reduce *lsuf* startup overhead, it may also cause *lsuf* to hang when the kernel doesn't respond to a function. Use this option cautiously.

- p s** excludes or selects the listing of files for the processes whose optional process IDentification (PID) numbers are in the comma-separated set *s* – e.g., “123” or “123,^456”. (There should be no spaces in the set.)

PID numbers that begin with “^” (negation) represent exclusions.

Multiple process ID numbers are joined in a single ORed set before participating in AND option selection. However, PID exclusions are applied without ORing or ANDing and take effect before other selection criteria are applied.

- P** inhibits the conversion of port numbers to port names for network files. Inhibiting the conversion may make *lsuf* run a little faster. It is also useful when port name lookup is not working properly.

- +|-r [t[m<fmt>]]**

puts *lsuf* in repeat mode. There *lsuf* lists open files as selected by other options, delays *t* seconds (default fifteen), then repeats the listing, delaying and listing repetitively until stopped by a condition defined by the prefix to the option.

If the prefix is a ‘-’, repeat mode is endless. *Lsof* must be terminated with an interrupt or quit signal.

If the prefix is ‘+’, repeat mode will end the first cycle no open files are listed – and of course when *lsof* is stopped with an interrupt or quit signal. When repeat mode ends because no files are listed, the process exit code will be zero if any open files were ever listed; one, if none were ever listed.

Lsof marks the end of each listing: if field output is in progress (the **-F**, option has been specified), the default marker is ‘m’; otherwise the default marker is “=====”. The marker is followed by a NL character.

The optional “m<fmt>” argument specifies a format for the marker line. The <fmt> characters following ‘m’ are interpreted as a format specification to the *strftime*(3) function, when both it and the *localtime*(3) function are available in the dialect’s C library. Consult the *strftime*(3) documentation for what may appear in its format specification. Note that when field output is requested with the **-F** option, <fmt> cannot contain the NL format, “%n”. Note also that when <fmt> contains spaces or other characters that affect the shell’s interpretation of arguments, <fmt> must be quoted appropriately.

Repeat mode reduces *lsof* startup overhead, so it is more efficient to use this mode than to call *lsof* repetitively from a shell script, for example.

To use repeat mode most efficiently, accompany **+|-r** with specification of other *lsof* selection options, so the amount of kernel memory access *lsof* does will be kept to a minimum. Options that filter at the process level – e.g., **-c**, **-g**, **-p**, **-u** – are the most efficient selectors.

Repeat mode is useful when coupled with field output (see the **-F**, option description) and a supervising *awk* or *Perl* script, or a C program.

-R directs *lsof* to list the Parent Process IDentification number in the PPID column.

-s [p:s] *s* alone directs *lsof* to display file size at all times. It causes the SIZE/OFF output column title to be changed to SIZE. If the file does not have a size, nothing is displayed.

The optional **-s p:s** form is available only for selected dialects, and only when the **-h** or **-?** help output lists it.

When the optional form is available, the *s* may be followed by a protocol name (*p*), either TCP or UDP, a colon (‘:’) and a comma-separated protocol state name list, the option causes open TCP and UDP files to be excluded if their state name(s) are in the list (*s*) preceded by a ‘^’; or included if their name(s) are not preceded by a ‘^’.

When an inclusion list is defined, only network files with state names in the list will be present in the *lsof* output. Thus, specifying one state name means that only network files with that lone state name will be listed.

Case is unimportant in the protocol or state names, but there may be no spaces and the colon (‘:’) separating the protocol name (*p*) and the state name list (*s*) is required.

If only TCP and UDP files are to be listed, as controlled by the specified exclusions and inclusions, the **-i** option must be specified, too. If only a single protocol’s files are to be listed, add its name as an argument to the **-i** option.

For example, to list only network files with TCP state LISTEN, use:

```
-iTCP -sTCP:LISTEN
```

Or, for example, to list network files with all UDP states except Idle, use:

```
-iUDP -sUDP:Idle
```

State names vary with UNIX dialects, so it’s not possible to provide a complete list. Some common TCP state names are: CLOSED, IDLE, BOUND, LISTEN, ESTABLISHED, SYN_SENT, SYN_RCDV, ESTABLISHED, CLOSE_WAIT, FIN_WAIT1, CLOSING, LAST_ACK,

FIN_WAIT_2, and TIME_WAIT. Two common UDP state names are Unbound and Idle.

See the *lsuf* FAQ (The **FAQ** section gives its location.) for more information on how to use protocol state exclusion and inclusion, including examples.

The **-o** (without a following decimal digit count) and **-s** option (without a following protocol and state name list) are mutually exclusive; they can't both be specified. When neither is specified, *lsuf* displays whatever value – size or offset – is appropriate and available for the type of file.

Since some types of files don't have true sizes – sockets, FIFOs, pipes, etc. – *lsuf* displays for their sizes the content amounts in their associated kernel buffers, if possible.

-S [t] specifies an optional time-out seconds value for kernel functions – *lstat(2)*, *readlink(2)*, and *stat(2)* – that might otherwise deadlock. The minimum for *t* is two; the default, fifteen; when no value is specified, the default is used.

See the **BLOCKS AND TIMEOUTS** section for more information.

-T [t] controls the reporting of some TCP/TPI information, also reported by *netstat(1)*, following the network addresses. In normal output the information appears in parentheses, each item except TCP or TPI state name identified by a keyword, followed by '=', separated from others by a single space:

```
<TCP or TPI state name>
QR=<read queue length>
QS=<send queue length>
SO=<socket options and values>
SS=<socket states>
TF=<TCP flags and values>
WR=<window read length>
WW=<window write length>
```

Not all values are reported for all UNIX dialects. Items values (when available) are reported after the item name and '='.

When the field output mode is in effect (See **OUTPUT FOR OTHER PROGRAMS**.) each item appears as a field with a 'T' leading character.

-T with no following key characters disables TCP/TPI information reporting.

-T with following characters selects the reporting of specific TCP/TPI information:

```
f      selects reporting of socket options,
        states and values, and TCP flags and
        values.
q      selects queue length reporting.
s      selects connection state reporting.
w      selects window size reporting.
```

Not all selections are enabled for some UNIX dialects. State may be selected for all dialects and is reported by default. The **-h** or **-?** help output for the **-T** option will show what selections may be used with the UNIX dialect.

When **-T** is used to select information – i.e., it is followed by one or more selection characters – the displaying of state is disabled by default, and it must be explicitly selected again in the characters following **-T**. (In effect, then, the default is equivalent to **-Ts**.) For example, if queue lengths and state are desired, use **-Tqs**.

Socket options, socket states, some socket values, TCP flags and one TCP value may be reported (when available in the UNIX dialect) in the form of the names that commonly appear after *SO_*, *so_*, *SS_*, *TCP_* and *TF_* in the dialect's header files – most often *<sys/socket.h>*, *<sys/socketvar.h>* and *<netinet/tcp_var.h>*. Consult those header files for the meaning of the

flags, options, states and values.

“SO=” precedes socket options and values; “SS=”, socket states; and “TF=”, TCP flags and values.

If a flag or option has a value, the value will follow an ‘=’ and the name -- e.g., “SO=LINGER=5”, “SO=QLIM=5”, “TF=MSS=512”. The following seven values may be reported:

| Name Reported | Description (Common Symbol) |
|------------------|--------------------------------------|
| KEEPALIVE | keep alive time (SO_KEEPALIVE) |
| LINGER | linger time (SO_LINGER) |
| MSS | maximum segment size (TCP_MAXSEG) |
| PQLEN | partial listen queue connections |
| QLEN | established listen queue connections |
| QLIM | established listen queue limit |
| RCVBUF | receive buffer length (SO_RCVBUF) |
| SNDBUF | send buffer length (SO_SNDBUF) |

Details on what socket options and values, socket states, and TCP flags and values may be displayed for particular UNIX dialects may be found in the answer to the “Why doesn’t *lsf* report socket options, socket states, and TCP flags and values for my dialect?” and “Why doesn’t *lsf* report the partial listen queue connection count for my dialect?” questions in the *lsf* FAQ (The **FAQ** section gives its location.)

-t specifies that *lsf* should produce terse output with process identifiers only and no header – e.g., so that the output may be piped to *kill*(1). **-t** selects the **-w** option.

-u s selects the listing of files for the user whose login names or user ID numbers are in the comma-separated set *s* – e.g., “abe”, or “548,root”. (There should be no spaces in the set.)

Multiple login names or user ID numbers are joined in a single ORed set before participating in AND option selection.

If a login name or user ID is preceded by a ‘^’, it becomes a negation – i.e., files of processes owned by the login name or user ID will never be listed. A negated login name or user ID selection is neither ANDed nor ORed with other selections; it is applied before all other selections and absolutely excludes the listing of the files of the process. For example, to direct *lsf* to exclude the listing of files belonging to root processes, specify “-u^root” or “-u^0”.

-U selects the listing of UNIX domain socket files.

-v selects the listing of *lsf* version information, including: revision number; when the *lsf* binary was constructed; who constructed the binary and where; the name of the compiler used to construct the *lsf* binary; the version number of the compiler when readily available; the compiler and loader flags used to construct the *lsf* binary; and system information, typically the output of *uname*’s **-a** option.

-V directs *lsf* to indicate the items it was asked to list and failed to find – command names, file names, Internet addresses or files, login names, NFS files, PIDs, PGIDs, and UIDs.

When other options are ANDed to search options, or compile-time options restrict the listing of some files, *lsf* may not report that it failed to find a search item when an ANDed option or compile-time option prevents the listing of the open file containing the located search item.

For example, “*lsf* -V -iTCP@foobar -a -d 999” may not report a failure to locate open files at “TCP@foobar” and may not list any, if none have a file descriptor number of 999. A similar situation arises when HASSECURITY and HASNOSOCKSECURITY are defined at compile time and they prevent the listing of open files.

- +|-w** Enables (+) or disables (-) the suppression of warning messages.
- The *lsOf* builder may choose to have warning messages disabled or enabled by default. The default warning message state is indicated in the output of the **-h** or **-?** option. Disabling warning messages when they are already disabled or enabling them when already enabled is acceptable.
- The **-t** option selects the **-w** option.
- x** [*fl*] may accompany the **+d** and **+D** options to direct their processing to cross over symbolic links and/or file system mount points encountered when scanning the directory (**+d**) or directory tree (**+D**).
- If **-x** is specified by itself without a following parameter, cross-over processing of both symbolic links and file system mount points is enabled. Note that when **-x** is specified without a parameter, the next argument must begin with '-' or '+'.
 The optional 'f' parameter enables file system mount point cross-over processing; 'l', symbolic link cross-over processing.
- The **-x** option may not be supplied without also supplying a **+d** or **+D** option.
- X** This is a dialect-specific option.
- AIX:**
- This IBM AIX RISC/System 6000 option requests the reporting of executed text file and shared library references.
- WARNING:** because this option uses the kernel `readx()` function, its use on a busy AIX system might cause an application process to hang so completely that it can neither be killed nor stopped. I have never seen this happen or had a report of its happening, but I think there is a remote possibility it could happen.
- By default use of `readx()` is disabled. On AIX 5L and above *lsOf* may need `setuid-root` permission to perform the actions this option requests.
- The *lsOf* builder may specify that the **-X** option be restricted to processes whose real UID is root. If that has been done, the **-X** option will not appear in the **-h** or **-?** help output unless the real UID of the *lsOf* process is root. The default *lsOf* distribution allows any UID to specify **-X**, so by default it will appear in the help output.
- When AIX `readx()` use is disabled, *lsOf* may not be able to report information for all text and loader file references, but it may also avoid exacerbating an AIX kernel directory search kernel error, known as the Stale Segment ID bug.
- The `readx()` function, used by *lsOf* or any other program to access some sections of kernel virtual memory, can trigger the Stale Segment ID bug. It can cause the kernel's `dir_search()` function to believe erroneously that part of an in-memory copy of a file system directory has been zeroed. Another application process, distinct from *lsOf*, asking the kernel to search the directory – e.g., by using `open(2)` – can cause `dir_search()` to loop forever, thus hanging the application process.
- Consult the *lsOf* FAQ (The **FAQ** section gives its location.) and the *00README* file of the *lsOf* distribution for a more complete description of the Stale Segment ID bug, its APAR, and methods for defining `readx()` use when compiling *lsOf*.
- Linux:**
- This Linux option requests that *lsOf* skip the reporting of information on all open TCP, UDP and UDPLITE IPv4 and IPv6 files.
- This Linux option is most useful when the system has an extremely large number of open TCP, UDP and UDPLITE files, the processing of whose information in the `/proc/net/tcp*` and `/proc/net/udp*` files would take *lsOf* a long time, and whose reporting is not of interest.

Use this option with care and only when you are sure that the information you want *lsOf* to display isn't associated with open TCP, UDP or UDPLITE socket files.

Solaris 10 and above:

This Solaris 10 and above option requests the reporting of cached paths for files that have been deleted – i.e., removed with *rm*(1) or *unlink*(2).
